Foreword

The annual Sinergie-SIMA Management Conference is more than an opportunity to present and discuss research findings. It is a moment in which our scientific community comes together to reflect on the transformations affecting firms and organizations and, at the same time, on the evolution of management as a discipline.

The 2026 Conference, hosted by the University of Pavia and entitled Transforming Management in the Era of Post-Globalization and Agentic Economy, invited us to consider this double transformation. We are experiencing profound changes whose direction, scope, and consequences are often difficult to anticipate. Understanding them is already a demanding task. Management must then translate them into organizational choices, processes, and practices that work in concrete contexts.

A significant part of managerial work has traditionally consisted of collecting information, synthesizing it, and transforming it into reports, scenarios, forecasts, and decisions. Artificial intelligence does not "know everything", but it greatly increases the capacity to process information. As a result, managerial value no longer resides primarily in access to information or in routine analysis, but in the ability to steer how knowledge is generated, filtered, integrated, and critically interpreted. Managers are therefore called upon to become even more critical interpreters. They must recognize ambiguities, balance conflicting objectives, and assess organizational constraints, as well as the reputational, social, political, and institutional implications of different courses of action. Information may be increasingly abundant and accessible, but judgment and responsibility cannot be delegated to a technological system.

The nature of coordination is also changing. Management has always involved coordinating people, organizational units, and processes. Today, alongside people, there are data, algorithms, platforms, and artificial agents. Human teams are increasingly becoming hybrid systems. The challenge is to design work architecture in which human and artificial intelligence can cooperate effectively, without people losing control, competence, or responsibility. Technology should strengthen human capabilities. It should not reduce the human contribution to the passive execution of technologically generated instructions or subject individuals and organizations to an unsustainable acceleration of productivity expectations.

The limits of these technologies are not yet fully understood, nor is their medium- and long-term impact on organizations and society. What is already clear, however, is that the way artificial intelligence enters organizations changes decision-making processes and redistributes responsibilities, competencies, and power. Management, therefore, does not disappear. It changes its nature. If the nature of management changes, the responsibility of our scientific community must also evolve. We must examine whether the concepts and theories we use to interpret organizations remain adequate. We must investigate how technologies transform work, coordination, authority, and accountability. We must also reflect on the contributions that management studies can make to firms, institutions, and society in a period of rapid, sometimes contradictory change. The "SIMA Manifesto degli studi di management" was developed in this spirit: not as a definitive answer, but as a platform for discussion. It invites us to question what matters today for our discipline, whether the categories we use to interpret emerging phenomena are still appropriate, and what relationship management scholars intend to build with firms, institutions, and society.

The papers collected in these Proceedings provide tangible evidence of the vitality and diversity of our community. They represent different theoretical perspectives, methodological approaches, and fields of inquiry. Together, they demonstrate the ability of management research to address complex questions with rigor, openness, and responsibility. They also reflect a community capable of bringing together research and teaching, senior and younger scholars, international engagement, and dialogue with firms and institutions. This ability to connect different dimensions of academic life is one of the distinctive strengths of the Sinergie-SIMA Conference. A scientific conference truly fulfills its purpose when it is not merely a program of scheduled sessions, but becomes a space inhabited by its community: a space in which papers are presented and discussed, questions are raised, different perspectives are compared, relationships are developed, and new collaborations begin. Attention must be devoted to younger scholars. Their ideas, questions, and research trajectories are essential to the future of our discipline. Creating opportunities for their development, supporting their participation in the scientific community, and encouraging research that combines academic quality with practical relevance are central responsibilities for SIMA.

I would like to express my sincere gratitude to Sinergie Italian Journal of Management, the University of Pavia, the Conference Chairs, the scientific and organizing committees, the Chairs of the tracks and SIMA thematic groups, the reviewers, and all those who contributed to the organization of the Conference and to the preparation of this volume. Above all, I thank the authors and participants who presented their work, discussed papers, raised questions and animated the many opportunities for exchange. Their engagement made the Conference the expression of a living scientific community.

A conference ends well when it does not close a discussion but leaves participants eager to continue it. I hope that these Proceedings will carry forward the ideas, questions, relationships, and new possibilities for joint work that emerged in Pavia and will strengthen the capacity of management research to understand and responsibly shape the transformations of our time.

Beatrice Luceri, President of Italian Society of Management (SIMA)

Editorial Note

To the reader,

This volume contains the short papers presented at the Sinergie-SIMA 2026 Management Conference, hosted by the University of Pavia on 28 and 29 May 2026. The Conference, entitled *Transforming Management in the Era of Post-Globalization and Agentic Economy*, provided an opportunity to discuss the transformations affecting organizations, managerial practices, and management research.

The conference program included contributions related to:

- the main Conference theme;
- the research areas represented by the SIMA thematic groups;
- management case studies.

The diversity of the subjects addressed, theoretical perspectives adopted, and the methodological approaches employed reflected the breadth and vitality of the Sinergie-SIMA scientific community.

The Conference call invited the submission of both short and long papers. Overall, the editorial team received 315 submissions, consisting of 249 short papers and 66 long papers.

All submissions underwent the peer-review process established for the Conference. Short and long papers were evaluated by 245 reviewers, selected from the Sinergie and SIMA scientific communities on the basis of their expertise in the subjects addressed.

The submissions were assessed according to the following criteria:

- clarity of the research aims;
- appropriateness and rigor of the methodological approach;
- originality and innovativeness of the contribution;
- theoretical and practical relevance;
- clarity of communication;
- quality and significance of the bibliographical foundations.

For the short and long papers, the evaluation followed the peer review process, with a double-blind review performed by, respectively, one and two referees - university lecturers and experts about the topic - selected from among members of the SIMA community. At the end of the evaluation process, the authors received the reviewers' reports and incorporated their observations into the presentation and discussion of their work at the Conference.

The evaluation process resulted in the acceptance of 296 papers. The present volume contains 216 short papers whose authors authorized their publication.

All the contributions included in the volume were presented and discussed during the Conference and are made available online through the Sinergie-SIMA Management Conference portal (*https://www.sijmsima.it/*). The papers collected here should be understood not only as individual research contributions, but also as evidence of the questions, perspectives, and developing research trajectories that characterized the scientific debate in Pavia.

We wish to thank the authors for entrusting their work to the Conference; the reviewers for the quality and care of their assessments; the track and thematic group Chairs for coordinating the evaluation and discussion processes; and all participants for contributing to an open and constructive scientific exchange.

We hope that this volume will support the further development of the research presented during the Conference and contribute to the wider debate on the transformation of management and organizations.

The Conference Chairs

LONG PAPERS - TABLE OF CONTENT

Track: Artificial Intelligence in Management

Human-Centered AI and Entrepreneurship Education: Insights from a Gioia Method Study
Mariacarmela Passarelli, Ernesto William De Luca, Francesca Filice 3

Strategic Sensing under VUCA Conditions:
A Critical Reflection on Forecasting, Anchoring Bias, and Agentic AI
Giuseppina Lo Mascolo, Gabriella Levanti, Arabella Mocciaro Li Destri 23

Human-Centered AI and Entrepreneurship Education: Insights from a Gioia Method Study

MARIACARMELA PASSARELLI[1]*, ERNESTO WILLIAM DE LUCA[2], FRANCESCA FILICE[3]

Abstract

Frame of the research. *Entrepreneurship Education (EE) has evolved toward theory-informed, design-oriented architectures, yet the integration of Human-Centered Artificial Intelligence (HCAI) remains underexplored. As EE embraces AI-enabled pedagogies, a critical gap persists in understanding how HCAI can shape program design to foster responsible entrepreneurial leaders.*

Purpose of the paper. *This study aims to examine how HCAI can be conceptually and practically integrated into Entrepreneurship Education Programs (EEPs).*

Methodology. *An exploratory qualitative design was employed, using a Gioia methodology analysis of 119 open-ended survey responses from students enrolled in a Master's program in Human-Centered Artificial Intelligence in Germany. Data were inductively coded and iteratively theorized to develop a grounded framework.*

Results. *Findings reveal that HCAI could shape EEPs through three interdependent pillars that can generate a Holistic Entrepreneurship Education Program Architecture (HEEPA): Integrated Learning Architecture; Institutionalization of Ethics and Collaborative and Enabling Learning Ecosystem.*

Research limitations. *Single-case, cross-sectional design limits generalizability; long-term effects on entrepreneurial behavior and venture outcomes remain untested.*

Managerial implications. *Universities must move beyond additive AI modules toward pedagogical redesign where ethics-by-design and human agency shape curricula, assessment, and governance. Policymakers should invest in translational infrastructures, interdisciplinary networks, and ethical governance frameworks.*

Originality of the paper. *The study advances EE theory by reconceptualizing HCAI not merely as a tool or topic, but as a transformative design logic for holistic, ethically grounded program architecture.*

Keywords: *Human-centered AI; entrepreneurship education; GIOIA methodology*

1. Introduction

Entrepreneurship Education (EE) has matured from an experience driven "craft" to a theory informed, design-oriented field where program architecture, learning processes, and outcomes are explicitly modelled and assessed. Its scope now extends beyond venture creation to include broader capabilities, opportunity recognition, experimentation, coordination, and responsible decision making, delivered through diverse pedagogical configurations and institutional settings (Passarelli and Bongiorno, 2025). Scholars have emphasized the need to clarify what EE develops (mindsets, competencies, behaviours), how learning is activated (didactic logics, processes), and when programs yield meaningful outcomes (Fayolle and Gailly, 2008).

In parallel, EE has become an increasingly technology-rich field; digital platforms, serious games, simulations, and blended formats have scaled experiential learning, enabled iterative practice, and supported more flexible participation across cohorts and geographies. Some systematic evidence suggests that online and blended entrepreneurship education has grown as a distinct stream, with educational technologies like Web 2.0, cloud computing, and AI used to support learning by doing mechanisms (experimentation, feedback, reflection, social interaction). Moreover, devices such as laptops, tablets, and smartphones now mediate entrepreneurial knowledge development.

Many studies have been developed, which adopted different technologies in online and blended EE such as Web 2.0 (Jones & Iredale, 2009), cloud computing (Holinska et al., 2019; Ratten, 2013),

[1] Associate Professor of Entrepreneurship, University of Calabria , mariacarmela.passarelli@unical.it (* Presenter)
[2] Professor of Human-Centred Artificial Intelligence, University of Magdeburg, ernesto.deluca@ovgu.de
[3] Graduate Student at University of Calabria, francyfilice1@gmail.com

digital technology (Rippa & Secundo, 2019), Massive Open Online Courses (MOOCs) (Al-Atabi & DeBoer, 2014; Vitiello et. Al., 2017; Cirulli et al., 2016; Resei et al., 2018; Vorbach et al., 2019), and Serious Games (SGs) (Protopsaltis et al., 2014; Romero & Usart, 2013). Moreover, there is a rapid diffusion of Artificial intelligence, particularly generative AI (GenAI) and Large Language Models (LLMs). Specifically, AI is entering EE in at least two complementary ways. First, it becomes part of the entrepreneurial domain itself, in fact entrepreneurs increasingly build, integrate, or compete with AI-enabled products, services, and business models, implying that foundational AI literacy (e.g., data, ML basics, model limitations, deployment constraints) is becoming strategically relevant for opportunity evaluation and venture execution. Second, AI becomes part of the pedagogical toolkit, supporting ideation, business modelling, market analysis, prototyping, communication, and reflective learning (Stewart et al, 2025; Gong et al., 2025; Zulfiqar et al., 2025; Somià & Vecchiarini, 2023).

The concept of Artificial Intelligence (AI) has evolved significantly since its emergence as a formal scientific field in the mid-20th century. What began as a philosophical inquiry into whether machines can emulate human thinking has matured into a diverse, multidisciplinary domain with applications across sectors. Definitions of AI are not static; they reflect technological paradigms, theoretical models, and societal expectations of their time. The earliest definitions of AI focused on mimicking human thought, as exemplified by the "Turing Test" and Haugeland's "machines with minds". (Haugeland, 1985; Turing, 1950). By 2025, AI definitions have incorporated socio-technical dimensions such as trust, accountability, and ethical alignment. Definition proposed by the OECD, UNESCO, and embedded in the European Union, stresses human-centeredness, transparency, and legal compliance (EU, 2024).

In this framework, the concept of HCAI has been emerging. The main idea of HCAI applications is to be able to use AI-based tools to improve human performance while preserving human values (Jörs & De Luca, 2025). Human-Centered Artificial Intelligence (HCAI) provides a rigorous conceptual anchor for addressing this challenge. Shneiderman's HCAI framework advances a two-dimensional design logic that seeks high levels of automation while preserving high levels of human control, with the explicit goal of producing AI systems that are reliable, safe, and trustworthy while enhancing human performance and agency (Shneiderman, 2020). This perspective is especially relevant in entrepreneurship because startups typically operate under resource scarcity and high uncertainty, conditions that may incentivize design shortcuts and over-automation, often with substantial downstream costs. Automatically, this becomes central to entrepreneurship education, that get ready future founders and equips them to avoid over-automation, preserve human judgment where it matters, and reduce downstream technical, ethical, and reputational costs.

Despite growing research on AI in Management and Entrepreneurship Education (Moheno et al., 2024; Dissanayake et al., 2025; Gong et al., 2025), studies explicitly linking HCAI and EE remain scarce (Alfredo et al., 2024; Schmager et al., 2025). Addressing this gap, the study examines how to conceptualize HCAI's role in EE. The paper reviews EE the literature, emphasizing interdisciplinary integration, learner centered design, and emotional well-being; then it analyses HCAI integration by identifying the research gap, and attempt to state the research question. Then, it proposes a qualitative empirical analysis and explains the main findings. The paper concludes with implications, limitations, and future research directions.

2. Main issues in Entrepreneurship Education Literature

According to Passarelli and Bongiorno (2025), Entrepreneurship Education (EE) is increasingly shaped by cross-disciplinary integration with pedagogy, psychology, ethics, and neuroscience, moving away from "one-size-fits-all" toward learner-centered, mixed-knowledge curricula (Landström et al., 2022; Kazakeviciute et al., 2016; Vázquez-Parra et al., 2022). Psychology enhances problem-solving and creativity (Xie et al., 2022), pedagogy supports context-tailored course design (Guerrero et al., 2020), and an emerging neuroscience stream links neurocognitive mechanisms to

entrepreneurial skill development (Moore et al., 2021; Lanivich et al., 2024; Wang et al., 2021). This multidisciplinary turn foregrounds diversity, neurodiversity, culture, race, gender, as a design requirement for more "ergonomic" EE programs (Brieger & Gielnik, 2021; Lanivich et al., 2024).

A second pillar concerns emotional intelligence and well-being. Emotional intelligence, perceiving, using, understanding, regulating emotions, is central to EE effectiveness, influencing engagement, creativity, and decision-making (Aly et al., 2021; Lackéus, 2014; Keller & Kozlinska, 2019; Zampetakis & Moustakis, 2010; Foo, 2011; Omorede et al., 2015). This supports aligning EE with learners' diverse needs, motivations, and backgrounds (Mwasalwiba, 2010; OECD & Lackéus, 2015; Maritz & Brown, 2013; Duval-Couetil & Long, 2014; Matricano, 2024b; Hahn et al., 2020; Liao et al., 2022; Fayolle & Gailly, 2015; Bauman & Lucy, 2021).

Implementation depends on educators combining technical competence with affective and relational qualities (Frenzel et al., 2009), and on teaching designs integrating venture topics (finance, BMC, planning, innovation, IPR, marketing) with action-oriented methods (action learning, cases, design thinking, testimonials) while addressing ethics and social responsibility (Samuel & Rahman, 2018; Duval-Couetil & Long, 2014; Sirelkhatim & Gangi, 2015; Rasmussen & Sørheim, 2006; Linton & Klinton, 2019; Béchard & Grégoire, 2005; Igwe et al., 2021). EE requires enabling ecosystems, infrastructure, support, experiential opportunities, that also support well-being (Clark et al., 2021; Belitski & Heron, 2017; Bischoff et al., 2018; Jones et al., 2020; Enrique et al., 2024; Arranz et al., 2017).

Emerging directions for EE (Pittaway & Cope, 2007; Haase & Lautenschläger, 2011; Fayolle & Gailly, 2015; Fellnhofer, 2019; Ratten & Jones, 2021; Matricano, 2024) include: (1) customizing programs through adaptive, iterative designs, diagnostics, core modules, electives, mentorship, supported by AI-driven platforms; (2) strengthening universities' ecosystem role as anchors for incubators, research centers, and networks fostering venture creation and responsible innovation (Etzkowitz, 2003); and (3) deepening attention to ethics, as new technologies (AI, IoT) and graduates' societal impact demand greater scrutiny (Lindner, 2018; Tesfayohannes & Driscoll, 2010; Vallaster et al., 2019).

3. Human centered Artificial Intelligence (HCAI) in Entrepreneurship Education

In recent years, the rapid advancement of AI technologies has profoundly reshaped entrepreneurship education, enabling more personalized, adaptive, and innovative learning experiences. Recent studies suggest that EE is gradually moving toward interdisciplinary integration, practice-oriented instruction, and greater use of digital technologies (Xu, 2024). Universities now integrate incubators, competitions, MOOCs, VR, and AR to enhance practical training and accessibility (Anjum et al., 2020; Thottoli et al., 2024). Nevertheless, EE still faces challenges: theoretical overload, weak hands-on learning, mentor shortages (Hameed & Irfan, 2019; Kraus et al., 2019), and underdeveloped assessment systems (Bolzani & Luppi, 2021; Scroccaro et al., 2025). These gaps underscore the need to investigate how emerging technologies, particularly HCAI, can help address such gaps and potentially support the effectiveness of EE.

HCAI aims to enhance human performance while preserving human values. It pursues two parallel goals: empowerment, keeping humans meaningfully "in the loop" to ensure safety, autonomy, and self-determination, and ethical compliance, embedding fairness, accountability, interpretability, and transparency as first-order design constraints. HCAI also emphasizes reliability, safety, and trustworthiness. In smart education, HCAI reasserts a humanistic mandate by embedding values from the outset, acting as a catalyst for learning, inclusion, and accessibility. Achieving this potential, however, requires a paradigm shift in educational programs to support effective human–AI collaboration, one that prioritizes the development of metacognitive capacities (e.g., critical judgment, calibration of trust, and anti-overreliance) alongside technical competence, rather than focusing primarily on generic communication principles (Le Dinh et al.,2025).

According to the literature review proposed by Le Dinh et al, 2025, HCAI is conceptualized unevenly across disciplines. Operationalizing it demands genuine interdisciplinary integration around pillars such as human capability, controllability, autonomy, calibrated trust, learner-centered design, and information literacy. Importantly, "more AI" does not automatically yield "new pedagogy"; without intentional redesign, AI often amplifies existing instructional logics.

While numerous studies examine AI in EE (Gong et al., 2025) and HCAI in education broadly (Le Dinh et al., 2025), the specific role of HCAI in EE remains underexplored. To address this gap, we attempt to answer the following question: *Which role does Human-Centered AI (HCAI) play in Entrepreneurship Education Programs (EEPs) for shaping a new generation of responsible leaders?*

4. Qualitative analysis

4.1 Research setting: the case of Master's Program in HCAI in Germany

Despite there are some international programs on Human Centered Artificial Intelligence[4], we focus on the first international master program that link Human-Centered AI education to Entrepreneurship Education. Specifically, we concentrated on the Master's Program in Human-Centered Artificial Intelligence at Otto-von-Guericke University Magdeburg. The program trains AI professionals with an emphasis on ethics, human-centered design, and responsible entrepreneurship. In fact, it is an interdisciplinary program that integrates technical proficiency with a deep understanding of social and ethical implications, preparing graduates to develop AI solutions that are safe, fair, and provide entrepreneurial projects that generate benefits to society. At the beginning of the program, most of the students had an initial project idea that would like to explore. A set of venture ideas across multiple sectors (creative AI, mobility, social media, trust & safety, accessibility, education, health, energy, industry, data, and fintech), focused on applying human-centered AI to solve real problems.

Tab. 1: Students' entrepreneurial ideas

Sector	Idea
Music / Creative AI	Personalized music recommendation based on emotional context
	AI-generated soundscapes for immersive experiences
	Adaptive AI music composition
Mobility / Infrastructure	Advanced mobility (flying cars, hoverboards)
	Improved rail network in Germany with separated passenger vs freight transport
Social media	Startup/platform changing how people interact with social media
	Gen AI for social media + regulation / compliance
Trust & Safety	Fake news detection
Accessibility	AI-driven assistive technologies (e.g., intelligent voice assistants)
	Real-time translation tools for the hearing impaired
	Accessibility tools for digital content consumption
Education	Startup selling tech products for students
	AI platforms for personalized learning experiences
	Personalized AI learning assistants / adaptive tutors
Ethics & Governance	Ethical AI governance dashboard (audits fairness / accountability / explainability)
Fairness in HR	Bias-resistant AI for recruitment (fair resume screening / interviews)
Healthcare HCAI	Human-centered AI-assisted diagnostic tool supporting doctor–patient interaction

Mental health	Mental health detection and prevention
	Ethical recommendation systems to promote well-being/resilience and positive behavior
Energy / IoT	Predictive maintenance + energy optimization for renewables
Business Intelligence	AI-powered market research tool (competitor analysis + trend prediction)
	Business intelligence dashboard with AI for real-time visualization & decisions
Industrial	AI add-ons for industrial tools (Oracle PLM, Enovia, SAP)
	Migrating legacy applications into human-centric AI applications
MedTech	Early detection of cancer
Data Cloud	Scalable cloud-based data solutions for SMEs
	Shortening / optimizing data pipelines
FinTech	FinTech startup for financial decision support (behavioral finance)
Smart city and Smart mobility payments	AI-driven traffic signal systems
	Auto-generated toll payments based on miles traveled

Source: our elaboration

The program follows a staged learning pathway. First, it builds a shared foundation in human-centered and responsible AI, blending technical literacy with ethical practice, privacy, security, and user-centered design. Second, students deepen their expertise through specialized topics, explainability, fairness, discrimination, and research data management for reproducibility and responsible sharing. Third, the curriculum shifts from instruction to application via the incubator-style "Innovation Experience." Here, students attend targeted entrepreneurship seminars (e.g., business models, business planning, canvas design), submit project proposals, and iterate through mentoring and feedback while developing prototypes in collaboration with external stakeholders. The incubator offers a distinctive environment for transforming ideas into impactful AI solutions, combining creativity, hands-on support, and access to industry expertise. The pathway concludes with a public Demo Day, where students present outcomes to partners, strengthening professional readiness and building bridges to industry, research, or venture creation in human-centered AI.

4.2 Gioia Methodology: research design and analysis

We adopted an exploratory qualitative design to investigate how HCAI can be integrated into Entrepreneurship Education Programs (EEPs), focusing on students' perspectives to uncover the logics by which HCAI shapes program architecture. Data come from a qualitative survey of students enrolled in the program and interested in the Innovation Experience Incubator. Exploratory inquiry is suited to emerging constructs and theory elaboration rather than hypothesis testing (Eisenhardt, 1989; Miles et al., 2018). Our approach is abductive, iterating between empirical material and extant literature to refine interpretation (Langley, 1999; Pratt, 2009).

Data analysis followed the Gioia Methodology (Gioia et al., 2013). We selected this approach because it offers a structured framework for examining complex, interpretive phenomena, capturing participants lived experiences while foregrounding reflection and contextual influence. Its inductive, data-driven nature is especially valuable where existing theories may not fully explain diverse educational practices. Compared to unstructured case designs without systematic coding, the Gioia method ensures greater rigor (Magnani & Gioia, 2023). It grounds theory in real-world experiences, traces processes and change over time, and is thus particularly suited to studying skill development, mindset evolution, and identity formation in EE.

Analysis followed three stages (Magnani & Gioia, 2023): (a) developing first-order (informant-centered) codes, second-order (theory-centered) themes, and aggregate dimensions; (b) constructing a grounded theoretical representation through constant data comparison; and (c) presenting findings via a data-driven narrative supported by second-order themes and first-order quotations. This rigorous approach to evidence collection and coding aligns with the standards of qualitative research.

4.3 Main steps and results

The application of Gioia methodology included the following stages (Darcis et al., 2024). The research process began with the theorization stage, where a matching between two broad streams of literature is proposed (Entrepreneurship Education and HCAI).

The results include general issues referring to learning mechanisms, affective and psychological layer, governance standards of HCAI, career orientation and the perceived support from the context. Stemming from the literature, a survey was created.

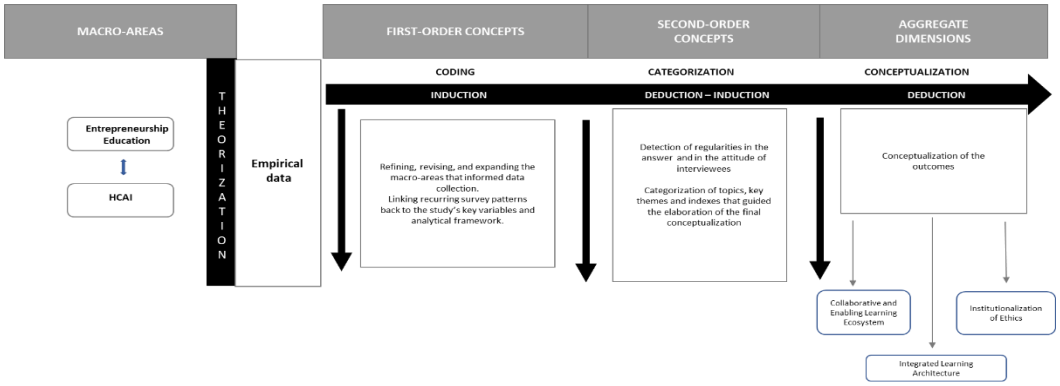
Tab. 2: Leading themes and survey

Theoretical issues	**Key literature anchors**	**Survey item(s)**
Learning mechanisms	Neck & Greene (2011); Pittaway & Cope (2007); Ratten & Jones (2021); Rasmussen & Sørheim (2006); Kolb (1984) Aly et al. (2021); Lackéus (2014); Mayer & Salovey (1995); Frenzel et al. (2009) Passarelli & Bongiorno (2025); Fayolle & Gailly (2015); Mwasalwiba (2010); OECD & Lackéus (2015)	What learning methods do you prefer? Which practical experiences would you include in the program (i.e. internships)? What learning methods do you prefer? Which features of the program are most relevant to you? Which areas of HCAI interest you the most?
Knowledge and skills	Xie et al. (2022); Schön (1983); Bandura (1997) Landström et al. (2022); Kazakeviciute et al. (2016); Vázquez-Parra et al. (2022); Neck & Greene (2011); Sirelkhatim & Gangi (2015)	What specific skills do you hope to acquire during the program? Which industries do you think will be most impacted by AI in the next 10 years?
Application domains	Isenberg (2010); Fellnhofer (2019)	Are you interested in specific applications of HCAI? Which areas of HCAI interest you the most?
Career orientation and employability outcomes	Duval-Couetil & Long (2014); Maritz & Brown (2013)	What career opportunities do you hope to achieve through the program? What are your long-term professional goals? Do you have initial project ideas or entrepreneurial ambitions?

Leadership and AI governance capability	OECD AI Principles (2019); NIST AI RMF (2023); Heifetz (1994) Shneiderman (2020); ISO 9241-210 (Human-centered design); Parasuraman et al. (2000)	What leadership skills do you think are most important for managing AI-driven workplaces? If you were to lead a team where AI plays a significant role, what would be your biggest concern? If you were to lead a team where AI plays a significant role, what would be your biggest concern?
Ethics issues	Béchard & Grégoire (2005); Igwe et al. (2021); OECD AI Principles (2019)	Which aspects of ethical AI and its practical application do you find most relevant?
External Support	Guerrero et al. (2020); Etzkowitz (2003); Belitski & Heron (2017); Bischoff et al. (2018); Clark et al. (2021); Spigel (2017); Stam (2015) Lindner (2018); Tesfayohannes & Driscoll (2010); Acemoglu & Restrepo (2019)	How interested are you in participating in projects within the incubator? What support would you expect from the incubator? How important is networking with industry experts and professionals? How do you think the program will impact wages, job security, inclusivity and inequality? If you were to lead a team where AI plays a significant role, what would be your biggest concern?

Source: our elaboration

All questions were open-ended, enabling students to express perspectives without predefined categories and capturing values, experiences, and behaviors not easily obtained through other methods (Darcis et al., 2024). An invitation email was sent to program participants; those interested completed an online survey. We collected 119 responses, all included in the study.



Data were analyzed following Gioia et al. (2013). Each author independently interpreted all answers to ensure validity and accuracy. The dataset comprised unstructured textual responses on career expectations, desired skills, long-term goals, ethical concerns, learning preferences, entrepreneurial intentions, and support needs. The survey served both as outreach and as a needs-assessment tool to align program development with student expectations.

Coding phase followed an inductive approach, linking raw data to theory (EE and HCAI). Independent coding ensured data triangulation.

Categorization phase employed a deductive-inductive process. First, open coding generated first-order terms close to participants' language. Through constant comparison and iterative discussion, these were clustered into second-order themes reflecting researcher-centric interpretation and theoretical sensemaking.

Conceptualization phase used a deductive approach to extract aggregate dimensions. This yielded three higher-order pillars of program architecture, Integrated Learning Architecture, Institutionalization of Ethics, Collaborative and Enabling Learning Ecosystem, which reaggregated second-order categories and were reconnected to key macro-challenges for EE in the HCAI era (Stutz & Sachs, 2018).

Fig. 2: Different phases of Gioia Methodology

Source: our elaboration

This process provides the Gioia data structure as an audit trail from raw evidence to theory (Gioia et al., 2013; Corbin & Strauss, 2015). Throughout the analysis, we used prior theory as sensitizing concepts, guiding attention without forcing pre-existing categories onto the data, until a stable structure emerged (Pratt, 2009). To enhance trustworthiness, we maintained an explicit chain of evidence linking representative quotations to first-order terms, second-order themes, and aggregate dimensions, and we iteratively refined the coding scheme through theme-based comparison and reconciliation (Miles et al., 2018). We also conducted reflexive checks to ensure that theoretical framing (e.g., HCAI, ethics-by-design, ecosystem embeddedness) informed interpretation without displacing informant-centric meanings (Gioia et al., 2013).

4.4 Connecting data and theory

The resulting model is a Holistic Entrepreneurship Education Program Architecture, that reflects a grounded yet theoretically connected account of how respondents understand the design principles, ethical infrastructure, and ecosystem conditions required to educate responsible HCAI-oriented entrepreneurial leaders (Gioia et al., 2013; Eisenhardt,1989; Langley,1999; Pratt,2009; Corbin & Strauss,2015; Miles et al.,2018). Systematic evidence in the literature shows the need of new learning contents (Passarelli & Bongiorno, 2025; Fayolle & Gailly, 2015; Mwasalwiba, 2010; Lackéus, 2014), that match technical topics with managerial tools: *«I expect sessions on entrepreneurship and project management. I hope to acquire both technical and soft skills required to build responsible and scalable AI systems. »*

Moreover, a sustained shift toward innovative teaching methods that privilege practice, action, and iterative learning over purely conceptual transmission emerges (Neck & Greene, 2011). Some suggested methods include: workshops, lectures, collaborative group works, project-based learning, case studies / real world problem solving, individual work / projects, interactive discussions, peer learning, seminars / conferences, internships, prototyping, guided tutorials, industry exposure, hackathons. Students show a strong preference for real-world, experience-based courses: *«I prefer a combination of hands-on learning and real-world problem solving. I find that practical experience helps solidify theoretical concepts. I appreciate a balanced approach that includes both structured lessons and opportunities for independent research and exploration. »*

The empirical analysis indicates a reorientation toward capability development, drawing on experiential, project-based, and competency-based designs that emphasize learning-by-doing and iterative action (Adesola et al., 2019; Heinonen & Ilonen, 2025; Klapper & Farber, 2016; Boldureanu et al., 2020; Westhead & Solesvik, 2016). Thus, the "about/for/through" typology appears particularly influential because it clarifies whether a course prioritizes conceptual understanding, preparation for entrepreneurial tasks, or practice-based enactment of entrepreneurial processes, through HCAI, supporting constructive choices about pedagogy and assessment. Consistent with this framing, programs should increasingly adopt interdisciplinary curricula, problem and challenge-based formats, team-based venture work, and design thinking to develop opportunity recognition, innovation behaviors, and execution capability (Baron & Tang, 2011; Linton & Klinton, 2019). Evidence indicates also the necessity of a student-centered design and the implementation of a real-world problem solving that tends to yield stronger entrepreneurial competence development and sustained engagement than lecture-dominant formats (Eustachio et al., 2025). Moreover, also the ecosystem-embedded learning (Gibb, 2002; Kazakeviciute et al., 2016; Rae, 2010) appears relevant. These challenges are amplified as EE expands beyond business schools into engineering and science contexts, where generic entrepreneurship modules may misalign with discipline-specific learning needs and with the development of cross-functional collaboration, managerial judgement, and innovation-oriented soft skills (Amalia & von Kortzfleisch, 2021). Collectively, these results position EE curriculum design not as a matter of content listing, but as a coherence problem, aligning new technologies, learning activities, technologies, new teaching methods requiring systematic yet context-sensitive design approaches and evaluation strategies capable of capturing both learning processes and sustained capability development, embedding an ethical approach (Nabi et al., 2017;

Ratten & Jones, 2021).

Respondents conceptualize skills development as a dual competence stack (Bandura, 1997). On one side, they emphasize socio-emotional and relational capabilities (emotional awareness, communication, teamwork, and "being more human"), suggesting that effective AI work requires interpersonal and human-centered sensitivity. On the other side, they highlight problem-solving, analytical reasoning, and applied machine learning skills aimed at addressing real-world problems. Together, these accounts portray an HCAI-ready profile where technical mastery is inseparable from human-facing competence: *«I want to strengthen my technical skills in areas like machine learning, natural language processing, and human-computer interaction. But just as importantly, I hope to develop a deeper understanding of ethics in AI, like how to identify bias in data, design fair algorithms, and build systems that are transparent and explainable. I'm really looking to become someone who can create AI that's not just powerful, but also responsible and user-focused. I hope to acquire Problem solving skills, analytical skills, logical thinking and applications to solve real world problems with AI. »*

The integration of HCAI into venture creation process stimulates also a concrete curriculum design challenge; thus, programs must prepare students not only to innovate with HCAI, but to do so in ways that anticipate problems, calibrate trust, and sustain legitimacy under increasing scrutiny (Shneiderman, 2020).

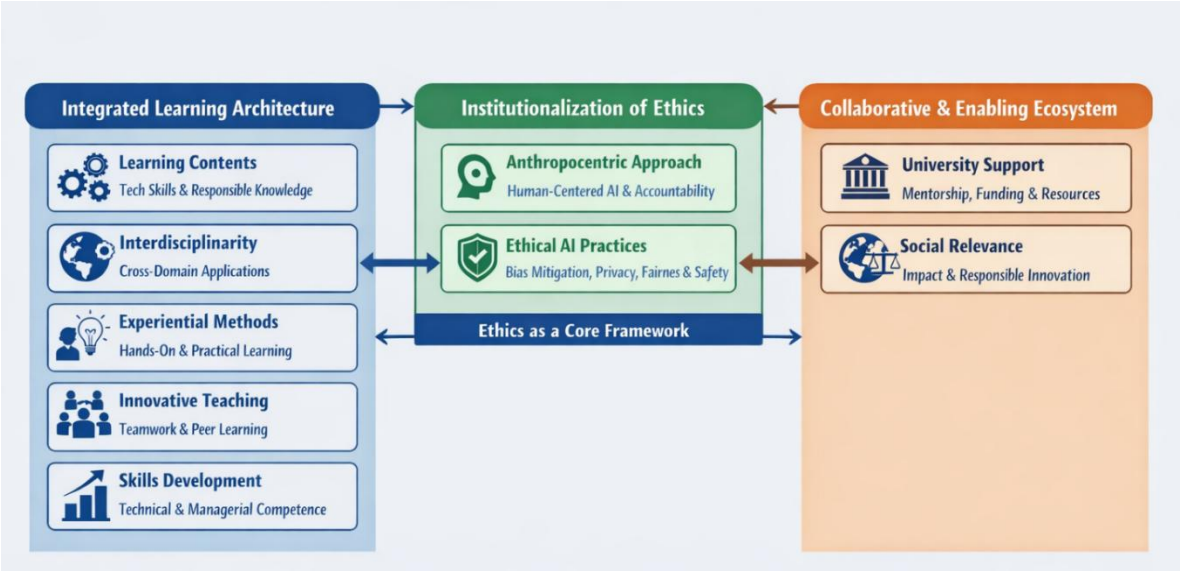
The result shows another aspect related to interdisciplinary. Responders see it as a purposeful integration of domains (Passarelli and Bongiorno, 2025) (Ethics, education, healthcare, entrepreneurship, finance, marketing, law, policy-making, communication), that lead human-centered, explainable, and responsible AI: *«On the long run the interdisciplinary nature of the program, especially its emphasis on ethics, transparency, and user-centered AI, aligns well with my interests in building explainable AI systems and personalized recommender technologies. I would like to see more opportunities for interdisciplinary collaboration with fields like psychology, sociology, and ethics, enabling a deeper understanding of human factors in AI design. »* Respondents have a strong attention to the "human aspects". Specifically, they articulate an anthropocentric view of HCAI in which model accuracy is necessary but insufficient. They emphasize transparency and accountability as prerequisites for trust, and they frame ethical alignment with human values as a core design requirement. In parallel, they describe human–AI collaboration as an augmentation logic, where AI should support rather than replace human decision-making, thereby preserving human agency. This orientation implies curricular needs that integrate AI foundations with ethics/policy and human factors (including emotions and trust dynamics), positioning trust as a designable outcome rather than a by-product: *«I believe it's crucial to not only develop accurate models but also ensure they are transparent, accountable, and aligned with human values. Course should cover not only AI and AI ethics and policies aspects but also human aspects, like Human emotions and its alignment with AI. I believe the integration of explainable AI and the development of robust, ethical AI frameworks for real-world applications are often. »*

The analysis highlights the ethics-by-design traditions where the values including fairness, privacy, autonomy, and inclusion should be systematically translated into design requirements through conceptual, empirical, and technical investigations, rather than appended as standalone discussions (Béchard & Grégoire, 2005; Igwe et al. ,2021; OECD AI Principles, 2019).

Open-ended responses focus also on the external support: *«From the incubator, I would expect a supportive environment that offers both mentorship and practical resources to help bring ideas to life. This includes access to experienced advisors, both academic and industry experts, who can guide the development of ethically sound and user-focused AI solutions. »*, specifically, they reveal a consistent expectation that the university incubator should function as a full-stack enablement platform rather than a symbolic entrepreneurship space. Participants repeatedly describe the need for mentorship (from both industry experts and researchers) to guide project development, troubleshoot technical and organizational barriers, and navigate uncertainty during early-stage innovation work. In parallel, they emphasize access to technical resources, notably computing infrastructure,

specialized tools, and datasets, as a prerequisite for building and testing HCAI solutions.

Respondents also frame the incubator as a broker of social capital, expecting structured networking opportunities that connect them with potential collaborators, investors, and external stakeholders. Beyond technical and relational resources, they explicitly request support for funding and business development (e.g., fundraising guidance, venture development support), as well as financial and legal assistance, implicitly pointing to needs around intellectual property, compliance, contracts, and venture formalization (Bandera and Thomas, 2017). Finally, several accounts indicate a demand for capability-building formats such as workshops on entrepreneurship, project management, and ethical AI practices, suggesting that students interpret incubator participation as professional formation oriented toward real-world implementation: *«I would expect the incubator to offer mentorship from experts, access to tools and resources, networking opportunities and help with funding and business development to support my ideas or projects. I would expect the incubator to provide mentorship from industry experts and researchers to guide project development and help navigate challenges. Access to technical resources and tools, such as computing infrastructure and datasets, would be crucial. I expect support with networking opportunities to connect with potential collaborators, investors, and stakeholders is also important.»*



These support expectations are closely tied to participants' longer-term aspirations. While some respondents' position incubator participation as a pathway to collaborate with innovative firms on applied AI and digital engineering projects, others explicitly articulate a future goal of founding ventures that address societal challenges. This connection indicates that students envision the incubator as an institutional mechanism that reduces resource scarcity, accelerates learning-by-doing, and strengthens legitimacy through industry exposure and partnerships: *«I aim to collaborate with innovative companies, contributing to impactful AI and digital engineering projects. In the long term, I aspire to start my own venture focused on creating technology solutions that address societal challenges and improve lives.»*

Alongside support expectations, the data also highlight a strong social relevance orientation in how respondents frame HCAI applications. Participants frequently identify healthcare, education, and public policy as priority domains, emphasizing that these contexts directly affect people's lives and therefore require human-centered design choices. They associate HCAI's value with improvements in decision-making quality, accessibility, and personalized support, portraying human-centered AI not merely as a technical approach but as a societal commitment to usability, inclusion, and meaningful impact. Taken together, these responses suggest that an HCAI-ready program and its incubator ecosystem are evaluated by students through a dual lens: the availability of institutional and ecosystem resources that enable project execution and venture formation, and the degree to which projects can be oriented toward tangible human and societal outcomes: *«I am especially interested in the application of human-centered AI in healthcare, education, and public policy. These fields have a direct impact on people's lives. I believe that AI systems designed with a human-centered approach can improve decision-making, accessibility, and personalized support.»*

5. Discussion

The qualitative analysis shows that Human-Centered AI (HCAI) plays a crucial role in Entrepreneurship Education Programs (EEPs) by creating a Holistic Entrepreneurship Education Program Architecture (HEEPA) for shaping a new generation of responsible leaders. HEEPA is a structure built on three main pillars (Aggregate Dimensions): *Integrated Learning Architecture, Institutionalization of Ethics, and Collaborative and Enabling ecosystem*.

Fig. 3: HEEPA Architecture

Source: our elaboration

In line with the Gioia findings, the constructs grouped under the *Integrated Learning Architecture* pillar are reflected in five second-order categories: learning contents, interdisciplinarity, experiential methods, innovative teaching, and skills development, which collectively portray an "HCAI-ready" EEP as a coherent learning architecture rather than a mere bundle of courses (Passarelli & Bongiorno, 2025; Fayolle & Gailly, 2015; Landström et al., 2022; Neck & Greene, 2011; Kolb, 1984; Schön, 1983; Bandura, 1997; Pittaway & Cope, 2007; Rasmussen & Sørheim, 2006; Guerrero et al., 2020; Spigel, 2017). Respondents describe a deliberate alignment between content, pedagogy, and professional formation. The curriculum is anchored in a robust technical and conceptual base, while simultaneously integrating responsibility-related knowledge and entrepreneurial tools. In this framing, "being HCAI-ready" entails the capacity to work with both the capabilities and the constraints of AI systems. Interdisciplinarity is emphasized through application arenas where trade-offs and contextual complexity become visible. Pedagogically, respondents privilege experiential and practice-based formats that resemble real innovation work, implying that HCAI competence develops through iterative cycles of problem framing, design choices, testing, and evaluation under constraints. They also stress that innovative teaching extends learning beyond individual mastery into relational and collective processes. Finally, skills development is described as a "professional stack" that bridges technical implementation and managerial responsibility, positioning the EEP as a pipeline for translating, governing, and operationalizing AI in organizational settings.

The second pillar, *Institutionalization of Ethics*, is grounded in ethics-by-design priorities and human-centeredness (OECD AI Principles, 2019; Igwe et al., 2021; Shneiderman, 2020; ISO 9241-210; Parasuraman et al., 2000). Two second-order categories dominate respondents' accounts. The Anthropocentric approach foregrounds, and a strong concern with avoiding overreliance. The focus is not simply usability, but safeguarding human agency and judgment while maintaining alignment with responsibility expectations. The Application of Ethical AI translates this orientation into concrete requirements, treating ethics as an engineering and governance challenge as much as a philosophical one. Accordingly, respondents argue that it is insufficient to add a standalone "AI ethics" module to an otherwise technical curriculum: ethics must function as an infrastructure and a guiding logic shaping design, evaluation, legitimation, and responsibility allocation, particularly in relation to GenAI and cognitive offloading risks.

Finally, constructs associated with the *Collaborative and Enabling Learning Ecosystem* pillar, ecosystem embeddedness and institutional resources, as well as social relevance in terms of labor

impacts, inequality, and policy, align with the Gioia categories of university support and social relevance (Etzkowitz, 2003; Belitski & Heron, 2017; Clark et al., 2021; Lindner, 2018; Tesfayohannes & Driscoll, 2010; Acemoglu & Restrepo, 2019). Respondents emphasize that capability-building requires institutional scaffolding treated as integral to the learning-to-implementation pipeline rather than peripheral support. Social relevance is framed as an explicit orientation toward impact and long-term consequences. In this view, an HCAI-ready EEP is evaluated not only by technical outputs or entrepreneurial intent, but by its capacity to generate solutions that are legitimate, accountable, and aligned with public value.

Within this perspective, "HCAI" is treated as a pedagogical design rather than simply "using AI tools" in class. The core idea is that HCAI can work as an ethical learning enactor in EEPs.

6. Conclusions

The paper advances the discourse on Entrepreneurship Education (EE) by proposing and empirically grounding a framework for integrating Human-Centered Artificial Intelligence (HCAI). It demonstrates that HCAI's role extends beyond being a mere pedagogical tool or a subject domain; it acts as a transformative design logic for constructing holistic educational architectures. The resulting model, the Holistic Entrepreneurship Education Program Architecture (HEEPA), posits that educating responsible, AI-savvy entrepreneurial leaders requires the simultaneous and interdependent development of three pillars: Integrated Learning Architecture, Institutionalization of Ethics and Collaborative and Enabling Learning Ecosystem The paper argues that "HCAI readiness" in entrepreneurship is not achieved by adding AI modules to existing courses but by re-engineering programs where ethical reasoning and human control are enacted through entrepreneurial practice itself. This approach ensures that the next generation of entrepreneurs is equipped not only to build with AI but to do so in a manner that is trustworthy, accountable, and aligned with broader societal well-being, thereby fulfilling the core promise of human-centered innovation (Matricano, Vesci, Passarelli, 2026).

7. Implications, limitations and further research

The analysis yields critical insights and implications for universities and policymakers, while positioning HCAI as a new frontier for entrepreneurship education research.

Graduates increasingly need HCAI-enabled capabilities, data analysis, intelligent marketing, AI-supported finance, and strategic decision-making. Embedding HCAI in EEPs can strengthen innovative capacity and translate ideas into testable solutions (Chen et al., 2024; Somià & Vecchiarini, 2024, 2023), support core entrepreneurial routines (Thanasi-Boçe & Hoxha, 2024), and reinforce transversal competencies: communication, teamwork (Benhayoun & Lang, 2021; Samanthi & Gooneratne, 2023), leadership (Xu et al., 2022), lifelong learning (Akhtar et al., 2024; Dimes & De Villiers, 2021, problem-solving (Kurtzke & Setkute, 2021), reflective and critical thinking (Dimes & De Villiers, 2021; Bell & Bell, 2023; Brabete et al., 2024; Sollosy & McInerney, 2022), relationship management and analytical/creative thinking (Cardon et al., 2024). This demands curricula that intentionally couple technical, entrepreneurial, and ethical outcomes within a multidisciplinary architecture. Crucially, integration is not merely tool-additive: it requires pedagogical redesign where human agency and ethics-by-design shape learning activities, assessment, and project governance.

For policymakers, advancing HCAI-ready EE requires investment beyond curricula: strengthening university incubators and translational hubs (computing, data, prototyping, mentoring), funding interdisciplinary networks linking students with firms, public institutions, and civil society, and developing ethical governance frameworks (standards, audit, regulation) embeddable in education

and scalable to real-world deployment. Practical instruments, targeted grants, industry–university vouchers, challenge-based pilots, ethics-by-design incentives, can lower barriers and operationalize HCAI principles beyond the classroom, fostering innovation that is both competitive and socially legitimate.

The study has limitations that also open promising directions for future research. The qualitative single-case design (specific HCAI program in Germany) limits generalizability; learner perceptions were captured at one point in time, leaving long-term effects on entrepreneurial behavior, venture outcomes, and ethical practice untested. Future research should adopt longitudinal, cross-cultural designs with larger, more diverse samples across educational stages and national contexts to systematically compare perceptions, trace capability development, and evaluate sustained impacts on ethical reasoning, venture creation, and professional practice.

Appendix 1: Different phases of Gioia analysis

Aggregate dimension: **Integrated Learning Architecture**		
2nd order	***1st order***	***Raw data***
Learning Contents	*UI/UX design, social impact assessment, different AI models, prompt engineering, real life applications, LLMs modelling, gen AI, risk analysis and management, bias detection, Canvas, design thinking, Project Management, bridging technical AI and business intelligence, IP, Using AI in Product development via Agile methodologies, Risk management, decision support, Interdisciplinary and Economic thinking, Investing strategies*	*I expect sessions on entrepreneurship and project management* *I hope to acquire both technical and soft skills required to build responsible and scalable AI systems.*
Experiential methods	*Workshops* *Lectures* *Collaborative group works* *Project-based learning* *Case studies / Real world problem solving* *Individual work / projects* *Interactive discussions* *Peer learning* *Seminars / Conferences* *Internships* *Prototyping* *Guided tutorials* *Industry exposure* *Hackathons* *Weekly assignments* *Visual cues* *Interactive simulations* *Lab sessions* *Collaborative group works, peer learning, interactive discussions*	*I prefer a combination of hands-on learning and real-world problem solving.* *I find that practical experience, such as coding exercises and case studies, helps solidify theoretical concepts.* *I appreciate a balanced approach that includes both structured lessons and opportunities for independent research and exploration.* *I prefer collaborative work and discussions also enhance my understanding.* *I value diverse perspectives and peer learning.*
Skills development	*Importance of human emotions, soft skills, Team work and communication skills*	*Skills needed to be more like a human being and less like a compulsive instinctive creature.* *I hope to acquire Problem solving skills, analytical skills, logical thinking, machine learning methods and applications to solve real world problems with AI.*
Interdisciplinarity	*Ethics, education, healthcare, entrepreneurship, finance, marketing, law, policy-making, communication*	*On the long run the interdisciplinary nature of the program, especially its emphasis on ethics, transparency, and user-centered AI, aligns well with my interests in building explainable AI*

		systems and personalized recommender technologies. *I would like to see more opportunities for interdisciplinary collaboration with fields like psychology, sociology, and ethics, enabling a deeper understanding of human factors in AI design.*
Aggregate dimension: **Institutionalization of Ethics**		
2nd order	***1st order***	***Raw data***
Anthropocentric approach	*Human-AI trust, AI and emotional intelligence, human-AI collaboration*	*I believe it's crucial to not only develop accurate models but also ensure they are transparent, accountable, and aligned with human values.* *I'm also fascinated by how AI can be designed to collaborate with people—augmenting rather than replacing human decision-making.* *These areas of HCAI excite me because they focus on building systems that earn user trust and have a meaningful, ethical impact on society.* *Course should cover not only AI and AI ethics and policies aspects but also human aspects, like Human emotions and its alignment with AI, etc*
Ethical AI practices	*Impact assessment, explainable AI, practical implementation, transparency and fairness, inclusion, compliance with AI principles*	*I believe the integration of explainable AI and the development of robust, ethical AI frameworks for real-world applications are often underestimated.* *Some aspects should be emphasized to ensure transparency, fairness, and trust in AI systems.*
Aggregate dimension: **Collaborative and enabling Ecosystem**		
2nd order	***1st order***	***Raw data***
University support	*Mentorship, networking opportunities, access to technologies and resources, funding opportunities, financial and legal assistance, internship and collaboration with firms*	*I would expect the incubator to offer mentorship from experts, access to tools and resources, networking opportunities and help with funding and business development to support my ideas or projects.* *I would expect the incubator to provide mentorship from industry experts and researchers to guide project development and help navigate challenges. Access to technical resources and tools, such as computing infrastructure and datasets, would be crucial.*

		I expect support with networking opportunities to connect with potential collaborators, investors, and stakeholders is also important. *I aim to collaborate with innovative companies, contributing to impactful AI and digital engineering projects. In the long term, I aspire to start my own venture focused on creating technology solutions that address societal challenges and improve lives.*
Social relevance	*Consciousness, social responsibility, practical applications*	*I am especially interested in the application of human-centred AI in healthcare, education, and public policy. These fields have a direct impact on people's lives.* *I believe that AI systems designed with a human-centred approach can improve decision-making, accessibility, and personalized support*

Strategic Sensing under VUCA Conditions: A Critical Reflection on Forecasting, Anchoring Bias, and Agentic AI

GIUSEPPINA LO MASCOLO[1], GABRIELLA LEVANTI[2], ARABELLA MOCCIARO LI DESTRI[3]

Abstract

Frame of the research. Contemporary organizations increasingly operate under persistent VUCA conditions, where volatility, uncertainty, complexity and ambiguity undermine predictive approaches to strategy. Despite advances in analytics and artificial intelligence, organizations continue to experience delayed adaptation, interpretive rigidity and systematic decision biases, particularly in relation to forecasting practices and strategic sensing.
Purpose of the paper. This paper critically examines how the emergence of agentic AI reconfigures the relationship between forecasting systems, anchoring mechanisms and strategic sensing under persistent VUCA conditions, challenging dominant assumptions that advanced AI primarily improves prediction or mitigates cognitive bias.
Methodology. The study adopts a theory-informed critical reflection approach, integrating and problematizing insights from strategic management, dynamic capabilities, behavioural strategy, forecasting research and emerging literature on agentic AI to develop a diagnostic conceptual framework.
Results. The paper conceptualizes strategic sensing as a hybrid human–AI and tension-filled process in which agentic systems become constitutive elements of sensing. Rather than eliminating anchoring, agentic AI redistributes and reshapes cognitive and algorithmic constraints, generating persistent tensions between prediction and interpretation, speed and reflection, autonomy and control, and learning and lock-in.
Research limitations. As a critical reflection, the study does not provide empirical validation or causal testing and focuses on organizational-level strategic sensing, leaving broader institutional and regulatory dimensions unaddressed.
Managerial implications. Managers are encouraged to rethink decision architectures and governance arrangements, focusing less on predictive optimization and more on preserving interpretive flexibility and collective sensemaking within hybrid human–AI sensing systems.
Originality of the paper. The paper offers a novel reframing of forecasting and agentic AI as interpretive infrastructures shaping strategic meaning, rather than as purely technical solutions to uncertainty.

Keywords: *Strategic sensing, Agentic artificial intelligence, VUCA environments, Anchoring bias, Dynamic capabilities, Strategic Sensemaking*

1. Introduction

Management research has long conceptualized forecasting as a technical support function aimed at informing decision-makers through probabilistic estimates of future outcomes (Trapero et al., 2010; Fahiminia et al., 2022). Within this paradigm, strategy has traditionally been framed as the deliberate effort of organizations to secure long-term advantage by committing to coherent courses of action and resisting short-term pressures (Adner, 2017). Classical definitions emphasize positioning and internal coherence: Porter (1996), for instance, defines strategy as the creation of a unique and valuable position grounded in a system of interlocking activities. Such analytical conceptions implicitly assume environments characterized by relative stability, interpretable cause–effect relationships, and uncertainty that can be progressively reduced through improved analysis.

These assumptions have become increasingly untenable. Contemporary competitive environment is marked by demand volatility, technological disruption, geopolitical instability, and recurrent external shocks, conditions under which uncertainty is not episodic but structural. The concept of VUCA, volatility, uncertainty, complexity, and ambiguity, has emerged as a dominant framework to capture this shift (Green et al., 2019; Sari et al., 2023). Under uncertain and volatile

conditions, future states are unstable, non-linear, and subject to sudden regime shifts, limiting the strategic value of forecasting when it is treated solely as a predictive exercise.

In response, management research has emphasized agility, adaptability, and learning-oriented cultures as key organizational responses to complex environments. Transformational leadership has been proposed as a mechanism to foster collective sensemaking and adaptability (Malik, 2023), while organizational agility and flexible structures are viewed as prerequisites for timely strategic adjustment (Zhang, 2024; Kayyali, 2025; Kaivo-oja and Lauraéus, 2018). Yet, despite unprecedented access to data, computational power, and advanced analytics, firms continue to experience systematic forecasting failures, delayed strategic responses, and persistent decision biases.

This paradox suggests that the core challenge is not the absence of information or analytical sophistication, but the way in which forecasts are interpreted, anchored, and incorporated into strategic reasoning. Recent advances in artificial intelligence, particularly the emergence of agentic AI, further complicate this landscape. While agentic systems promise autonomy, adaptive learning, and continuous environmental interaction (Hossaini and Seilani, 2025; Raptis et al., 2025), their implications for strategic sensing under VUCA conditions remain under-theorized.

Accordingly, this paper does not ask whether agentic AI improves forecasting accuracy or resolves cognitive bias. Instead, it critically examines how the introduction of agentic AI reconfigures the relationship between forecasting, anchoring mechanisms, and strategic sensing under persistent ambiguous conditions.

Despite the growing literature on dynamic capabilities, behavioural strategy, and artificial intelligence, these streams have largely evolved in parallel. Dynamic capabilities research has remined predominantly human-centric, focusing on managerial cognition or organizational routines (Teece, 2018), while forecasting research has emphasized predictive accuracy over interpretive effects (Trapero et al., 2010). At the same time, emerging studies on agentic AI have primarily focused on performance, autonomy, and governance without fully integrating these systems into theories of strategic capability (Hosseini and Seilan, 2025).

This paper contributes by bridging these streams and advancing a critical reframing of strategic sensing as a hybrid human-AI process, in which forecasting systems and agentic AI jointly shape interpretation under VUCA conditions.

2. VUCA and the Limits of Predictive Strategy

The VUCA framework captures environments in which volatility, uncertainty, complexity, and ambiguity jointly undermine linear planning and predictive control (Green et al., 2019). Unlike traditional risk-based settings, VUCA environments are characterized by unstable distributions, non-stationary dynamics, and weak or delayed feedback loops (Sari et al., 2023). In such contexts, additional data or more sophisticated models do not necessarily improve strategic sensing, as the underlying structure of the environment itself is subject to change.

This poses a fundamental challenge to traditional strategic frameworks, which treat uncertainty as a temporary obstacle to be managed through analysis, forecasting, and optimization. Even adaptive and learning-oriented approaches often retain an implicit belief that improved sensing will eventually converge toward more accurate representations of the future (Mintzberg, 1994; Wolf and Floyd, 2017). Ambiguous conditions problematize this belief by rendering the future partially indeterminate and endogenously shaped by strategic action itself.

In response, management research has increasingly focused on organizational agility and adaptive capacity as strategic imperatives. Transformational leadership (Malik, 2023), flexible organizational structures (Kayyali, 2025), and learning-oriented cultures (Kaivo-oja and Lauraéus, 2018) are frequently proposed as mechanisms to cope with volatility and uncertainty. However, these prescriptions often overlook the cognitive processes through which uncertainty is interpreted and

acted upon, implicitly assuming that better leadership or culture will translate into better strategic sensing.

Under these conditions, the problem of strategy shifts from predicting future states to continuously revising interpretations of evolving environments. It is precisely within this shift that the role of forecasting, cognition, and AI must be reconsidered.

3. Forecasting, Strategic Capabilities, and Anchoring Bias

Within strategic management, forecasting is typically associated with the *sensing* component of dynamic capabilities (Teece, 2007; 2018). Forecasts are expected to support strategic decision-making by identifying trends, anomalies, and emerging opportunities (Nguyen et al., 2021). However, behavioural strategy research highlights a critical tension: forecasts do not merely inform decisions; they also structure cognition.

Anchoring bias leads decision-makers to rely disproportionately on initial information or reference points, adjusting insufficiently as new data emerge (Furnham et al., 2012; Rastogi et al., 2020). Under VUCA conditions, this bias is amplified rather than attenuated, as ambiguity and complexity increase reliance on simplified mental models (Dhakal and Lamsal, 2023). Emotional states further influence anchoring, affecting how individuals interpret and update forecasts (Jung and Young, 2019).

Importantly, predicting systems themselves can become sources of anchoring (Campbell and Sharpe, 2009; Kusev et al., 2018). When their outputs are treated as authoritative representations of the future, they reinforce cognitive rigidity and delay strategic revision (Kusev et al., 2018). In this sense, forecasting is not a neutral input into strategic capabilities, but an active force shaping sensemaking and interpretation. Rather than enabling adaptation, forecasts may contribute to lock-in, particularly when organizations operate under persistent uncertainty (Campbell and Sharpe, 2009).

This tension becomes particularly critical when forecasting systems are embedded in increasingly automated and AI-driven decision environments, where anchors may be reinforced not only cognitively but also algorithmically.

4. The Emergence of Agentic AI: A Qualitative Shift

Recent advances in artificial intelligence introduce a qualitative shift in this dynamic. Agentic AI systems, distinct from generative AI, which primarily produces outputs in response to promts, are characterized by autonomous goal pursuit, adaptive learning, and continuous interaction with their environment (Hossaini and Seilani, 2025; Raptis et al., 2025). Unlike traditional decision-support or generative AI systems, agentic AI does not operate episodically in response to managerial queries; it persistently monitors signals, updates internal representations, and initiates actions. For istance, in data-intensive organizational settings, agentic systems can continuously monitor multiple streams of internal and external signals, dynamically prioritize emerging patterns, and trigger revisions in strategic attention without direct human intervention.

These properties have profound implications for strategic sensing. Forecasting systems endowed with agentic capabilities no longer function solely as informational inputs; they actively shape the temporal structure of decision-making by sustaining attention, prioritizing signals, and prompting revisions of strategic interpretations (Garg, 2025).

However, recent research cautions against solutionist interpretations of agentic AI. Under VUCA conditions, future states remain partially unknowable and subject to endogenous change. As Townsend et al. (2024) argue, attempts to render such futures fully computable risk overlooking the irreducible uncertainty inherent in complex adaptive systems. Within this context, agentic AI may

externalize, multiply, or accelerate anchoring mechanisms rather than eliminate them, producing new forms of *algorithmic anchoring* (Carter and Liu, 2025) and interpretive lock-in.

5. Strategic Sensing as a Hybrid, Tension-Filled Process

Strategic sensing under persistent VUCA conditions can be conceptualized as a circular, non-linear and hybrid process in which human interpretation and agentic AI jointly construct strategic meaning (Figure 1). The circular structure reflects the absence of a stable decision endpoint and emphasizes that, in volatile, uncertain, complex and ambiguous environments, strategic sensing unfolds as a continuous process of interpretation rather than as a sequence of analytical steps leading to optimized choices.

At the core of the framework lies strategic sensing as a hybrid human–AI capability. Human interpretation and agentic AI are represented as co-present and interconnected components of the same sensing process, rather than as separate or hierarchical actors. This representation reflects the growing interdependence between managerial judgment, experience and sensemaking on the one hand, and autonomous monitoring, adaptive learning and signal prioritization performed by agentic systems on the other (Hossaini and Seilani, 2025; Raptis et al., 2025; Garg, 2025). Strategic sensing therefore emerges from their continuous interaction, not from the substitution of human cognition with artificial agency.

In this context, forecasting models and foresight practices are positioned as inputs that feed the strategic sensing process rather than as mechanisms that directly generate strategic decisions. Forecasting systems, whether statistical or machine-learning-based, provide structured expectations about possible future developments, supporting the sensing component of dynamic capabilities (Teece, 2007; 2018; Nguyen et al., 2021). Foresight and sensemaking practices complement these analytical inputs by fostering interpretive revision, alternative framing and collective reflection on emerging futures (Fergnani, 2022). Their role is therefore not to reduce uncertainty, but to sustain the continuous reconstruction of strategic meaning under conditions in which environmental change remains partially indeterminate.

Anchoring mechanisms are a transversal field permeating both human interpretation and agentic AI. They do not disappear in hybrid sensing systems, but are redistributed across human and algorithmic components. Behavioural research demonstrates that decision-makers tend to rely excessively on initial forecasts and historical reference points (Furnham et al., 2012; Rastogi et al., 2020; Dhakal and Lamsal, 2023), while emotional states further shape how anchors are adopted and revised (Jung and Young, 2019). At the same time, agentic systems may introduce algorithmic reference points that stabilize expectations and prioritization schemes, potentially generating new forms of algorithmic anchoring and interpretive lock-in (Townsend et al., 2024). In this regard, anchoring can be visualized as a persistent cognitive and computational constraint that operates and can be nourished across the entire sensing process.

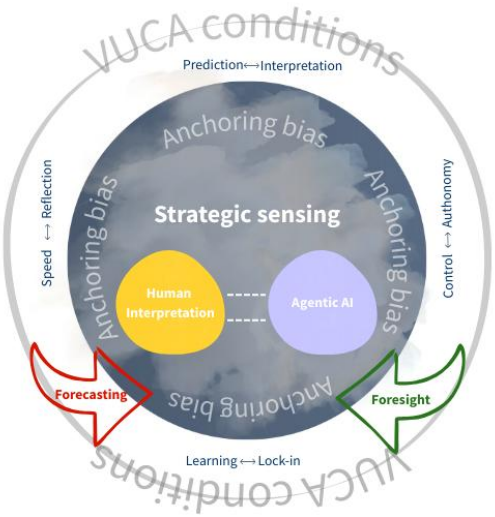

Figure 1 - Strategic sensing under VUCA conditions as a hybrid, tension-filled process.

The figure conceptualizes strategic sensing as a circular and non-linear hybrid human–AI process embedded in persistent VUCA conditions (volatility, uncertainty, complexity and ambiguity). Human interpretation and agentic AI jointly construct strategic meaning within a shared sensing core, while forecasting models and foresight practices feed the process as complementary analytical and interpretive inputs rather than as direct drivers of strategic decisions. Anchoring mechanisms, both human and algorithmic, permeate the entire sensing process, reshaping the locus of cognitive constraint rather than eliminating bias. The framework highlights four persistent tensions that structure hybrid strategic sensing under VUCA conditions: prediction versus interpretation, speed versus reflection, autonomy versus control, and learning versus lock-in.

The framework highlights four persistent tensions that structure hybrid strategic sensing under VUCA conditions:

1. **Prediction versus interpretation**. While forecasting systems are designed to improve predictive representations of the future, strategic sensing increasingly depends on the ability to reinterpret signals, anomalies and deviations as they unfold. The strategic value of forecasting thus lies less in accuracy and more in its capacity to stimulate interpretive revision;
2. **Speed versus reflection**. Agentic AI enables continuous monitoring and rapid updating of expectations, but accelerated sensing cycles may limit opportunities for deliberate reflection and collective sensemaking. Under persistent uncertainty, faster sensing does not necessarily translate into more adaptive strategy;
3. **Autonomy versus control**. Agentic systems increasingly initiate monitoring, prioritization and alerting activities without direct human intervention. While this autonomy expands organizational sensing capacity, it simultaneously raises questions about managerial oversight, accountability and the governance of interpretive processes;
4. **Learning versus lock-in**. Hybrid sensing systems may support adaptive learning by enabling recursive updating and exposure to weak signals. However, both human and algorithmic anchors may stabilize dominant interpretations, producing path dependencies and reinforcing existing strategic frames.

Taken together, these tensions indicate that agentic AI does not resolve the fundamental challenges of strategic sensing under VUCA conditions. Instead, it reshapes the temporal structure, cognitive architecture and governance of sensing processes. Strategic capability therefore lies not in eliminating uncertainty or bias, but in sustaining interpretive openness in the presence of persistent human and algorithmic anchors and in managing the tensions that inevitably emerge within hybrid human–AI sensing systems (Fergnani, 2022; Mussweiler et al., 2000).

6. Theoretical implication

This critical reflection contributes to management and strategy research by challenging three deeply embedded assumptions concerning forecasting, strategic capabilities and the role of artificial intelligence under persistent VUCA conditions.

First, the paper questions the dominant treatment of forecasting as a primarily predictive and instrumental input to strategic decision-making. By conceptualizing forecasts as interpretive artefacts that actively structure managerial attention, expectations and sensemaking processes, it shifts the analytical focus from accuracy and model performance to the cognitive and organizational effects of forecasting systems (Trapero et al., 2010; Fahiminia et al., 2022). This perspective complements and extends existing forecasting research by foregrounding how analytical outputs participate in the construction of strategic meaning rather than merely supporting it.

Second, the paper problematizes the largely human-centric orientation of dynamic capabilities theory by reinterpreting strategic sensing as a hybrid and distributed capability emerging from the continuous interaction between human judgement and agentic systems. While dynamic capabilities research has traditionally emphasized managerial cognition and organizational routines as the primary foundations of sensing, seizing and transforming (Teece, 2018; Eisenhardt and Martin, 2017), the framework developed here highlights how artificial agency becomes constitutive of sensing processes themselves, thereby calling for a reconsideration of how strategic capabilities are conceptualized and theorized in digitally augmented organizations.

Third, the paper challenges prevailing managerial and technological narratives that portray agentic AI as a means to overcome uncertainty and mitigate cognitive biases. Building on recent critiques of computable futures and algorithmic rationality (Townsend et al., 2024), it advances a more ambivalent view of agentic systems, showing how they may simultaneously enable continuous environmental monitoring and reinforce new forms of cognitive and algorithmic anchoring under VUCA conditions. In doing so, the paper contributes to a more critical and theoretically grounded understanding of artificial intelligence in strategy, moving beyond solution-oriented accounts toward an interpretation of AI as a structural component of contemporary strategic sensemaking.

7. Practical implication

Rather than offering prescriptive guidance, this paper encourages managers to critically reflect on how contemporary decision architectures shape strategic interpretation under persistent VUCA conditions. In particular, it draws attention to the often-overlooked role of forecasting systems as cognitive infrastructures that build expectations, stabilize reference points, and channel managerial attention, thereby functioning as powerful anchoring devices rather than neutral analytical supports.

The increasing integration of agentic AI further transforms this landscape by redistributing not only analytical tasks, but also responsibility for monitoring, prioritization, and the timing of strategic attention. As autonomous systems continuously filter signals and trigger revisions, managerial agency is reconfigured rather than simply augmented. Managers are therefore confronted with new forms of interpretive dependence on algorithmic systems, which may remain largely opaque while exerting substantial influence on what is perceived as relevant, urgent, or plausible.

From a practical perspective, the central managerial challenge is not to improve predictive performance, but to deliberately design decision architectures and governance arrangements that preserve spaces for interpretive questioning, collective sensemaking, and the contestation of dominant analytical frames. Under conditions in which both human and algorithmic anchors coexist, maintaining strategic flexibility requires organizations to actively monitor how forecasts and agentic systems shape attention, suppress alternative interpretations, and contribute to emerging forms of strategic lock-in.

In this sense, managerial practice under VUCA conditions increasingly revolves around the governance of hybrid human–AI sensing systems, rather than the optimization of individual analytical tools. The practical relevance of agentic AI therefore lies less in its capacity to deliver better predictions and more in how it reshapes the organization's ability to continuously revise assumptions, sustain interpretive plurality, and remain responsive to unfolding uncertainty. In this perspective, managers may critically reflect on their current decision architectures by asking to what extent do their forecasting system act as anchor rather than inputs; how does agentic AI shape what is perceived as relevant or urgent in their organisation; and where do they preserve space for interpretive questioning and strategic revision.

8. Conclusion and Future Research

Under persistent VUCA conditions, the central strategic challenge is not to predict the future more accurately, but to sustain the organizational capacity to continuously revise interpretations as environments evolve. This paper has argued that forecasting systems, long treated as neutral supports to managerial judgment, actively participate in the construction of strategic meaning and may operate as powerful anchoring devices that stabilize expectations even when environmental conditions call for revision.

The emergence of agentic AI fundamentally reshapes this landscape. By continuously monitoring, prioritizing, and recombining signals, agentic systems become constitutive elements of strategic sensing rather than external analytical tools. However, this transformation does not resolve the indeterminacy of complex environments. Instead, it redistributes cognitive and interpretive constraints across hybrid human–AI systems and introduces new forms of algorithmic anchoring and strategic lock-in.

Future research should therefore move beyond evaluating the performance effects of artificial intelligence or the accuracy of forecasting models, and instead examine how different configurations of human and agentic systems shape interpretive processes, attention dynamics, and learning trajectories over time. In particular, empirical studies in high-frequency and uncertainty-intensive settings, such as hospitality, mobility, retail, and digital platforms, could investigate how hybrid sensing architectures influence the emergence, persistence, and revision of strategic frames, as well as the dynamics of anchoring and adaptation under VUCA conditions. Such work would advance a more realistic and theoretically grounded understanding of strategic adaptation in organizations increasingly shaped by agentic technologies.

As a theory-informed critical reflection, this paper does not aim to provide empirical validation or to establish causal relationships between agentic AI, forecasting practices, and strategic outcomes. Its purpose is to problematize dominant assumptions and to clarify conceptual tensions that emerge when strategic sensing is increasingly performed by hybrid human–AI systems under persistent ambiguous and volatile conditions.

Accordingly, the framework developed in this study should be interpreted as a diagnostic and analytical device rather than as a prescriptive or predictive model. While the arguments are grounded in established streams of research in strategic management, behavioural strategy, forecasting and artificial intelligence, future empirical research is required to examine how the proposed tensions manifest across organizational settings, technological configurations and governance arrangements.

Finally, this paper focuses on organizational-level strategic sensing and does not explicitly address broader institutional, regulatory or ethical dimensions of agentic AI, which represent important complementary avenues for future inquiry.

Track: Entrepreneurship

Configuring Entrepreneurial Ecosystems: Evidence from a Ten Pillar Cluster Analysis

MARILENA BREDICE[1], ANNA VITTORIA FORMISANO[2], MICHELE MODINA[3]

Abstract

Frame of the research. *Entrepreneurial ecosystems are increasingly recognized as complex systems shaped by the interaction of multiple interdependent dimensions. However, empirical research often adopts linear or pillar-by-pillar approaches, providing limited insight into how these dimensions combine into distinct ecosystem configurations at the regional level.*

Purpose of the paper. *This paper aims to identify and interpret configurations of entrepreneurial ecosystems by examining how key ecosystem pillars co-occur across different ecosystem configuration. Specifically, it addresses whether entrepreneurial ecosystems can be meaningfully classified into distinct regional types based on the joint presence and consolidation of their core dimensions.*

Methodology. *The study analyzes a dataset of NUTS2 regions using ten ecosystem pillars capturing structural, institutional, financial, and cultural conditions. A clustering analysis is employed to derive a typology of entrepreneurial ecosystems, complemented by v-tests, mean comparisons, and standard deviations to assess both inter-cluster differentiation and intra-cluster variability.*

Results. *The analysis identifies three distinct ecosystem configurations, each characterized by specific combinations of ecosystem pillars. The clusters differ not only in their average levels of ecosystem development, but also in the degree of internal consolidation of individual dimensions. More mature ecosystems display the simultaneous presence of multiple enabling conditions, while softer dimensions such as entrepreneurial culture remain more heterogeneous even in advanced contexts.*

Research limitations. *The study relies on cross-sectional data and does not capture dynamic transitions between ecosystem configurations over time.*

Managerial implications. *The proposed typology supports place-based policy design by highlighting that regions face different structural constraints and opportunities depending on their ecosystem configuration.*

Originality of the paper. *The paper contributes to the literature by adopting a configurational, region-level perspective and by providing a ten-pillar, cluster-based typology of entrepreneurial ecosystems.*

Keywords: *entrepreneurial ecosystems; cluster analysis; regional development; ecosystem pillars; NUTS2; regional policy*

1. Introduction

Entrepreneurial activity differs significantly depending on the territorial context in which it develops. Even within the same national context, regions show wide differences in terms of institutional quality, available resources, infrastructure, and modes of interaction between different economic actors.

Entrepreneurship is therefore no longer analyzed exclusively at the level of the individual enterprise, but rather the structural and relational conditions rooted in the territories are analyzed (Boschma, 2005; Stam, 2015; Autio et al., 2018).

In this context, the concept of entrepreneurial ecosystem is necessary to interpret how regional environments enable or constrain entrepreneurial activity over time. Entrepreneurial ecosystems are structured sets of interdependent actors, resources, and institutions, whose joint functioning influences a territory's ability to generate and sustain entrepreneurship in an innovative and growth-oriented way (Mason & Brown, 2014; Acs et al., 2017; Malecki, 2018; Queissner et al., 2025). Therefore, entrepreneurial output is not the result of isolated individual factors but arises from the alignment and interaction of multiple elements of the ecosystem in specific territorial contexts.

[2] University of Molise, *annavittoria.formisano@unimol.it*
[3] University of Molise, *michele.modina@unimol.it*

The different dimensions of the ecosystem - such as institutions, finance, human capital, knowledge production, infrastructure, culture, networks, leadership, demand conditions, and intermediary services - do not act in isolation but influence each other through joint reinforcement processes (Isenberg, 2010; Stam & Van de Ven, 2021; Leendertse et al., 2022a). Their ability to support entrepreneurial activity within specific regional contexts therefore depends on how these dimensions intertwine and combine (Stam, 2015; Autio et al., 2018; Theodoraki et al., 2022).

Regions support entrepreneurship through different combinations of the same fundamental elements of the ecosystem, in relation to different institutional structures and local coordination mechanisms (Brown & Mason, 2017; Spigel & Harrison, 2018; Filip & Setzer, 2025).

Nevertheless, much of the empirical research on entrepreneurial ecosystems is still based on additive-linear approaches, in which ecosystems are measured through synthetic indices or by analyzing the marginal effects of individual dimensions on entrepreneurial outputs (Acs et al., 2017; Szerb et al., 2019; Bosma et al., 2020; Hess et al., 2025). Although these approaches have contributed significantly to advances in the measurement and comparability of ecosystems, they offer limited insight into how ecosystem elements coexist and consolidate. As a result, there is still a lack of systematic understanding of the possibility of describing entrepreneurial ecosystems as distinct configurations, characterized by specific combinations and degrees of consolidation of their fundamental dimensions.

Therefore, the objective of this article is to analyze whether European NUTS2 regions can be classified into distinct ecosystem types based on the joint presence and alignment of ten key ecosystem pillars and a ecosystem output. Using cluster analysis, the study identifies configurations of entrepreneurial ecosystems and analyzes both the differentiation between clusters and their internal coherence.

In this way, the paper offers three main contributions. First, it reinforces a configurational interpretation of entrepreneurial ecosystems, showing that performance emerges from the alignment of complementary dimensions rather than from isolated individual strengths. Second, it proposes an empirical typology of regional entrepreneurial ecosystems, providing a structured framework for interpreting ecosystem heterogeneity across regions. Finally, it generates relevant insights for the design of place-based policies, highlighting how regions face different constraints and opportunities depending on the specific configuration of their ecosystem.

The rest of the article is organized as follows. The next section presents the literature on entrepreneurial ecosystems and their regional bases. This is followed by a section dedicated to methodology and data. The next section illustrates the results of the cluster analysis, while the final section discusses the implications of the results and outlines possible directions for future research.

2. Literature Review

Regional economic systems differ markedly in their capacity to support entrepreneurial activity, reflecting variations in institutional arrangements, resource endowments and patterns of interaction among local actors. Such heterogeneity has been documented across territories and is increasingly analysed through approaches that emphasise the structural conditions embedded in specific places, rather than firm-level or individual-level explanations (Boschma, 2005; Audretsch & Belitski, 2017; Filip & Setzer, 2025). From this perspective, entrepreneurial outcomes emerge from place-specific configurations shaped by historical trajectories and contextual conditions (Prokop & Thompson, 2023).

Within this analytical framework, the entrepreneurial ecosystem has been conceptualised as a structured set of actors, resources and institutional arrangements that collectively shape a territory's capacity to generate and sustain entrepreneurial activity over time (Mason & Brown, 2014; Malecki, 2018; Lado et al., 2024). Ecosystems are not defined solely by the intensity of new firm creation, but by their ability to support forms of entrepreneurship characterised by innovation, growth potential

and integration into wider markets (Acs et al., 2017; Brown & Mason, 2017). Accordingly, entrepreneurial ecosystems are understood as configurations of interdependent elements whose joint functioning influences entrepreneurial outcomes.

The main components of entrepreneurial ecosystems operate through interrelated mechanisms rather than in isolation. Institutional and governance arrangements shape the regulatory environment and influence incentives and expectations faced by economic actors (North, 1990; Acs et al., 2017), while cultural orientations affect attitudes towards risk, failure and entrepreneurial success and contribute to the social legitimacy of entrepreneurship over time (Isenberg, 2010; Welter, 2011; Kibler et al., 2017; Stam & Van de Ven, 2021). Relational networks among entrepreneurs, organisations and support actors facilitate information flows, access to complementary resources and learning processes, shaping opportunity recognition and coordination dynamics (Stam, 2015; Spigel, 2017; Spigel & Harrison, 2018; Wurth et., 2022).

Access to financial resources, the availability of human capital and the presence of knowledge bases further influence ecosystem functioning by affecting the emergence, selection and growth of entrepreneurial initiatives (Lerner, 2009; Acs et al., 2017; Florida, 2019). In more developed ecosystems, coordination among actors is often supported by forms of distributed leadership exercised by experienced entrepreneurs, intermediary organisations and institutional actors, contributing to the coherence of ecosystem dynamics (Brown & Mason, 2017; Feld, 2020; Kuckertz et al., 2020). The effectiveness of these elements depends on their interaction within specific territorial contexts rather than on their isolated presence.

Regions represent a particularly relevant level at which entrepreneurial ecosystems take shape and evolve. Even within the same national setting, regions exhibit substantial differences in institutional quality, infrastructural endowments, knowledge bases and access to markets, resulting in distinct ecosystem structures and development trajectories (Stam, 2015; Autio et al., 2018; Theodoraki et al., 2022; Queissner et al., 2025, Hess et al., 2025). Consequently, regional entrepreneurial ecosystems are not expected to converge towards a single model but instead display a plurality of configurations reflecting place-specific conditions (Komlós et al., 2025).

The outcomes associated with entrepreneurial ecosystems extend beyond firm entry rates and are increasingly assessed in terms of the quality and sustainability of entrepreneurial activity. Innovative and growth-oriented ventures provide an indication of favourable ecosystem conditions (Stam, 2015; Acs et al., 2017; Audretsch et al., 2024), while longer-term effects materialise through broader regional dynamics such as productivity, employment and economic growth (Audretsch et al., 2006; Belitski & Desai, 2016). In advanced economies, start-up rates alone offer limited insight into ecosystem performance, whereas the characteristics of entrepreneurial activity play a more informative role (Shane, 2009; Mason & Brown, 2017; Candeias & Sarkar, 2024).

To the best of our knowledge, empirical research on entrepreneurial ecosystems has largely relied on additive and linear approaches, operationalizing ecosystems through composite indices or by examining the marginal effects of individual dimensions. While these approaches have enhanced measurement and comparability, they provide limited insight into how ecosystem elements co-occur and consolidate into internally coherent configurations characterized by specific combinations and degrees of consolidation. Building on this perspective, this study addresses the following research question:

R.Q: Are there recognizable configurations of entrepreneurial ecosystems, and what distinguishes them in terms of combinations and consolidation of their key dimensions?

3. Methodology and data

3.1 Methodology

Cluster analysis is a multivariate statistical technique used to identify homogeneous groups of observations based on similarities measured across multiple variables considered simultaneously

(Romesburg, 1984; Johnson & Wichern, 2002). The method belongs to the class of unsupervised procedures, as it does not require a predefined classification of the units of analysis (McLachlan, 1992; Punj & Stewart, 1983).

The objective of cluster analysis is to identify latent types or structures within heterogeneous populations, without imposing causal relationships or functional models a priori (Punj & Stewart, 1983; Ketchen & Shook, 1996). This approach is consistent with a configurational approach, in which phenomena are interpreted as the result of combinations of characteristics rather than the additive effects of individual variables (Meyer et al., 1993; Ketchen et al., 1997).

The application of cluster analysis requires the definition of a distance measure, the selection of a clustering algorithm and the determination of the number of clusters to be extracted (Romesburg, 1984; Johnson & Wichern, 2002). These choices affect the internal consistency and stability of the solutions obtained and must therefore be evaluated in relation to the exploratory objective of the analysis (Ketchen & Shook, 1996; Hair, 2009).

Among hierarchical clustering methods, Ward's method is designed to minimise intra-cluster variance at each stage of the aggregation process, producing compact and well-separated groups (Ward, 1963). The resulting clusters are interpreted as ideal types or analytical configurations, useful for describing and comparing distinct profiles, without attributing to them a normative or causal meaning that exceeds the exploratory nature of the method (Ketchen et al., 1997; Fiss, 2007).

3.2 Data collection

To explore the differences between entrepreneurial ecosystems in terms of internal composition and outcomes, we used the dataset “Regional metrics for entrepreneurial ecosystems in Europe” developed by Leendertse et al. (2022b), which operationalizes entrepreneurial ecosystems at the NUTS-2 regional level according to the framework proposed by Stam and Van de Ven (2021). Within this framework, ecosystems are described through a set of ten interrelated elements—including institutions, finance, intermediaries, infrastructure, knowledge, human capital, leadership, networks, demand, and culture—captured through standardized statistical indicators (Leendertse et al., 2022a).

Rather than assessing the isolated effect of individual elements, the clustering procedure is employed to identify recurring configurations of ecosystem components across regions. This approach allows regions to be grouped based on similarities in the joint distribution of ecosystem elements, thereby highlighting distinct ecosystem profiles. The dataset further includes measures of entrepreneurial output, proxied by the presence of innovative startups and unicorn firms, which enable an examination of how different ecosystem configurations are associated with varying levels of productive entrepreneurship. Detailed information on indicator selection and data construction (Tab. 1) is provided by Leendertse et al. (2022a), ensuring transparency and replicability of the analytical framework.

Tab 1. Operationalization of the indicators of EE elements and output

Elements	*Description*	*Empirical indicators*	*Data source*
Formal institutions	The rules of the game in society	Two composite indicators measuring the overall quality of government (consisting of scores for corruption, accountability, and impartiality) and the ease of doing business	Quality of Government Survey (QOG) and the World Bank Doing Business Report
Entrepreneurship culture	The degree to which entrepreneurship is valued in a region	A composite measure capturing the regional entrepreneurial culture, consisting of entrepreneurial motivation, cultural and social norms, importance to be innovative, and trust in others	Global Entrepreneurship Monitor (GEM) and European Social Survey (ESS)

Elements	*Description*	*Empirical indicators*	*Data source*
Networks	The connectedness of businesses for new value creation	Percentage of SMEs that engage in innovative collaborations as a percentage of all SMEs in the business population	Regional Innovation Scoreboard (RIS)
Physical Infrastructure	Transportation infrastructure and digital infrastructure	Four components in which the transportation infrastructure is measured as the accessibility by road, accessibility by railway and number of passenger flights and digital infrastructure is measured by the percentage of households with access to internet	Regional Competitiveness Index (RCI)
Finance	The availability of venture capital and access to finance	Two components: The average amount of venture capital per capita and the percentage of SMEs that is credit constrained	Invest Europe and European Investment Bank (EIB)
Leadership	The presence of actors taking a leadership role in the ecosystem	The number of coordinators on H2020 innovation projects per capita	Community Research and Development Information Service (CORDIS)
Talent	The prevalence of individuals with high levels of human capital, both in terms of formal education and skills	Four components: The percentage of the population with tertiary education, the percentage of the working population engaged in lifelong learning, the percentage of the population with an entrepreneurship education, the percentage of the population with e-skills	Eurostat and the Global Entrepreneurship Monitor (GEM)
New Knowledge	Investments in new knowledge	Intramural R&D expenditure as a percentage of Gross Regional Product	Eurostat
Demand	Potential market demand	Three components: disposable income per capita, potential market size expressed in GRP, potential market size in population. All relative to EU average.	Regional Competitiveness Index (RCI)
Intermediate services	The supply and accessibility of intermediate business services	Two components: the percentage of employment in knowledge-intensive market services and the number of incubators/accelerators per capita	Eurostat and Crunchbase
Output	Entrepreneurial output	The number of Crunchbase firms founded in the past five years per capita	Crunchbase
	Unicorn output	The absolute number of unicorns in the region founded in the last ten years	CB Insights and Dealroom

Source: Leendertse et al. (2022a)

3 Results

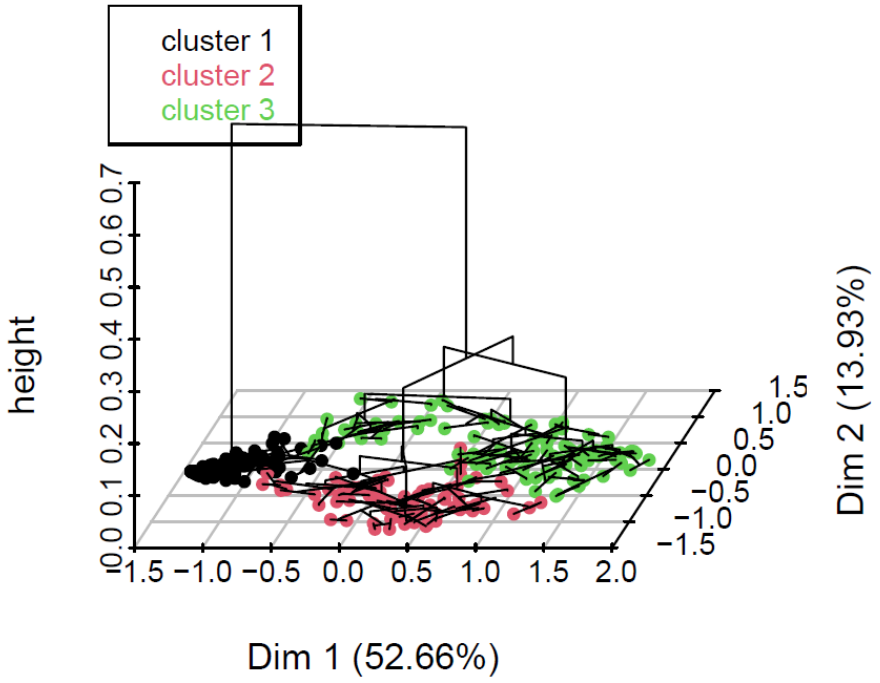

Figure 1 shows the results of the cluster analysis applied to the entrepreneurial ecosystems analyzed at the NUTS 2 regional level, projected into the space defined by the first two dimensions obtained from the dimensional reduction of the data. Each point corresponds to an ecosystem and is colored according to the cluster to which it belongs, allowing the structure of the groups and the relative distances between the observations to be viewed simultaneously. The coordinates of the points are derived from standardized variables; consequently, zero represents the overall average of the system, and positive and negative values indicate deviations from this reference.

The clusters show an orderly separation along the first dimension, which explains more than half of the overall variability (52.66%) and reflects systematic differences in the overall level of

contribution of ecosystems to the observed dynamics. Cluster 1 (black), identified by negative values, groups ecosystems that have levels below the global average for all the variables considered, indicating a limited capacity to simultaneously activate the components of the system. At the opposite extreme, cluster 3 (green), positioned on positive values, aggregates ecosystems that consistently exceed the global average, suggesting more structured configurations and a greater overall intensity of the activities observed. The clearly distinguishable intermediate cluster 2 (red) occupies a central position along the main gradient and is characterized by a mixed profile, in which above- and below-average dimensions coexist, indicating ecosystems with partially developed mechanisms and functioning that are not yet fully integrated.

The second dimension, which explains a smaller proportion of variance (13.93%), helps to differentiate ecosystems within clusters, highlighting differences in profile composition at the same overall level. The dispersion of points along this axis indicates that ecosystems belonging to the same cluster can be located at similar levels of the main gradient through different combinations of the variables analyzed, suggesting heterogeneous modes of organization and specialization.

Source: own elaboration

The distribution of countries across clusters provides additional insight into the prevalence of different ecosystem configurations. Cluster 3 emerges as the most populated group, comprising 106 countries, suggesting that relatively mature and well-functioning entrepreneurial ecosystems are not exceptional cases but represent a widely observed configuration within the sample. By contrast, Cluster 2 is the least numerous, with 79 countries, indicating that intermediate ecosystem configurations—characterized by partial alignment of ecosystem pillars—are comparatively less common. Cluster 1 occupies an intermediate position in terms of size, with 88 countries, reflecting the broad diffusion of less developed or structurally constrained ecosystem configurations.

Importantly, these differences in cluster size should not be interpreted as a ranking of performance, but rather as evidence of the relative diffusion of distinct ecosystem types. The fact that the most advanced configuration is also the most populated underscores the coexistence of multiple development paths and suggests that mature ecosystems can emerge across a wide range of contexts, while intermediate configurations may represent more transitory or less stable arrangements.

Source: own elaboration

Tables 2, 3, and 4 show the results of the cluster description procedure using the v-test. The v-test measures the standardized distance between the mean of the variable in the cluster and the overall mean. High absolute values indicate a strong discriminating ability of the variable in defining the cluster. As regards the sign, a negative sign indicates that the variable is under-represented in the cluster, while a positive sign indicates that the variable is over-represented in the cluster. The test also allows to calculate the mean in category, which represents the average level of the variable in the cluster, compared with the overall mean, which is the average for the entire sample. In addition, the sd in category was also calculated to assess the internal heterogeneity of the cluster, and the overall sd, which provides a benchmark of overall variability.

Cluster 1 is characterized by negative and highly significant values across all variables, with v-tests ranging from -7.3 to -11.3. This is a systemically weak cluster, in which no pillar of the entrepreneurial ecosystem reaches levels close to the sample average. The means in category are extremely low for all variables (generally between 0.04 and 0.12), while the overall means are consistently around four to five times higher. This gap indicates a generalized structural deficit.

In particular, the pillars related to finance (v = -11.31) and physical infrastructure (v = -10.90) show the highest deviations, and their respective means in category (0.05 and 0.08) are drastically lower than the overall means (0.44 and 0.49, respectively). This indicates ecosystems with limited access to capital and insufficient infrastructure, conditions that prevent any scaling dynamics.

For the pillars related to formal institutions, culture, and demand, the v-tests are very similar (≈ -10), suggesting that ecosystem fragility is not only economic but also institutional and cultural, with markets that are not very receptive to innovation and high-growth entrepreneurship. This is also confirmed by entrepreneurial output (v = -9.24), which is consistently low: the absence of startups and unicorns is not an anomaly, but the systemic consequence of other shortcomings.

At the same time, dynamics related to human capital (v = -10.85) and knowledge (v = -8.81) are strongly underrepresented, and the combination of low means (-10.85 and -8.81, respectively) and category sd lower than the overall sd indicates that the weakness is homogeneous, not due to a few extreme cases. Consistently, the Networks variable has a negative v-test (−8.99) and an extremely low average (0.08), highlighting ecosystems characterized by weak relationships and poor interaction between actors.

The intermediate variable shows a similar pattern (v-test = −8.44), with a cluster average of 0.126 compared to an overall average of 0.428. This signals the almost total absence of organizational infrastructures supporting entrepreneurship, such as incubators, accelerators, and intermediaries.

It follows that Cluster 1 represents immature, peripheral ecosystems lacking self-reinforcing mechanisms, where no single dimension can compensate for the others. In terms of policy, it is not a question of ‘activating’ entrepreneurship, but of building the minimum basic conditions.

Source: own elaboration

Cluster 2 includes those ecosystems that are structured but have low entrepreneurial activation and show clear internal polarization with positive and significant values for structural and institutional variables and negative and significant values for leadership, intermediaries, and output. This cluster represents ecosystems that are potentially favorable but unable to transform resources into entrepreneurial results.

The variables culture, formal institutions, and finance have high positive v-tests (6.35, 6.04, and 5.77, respectively). The means in category are all above 0.67, compared to an overall mean between 0.43 and 0.49. The sd in category is often similar to or lower than the overall sd, indicating a favorable cultural environment, functioning institutions, and good access to financial resources.

As for the pillars of talent, demand, and physical infrastructure, these are also significantly above average, but with more moderate v-tests (4.26, 4.20, and 3.62, respectively). These dimensions provide an enabling foundation but are not sufficient to generate autonomous growth dynamics. Instead, the pillars of leadership (v = -6.92), intermediate (v = -4.51), and output (v = -5.24) constitute the bottleneck of the cluster. Cluster averages are drastically lower than overall means, with low internal variability, a sign that the deficiency is structural. Leadership shows an extremely low cluster mean in categories (0.11) compared to the overall mean (0.39), with a low standard deviation, indicating a systematic lack of leading actors. Similarly, the weakness of the intermediate variable (mean in category 0.25 compared to overall mean 0.43) signals the absence of intermediaries capable of stimulating and supporting entrepreneurial initiatives.

Overall, cluster 2 represents potentially strong ecosystems, but characterized by a lack of entrepreneurial activity. This is a classic case of a “latent ecosystem” in which the conditions are present, but there is a lack of leading players, intermediaries, and coordination mechanisms capable of activating the system.

Source: own elaboration

Cluster 3 represents mature, coherent, high-performance ecosystems, showing positive and highly significant values across all variables, with v-tests reaching extremely high values (up to 13.7). It is the only cluster in which all pillars of the ecosystem are simultaneously above average. The mean in category values are consistently higher than the overall mean values, while the sd in category values are often high, suggesting internal heterogeneity compatible with complex and mature ecosystems.

The output variable has the highest v-test (13.74), with a Mean in category of 0.8686, almost double the Overall mean (0.44). The sd in category (0.24) is lower than the Overall sd (0.41), indicating that high entrepreneurial output is widely shared within the cluster and not driven by a few extreme cases. This result signals a structured and widespread capacity to generate new businesses and high-growth companies.

The dimensions leadership (v = 13.46), and intermediate (v = 12.29) are the most discriminating variables. The means in category exceed 0.80, compared to overall means below 0.44, indicating ecosystems strongly characterized by the presence of leading players and intermediary infrastructures.

The pillars knowledge, talent, and networks have v-tests between 6 and 8, with the sd in category often higher than the overall sd, suggesting internal heterogeneity, typical of complex and dynamic ecosystems.

For the Demand variable, the v-test is equal to 5.93, with a mean in category of 0.63 compared to an overall mean of 0.45. The sd in category (0.39) is slightly lower than the Overall sd (0.41), suggesting that the presence of receptive markets is a widespread characteristic, but not perfectly uniform.

Even the 'context' variables (such as demand, finance, and institutions) are significantly above average, indicating that entrepreneurial performance is achieved thanks to their consistency with the rest of the system. In this cluster, dimensions related to finance, formal institutions, and entrepreneurial culture are all significantly overrepresented compared to the sample average, outlining a favorable but not perfectly homogeneous context. In particular, the Finance variable has a v-test of 5.48, with a mean in category of 0.66, significantly higher than the overall mean (0.49). The category sd (0.38), which is lower than the Overall sd, indicates that access to financial resources is not only high but also relatively uniform within the cluster, suggesting the presence of developed financial markets that are widely accessible to ecosystem actors.

The formal institutions variable also shows a positive and significant v-test (4.58), with a mean in category of 0.58 compared to an overall mean of 0.44. In this case, the sd in category (0.41) is very similar to the overall sd (0.42), indicating that the quality of the institutional context is higher overall in the cluster, while maintaining a level of internal variability comparable to that observed in the entire sample. Finally, entrepreneurial culture presents a positive but more moderate v-test (3.89), with a mean in category of 0.59, higher than the overall mean (0.46). The category sd (0.42), slightly higher than the overall sd, indicates greater heterogeneity in the spread of attitudes favorable to entrepreneurship. This indicates that, within the cluster, entrepreneurial culture is less uniformly distributed than other dimensions and may represent a component of internal differentiation rather than a fully consolidated and homogeneous factor.

In summary, cluster 3 represents mature ecosystems, in which there are strong self-reinforcing dynamics between the various pillars, capable of attracting resources and talent. Here, the simultaneous presence of conditions that favor entrepreneurial output signals a fully functioning ecosystem, in which the different dimensions reinforce each other.

4 Conclusion and discussion

Cluster analysis addresses the question of whether entrepreneurial ecosystems can be meaningfully grouped into distinct configurations, revealing systematic patterns of coexisting dimensions and highlighting the existence of qualitatively different types of ecosystems. Leendertse et al. (2022b), the authors of the dataset used, perform a cluster analysis primarily as a robustness check for the Entrepreneurial Ecosystem Index, demonstrating that the resulting clusters largely mirror the index ranking and its geographical distribution. Our study takes a conceptually different approach. Rather than interpreting clusters as ordinal levels of performance, we conceptualize them as distinct structural profiles of entrepreneurial ecosystems. Deliberately moving away from spatial visualizations, which tend to reinforce well-known patterns such as the dominance of capital regions over rural areas and can lead to deterministic geographical interpretations, our analysis focuses on the underlying mechanisms that shape the functioning of the ecosystem. The clustering procedure is then used to separate geographical location from business performance and to identify heterogeneous combinations of ecosystem elements that transcend geographical boundaries. This perspective allows us to highlight qualitative differences in ecosystem configurations that remain hidden in one-dimensional indices.

The results clearly show that regional entrepreneurial ecosystems are not distributed along a linear continuum of development, but are organized into distinct systemic configurations, characterized by different levels of activation capacity and alignment between the pillars of the ecosystem.

From this perspective, the clusters identified do not simply represent different levels of performance, but different organizational models. The ecosystems in cluster 1 have negative values for all ecosystem pillars, reflecting systemically weak configurations in which the widespread lack of resources, infrastructure, institutions, and human capital limits the activation of entrepreneurial dynamics. The weakness is homogeneous and transversal to all dimensions considered, indicating the absence of compensatory mechanisms, so that no pillar appears capable of independently sustaining the system or triggering strengthening processes. This suggests that, in these contexts, high-growth entrepreneurship cannot be stimulated through isolated sectoral interventions but requires the simultaneous construction of minimum conditions for systemic functioning.

At the opposite end of the spectrum, cluster 3 represents consolidated and successful ecosystems characterized by the simultaneous presence of all pillars at above-average levels. In these contexts, entrepreneurial performance appears to be a phenomenon emerging from mutually reinforcing dynamics between actors and resources. The high presence of leadership mechanisms and intermediary infrastructures indicates that coordination and the ability to provide support services to entrepreneurship play an essential role in transforming structural potential into entrepreneurial output. The relative internal heterogeneity observed in some dimensions, such as knowledge, networks, and

talent, is consistent with the complex nature of advanced ecosystems, in which different specializations and multiple development trajectories coexist. Rather than signaling fragility, this heterogeneity represents a source of resilience and adaptability.

Particularly interesting is the intermediate configuration identified in cluster 2, which cannot be interpreted simply as a transitional stage between weak and strong ecosystems. These ecosystems have favorable structural and institutional conditions—in terms of culture, institutions, finance, talent, and infrastructure—but low levels of entrepreneurial activation and a marked lack of leadership and intermediaries. This combination suggests the existence of "latent" ecosystems, in which resources are available but are not effectively mobilized. The absence of leading actors and coordination mechanisms prevents the transformation of potential into concrete results, highlighting that the development of the ecosystem does not depend exclusively on the availability of resources, but also on the capacity for orchestration and collective activation.

The distribution of cases in clusters offers further insights for interpretation. The fact that the most advanced cluster is also the most populated indicates that mature and functional ecosystems are not isolated exceptions, but relatively widespread configurations. This data suggests that ecosystem maturity can emerge in heterogeneous territorial contexts and is not necessarily limited to a few highly developed areas. At the same time, the smaller size of the intermediate cluster may indicate that latent configurations are less stable over time, tending to evolve towards more coherent models or regress in the absence of activation mechanisms. This reinforces the idea that ecosystem development is a dynamic and non-linear process, influenced by the interaction between structural conditions and coordination capabilities.

The analysis has both academic and practical implications. From a theoretical point of view, the results confirm the usefulness of a configurational approach to the study of entrepreneurial ecosystems, in which performance is interpreted as the outcome of the alignment between complementary pillars. Consistent with the existing literature, empirical evidence suggests that the presence of individual favorable conditions is not sufficient to generate sustained entrepreneurial dynamics in the absence of systemic coherence. In particular, the role of leadership and intermediation dimensions emerges as crucial in linking structural resources to entrepreneurial outputs, indicating the need to integrate variables related to ecosystem governance and coordination capacity among actors into future analyses. Furthermore, the identification of a cluster characterized by strong structural endowment, but low entrepreneurial activation invites us to distinguish conceptually between the potential capacity and actual capacity of the ecosystem. This distinction opens new research perspectives on the mechanisms through which resources are mobilized and transformed into entrepreneurial activities, as well as on the factors that facilitate or hinder these processes.

From a managerial and policy perspective, the results highlight the importance of differentiated strategies depending on the ecosystem configuration. In weaker ecosystems, interventions should focus on building basic conditions – infrastructure, access to resources, and knowledge – rather than on initiatives aimed at the growth of isolated startups. In latent ecosystems, on the other hand, the priority is to strengthen coordination and support mechanisms and the ability to activate existing resources. In mature contexts, policies should aim to maintain and improve entrepreneurial dynamics, promoting diversification, innovation, international openness, and system resilience.

Overall, the results suggest that regional entrepreneurial development policies cannot be uniform but must be adapted to the specific configuration of the regional ecosystem. A one-size-fits-all approach risks being ineffective if it does not consider the structural differences and operating mechanisms that characterize each context.

In summary, the results highlight the existence of three clearly distinguishable systemic configurations of entrepreneurial ecosystems, in which the maturity of an ecosystem emerges as the result of cumulative dynamics and mutual reinforcement between structural resources, institutions, networks, and leading actors.

Despite adopting a configurational interpretation of clusters, the analysis remains constrained by

the static and aggregate nature of the underlying dataset, which limits the ability to capture the temporal evolution and causal dynamics of entrepreneurial ecosystem configurations. Moreover, the reliance on secondary indicators may only partially reflect informal or micro-level interactions within ecosystems.

Future research could extend this approach by examining how ecosystem configurations evolve over time and by linking specific configurational profiles to entrepreneurial outcomes such as resilience, innovation quality, or growth trajectories. Additionally, integrating micro-level or qualitative data could further enrich the understanding of the mechanisms through which different ecosystem configurations emerge and consolidate across contexts.

Determining the Characteristics of Private Debt Targets: Evidence from Italy

MAREK KACER[1], NICHOLAS WILSON[2], MICHELE LERTORA[3], MARGHERITA MIETTO[4], ANNA GERVASONI[5]

Abstract

Research on private debt has examined funds, contracts and returns; much less is known about the firms that receive direct-lending finance. This paper moves the analysis to the borrower side through a population-level study of Italian private debt transactions. It combines more than ten million Italian firm-year observations for 2013-2023 with proprietary deal data from the Italian Association of Private Equity, Venture Capital and Private Debt (AIFI), and estimates logit selection models to identify the characteristics associated with first-time private debt funding. The estimates reveal a sharply bounded borrower profile. Private debt investors favour larger, moderately profitable and moderately riskier firms with intermediate asset tangibility, while avoiding firms that are persistently loss-making, wholly intangible, highly collateralised or excessively risky. The evidence is consistent with private debt operating not as a simple substitute for bank lending but as a specialised contracting arrangement for firms whose risks are non-standard yet contractible: too opaque, growth-oriented or insufficiently collateralised for the lowest-cost bank segment, but sufficiently large and cash-generative to bear the fixed costs of due diligence, covenant design and monitoring.

Keywords: *Private debt; direct lending; non-bank finance; borrower selection; firm characteristics; alternative credit; Italy; middle-market firms.*

1. Introduction

Following the Global Financial Crisis (GFC), regulatory tightening and shifts in investor demand have driven a structural reallocation of corporate credit from banks to non-bank intermediaries (Ivashina and Scharfstein, 2010; Chernenko, Erel and Prilmeier, 2022; Erel and Inozemtsev, 2025). Private debt (PD) funds - the principal vehicle through which institutional capital now lends directly to companies - have grown to roughly $1.34 trillion of assets under management in the US and approximately $2 trillion globally by mid-2024 (Cai and Haque, 2024; Berrospide et al., 2025), an expansion unmatched by any other major asset class in the post-GFC era. The literature, however, has studied this asset class largely from the supply side, characterising fund-level returns, fee structures and contracting practices (Cumming and Fleming, 2013; Munday et al., 2018; Böni and Manigart, 2022; Block et al., 2024; Buchner et al., 2024). The demand side - which firms borrow from PD funds, and how those firms differ from the broader corporate population - remains far less developed. The firm-level evidence that does exist is concentrated almost exclusively on US middle-market borrowers, the great majority of whom are private-equity-sponsored (Chernenko, Erel and Prilmeier, 2022; Jang, 2024; Haque, Mayer and Stefanescu, 2025; Davydiuk, Marchuk and Rosen, 2024).

The argument developed here is that this evidence base leaves open the more general theoretical question: in which segment of the corporate credit market does private debt operate, and under what conditions? Private debt is not merely an alternative source of bank-like finance. It is a specialised contracting arrangement that becomes valuable where standard collateral-based banking and public

debt markets are incomplete. Direct lenders extend credit to firms that are too informationally opaque, insufficiently collateralised or moderately risky for standardised bank lending, yet sufficiently large, cash-generative and monitorable to support bespoke covenants, due diligence and post-investment monitoring. This characterisation brings together four strands of theory - credit rationing under information asymmetry (Stiglitz and Weiss, 1981), collateral as a screening device (Bester, 1985; Besanko and Thakor, 1987), delegated monitoring under fixed costs (Diamond, 1984; Holmström and Tirole, 1997), and substitution between regulated and unregulated intermediaries (Chernenko, Erel and Prilmeier, 2022; Avalos, Doerr and Pinter, 2025) - into a coherent set of predictions about the private debt borrower.

Italy provides a particularly informative bank-dependent setting in which to test this account. Italian corporate finance remains strongly bank-based, and the corporate sector is dominated by private, owner-managed and informationally opaque firms whose profile is precisely that for which credit-rationing theory predicts the largest misallocation of bank credit (Petersen and Rajan, 1994; Detragiache, Garella and Guiso, 2000; Aristei and Gallo, 2017). Until 2012, the Italian Banking Law reserved corporate lending to authorised credit institutions. A deliberate decade-long sequence of legislative interventions then opened channels for direct non-bank lending. Recent cross-country evidence by Avalos, Doerr and Pinter (2025) shows that private credit grows fastest in the institutional environments Italy exemplifies: stringent banking regulation, low policy rates and a less efficient banking sector. Because Italy is not a mature, sponsor-driven market like the US or the UK, its borrower profile is not an artefact of leveraged-buyout selection. It therefore provides a useful test of whether the borrower-selection observed in mature private-credit markets reflects a general response to credit-market frictions or is specific to particualr institutional environments.

The empirical design combines the universe of Italian companies in Orbis - more than ten million firm-year observations over 2013-2023 - with a proprietary dataset of direct-lending transactions sourced through AIFI. Logit selection models with non-linear specifications test six theoretically grounded hypotheses on the size, profitability, cash-flow stability, asset tangibility, default risk and sectoral profile of PD recipients.

The paper makes three contributions. First, it shifts the empirical analysis of private debt from fund-level performance to borrower-level selection in a major Eurozone economy and, to the best of current knowledge, provides one of the first population-level analyses not dominated by sponsor-backed transactions. Second, it develops and tests a theory-led account of private debt as a specialised contracting response to credit-market frictions. PD investors target precisely the firms that credit-rationing and collateral models predict will be underserved by competitive bank markets - moderately risky, intermediate-tangibility, mid-sized firms with positive but moderate profitability - and avoid both ends of the quality distribution. The non-linear specifications recover relations that linear models miss. Third, the paper distinguishes between mechanism generalisation, which is portable across markets because it follows from general credit-market frictions, and institutional generalisation, which depends on country-specific legal, regulatory and market structures. The comparison between Italy and the US, UK, German and French markets clarifies which findings are likely to be relevant across jurisdictions and which are institutionally contingent.

The remainder of the paper is organised as follows. Section 2 sets out the background to private debt, the institutional and regulatory context of the Italian market, the theoretical framework and the resulting hypotheses. Section 3 describes the data and methodology. Section 4 presents the empirical results. Section 5 concludes with policy and research implications.

2. Private debt: background and literature

2.1 Background

Private debt is the institutional channel through which non-bank investors lend directly to private and mid-market companies. The instruments are bespoke rather than standardised. Loans are privately negotiated, tailored to the borrower's cash-flow profile and growth plans, and held to maturity by the originating fund or a small club of co-investors. The contrast with bank lending lies less in price than in contracting flexibility: private debt funds are willing to invest the underwriting effort required to size, structure and monitor loans that do not fit a standardised template (McGeown, Power and Shinnick, 2025).

The borrower base differs across markets. In the US and the UK, the great majority of recorded direct-lending transactions are private-equity-sponsored, typically associated with leveraged buyouts, dividend recapitalisations and unitranche refinancings (Block et al., 2024; Buchner et al., 2024; Davydiuk, Marchuk and Rosen, 2024). In bank-dependent continental markets, direct lending is used more widely for growth finance: acquisition-led expansion, capital expenditure, or investment in intangibles that are difficult to pledge as collateral. The common feature is that the borrower needs finance whose structure or purpose lies outside the conventional collateral-and-cash-flow template that banks underwrite at scale.

Policy interest in private debt rests on the same observation. In bank-centred economies, the contraction of post-Basel bank lending to SMEs and lower-rated mid-market firms has left a financing gap that public capital alone cannot fill (British Business Bank, 2020, 2025; Patalano and Roulet, 2020). Private debt offers a route through which institutional capital can reach this segment, provided the underwriting and monitoring costs of bespoke contracts are recoverable in the deal. Whether private debt actually reaches the borrowers it is theoretically best placed to serve is therefore an empirical question, not a definitional one.

The Italian market provides an unusually informative testbed for that question. Italian corporate finance has been heavily bank-dependent for decades, the underlying SME population is large and informationally opaque, and the legal framework for direct non-bank lending was constructed deliberately, in stages, between 2012 and 2024. The remainder of Section 2 sets out the institutional and regulatory background (2.2), the four credit-market frictions that motivate the analysis (2.3), and the resulting hypotheses on borrower selection (2.4).

2.2 Institutional and regulatory context: Italy and international comparators

The Italian private debt market did not emerge in an institutional vacuum. It developed within a corporate-finance system historically dominated by banks, private ownership and relationship lending, and was accelerated by reforms that progressively opened legal channels for non-bank credit. This context matters for the empirical analysis. Firms that obtain private debt in Italy are not selected from the same financial ecosystem as US or UK sponsor-backed borrowers. They are selected from a bank-dependent economy in which informational opacity, collateral constraints and regulatory pressure on banks create a specific space for alternative credit. This section sets out the institutional features of Italian corporate finance, the regulatory architecture through which private debt became possible, and the main differences between Italy and the larger private credit markets of the US, UK, Germany and France.

2.2.1 Structural features of the Italian corporate-finance system

Italy provides a particularly revealing setting in which to examine the emergence of private debt. Its corporate sector has long been organised around bank finance, private ownership and relationship lending. The overwhelming majority of Italian firms are SMEs: among approximately 200,000 organised companies with more than ten employees, fewer than 500 are listed on a regulated exchange. Family-owned and owner-managed firms dominate the corporate population, and many

exhibit the informational opacity typical of private-company finance. They publish more limited accounts than listed firms, are rarely externally rated, and have historically relied on close, long-standing relationships with one or two local banks (Aristei and Gallo, 2017; Detragiache, Garella and Guiso, 2000).

This structure has given Italian corporate finance a markedly bank-centred character. Bank credit accounts for the great majority of Italian corporate liabilities, at levels substantially above those observed in the US and above the European average (Equita and Luiss, 2024; ECB, 2024; Cai and Haque, 2024). The historical fragmentation of the banking system, including the importance of mutual and cooperative banks, reinforced this pattern by sustaining relationship-based lending technologies in which soft information, local knowledge and repeated interaction substituted for arm's-length credit assessment (Petersen and Rajan, 1994; Berger and Udell, 2006).

The capacity of this bank-centred system to meet corporate financing needs has, however, been weakened by two related developments. The first is regulatory. Post-Basel III capital requirements and, for Italian banks, the implementation of IFRS 9 have raised the cost of holding lower-rated and SME exposures on bank balance sheets. The effect has been to make credit to informationally opaque and higher-risk firms more expensive for banks to originate and retain (Cortés et al., 2020; Ricci, Soggia and Trimarchi, 2023). The second is structural. Consolidation within the Italian banking sector has reduced the number of relationship-lending counterparties available to firms, particularly in local markets where access to finance had traditionally depended on repeated interaction with local lenders.

Italy therefore brings together, in concentrated form, several conditions under which credit-rationing theory predicts a role for non-bank finance: a large population of private SMEs, substantial informational opacity, heavy dependence on bank lending, and a banking sector facing tighter capital and provisioning constraints. Recent cross-country evidence is consistent with this interpretation. Avalos, Doerr and Pinter (2025) show that private credit expands most strongly in systems marked by stringent bank regulation, low policy rates and less efficient banking sectors. From the perspective of credit-rationing and relationship-lending theory, Italy is not a marginal case. It is a setting in which the residual demand for non-bank credit should be especially pronounced (Stiglitz and Weiss, 1981; Petersen and Rajan, 1994).

2.2.2 The Italian regulatory architecture for non-bank lending

The Italian case is also distinctive because the emergence of private debt has been closely connected to regulatory change. Until 2012, the Italian Banking Law - the Testo Unico Bancario, Legislative Decree No. 385/1993 - reserved corporate lending primarily to authorised credit institutions. Legal channels through which non-bank lenders could provide credit directly to Italian companies were therefore highly constrained. The private debt market did not develop simply as a spontaneous market response to investor demand; it was enabled by legislative reforms that progressively opened the supply of non-bank credit.

The first important step was the Decreto Sviluppo - Decree-Law No. 83/2012 - usually referred to as the Minibond Reform. This reform removed important obstacles to bond issuance by unlisted SMEs, including by extending to non-listed issuers a more favourable tax treatment previously associated with listed companies: deductibility of interest subject to the relevant thin-capitalisation rules, exemption from withholding tax on certain cross-border interest payments, and access to the substitute-tax regime for security issuance costs (Gervasoni, 2014). The 2014 Decreto Competitività - Decree-Law No. 91/2014 - broadened the range of eligible instruments, allowed insurance companies and securitisation vehicles to subscribe to direct loans, and clarified the regulatory treatment of private credit funds.

The decisive shift came with Decree-Law No. 18/2016, which formally authorised European Alternative Investment Funds to grant loans directly to Italian companies under the supervision of the Bank of Italy, subject to leverage and risk-spreading requirements. Subsequent reforms reinforced the institutional base of the market. The 2017 PIR regime - Piani Individuali di Risparmio - channelled

retail savings into qualifying investment vehicles, including private debt funds. More recently, the EU ELTIF 2.0 reform, applicable from January 2024, has reduced some of the regulatory frictions associated with the cross-border distribution of long-term investment funds and lowered minimum-investment thresholds.

Taken together, these reforms created the institutional conditions for a market that had previously been only weakly developed. Direct-lending volumes recorded by AIFI rose from approximately €0.5 billion in 2016 to €4.96 billion in 2024 (AIFI, 2025). Public and quasi-public investors have also played an important role. Cassa Depositi e Prestiti, Mediocredito Centrale and SACE have acted, in different ways, as anchor investors or supporting institutions in the development of private credit channels, performing a role comparable to that played by the European Investment Fund in the broader European SME finance architecture (Kraemer-Eis et al., 2022).

2.2.3 International comparators

The Italian market is best understood in comparative perspective. It differs from the US and UK private credit markets not only in scale, but also in structure, institutional origin and borrower profile.

The US private credit market is much larger and more mature. At approximately $1.34 trillion of assets under management by mid-2024, it is at least an order of magnitude larger than the Italian market (Berrospide et al., 2025). It is also closely connected to the private-equity ecosystem. A substantial share of US direct lending takes the form of unitranche loans to private-equity-sponsored borrowers, often in connection with leveraged buyouts, dividend recapitalisations and other sponsor-led transactions. Block et al. (2024) and Jang (2024) report that much of the surveyed direct-lending market involves PE-sponsored firms, while Haque, Mayer and Stefanescu (2025) show that the typical US private debt borrower is larger, more highly levered and more often loss-making than the typical bank borrower. The Italian market is different. AIFI transaction data point to a materially less sponsor-driven market, with senior and amortising facilities, together with minibond-style instruments, playing a more visible role than in mature unitranche-dominated markets.

The UK occupies an intermediate position. It is the second-largest private credit market in Europe and, like the US, is heavily connected to private equity. The Deloitte UK and European Private Debt Deal Tracker shows that the great majority of recorded transactions are associated with PE-backed assets, and that unitranche structures dominate transaction counts. At the same time, the UK has used public-policy institutions to push private credit further down the firm-size distribution. The British Business Bank's fund-of-funds model has channelled capital into managers willing to lend below the natural commercial floor of the larger unitranche market, thereby addressing the smaller end of the SME finance gap more directly than would be expected from purely commercial fund allocation (British Business Bank, 2025).

Germany and France offer further points of comparison. Germany shares with Italy a large SME and mid-market corporate base, but its financing system has also been shaped by the Schuldscheindarlehen tradition, which has historically provided an alternative private-placement channel for larger Mittelstand firms. France sits between Italy and the UK. Its market has been shaped by the Loi PACTE, the role of Bpifrance as an anchor investor, and a more developed euro-PP market.

Italy is therefore distinctive in three respects. First, the depth of bank dependence and the scale of the private SME sector create substantial latent demand for non-bank credit. Second, the supply of private debt has been opened largely through explicit legislative reform rather than through the organic development of a sponsor-led private-credit ecosystem. Third, the market is more oriented towards non-sponsored growth finance for mid-market industrial firms than towards the LBO-driven structures that dominate much of the US and UK evidence. The Italian borrower profile is therefore not an artefact of sponsor selection, making Italy an informative setting in which to test whether the borrower-selection patterns identified in mature private-credit markets reflect general contracting responses to credit-market frictions or market-specific institutional arrangements.

2.3 Credit-market frictions, contracting arrangements, and private debt borrower selection

Private debt is best understood as a specialised contracting arrangement that emerges when standard banking and public-debt markets are incomplete. The four mechanisms below - drawn from credit-rationing, collateral, intermediation and contracting theory - together identify a bounded intermediate segment of the corporate credit market and characterise the firm-level profile of borrowers within it. The hypotheses in Section 2.4 are observable implications of these four mechanisms.

Mechanism	Theoretical foundation	Implication for PD borrower selection
(i) Credit rationing under information asymmetry	Stiglitz and Weiss (1981); Petersen and Rajan (1994); Berger and Udell (1998, 2006)	Banks ration credit where borrower quality is hard to observe and risk cannot be fully priced through standardised lending. The marginal rationed borrower is riskier and more opaque than the marginal funded borrower but is not in distress. PD borrowers should accordingly be riskier and less standard than bank-only borrowers, but not at the distress end of the distribution.
(ii) Collateral and asset tangibility	Bester (1985); Besanko and Thakor (1987); Lian and Ma (2021)	Collateral acts as a separating mechanism in equilibrium credit contracts: highly collateralised firms can be served cheaply by banks, while firms with no pledgeable collateral cannot be screened at all. The residual demand that PD funds can profitably serve consists of borrowers with *intermediate* tangibility — sufficient to provide downside protection, insufficient to be priced by collateral-based lenders.
(iii) Transaction costs and monitoring scale economies	Diamond (1984); Holmström and Tirole (1997); Williamson (1988)	Bespoke due diligence, structuring, and post-investment covenant monitoring involve fixed costs that must be amortised across the loan. PD borrowers should therefore be sufficiently large to make this monitoring economic, but not so large that cheaper bank syndication or public debt-market alternatives dominate.
(iv) Cash-flow contracting	Lian and Ma (2021); Block et al. (2024); Jang (2024); Holmström and Tirole (1997)	Direct lenders underwrite repayment capacity using forward-looking cash-flow assessment, covenants, and intensive monitoring rather than relying solely on collateral. PD borrowers should therefore have positive and stable operating cash flows; persistently loss-making firms should be systematically avoided.

The unifying model is that PD funds finance contractible but non-standard borrowers: firms whose risks can be priced, structured, monitored and controlled through private contracts, but which fall outside the standardised template of bank or public-debt markets. The four mechanisms above each contribute one dimension to this characterisation, and the empirical hypotheses test their joint implications.

A small but rapidly growing empirical literature has begun to test components of this model, almost exclusively on US data and overwhelmingly on PE-sponsored transactions. Chernenko, Erel and Prilmeier (2022) show that US firms borrowing from non-banks are systematically those for which bank lending has become more regulated and constrained - namely, more highly levered, less profitable and more reliant on intangible assets. Loumioti (2022) shows that direct lenders step in

when bank-loan and securitised-debt issuance weakens, providing credit to borrowers with limited financing alternatives. Davydiuk, Marchuk and Rosen (2024) document that Business Development Companies - the principal US vehicle for retail private credit - substitute for traditional lenders along the dimensions where bank regulation bites hardest. Jang (2024) and Jang, Kim and Sufi (2025) show, using regulatory data, that direct lenders impose stricter protective covenants than banks and serve borrowers more concentrated in intangible-capital industries. Avalos, Doerr and Pinter (2025) extend this finding cross-country: in the BIS sample, private credit grows fastest in countries with stringent banking regulation, low policy rates and a less efficient banking sector. Cai and Haque (2024) document that US private debt borrowers pay a meaningful spread premium over comparable syndicated leveraged-loan borrowers, consistent with the higher contracting and monitoring intensity of direct lending. Recent FDIC research (Haque, Mayer and Stefanescu, 2025) reconciles substitution and complementarity: PD substitutes for banks' riskier term loans while complementing banks' provision of liquidity through credit lines.

European evidence is sparse but qualitatively consistent. Block et al. (2024) survey European GPs and report a strong preference for medium-cyclicality manufacturing and for borrowers with low-to-medium profitability and stable cash flows; Buchner et al. (2024) document the role of PE sponsorship in European deal flow; McGeown, Power and Shinnick (2025) provide Irish SME evidence consistent with non-bank lending acting as a substitute for SME bank debt. The British Business Bank's (2025) interim evaluation of UK debt funds documents a strong concentration of PD activity in mid-sized firms and a heavy emphasis on cash-flow predictability among fund managers.

What this evidence base has yet to do is test the four mechanisms jointly in a setting where firm-level data on the entire borrower population are available, the sample is not dominated by sponsor-backed transactions, and the institutional environment provides identifying variation in the supply of non-bank credit. The Italian setting allows all three. Wilson, Amini and Wright (2022) provide a methodological precedent in private equity by using a similarly structured population sample to characterise the equilibrium private-equity target. The present paper extends this profiling approach to private debt and connects the resulting estimates to the four-mechanism framework above.

2.4 Private debt targets: the development of hypotheses

The four mechanisms in Section 2.3 jointly characterise the equilibrium PD borrower as contractible but non-standard. This characterisation is translated into six testable hypotheses on size, profitability, cash-flow stability, asset tangibility, default risk and sectoral composition. Each hypothesis is mapped to the underlying mechanism and allows for a non-linear specification: the mechanisms imply floor and ceiling effects, because firms below the relevant floor are uneconomic to monitor or impossible to screen, while firms above the ceiling are better served elsewhere. Most predicted relations are therefore inverted-U shaped rather than monotone.

H1 (Size) - mechanism (iii). Delegated-monitoring theory (Diamond, 1984; Holmström and Tirole, 1997) implies that the fixed costs of due diligence, structuring and ongoing covenant monitoring create a minimum efficient borrower size below which the per-loan profitability of the intermediary is negative. At the upper end, large firms have alternative access to syndicated bank credit and public bond markets, which intermediate at lower marginal cost because information-production costs are lower.

> **H1.** The probability of receiving private debt financing increases with firm size over the SME and middle-market range, attenuating for very large firms with access to cheaper bank-syndication or public-debt alternatives.

H2 (Profitability) - mechanisms (i) and (iv). Pecking-order theory (Myers and Majluf, 1984) predicts that highly profitable firms self-finance and avoid information-sensitive external financing.

Conversely, persistently loss-making firms cannot credibly service debt at any feasible interest rate, and credit-rationing models (Stiglitz and Weiss, 1981) imply that they are rationed out of the lender's optimal contract. The substitution result of Chernenko, Erel and Prilmeier (2022) sharpens this prediction in the PD-versus-bank context: PD lenders may accept moderately profitable borrowers that banks reject, but they cannot price persistent losses any more than banks can.

> **H2.** The probability of PD financing displays an inverted-U relation with profitability: PD lenders avoid both persistently loss-making firms and the most profitable firms, which self-finance or borrow more cheaply elsewhere. A binary loss indicator should carry a strong negative effect.

H3 (Cash-flow stability) - mechanism (iv). In Holmström and Tirole's (1997) model of intermediated finance, the lender's ability to substitute monitoring for collateral relies on the borrower's pledgeable income: the share of cash flows that can credibly be committed to debt service. Volatile cash flows reduce pledgeable income and tighten the borrowing constraint (Lian and Ma, 2021). Cash-flow-based lending therefore favours borrowers with stable, predictable cash flows, in contrast to asset-based bank lending, which is anchored on collateral values.

> **H3**. The probability of PD financing decreases with the volatility of operating cash flows; PD lenders prefer firms with a stable, predictable cash-flow record.

H4 (Asset tangibility) - mechanism (ii). The role of asset tangibility in PD selection is the paper's sharpest test of the contractible-but-non-standard logic. In the classical collateral-as-screening framework (Bester, 1985; Besanko and Thakor, 1987), collateral acts as a separating device: high-tangibility borrowers can be priced cheaply by banks, while borrowers with no pledgeable collateral cannot be screened at all and are excluded from every contract that requires partial security. Lian and Ma (2021) document that, even in the US, only around 20% of non-financial corporate debt is collateralised by physical assets and roughly 80% is cash-flow-based, with the cash-flow share rising systematically with size and away from asset-heavy sectors. PD funds - characterised by Block et al. (2024), Jang (2024), and Haque, Mayer and Stefanescu (2025) as predominantly cash-flow lenders - therefore find their natural niche at intermediate tangibility: high enough to provide downside protection in covenant negotiations and recoveries, but low enough that traditional collateral-based lenders do not undercut them. Both extremes are unattractive. Zero-tangibility firms cannot be partially secured at all, while asset-heavy firms in real estate, construction and asset finance are well served by traditional secured bank lending.

> **H4.** The probability of PD financing is highest among firms with intermediate levels of asset tangibility. The relation is inverted-U shaped: firms with no tangible assets lack sufficient downside protection and are systematically excluded, while highly collateralised firms are more easily served by traditional bank credit. A binary indicator for zero tangible assets should carry a strong negative effect.

H5 (Default risk) - mechanism (i). Stiglitz and Weiss's (1981) credit-rationing equilibrium predicts that, at the bank's threshold interest rate, the marginal rationed borrower has higher default risk than the marginal funded borrower. Non-bank intermediaries that substitute monitoring for the bank's collateral- and reputation-based screening can in principle serve some, but not all, of the rationed segment: beyond a certain default-risk threshold, the cost of expected restructuring and renegotiation outweighs the lender's monitoring premium, and even direct lenders decline. Chernenko, Erel and Prilmeier (2022) and Jang (2024) provide direct empirical support: PD borrowers are significantly riskier than bank-only borrowers but cluster well below the distress thresholds occupied by special-situations and turnaround capital.

H5. The probability of PD financing is non-linear in firm default risk: PD lenders accept moderately higher default risk than banks but decline beyond the point at which risk ceases to be contractible through pricing and covenants.

H6 (Sector) - mechanisms (iii) and (iv). The combination of cash-flow-based lending and intensive monitoring favours sectors with predictable, contractually anchored revenue streams and limited exposure to the working-capital cycle, while disfavouring sectors with high cyclicality, long real-estate investment cycles or asset-substitution problems. Williamson's (1988) corporate-finance and asset-specificity arguments imply that sectors with general-purpose, redeployable assets are more easily served by both bank and non-bank lenders, while sectors with specialised assets benefit disproportionately from the bespoke contracting that PD provides.

H6. Sectoral composition systematically influences the probability of PD financing, with PD more likely in sectors where cash flows are predictable and bespoke monitoring can substitute for collateral, and less likely in sectors naturally served by asset-backed bank lending or exposed to high cyclicality.

3. Method and research design

To identify the market segment pursued by private debt lenders, the paper estimates how firm characteristics affect the probability of receiving PD funding, allowing for non-linearities in profitability, cash flow, size, asset tangibility and default risk. The approach is designed to distinguish the firms most likely to attract private debt from the broader Italian corporate population, and to assess whether their profile is consistent with the contractible-but-non-standard borrower described in Section 2.

3.1 Data and sample

The empirical analysis constructs a dataset containing firm-level information and private debt deal data for companies in Italy. The firm population is taken from the Orbis historical database and covers all available Italian company-year observations from 2013 to 2023, extracted from the December 2024 bulk dataset. In addition to accounting data, the dataset includes industry classification, location and company status.

The key additional element is information on private debt transactions. Because private debt deals are often not publicly disclosed, the paper uses an anonymised proprietary dataset of direct-lending transactions held by AIFI. AIFI compiles these records through an annual survey of member and non-member private debt funds active in Italy, and supplements them with deals identified from commercial databases and the trade press. The dataset therefore captures close to the full universe of direct-lending transactions in Italy over the sample period.

From an initial sample of more than 500 private debt transactions, the analysis is restricted to firms receiving their first private debt financing. Multiple tranches relating to the same deal are consolidated, and observations with missing tax codes are excluded. This produces a sample of 373 firms receiving first-time direct-lending finance, which is then matched to the Orbis company population using the unique firm identifier. The main estimation sample contains 10,182,495 company-year observations. For each company receiving private debt funding, the sample contains only one observation: the year immediately preceding the funding year.

3.2 Descriptive statistics

Table 1 presents the annual distribution of firms in the sample between 2013 and 2023, distinguishing between those that obtained private debt financing ("Yes") and those that did not

("No"). The dataset comprises a total of 10,182,495 firm-year observations, of which only 373 correspond to firms receiving private debt funding. This represents a small share of the population, highlighting the rarity of private debt transactions among Italian firms during the period. The number of PD-funded firms shows modest fluctuations across years, ranging from a low of 16 in 2013 to a peak of 58 in 2020.[6] Figure 1 offers a graphical overview of the number of deals. In contrast, the number of non-funded firms remains stable and large throughout the period, reflecting the consistency of the underlying population of firms in the database.

[Insert Table 1 and 2 here]

Table 2 provides descriptive statistics comparing the companies funded by private debt with those that were not funded across a range of financial and industry characteristics. The table reports mean, standard deviation, and distributional moments (minimum, median, and maximum) for each variable for the whole sample, together with tests of differences in means (t-tests) and standardized differences (Cohen's d). Across the full sample, firms have an average log total asset value of 12.8, indicating a broad range of firm sizes. However, PD firms are substantially larger—mean (median) total assets of EUR 180 (30) million vs. EUR 8 (0.38) million. This result indicates that private debt is predominantly accessed by larger firms within the corporate population.

In terms of profitability and risk, PD-funded firms exhibit slightly higher ROA (mean ROA 2.4% vs. 0.7%) and are less likely to report losses (17% versus 34%), both statistically significant. They also display less volatile cash flows (mean of 1.00 compared to 1.59), consistent with the idea that private debt investors target financially stable firms. The PD-funded firms have fewer cases of no tangible assets (4% vs 21%), suggesting that asset tangibility may play a role in securing private debt financing. The small but significant differences in the probability of default show that PD-funded firms are slightly riskier.

Industry composition reveals that private debt is highly concentrated in manufacturing, which represents more than half of the PD funded firms (52%), compared with only 14% in the sample of non-funded firms. Conversely, PD funded firms are underrepresented in construction, retail, and real estate, sectors that tend to exhibit higher volatility and lower collateral quality. Significant differences also emerge in a few smaller sectors (e.g., mining, water supply, information, arts, and other services), though these are less economically important.

Overall, the descriptive statistics indicate that firms obtaining private debt financing are larger, with evidence of profitability, are riskier, and have medium levels of intangible assets than their peers. They are also concentrated in capital-intensive sectors such as manufacturing, aligning with the expectation that private debt providers prefer established firms with tangible assets and predictable cash flows. These patterns provide an important baseline for the empirical analysis that follows, suggesting that firm characteristics and industry affiliation play a major role in determining access to private debt markets and that the target market for PD funds is very nuanced.

3.3 Variables and methodology

The aim of this paper is to profile recipients of private debt funding and therefore the dependent variable is defined as an indicator of funding. Independent variables are specified in line with the proposed hypotheses. To capture the effect of firm size (H1), we use the natural logarithm of total assets. A quadratic term is included to address potential non-linear effects. Profitability (H2) is represented by return on assets (ROA), supplemented by its squared term to account for nonlinearities. An indicator for loss-making firms is added to assess PD funders' willingness to finance such entities. Cash flow volatility (H3) is measured by the absolute value of the coefficient of variation in cash flows over the preceding five-year period. Its quadratic term is also incorporated. The role of tangible assets (H4) is operationalized through the ratio of tangible assets to total assets,

[6] We have just one private debt deal for 2023 in our main estimation sample and this is because of incomplete coverage of year 2023, due to financial reporting lags, in our bulk dataset from Orbis that was extracted as of December 2024.

along with its squared term. An indicator for firms with no tangible assets is also included. Firm-level credit risk (H5) is represented by the predicted probability of default calculated based on the model described in Appendix A2, along with its quadratic term. Finally, we examine industry differences (H6), employing two-digit NACE codes to classify industry sections. All models control for industry, regional, and time fixed effects. Variable definitions and further construction details are provided in Appendix A1.

To test our hypotheses, we employ multivariate binary logistic regression models that determine PD funding. Logistic regression is a conditional probability function, where the probability of funding is determined by a set of several covariates and the respective vectors of coefficients β that measure the effects of the independent variables on probability of PD funding. We use the following equation:

$$P(\Omega_t) = 1/\{1 + exp\ exp\left[-\left(\alpha + X_{i,t}\beta + FE_{i,t}\right)\right]\} \quad (1)$$

where $Y_{i,t+1}$ is the indicator of PD funding, $X_{i,t}$ is the vector of independent variables and $FE_{i,t}$ are fixed effects. The temporal specification of the model, where the dependent variable is forwarded one year into the future, mitigates potential endogeneity concerns.

4. Empirical results

The results of the multivariate logit analysis reveal that PD investors in Italy systematically target larger, moderately profitable, and riskier firms with intermediate levels of asset tangibility, while avoiding loss-making, excessively risky, or highly collateralized borrowers.

Table 3 reports logistic panel regression estimates for the full sample of all firms, estimating the likelihood of receiving private debt (the dependent variable is an indicator of PD funding) using logit specifications that progressively add firm fundamentals, risk, asset structure, and industry composition, with region and year fixed effects throughout.

[Insert Table 3 here]

In Model 1 (Table 3), the coefficient on Total Assets (log) is positive and statistically significant at the 1 percent level, confirming H1 and indicating that private debt (PD) investors favour larger firms.

In Model 2, where a quadratic term is introduced to test for non-linear effects, the coefficient on Total Assets (log) remains positive, while the squared term is negative and significant. This pattern reveals an inverted U-shaped relationship between firm size and the likelihood of obtaining PD financing. The estimated inflection point—approximately €900 million in total assets (calculated as exp(5.732 / (−2 × −0.139))—lies well above the 99th percentile of Italian firms, implying that, for nearly the entire population, the relationship is effectively monotonically positive. This pattern indicates that the likelihood of receiving PD initially rises with firm size, but the marginal effect diminishes for very large firms. Finally, in the comprehensive specification (Model 15), which simultaneously includes all hypothesized firm characteristics, the coefficient on firm size remains positive and highly significant, confirming the robustness of the result across model specifications.

In economic terms, this pattern implies that PD funds target the mid- to upper mid-market segment: firms that are sufficiently large to justify the fixed costs of due diligence, monitoring, and customized structuring, yet not so large as to have access to cheaper or more standardized sources of financing such as syndicated bank loans or public bond markets. This interpretation is consistent with prior evidence showing that medium-sized enterprises are the most active non-bank borrowers, while small firms are constrained by informational opacity and high relative monitoring costs, and very large firms can access capital-market financing or syndicated bank credit (Berger and Udell, 1998; Ferrando and Mavrakis, 2017; Harrison et al., 2022; Owen et al., 2022; Block et al., 2024; Jang, 2024;

Erel and Inozemtsev, 2025; McGeown et al., 2025). Banks, under regulatory pressure, have indeed shifted lending to larger and safer borrowers (Cortés et al., 2020).

In Model 3 (Table 3), the coefficient for Return on Assets (ROA) is positive but statistically insignificant, suggesting no evident linear relationship between profitability and the likelihood of obtaining private debt (PD) financing. This finding suggests that, on average, higher profitability does not systematically enhance the probability of securing PD. In Model 4, we introduce a dummy variable indicating loss-making firms (ROA < 0), on the premise that such companies are less appealing to PD investors. The estimated coefficient is negative and statistically significant, confirming that firms with negative profitability are considerably less likely to obtain PD funding. Model 5 further investigates possible non-linear effects by including a quadratic term for ROA. The coefficient on ROA^2 is negative and highly significant, and the calculated inflection point (approximately -0.14) is near zero, suggesting that PD funds are most inclined to finance companies exhibiting small positive profitability. Conversely, the likelihood of securing funding decreases for both highly profitable and loss-making firms.

From an economic perspective, PD funds are expected to avoid non-profitable companies, as market practitioners have confirmed. When a company's profitability is negative, investors typically must incorporate insurance-type clauses or credit protection mechanisms, which elevate transaction costs and ultimately diminish net returns. However, highly profitable firms are seldom targeted by PD funds, likely because they face greater competition from other financing sources, such as banks or capital markets (Zawadowski and Albuquerque, 2025), and have less incentive to accept the higher interest costs of private debt. Additionally, PD funds often finance firms with projects expected to enhance profitability over time. Thus, PD firms do not only assess initial profitability but also consider the firm's business plan and future potential.

In the comprehensive specification (Model 15), the dummy variable for loss-making firms remains negative and statistically significant. In contrast, the linear and quadratic terms for profitability lose their significance once all firm characteristics are considered together. This finding reinforces the notion that the critical threshold for selecting profitability determinants is the avoidance of losses, rather than sensitivity to incremental differences in positive profitability. Overall, these results provide partial confirmation of Hypothesis 2: PD investors favor profitable firms, but not excessively so, and they systematically avoid financing firms with negative profitability.

In Model 6, the coefficient for cash flow volatility - defined as the absolute value of the coefficient of variation of cash flows - is negative and highly significant. This finding indicates that companies with more volatile cash flows are less likely to secure private debt (PD) funding. These results support Hypothesis 3, suggesting that PD investors prefer firms with stable cash flows. In Model 7, which includes a quadratic term to investigate potential non-linear effects, the coefficient for the squared term is positive and significant. This finding implies a decreasing yet non-linear relationship: while the probability of obtaining PD funding declines with increasing volatility, the impact diminishes at extreme levels. Notably, the inflection point (approximately 5.45) lies above the 90th percentile of cash flow volatility, indicating that, for the vast majority of companies, the relationship remains consistently negative, consistent with our hypothesis. These results confirm that PD investors prioritize the borrower's ability to generate reliable, recurring cash flows over collateral availability (Block et al., 2024; Cumming et al., 2019). By focusing on cash-flow-based lending, PD funds can better assess debt serviceability and reduce default risk. However, in the full specification (Model 15), the coefficient for cash flow volatility loses its statistical significance when all firm characteristics are considered simultaneously. This attenuation likely reflects the shared explanatory power between cash flow stability and profitability or size, which also capture aspects of firm performance and financial resilience.

In Model 8 (Table 3), where the proportion of tangible assets to total assets is used as the test variable, the coefficient is negative but statistically insignificant, suggesting no clear linear relationship between asset tangibility and the likelihood of receiving PD funding. When we include

in Model 9 a dummy identifying firms with no tangible assets, the coefficient becomes negative and statistically significant, indicating that companies entirely lacking tangible collateral are less likely to receive PD financing. However, in the same specification, the continuous measure of tangibility becomes statistically significant and negative, implying that, among firms with at least some tangible assets, the probability of PD funding decreases as tangibility rises, consistently with H4.

To explore potential non-linear effects, Model 10 introduces a squared term for asset tangibility. Both the linear and quadratic coefficients are statistically significant, revealing an inverted U-shaped relationship between asset tangibility and the likelihood of PD financing. This indicates that PD investors target firms with intermediate levels of tangibility: the probability of PD funding initially increases with tangibility, but it begins to decline beyond the inflection point of approximately 0.29, roughly corresponding to the third quartile of the distribution. For most firms, therefore, the relationship remains consistent with H4, confirming that PD investors are more likely to fund companies with relatively lower collateral intensity. In the comprehensive specification (Model 15), the 'no tangible assets' dummy remains significant; the nonlinearity persists via a significant negative square term, while the linear term is not significant.

Economically, these results indicate that PD investors target a specific range of asset tangibility, avoiding both highly intangible firms, which lack sufficient collateral protection in default scenarios, and highly tangible ones, which are more easily served by traditional bank credit. This investment strategy is consistent with Jang (2024), who documents that direct loans involve fewer borrowing-base restrictions than bank loans, and with Block et al. (2024), who show that PD investors often finance firms with insufficient collateral to access syndicated bank credit.

In Model 11 we test H5 using the predicted probability of default as a proxy for firm risk. The coefficient on this variable is positive and statistically significant, while its squared term is negative and significant, indicating an inverted U-shaped relationship between firm risk and the likelihood of obtaining PD funding. The probability of PD financing therefore increases with firm risk up to a moderate level, but declines beyond an inflection point of approximately 0.00071—between the median and the third quartile of the sample distribution. This suggests that PD funds operate in the riskier segment of the borrower spectrum while avoiding excessively risky firms. In the comprehensive specification (Model 15), both the linear and quadratic terms remain statistically significant, confirming the robustness of this non-linear relationship even after controlling for size, profitability, asset tangibility, and cash-flow stability. From an economic perspective, these results suggest that PD investors are willing to lend to firms with higher default probabilities, riskier than those financed by banks (Carey et al., 1998; Chernenko et al., 2022; Erel and Inozemtsev, 2025). However, this risk-taking is bounded: beyond a certain level of default probability, firms become too risky to fit within PD funds' investment mandates. In such cases, the expected cost of covenant breaches and restructurings may outweigh potential returns, especially since direct loan borrowers are more likely to violate covenants than bank borrowers (Jang, 2024).

Across Models 1–15, we find consistent evidence supporting H6. Compared with the reference group of retail and wholesale trade, firms in the manufacturing, information, and human health sectors are most likely to obtain PD funding, whereas firms in the real estate sector are significantly less likely to do so. This behavior reflects the risk-return logic of cash-flow-based lending, where funds avoid sectors with high exposure to cyclical shocks. The evidence aligns with prior findings that PD funds target sectors offering resilient margins and moderate growth potential (Böni and Manigart, 2022; Block et al., 2024; Buchner et al., 2024).

5. Conclusions

This paper provides the first large-scale firm-level analysis of private debt financing in Italy and addresses a clear gap in the literature. Prior research on PD has largely focused on fund-level returns,

contracting and aggregate market behaviour, with limited evidence on the borrower side, especially in European contexts. By merging proprietary direct-lending transactions with more than ten million firm-year observations, the analysis identifies the firm profile most likely to attract PD funding.

The Italian evidence should not be read as implying that private debt markets are identical across countries. It suggests instead that the core selection mechanism is portable. PD funds tend to finance firms whose risks are too complex or insufficiently collateralised for standard bank lending but sufficiently contractible, after due diligence, for private monitoring. Market size, legal institutions, bank competition and fund maturity will affect the scale and form of this activity, but the underlying borrower profile is consistent with the broader international evidence on direct lending and private credit.

The results contrast sharply with evidence from the US and UK. The US PD market is structurally a leveraged-buyout-finance market in which the great majority of direct-lending transactions are PE-sponsored. The Italian PD borrower identified here - mid-sized, moderately profitable, intermediate-tangibility, intermediate-risk and less sponsor-dominated than the US and UK profile - reflects a different equilibrium use of the PD instrument: not primarily LBO leverage, but growth finance for the upper mid-market. The implications of the US literature on the financial-stability properties of PD therefore do not transfer mechanically to the Italian context. The UK, which sits closer to the US in deal structure but has used public co-investment to address the small-firm access problem (British Business Bank, 2025), illustrates a policy stance that the Italian setting could adapt. The findings suggest that Italy already has the institutional foundations to formalise a public co-investment vehicle dedicated to direct-lending funds operating at smaller deal sizes.

If policymakers wish private debt to reach smaller and more informationally opaque firms, the binding constraint is the fixed cost of underwriting and monitoring, not the aggregate supply of capital. Three policy measures with established precedents follow. First, public co-investment vehicles can act as anchor investors in funds committed to smaller deal sizes, sharing the fixed cost of operating in this segment. Second, partial first-loss guarantees on diversified direct-lending vehicles can lower the effective cost of capital for smaller borrowers without displacing commercial funds active in the upper mid-market. Third, aligning the tax and regulatory treatment of direct lending with adjacent instruments - minibonds and private placements - can remove wedges that raise the underwriting cost of smaller deals. Standardised documentation for smaller transactions would complement these measures. The objective is to extend the contractible segment of the credit market by lowering underwriting and monitoring costs, not to subsidise risk indiscriminately.

The central finding is that private debt funds do not simply finance “risky firms” or “asset-light firms”; they finance firms whose risks are contractible. The typical Italian PD borrower is large enough to absorb monitoring costs, profitable enough to service debt, risky or non-standard enough to fall outside the lowest-cost bank segment, sufficiently but not excessively collateralised, and concentrated in sectors where cash flows are predictable. This is a bounded intermediate space in the corporate credit market - distinct from both the lowest-risk segment served by traditional bank credit and the highest-risk segment served by special-situations capital - and identifying it is the principal theoretical contribution of the paper.

Table 1 Breakdown of the main estimation sample

	Private debt		
Year	No	Yes	Total
2013	970,304	16	970,320
2014	977,284	31	977,315
2015	993,320	30	993,350
2016	1,008,622	38	1,008,660
2017	1,030,312	24	1,030,336
2018	1,054,970	55	1,055,025
2019	1,082,625	49	1,082,674
2020	1,085,264	58	1,085,322
2021	1,088,719	32	1,088,751
2022	886,788	39	886,827
2023	3,914	1	3,915
Total	10,182,122	373	10,182,495

Notes:
The table shows the breakdown of company-year observations in the main estimation sample by year and private debt funding. For each company receiving private debt funding, the sample contains only one observation: the year immediately preceding the funding year.

Figure 1 Number of private debt deals in the main estimation sample

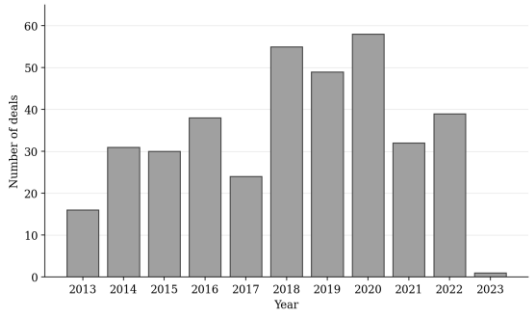

Table 2 Descriptive statistics

Notes:

The table reports descriptive statistics for the estimation sample used in the paper. The sample covers 2013-2023. The "Private debt funded" sample includes the pre-investment year for companies that obtained private debt financing. The "Not funded by private debt" sample includes all company-year observations for companies that did not receive private debt funding in 2013-2023. The table reports statistics for the whole sample and separately for the two subsamples. The penultimate column reports the p-value from the test of the difference in means between the two subsamples. Statistical significance is indicated by asterisks (* p < 10%, ** p < 5%, *** p < 1%). The final column reports the standardised difference between the two group means.

	Whole sample						Private debt funded			Not funded by private debt			PD-funded vs. non-funded

Table 3 Main estimation results

The table reports estimation results for the models testing the hypotheses stated in the paper. The models are estimated using logistic regression, with the dependent variable equal to one for companies receiving private debt funding and zero otherwise. For funded companies, the estimation sample includes the observation from the year immediately preceding the funding event. For all other companies, the estimation sample comprises company-year observations from the population of Italian companies over 2013-2023. t-statistics are reported in parentheses, with p-values indicated by asterisks (* p < 10%, ** p < 5%, *** p < 1%).

Appendix

Table A1 Definition of variables

	Definition	Source
Dependent variable		
PD funding	Equals unity if the company was funded by private debt funds, zero otherwise	AIFI
Main independent variables		
Total assets (log)	Total assets, natural logarithm	Orbis
ROA	Return on assets, computed as Net income / Total assets	Orbis
Indicator of loss	Equals unity if Return on assets is negative, zero otherwise	Orbis
Volatility of cash flows	Absolute value of coefficient of variation (mean / standard deviation) for cash flows computed for past five years, winsorised at 5% and 95%	Orbis
Tangible assets to total assets	Financial ratio, computed as Tangible assets / Total assets	Orbis
No tangible assets	Equals unity if Tangible assets equal zero, zero otherwise	Orbis
Probability of default	Insolvency risk score, winsorised at 10% and 90%. Details are presented in Appendix A2.	Own computation
Industry sector fixed effects		
Section A - Agriculture	Equals unity if the company operates in the industrial section Agriculture, forestry and fishing (divisions 01-03), zero otherwise	Orbis
Section B - Mining	Equals unity if the company operates in the industrial section Mining and quarrying (divisions 05-09), zero otherwise	Orbis
Section C - Manufacturing	Equals unity if the company operates in the industrial section Manufacturing (divisions 10-33), zero otherwise	Orbis
Section D - Electricity/Gas	Equals unity if the company operates in the industrial section Electricity, gas, steam and air conditioning supply (division 35), zero otherwise	Orbis
Section E - Water Supply	Equals unity if the company operates in the industrial section Water supply; sewerage, waste management and remediation activities (divisions 36-39), zero otherwise	Orbis
Section F - Construction	Equals unity if the company operates in the industrial section Construction (divisions 41-43), zero otherwise	Orbis
Section G - Wholesale/Retail	Equals unity if the company operates in the industrial section Wholesale and retail trade; repair of motor vehicles and motorcycles (divisions 45-47), zero otherwise	Orbis
Section H - Transportation	Equals unity if the company operates in the industrial section Transportation and storage (divisions 49-53), zero otherwise	Orbis
Section I - Accommodation	Equals unity if the company operates in the industrial section Accommodation and food service activities (divisions 55-56), zero otherwise	Orbis
Section J - Information	Equals unity if the company operates in the industrial section Information and communication (divisions 58-63), zero otherwise	Orbis
Section K - Financial	Equals unity if the company operates in the industrial section Financial and insurance activities (divisions 64-66), zero otherwise	Orbis
Section L - Real Estate	Equals unity if the company operates in the industrial section Real estate activities (division 68), zero otherwise	Orbis
Section M - Professional	Equals unity if the company operates in the industrial section Professional, scientific and technical activities (divisions 69-75), zero otherwise	Orbis
Section N - Administrative	Equals unity if the company operates in the industrial section Administrative and support service activities (divisions 77-82), zero otherwise	Orbis
Section O - Public Administration	Equals unity if the company operates in the industrial section Public administration and defence; compulsory social security (division 84), zero otherwise	Orbis
Section P - Education	Equals unity if the company operates in the industrial section Education (division 85), zero otherwise	Orbis
Section Q - Human Health	Equals unity if the company operates in the industrial section Human health and social work activities (divisions 86-88), zero otherwise	Orbis
Section R - Arts/Entertainment	Equals unity if the company operates in the industrial section Arts, entertainment and recreation (divisions 90-93), zero otherwise	Orbis

Section S - Other Service	Equals unity if the company operates in the industrial section Other service activities (divisions 94-96), zero otherwise	Orbis
Section T - Households	Equals unity if the company operates in the industrial section Activities of households as employers; undifferentiated goods- and services-producing activities of households for own use (divisions 97-98), zero otherwise	Orbis
Section U - Extraterritorial	Equals unity if the company operates in the industrial section Activities of extraterritorial organisations and bodies (division 99), zero otherwise	Orbis
Regional fixed effects		
Region Abruzzo	Equals unity if the company is based in the Abruzzo region, zero otherwise	Orbis
Region Basilicata	Equals unity if the company is based in the Basilicata region, zero otherwise	Orbis
Region Calabria	Equals unity if the company is based in the Calabria region, zero otherwise	Orbis
Region Campania	Equals unity if the company is based in the Campania region, zero otherwise	Orbis
Region Emilia-Romagna	Equals unity if the company is based in the Emilia-Romagna region, zero otherwise	Orbis
Region Friuli-Venezia Giulia	Equals unity if the company is based in the Friuli-Venezia Giulia region, zero otherwise	Orbis
Region Lazio	Equals unity if the company is based in the Lazio region, zero otherwise	Orbis
Region Liguria	Equals unity if the company is based in the Liguria region, zero otherwise	Orbis
Region Lombardia	Equals unity if the company is based in the Lombardia region, zero otherwise	Orbis
Region Marche	Equals unity if the company is based in the Marche region, zero otherwise	Orbis
Region Molise	Equals unity if the company is based in the Molise region, zero otherwise	Orbis
Region Piemonte	Equals unity if the company is based in the Piemonte region, zero otherwise	Orbis
Region Puglia	Equals unity if the company is based in the Puglia region, zero otherwise	Orbis
Region Sardegna	Equals unity if the company is based in the Sardegna region, zero otherwise	Orbis
Region Sicilia	Equals unity if the company is based in the Sicilia region, zero otherwise	Orbis
Region Toscana	Equals unity if the company is based in the Toscana region, zero otherwise	Orbis
Region Trentino-Alto Adige	Equals unity if the company is based in the Trentino-Alto Adige region, zero otherwise	Orbis
Region Umbria	Equals unity if the company is based in the Umbria region, zero otherwise	Orbis
Region Valle D'Aosta	Equals unity if the company is based in the Valle D'Aosta region, zero otherwise	Orbis
Region Veneto	Equals unity if the company is based in the Veneto region, zero otherwise	Orbis
Time fixed effects		
Year 2013	Equals unity for financial year 2013, zero otherwise	Orbis
Year 2014	Equals unity for financial year 2014, zero otherwise	Orbis
Year 2015	Equals unity for financial year 2015, zero otherwise	Orbis
Year 2016	Equals unity for financial year 2016, zero otherwise	Orbis
Year 2017	Equals unity for financial year 2017, zero otherwise	Orbis
Year 2018	Equals unity for financial year 2018, zero otherwise	Orbis
Year 2019	Equals unity for financial year 2019, zero otherwise	Orbis
Year 2020	Equals unity for financial year 2020, zero otherwise	Orbis
Year 2021	Equals unity for financial year 2021, zero otherwise	Orbis
Year 2022	Equals unity for financial year 2022, zero otherwise	Orbis
Year 2023	Equals unity for financial year 2023, zero otherwise	Orbis

Notes:

The table defines each variable used in the study. The final column reports the source of the key data items used to construct each variable. AIFI denotes the Italian Association of Private Equity, Venture Capital and Private Debt. Orbis denotes the Moody's company-information database.

Table A2 Failure prediction model

	Default
ROA using Net income (%)	-0.0257***
	(-65.49)
Collection period DSO (days)	0.00115***
	(23.49)
Credit period DPO (days)	0.00187***
	(46.13)
Cash to total assets (%)	-0.0698***
	(-51.65)
Current ratio (x)	-0.0287***
	(-8.73)
Solvency ratio (Asset based) (%)	-0.0270***
	(-82.35)
Constant	-6.695***
	(-465.46)
Observations	15,776,539
McFadden pseudo-R^2	0.184
AUC	0.890

Notes:
The table reports coefficient estimates from the failure-prediction model for the population of Italian companies over 1984-2023. The dependent variable is default, defined as the last available accounts before a change in company status to payment default, insolvency or bankruptcy. The coefficients are estimated using logistic regression. t-statistics are reported in parentheses, with p-values indicated by asterisks (* $p < 10\%$, ** $p < 5\%$, *** $p < 1\%$). The insolvency risk scores used to test H5 are the predicted default probabilities generated by this model.

Hybrid Entrepreneurial Agency: Reconfiguring Decision-Making in the era of AI-startups

CARMELA ELITA SCHILLACI[1], FEDERICO MERTOLI[1]

Abstract

Frame of the research. *The transition from digital transformation to AI transformation is reshaping entrepreneurship by embedding artificial intelligence within the cognitive and operational core of emerging ventures. While existing literature largely interprets AI as a performance-enhancing tool, its implications for the micro-foundations of entrepreneurial agency remain insufficiently conceptualized.*

Purpose of the paper. *The study aims to examine how the integration of AI as an operational component of the founding architecture reconfigures entrepreneurial agency, dynamic capabilities, and decision-making structures in AI-startups, advancing the concept of Hybrid Entrepreneurial Agency.*

Methodology. *A qualitative theory-building design based on multiple illustrative case studies is adopted. The empirical analysis draws on 14 AI-startups operating across heterogeneous sectors. Secondary data sources are analysed through a framework-guided pattern-matching approach to compare empirical configurations with theoretically derived dimensions.*

Results. *Findings identify four interrelated mechanisms: (i) redistribution of the cognitive function through AI-assisted hypothesis generation and validation; (ii) compression of executive cycles via reduced decision latency and intelligent automation; (iii) computational and asymmetric scalability enabled by cumulative learning effects; and (iv) strengthened governance requirements concerning accountability, architectural supervision, and risk management.*

Research limitations. *The reliance on secondary data and a context-specific sample constrains statistical generalisation and calls for longitudinal and quantitative extensions.*

Managerial implications. *AI integration emerges as an organisational design choice requiring early investment in data infrastructures, hybrid decision architectures, and governance protocols to ensure sustainable competitive advantage.*

Originality of the paper. *The study repositions the startup as a hybrid socio-technical system and contributes to extending dynamic capabilities theory by introducing algorithmic orchestration as an emerging constitutive dimension of entrepreneurial agency.*

Keywords: *AI Transformation; Entrepreneurial Agency; AI-startups; Dynamic Capabilities; Governance.*

1. Introduction

The classical literature on entrepreneurship has long interpreted the startup as an organisation aimed at reducing information asymmetries and market inefficiencies through technological innovation (Akerlof, 1978; Arrow, 1962; Kirzner, 2015).

In this perspective, the entrepreneur represents the main cognitive agent in the value creation process, who identifies opportunities, combines resources, and guides strategic choices under conditions of uncertainty (Knight, 1921; Schumpeter, 1934).

The most established approaches, such as Lean Startup (Blank & Dorf, 2020; Ries, 2011), while emphasising iterative cycles of experimentation and learning, maintain a decision-making structure centred on human intentionality.

However, the transition from Digital Transformation to AI Transformation introduces a structural discontinuity in this paradigm (Feroz & Kwak, 2024; Lee, 2025). If in previous technological waves technology assumed a predominantly instrumental role, in the era of artificial intelligence the distinction between creator and tool tends to progressively blur.

AI does not merely support entrepreneurial action, but participates in prediction, simulation, hypothesis generation, and validation of strategic choices (Agrawal et al., 2022; Jarrahi, 2018). In this context, it can be interpreted not only as a component of the tech stack but also as a constitutive

[1] University of Catania, Italy

element of the organisational architecture, capable of influencing the decision-making trajectories of the enterprise from the founding phase, leading to the establishment of so-called AI-startups (Pati et al., 2024).

If startups are traditionally described as temporary organisations engaged in discovering a scalable and repeatable business model in high-uncertainty contexts (Blank & Dorf, 2020; Freeman & Engel, 2007), in AI-startups, this definition is partial. Such companies do not limit themselves to seeking a business model, but architect systems capable of learning, adapting, and evolving over time through the integration of data, algorithmic models, and continuous feedback. The value does not reside exclusively in the product or service offered, but in the ability to orchestrate a distributed cognitive infrastructure, in line with the perspective of dynamic capabilities (Teece, 2017).

The true discontinuity introduced by AI, as highlighted by Agrawal et al. (2022), lies not only in automation but in the reduction of the cost of prediction. This has direct effects on decision-making processes, the speed of experimentation, and organisational configuration. In AI-startups, experimentation is not limited to the product but extends to algorithmic models, datasets, and operational processes. The organisation is configured as a socio-technical system (Pasmore et al., 2019) in which learning is continuous and the distinction between the development phase and the operational phase tends to dissolve (Davenport & Ronanki, 2018).

This change also profoundly affects the logic of growth. In traditional startups, scalability was predominantly associated with the expansion of organisational resources. In AI-startups, growth can be achieved through intelligent automation and system learning, generating forms of asymmetric scalability that allow small teams to produce disproportionate impacts relative to the resources employed (Tschang & Almirall, 2021). This dynamic suggests a transition from a resource-based logic to a cognitive-computational logic of scalability.

Despite the growing attention towards AI in management, the literature predominantly tends to treat these technologies as enablers of efficiency or performance. Their ontological implications on the very nature of entrepreneurship and the locus of organisational agency remain, however, still underexplored.

This shift calls into question the micro-foundations of entrepreneurial agency. If dynamic capabilities traditionally reside in managerial cognition and organisational routines (Teece, 2017), the integration of AI suggests a hybridisation of agency in which cognitive functions are partially externalised into algorithmic systems. This raises fundamental questions concerning intentionality, responsibility, and the distribution of decision authority within AI-spartups.

When AI is integrated into the validated learning cycle and contributes to the generation and evaluation of strategic hypotheses (Roundy, 2022), it no longer acts merely as a tool, but as a cognitive partner that intervenes in the construction of the startup's decision-making trajectories.

In light of these considerations, a significant theoretical gap emerges: The literature on entrepreneurship and managerial innovation has not yet provided an adequate conceptualisation of how the integration of AI as an operational component of the founding team redefines entrepreneurial agency, the foundations of dynamic capabilities, and the decision-making architecture of the startup.

Against this backdrop, the present study addresses the following research question: How does the integration of artificial intelligence as an operational component of the founding team redefine entrepreneurial agency, dynamic capabilities, and the decision-making architecture of AI-startups?

To address this question, the research adopts a qualitative design based on multiple cases, selected due to the central role played by artificial intelligence in decision-making and value creation processes. Through the comparative analysis of the examined companies, the aim is to explore how the cognitive, executive, scalable, and governance functions are reconfigured by the interaction between human judgement and algorithmic systems.

The objective is to develop a conceptualisation of Hybrid Entrepreneurial Agency, clarifying its implications for the micro-foundations of dynamic capabilities in AI-startups. In this way, the work contributes to the literature on entrepreneurship by overcoming a merely instrumental view of AI and

proposing a socio-technical perspective in which agency emerges from the structured interaction between human intentionality and algorithmic computational capability.

2. Theoretical background

2.1 Evolution of the Entrepreneurial Agency and the Lean Paradigm

The literature on entrepreneurship has traditionally attributed a central role to the entrepreneur in processes of innovation and economic transformation. In the Schumpeterian perspective, the entrepreneur is the agent of creative destruction, the one who introduces new productive combinations capable of reconfiguring markets and competitive structures (Schumpeter, 1934). In a different but complementary theoretical tradition, Knight (1921) distinguishes between measurable risk and incalculable uncertainty, attributing to the entrepreneur the function of making decisions under conditions of radical uncertainty, while Kirzner (1979) emphasises the dimension of alertness, that is, the ability to seize opportunities generated by informational asymmetries and market inefficiencies.

Over time, the debate has progressively shifted from the figure of the entrepreneur as an individual hero to the entrepreneurial process as a dynamic sequence of discovery, experimentation, and adaptation. The startup has thus been defined as a temporary organisation engaged in the search for a scalable and repeatable business model (Blank & Dorf, 2020; Ries, 2011). In this perspective, entrepreneurship is no longer just an individual creative act, but a structured process of exploration and continuous learning (Freeman & Engel, 2007).

At the same time, the field of entrepreneurial intention has highlighted the cognitive and intentional dimension of entrepreneurial action. Shapero and Sokol (1982) identify the combination of perceived desirability and perceived feasibility as the conditions preceding the entrepreneurial event, while Ajzen (1991) emphasises the predictive role of intention regarding behaviour. Bird (1988) links intentionality to the cognitive processes that guide the design of the enterprise, reinforcing the idea that entrepreneurial action is rooted in the mental representations of the founder.

Beyond the intentional dimension, entrepreneurial agency has progressively been interpreted through the lens of the micro-foundations of dynamic capabilities, according to which managerial cognition, organisational routines, and decision-making processes constitute the fundamental drivers of strategic renewal (Teece, 2017). In this perspective, the cognitive architecture of the entrepreneur not only represents the origin of opportunity recognition but also the place where the activities of sensing, seizing, and reconfiguring are concretely activated. Entrepreneurial agency thus emerges as a construct rooted in the mental processes and interpretative abilities of the founder, which guide the evolution of the organization over time. This perspective is further developed by McMullen et al. (2021), who propose a unified theory of entrepreneurial agency grounded in the intentional and cognitive dimensions of the entrepreneurial act, distinguishing it from broader organisational action and reinforcing the centrality of the founder's interpretative capacity as the locus of strategic initiative.

The Lean Startup paradigm has further formalised this cognitive centrality by proposing the Build–Measure–Learn cycle as a systematic mechanism for reducing uncertainty (Ries, 2011). The Minimum Viable Product (MVP) is conceived as an epistemic tool aimed at rapidly and iteratively testing value and business model hypotheses. Blank (2013) highlights the importance of Customer Discovery as a moment of empirical verification of entrepreneurial assumptions through direct market interaction. In this context, the emerging enterprise is interpreted as a dynamic system engaged in a constant process of exploration and exploitation, consistent with the broader tradition of organisational learning (Brix, 2019).

The Lean logic implicitly assumes that uncertainty can be reduced primarily through empirical interaction with the market. However, if artificial intelligence reduces the cost of forecasting (Agrawal et al., 2022), part of the uncertainty can be addressed ex ante through computational

inferences. This shift modifies the epistemic structure of experimentation: validation is no longer exclusively market-based, but takes on a hybrid, predictive-empirical configuration. The formulation and evaluation of strategic hypotheses can thus take place in part before the direct confrontation with the market, through simulations, algorithmic scenario generation, and predictive analysis.

Despite the methodological evolution introduced by Lean logic, a common assumption remains across different traditions: the generation of hypotheses, the interpretation of data, and the final decision remain predominantly human activities. Even where digital tools support the analysis, entrepreneurial agency remains centred on the founder. The learning cycle implicitly assumes a sequential and anthropocentric structure: first an hypothesis is formulated, then it is tested, and finally it is reformulated based on the results.

This approach becomes theoretically problematic when intelligent systems actively participate in the generation, simulation, and evaluation of strategic hypotheses. The integration of artificial intelligence into business processes introduces a potential discontinuity compared to this framework.

Intelligent systems are capable of generating product variants, simulating alternative scenarios, and analysing large volumes of data in real time, anticipating part of the validation process even before direct interaction with the market. The iterative cycle can thus evolve towards configurations of simultaneous and computational learning, where generation, simulation, and optimisation occur continuously and at non-anthropomorphic speeds. Learning no longer derives exclusively from empirical comparison with the market, but emerges from the interaction between data, predictive models, and managerial interpretation.

A significant conceptual tension thus arises between the anthropocentric foundations of entrepreneurial theory and the emergent role of algorithmic systems in strategic cognition. The issue is not only about efficiency or decision-making speed, but the reconfiguration of the locus of entrepreneurial agency itself.

When cognitive functions such as hypothesis generation, scenario simulation, and pattern recognition are partially externalised in algorithmic systems, entrepreneurial agency can no longer be conceptualised as exclusively human. It therefore becomes necessary to reconceptualise entrepreneurial agency within a socio-technical perspective, in which action is not located exclusively in the individual founder but emerges from the structured interaction between human intentionality and algorithmic computational capacity.

2.2 AI and the Reconfiguration of Entrepreneurial Agency

The transition from Digital Transformation to AI Transformation does not represent a mere technological evolution, but an ontological discontinuity in the way entrepreneurial action is conceived and practiced. If in previous technological waves software predominantly played an instrumental role, aimed at automating existing processes, in the era of artificial intelligence it directly intervenes in the cognitive sphere of the enterprise, impacting the formulation of hypotheses, the simulation of scenarios, and the configuration of strategic trajectories. This shift builds on a trajectory anticipated by Nambisan (2017), who argues that digital technologies fundamentally alter the nature of entrepreneurial action by introducing new modalities of opportunity creation, value co-creation, and boundary-spanning organising. The transition to AI transformation extends this logic further, moving from digital affordances to algorithmic agency. As highlighted by Agrawal et al. (2022), the true disruption introduced by AI does not lie so much in automation, but rather in the drastic reduction of the cost of prediction, with structural effects on the relationship between uncertainty, choice, and resource allocation.

In this context, the AI-startups cannot be interpreted as a traditional startups equipped with more sophisticated tools. It is rather configured as a socio-technical system in which artificial intelligence takes on the role of an operational partner, actively participating in value creation and the definition of strategic choices from the founding phase.

This configuration implies a redistribution of cognitive work: activities traditionally attributed to the founder — such as hypothesis generation, alternative evaluation, and trade-off analysis — are partially outsourced to algorithmic systems capable of learning, simulating, and optimising in real-time (Jarrahi, 2018).

This transformation primarily affects the cognitive function of the enterprise. Artificial intelligence amplifies the exploratory capacity of the entrepreneurial team, exponentially extending the space of analysable possibilities. Through predictive models, generative systems, and advanced simulation techniques, the startup can test alternative scenarios even before entering the market, anticipating part of the validation process.

The traditional Build–Measure–Learn cycle thus evolves towards configurations where generation, simulation, and optimisation occur continuously and non-sequentially, approaching a paradigm of augmented entrepreneurship. In this framework, validated learning does not disappear but hybridises: learning no longer derives exclusively from the ex-post comparison with the market, but rather from the constant interaction between data, models, and managerial interpretation (Roundy et al., 2022).

Cognitive reconfiguration also produces direct effects on the executive dimension. AI does not merely support analysis, but intervenes in compressing decision-making cycles and reducing information latency. The ability to generate code, content, financial analyses, and operational simulations drastically reduces time-to-market and transforms the MVP from a static prototype into an "evolutionary organism," capable of continuously adapting to user feedback.

In this sense, entrepreneurial action is no longer marked by discrete iterations, but takes the form of a continuous flow of micro-optimizations driven by the artificial partner. The founder, consequently, shifts from a role of direct executor to that of orchestrator of hybrid decision-making architectures.

Simultaneously, the configuration of scalability is changing. In AI-startups, growth does not solely depend on the expansion of human or financial resources, but on the ability of models to learn and improve through the accumulation of data. Thus, a form of asymmetrical scalability emerges, in which small teams can manage global volumes of users thanks to the integration of self-adaptive intelligent systems.

The competitive advantage is no longer solely anchored in the possession of static resources, but in the speed of learning of the system as a whole, consistent with an evolutionary reading of dynamic capabilities (Teece, 2017).

However, the increase in the operational autonomy of intelligent systems introduces new governance requirements. The opacity of models, the dependence on data quality, and the probabilistic nature of outputs make issues of accountability, supervision, and adaptive control central (Floridi, 2023; Liang et al., 2022; Schillaci et al., 2025; Talebi et al., 2025).

The Human-in-the-loop philosophy is progressively evolving towards Human-on-the-loop configurations, where human control is not exercised over every single decision, but over the overall behaviour of the system. Responsibility remains with the organization, but the founder's role extends to designing intervention thresholds, defining ethical constraints, and managing algorithmic risks.

Taken together, these transformations suggest that entrepreneurial agency can no longer be conceptualised as the exclusive property of the founding individual. Strategic action emerges from the structured interaction between human intentionality and computational power, configuring a form of Hybrid Entrepreneurial Agency in which the locus of action is distributed along an integrated socio-technical architecture. The AI startup thus appears as an adaptive system with continuous learning, in which cognition, execution, growth, and governance are deeply intertwined and co-evolve over time.

3. Methodology

This study adopts a qualitative research design orientated towards theoretical construction, based on a multiple case study strategy. The objective is to develop and refine an interpretative framework capable of explaining how artificial intelligence, when integrated as an operational component of the entrepreneurial architecture, reconfigures entrepreneurial agency.

The research therefore falls within the realm of theory-building studies based on qualitative evidence (Eisenhardt, 1989; Eisenhardt & Graebner, 2007; Gioia et al., 2013). Case studies are not treated as representative observations of a statistical universe, but rather as analytical devices for conceptual clarification. Empirical analysis takes on an explanatory and comparative function: each case allows us to observe how AI is structurally incorporated into business models, decision-making processes, and scalability dynamics. The design follows the logic of the multiple case study aimed at theoretical refinement through systematic comparison between organisational configurations (Eisenhardt, 1989; Yin, 2018).

The cases analysed were selected from AI-startup operating within the Le Village by CA Italia ecosystem, with particular reference to Le Village Sicilia. Le Village by CA represents a structured ecosystem of open innovation aimed at fostering interaction between startups, corporate partners, financial institutions, and academic actors. This context is particularly relevant for observing the structural integration of AI for at least three reasons.

Firstly, AI-startups frequently face constraints related to access to proprietary datasets, vertical use cases, and industrial validation environments. Inclusion in an ecosystem that connects startups with corporate partners allows AI to be seen not merely as a technological layer, but as an operational component integrated into real decision-making and production processes.

Secondly, the Village model enables a form of relational scalability. If AI enables technological scalability through automation and cumulative learning, the ecosystem promotes commercial validation and market access through structured partnerships. This allows for the analysis of the interaction between cognitive-computational scalability and network-based growth dynamics. This dynamic is consistent with Autio et al.'s (2018) perspective on entrepreneurial ecosystems and digital affordances, according to which the institutional and relational architecture of an ecosystem shapes the opportunity space available to ventures, influencing their growth trajectories and the modes through which they access and recombine resources.

Thirdly, the banking and institutional context introduces high standards of governance, compliance, and risk management. Startups integrated into the ecosystem are exposed from the early stages to regulatory constraints and accountability requirements that make the dimension of algorithmic governance particularly observable.

The selection of cases was carried out through purposive sampling. Startups that met the following criteria were included:

1. Artificial intelligence plays a central role in the value proposition.
2. AI is integrated into core decision-making or operational processes.
3. The sector of belonging allows for the observation of cognitive, executive, scalable, or governance implications of AI integration.
4. Sufficient documentation is available to reconstruct the architecture of the business model and the structural role of AI.

The sample includes startups operating in heterogeneous sectors in order to capture the variety of ways AI is integrated in different institutional and technological contexts. Such sectoral plurality allows for an analytical generalisation based on the identification of recurring patterns (Yin, 2018), rather than a statistical generalisation.

At the same time, the belonging of the cases to the same ecosystem represents a contextual condition that delineates the scope of validity of the results. The Village environment provides relational and institutional advantages that might not characterise completely independent startups.

The results must therefore be interpreted in terms of theoretical transferability and not empirical

universality.

The unit of analysis is constituted by the structural role of artificial intelligence within the organisational architecture and the business model of the startup. Consistent with the theoretical framework developed, the analysis focuses on four interconnected dimensions:

- the cognitive function of AI in the processes of generating, evaluating, and refining strategic hypotheses;
- the executive function of AI in compressing decision latency and restructuring operational processes;
- the computational configuration of scalability through cumulative learning mechanisms;
- the mechanisms of governance and accountability of algorithmic systems.

The focus is not on individual technological characteristics, but rather on the overall reconfiguration of entrepreneurial agency emerging from the interaction between human judgement and computational capabilities.

The data collection was primarily based on secondary sources, including corporate documentation (websites, pitch decks, one-pagers), institutional materials from the ecosystem, public interviews with founders, industry reports, and specialised articles. The predominant use of secondary data is consistent with the exploratory and theoretical-conceptual nature of the study and with the analysis of emerging organisational configurations in technologically dynamic contexts (Eisenhardt & Graebner, 2007).

In order to strengthen the methodological rigour of the study, specific validation procedures were adopted.

Construct validity was supported through the triangulation of multiple secondary sources, including corporate documentation (websites, pitch decks, one-pagers), institutional materials from the Le Village ecosystem, public interviews with founders, and industry reports.

Internal validity was strengthened through a systematic pattern matching process between the empirical configurations observed in the cases and the theoretical dimensions of the proposed framework (Yin, 2018).

Reliability was ensured through the explicit definition of case selection criteria and the transparent description of the analytical process, ensuring conceptual traceability of interpretative inferences. In line with the theory-building nature of the research, the results should be understood in terms of analytical generalisation rather than statistical generalisation (Eisenhardt, 1989; Yin, 2018).

Table 1 summarises the selected cases and constitutes the empirical basis for identifying cross-cutting patterns in the structural integration of artificial intelligence into entrepreneurial architectures.

Tab. 1: Selected startups

Startup	Sector	Description
Agrobit	AgriTech	Develops AI-based decision support systems for precision agriculture through image analysis and predictive agronomic modelling.
Vaimee	Industrial AI / Digital Twin	Provides interoperable digital twin solutions enabling simulation and optimisation of industrial systems.
Bandit	LegalTech	Uses AI and NLP to structure and optimise public tender documentation processes.
Audacia Innovations	MarketingTech	Applies predictive analytics to support strategic marketing planning and performance forecasting.
Longeviva	HealthTech	Integrates AI to personalise preventive health pathways using longitudinal biological and behavioural data.
Geen	HealthTech	Uses AI-powered tools to support informed health decision-making through structured medical information.
YourBes	EdTech	Develops adaptive AI-based learning systems that personalise educational content in real time.
ProfessionAI	EdTech	Offers AI-driven professional upskilling platforms with personalised learning trajectories.

Startup	Sector	Description
Liqex	FinTech	Provides AI-enabled orchestration of B2B payment flows to optimise liquidity and reduce friction.
EZ Lab	Agri-food Traceability	Develops digital traceability systems enhanced by AI to ensure compliance and transparency in supply chains.
Accudire	Pharma Supply Chain	Offers AI-supported tracking and compliance solutions for pharmaceutical logistics.
EV Field Service	EnergyTech	Uses predictive algorithms to optimise design and maintenance of EV charging infrastructures.
MUV	MobilityTech	Applies behavioural analytics to optimise sustainable mobility programs within organisations.
Snappel	TravelTech	AI-based tourism recommendation platform leveraging user preference data.

Source: our elaboration

4. Results

The comparative analysis of the case studies shows that the integration of artificial intelligence in the analysed startups does not simply represent a technological upgrade, but rather a systemic restructuring of the micro-foundations of entrepreneurial action. What emerges is not merely an increase in efficiency or a reduction in operational costs, but a redefinition of the distribution of organisational intelligence, decision-making timing, and nature of growth.

In all the analysed cases, a systematic redistribution of decision-making work between human actors and algorithmic systems emerges, consistent with the notion of Hybrid Entrepreneurial Agency proposed in the theoretical framework. AI intervenes structurally in the construction of the decision-making space, altering the way opportunities are identified, evaluated, and exploited. Entrepreneurial agency does not disappear, but is redistributed along a socio-technical architecture in which human judgement and computational capacity operate interdependently.

This redistribution takes on different configurations depending on the sector, data intensity, and the degree of regulation of the context, but it presents recurring patterns that allow for the articulation of four transformative dimensions: cognitive, executive, scalability, and governance.

4.1 Cognitive Function

In traditional startups, the entrepreneurial cognitive cycle follows a relatively linear sequence: market observation, interpretation, hypothesis formulation, experimentation, and learning. With the integration of AI, this sequence is partially reconfigured.

Predictive and generative models do not merely analyse data, but also contribute to the production of alternative scenarios, the selection of strategic options, and shaping the decision space. The reduction in the cost of forecasting allows for the exploration of a greater number of hypotheses in shorter times, transforming the inferential process into an iterative and data-intensive dynamic.

Analytical activity is progressively being delegated to models, while the human role is being repositioned in interpretation, validation, and the definition of decision thresholds. Entrepreneurial agency is not replaced, but redistributed along the cognitive architecture of the enterprise. In the cases of Agrobit and Vaimee, AI performs a "computational sensing" function. Agrobit translates multispectral images and agronomic data into operational metrics, making measurable phenomena traditionally entrusted to the tacit experience of the agronomist. The entrepreneurial act of "seeing" the field and formulating intervention hypotheses is no longer exclusively human: the model identifies patterns invisible to direct observation and pre-structures decision-making alternatives. In this setting, agency is distributed along the architecture of the system.

Vaimee, through the integration of interoperable digital twins, extends this logic from diagnosis to simulation. The entrepreneur does not merely react to observed conditions, but operates on

modelled scenarios that anticipate future states of the production system. Here, AI expands the space of explorative possibilities, transforming entrepreneurial activity from reactive to anticipatory.

In the case of Bandit, the cognitive transformation takes the form of regulatory abstraction. The regulatory complexity of public tenders is reorganised by AI models that extract constraints, suggest document structures, and transform a manual interpretative process into an assisted cognitive flow. The ability of entrepreneurial "alertness" intertwines with the system's capacity to identify recurring patterns in regulation.

At Audacia Innovations, AI reconfigures strategic marketing planning, transforming it into a continuous predictive process. The observation of data is no longer retrospective, but anticipatory: the model suggests probable performance trajectories, compressing the distance between analysis and decision.

In the healthtech domain, Geen and Longeviva introduce a particularly sensitive form of cognitive mediation. Linguistic models and clinical data organization systems do not merely retrieve information, but also modulate its priorities and comprehensibility. AI here operates as an epistemic infrastructure: it translates scientific complexity into individualised decision-making pathways, while maintaining final control within the organization.

In edutech (YourBes, ProfessionAI), the cognitive function becomes adaptive. The systems generate micro-hypotheses about the user's learning level and recalibrate content and difficulty in real-time. Validated learning is no longer just the result of market-product interaction, but of an endogenous cycle of algorithmic inference.

The recurring pattern is clear: the formulation of strategic and operational hypotheses is no longer exclusively human. AI participates in the generation, selection, and refinement of alternatives. Entrepreneurial agency becomes structurally distributed.

4.2 Executive Function

If the cognitive function concerns the construction of the decision-making space, the executive function pertains to the transformation of choices into concrete organisational action. In traditional startups, this transformation is characterised by a relatively linear sequence: analysis, deliberation, implementation. With the integration of artificial intelligence, this sequence is compressed, reorganised, and, in some cases, partially automated.

AI primarily intervenes on decision latency, that is, the time interval that separates the detection of a signal from the activation of a response. In the analysed cases, this latency is drastically reduced thanks to the systems' ability to process data in real-time, generate operational outputs, and activate procedures without intermediate manual interventions. However, the transformation is not limited to speed: it concerns the very structure of the execution process.

Intelligent automation does not simply overlay existing procedures, but re-encodes them. Routine activities – information gathering, verification of standard conditions, document generation, flow coordination – are progressively incorporated into the algorithmic architecture. Human work is not eliminated, but reallocated towards systemic supervision functions, exception management, and decision threshold design.

In the case of Liqex, the integration of AI in the synchronisation of B2B payment flows transforms financial execution from a sequential process to an algorithmically orchestrated networked process. In traditional models, payment management requires manual coordination, subsequent reconciliations, and ex post corrective interventions. Here, instead, the algorithm anticipates imbalances, optimises collection and payment priorities, and dynamically coordinates transactions. The action is no longer reactive to a deviation that has already occurred, but proactive in response to a flow forecast. Execution becomes predictive.

In Bandit, the document production for public tenders is no longer a fragmented activity involving regulatory interpretation, manual drafting, and final verification. Natural language processing models automatically structure the documentation based on the constraints extracted from the tender, generating coherent and formally compliant versions. This entails a profound reconfiguration of

executive work: the team no longer focuses on the material construction of the document, but on strategic validation and the management of non-standard cases. AI absorbs the repetitive, high-cognitive-intensity component, leaving human actors to manage ambiguities and critical choices.

In the cases of EZ Lab and Accudire, operating in agri-food and pharmaceutical traceability, artificial intelligence and digital infrastructures transform compliance from episodic fulfilment to a continuous process. The collection, harmonisation, and verification of data along the supply chain no longer occur at discrete moments, but are integrated into a continuous flow of control. The executive function takes on a systemic dimension: the action is not about intervening retrospectively on a non-conformity, but about designing a system that makes deviation less likely and immediately detectable. AI here enhances the capacity for seizing and reconfiguring, translating regulatory constraints into integrated operational logics.

In EV Field Service, the proprietary algorithm optimises the design, installation, and maintenance of electric vehicle charging infrastructures. Technical intervention is no longer scheduled exclusively based on reports or predefined calendars, but on predictive inferences related to usage, load, and failure probability. The executive function shifts from a corrective logic to a preventive logic. Uptime is not the result of an effective reaction, but of accurate forecasting. In this sense, AI modifies the temporal nature of organisational action, anticipating the event rather than responding to it.

In Muv, the behavioural analysis of employees regarding mobility choices allows for the dynamic adaptation of sustainable commuting programs. Organisational policies are no longer static, but adaptable based on emerging patterns. Execution does not consist of the rigid implementation of a plan, but in the continuous recalibration of measures based on the data collected. AI introduces a form of adaptive execution.

A common element across all cases concerns the transformation of the entrepreneurial role in the execution phase. If in traditional startups the founder is often directly involved in operational implementation, in AI-startup models their role tends to evolve towards that of orchestrator of decision-making architectures. Attention shifts from the direct management of activities to the design of parameters, the definition of intervention thresholds, and the supervision of the outputs generated by the system.

4.3 The Computational Nature of Scalability

In traditional startups, scalability is generally conceived as the ability to expand the volume of activities while maintaining a relatively stable cost structure. Such expansion typically involves a proportional increase in organisational resources: more customers require more personnel, more coordination, more infrastructure. Growth is therefore predominantly linear and resource-intensive.

In the models of AI-startups observed in the analysed cases, this logic is partially reconfigured. Growth does not depend solely on commercial expansion, but on the system's ability to learn and improve over time through the accumulation and processing of data. Scalability is not only economic, but cognitive.

The central element is the cumulative nature of algorithmic learning. The increase in the user base or interactions generates new data; the new data allows for the retraining or fine-tuning of models; more accurate models produce higher quality output; better output reinforces adoption and engagement, generating further data. A self-reinforcing cycle is thus established, in which growth and learning mutually feed each other.

On platforms like YourBes, the increase in students and training sessions not only leads to an expansion of the served market but also to a continuous improvement of the adaptive algorithm that personalises the content. Every interaction contributes to refining the system's ability to estimate the user's competence level and calibrate the difficulty of the educational materials. The quality of the service does not remain constant as the scale increases: it tends to improve. Growth thus becomes a cognitive multiplier.

A similar dynamic is observed in Snappel, where the increase in users and recorded preferences allows for the refinement of tourism recommendation systems. The proposed experience

progressively becomes more consistent with emerging behaviour patterns, reinforcing the perceived value and generating lock-in effects based not only on the network but also on the predictive quality of the system.

In Liqex, scalability takes on a systemic dimension. The increase in businesses connected to the platform generates a greater informational density on financial flows, improving the algorithm's ability to optimise synchronisations and payment priorities. The platform does not only grow in the number of transactions, but also in orchestration capacity. Complexity does not automatically translate into inefficiency, but into a potential improvement in the system's intelligence. In the cases of Agrobit and Longeviva, the computational nature of scalability is particularly evident. In Agrobit, the accumulation of environmental, agronomic, and seasonal data progressively increases the accuracy of the recommendations. The system becomes more capable of identifying correlations between climatic conditions, soil status, and crop yield. Similarly, in Longeviva, the integration of longitudinal biological and behavioural data enhances the model's ability to generate personalised preventive suggestions. In both cases, growth is not limited to expanding the customer base: it broadens the cognitive space of the system.

At Audacia Innovations, the analysis of multiple campaigns allows for continuous refinement of performance predictive models. Each new campaign becomes an additional dataset that enriches the ability to anticipate future results. The marketing strategy is no longer just the result of the team's experience, but of the cumulative learning of the system. The competitive advantage lies in the depth of the model.

These dynamics suggest that scalability in AI-startups takes on a cognitive-computational nature. It does not depend exclusively on the expansion of the workforce or the increase in tangible assets, but on the ability of the socio-technical architecture to learn over time. Performance is increasingly linked to the speed and quality of algorithmic updates.

This thus shapes a form of asymmetric scalability: relatively small teams manage to handle increasing volumes of decisions, interactions, and transactions without a proportional increase in the organisational structure. The increase in external complexity is absorbed by the algorithmic infrastructure. Growth is not linear with respect to human resources, but non-linear with respect to computational capacity.

However, this dynamic is neither automatic nor guaranteed. Computational scalability is heavily conditioned by the quality of the data infrastructure, the ability to ensure interoperability, the robustness of the models, and the management of biases. A fragile information infrastructure can turn expansion into vulnerability rather than cumulative advantage. Moreover, the increase in scale can introduce model generalisation issues or algorithmic drift that require continuous monitoring and retraining capabilities.

From the perspective of the micro-foundations of dynamic capabilities, computational scalability implies an extension of the reconfiguring capacity. It's not just about reallocating organisational resources, but constantly updating the system's learning logics. Sustainable growth depends on the ability to design architectures that integrate data accumulation, feedback loops, and model updates in a manner consistent with the strategy.

4.4 Governance and Algorithmic Accountability

If the integration of artificial intelligence reduces some forms of informational uncertainty—enhancing predictive capacity and compressing cognitive asymmetry among actors—it simultaneously introduces new complexities related to model opacity, data quality and provenance, dependence on historical training, and the inherently probabilistic nature of outputs.

The transformation concerns not only decision-making efficiency but also the structure of responsibility. In traditional startups, governance primarily coincides with direct control of decisions and supervision of operational processes. In AI-startup models, however, control shifts upstream: from individual decisions to the design of the decision-making architecture. The founder does not lose responsibility, but exercises it in a mediated and structural form.

Responsibility no longer consists exclusively in choosing between alternatives, but rather in defining the rules through which the system generates such alternatives. This implies the design of decision thresholds, human override mechanisms, validation protocols, audit systems, and continuous monitoring of algorithmic performance. Governance becomes a design function.

This reconfiguration is particularly evident in the regulated sectors analysed. In the healthcare domain, cases like Geen and Longeviva show how AI operates as an epistemic infrastructure that organises and prioritises clinical or behavioural information. However, precisely because the system intervenes in areas of high social sensitivity, the traceability of sources, the transparency of recommendations, and the possibility of human review become central elements. The algorithmic output is never self-sufficient: it must be placed within a clearly defined organisational responsibility framework. Reliability is not just technical, but institutional.

In the Bandit case, the automated reorganisation of regulatory requirements and the assisted generation of documentation raise accountability issues regarding interpretative accuracy. The system can abstract and structure regulatory complexity, but the ultimate responsibility for compliance remains with the organization using the platform. Governance, in this case, manifests itself in defining the boundaries between algorithmic suggestion and legal validation.

Similarly, in EZ Lab and Accudire, which operate in agri-food and pharmaceutical traceability, AI enhances continuous compliance infrastructures. However, the automation of data collection and verification along the supply chain does not eliminate the risk of error or manipulation. Governance translates into certification mechanisms, transaction auditability, and dataset quality control. Compliance is no longer an episodic event, but a process structurally embedded in the technological architecture.

What emerges transversally is a redistribution of risk. The informational uncertainty is reduced thanks to the predictive capacity of the models, but the design uncertainty increases: bias

es in datasets, algorithmic drift, dependence on external model or cloud infrastructure providers, explainability issues. The risk does not disappear; it shifts from the decision-making moment to the architectural moment.

In terms of micro-foundations, governance in AI-startups implies a redefinition of entrepreneurial agency as the capacity for algorithmic orchestration. The entrepreneur is no longer just the subject who takes risks under conditions of uncertainty (Knight, 1921), but the one who designs the conditions under which the system makes probabilistic decisions. The decision-making authority becomes distributed, but the responsibility remains concentrated.

The probabilistic nature of the outputs also requires the definition of intervention thresholds. The observed startups adopt, in various forms, human-in-the-loop or human-on-the-loop logics, in which the system operates autonomously within certain parameters, while human intervention is activated in the presence of anomalies, deviations, or high-stakes cases. Governance thus becomes a combination of controlled automation and strategic supervision.

This dimension is particularly relevant in models that operate on sensitive data or high-impact social decisions. The integration of AI forces startups to incorporate ethical, regulatory, and reputational considerations into their business model from the design phase. Governance is not an external constraint imposed by regulations, but a constitutive element of the value proposition and the legitimisation of the enterprise.

Taken together, the four mechanisms suggest that hybrid agency is not the sum of human and machine contributions, but the outcome of an orchestrated socio-technical architecture in which AI expands the option space (cognitive), compresses action cycles (executive), enables non-linear growth through cumulative learning (scalability), and simultaneously increases the need for design-based accountability (governance).

5. Theoretical Implications

The results emerging from the comparative analysis of the cases allow for a theoretical repositioning of entrepreneurial agency in the context of AI startups. Empirical evidence suggests that artificial intelligence should not be interpreted as a mere efficiency tool, but rather as a structural component of the entrepreneurial architecture. Such a configuration produces theoretical implications along four main directions: the ontological redefinition of the startup, the extension of the micro-foundations of dynamic capabilities, the evolution of the Lean paradigm, and the reconfiguration of entrepreneurial risk and governance.

First, the results suggest an ontological redefinition of the concept of startup in the era of AI transformation. The classical literature describes the startup as a temporary organization engaged in the search for a scalable and repeatable business model (Blank & Dorf, 2020; Ries, 2011). However, in the analysed cases, AI does not represent an ancillary technological resource integrated into the tech stack, but systematically participates in hypothesis generation, scenario simulation, operational translation of decisions, and learning processes (cognitive and executive dimensions). This results in a conception of the startup as a hybrid socio-technical system, in which the algorithmic dimension is not external to the entrepreneurial process, but co-constitutive of strategic action. Agency is no longer exclusively centred on the individual intentionality of the founder, but distributed along an integrated cognitive architecture.

Second, the study extends the debate on dynamic capabilities (Teece, 2017). Empirical evidence shows that AI strengthens sensing and seizing capabilities, reducing information latency and expanding the space of analyzable alternatives (cognitive dimension), as well as compressing execution cycles (executive dimension). However, the contribution goes beyond mere efficiency improvement. Configurations emerge where dynamic capabilities no longer consist solely of reallocating resources, but in designing, supervising, and retraining intelligent systems that learn over time (computational scalability dimension). A new micro-foundation thus emerges: algorithmic orchestration. The entrepreneur does not only coordinate human and material resources, but also adaptive computational architectures, extending the very nature of dynamic capability from a socio-technical key.

Third, the results allow for the proposal of an evolution of the Lean paradigm. The Build–Measure–Learn model (Ries, 2011) assumes iterative cycles driven by empirical validation through the market. In the analysed cases, the integration of AI allows for partial anticipation of validation through predictive simulations, automatic generation of variants, and real-time analysis. The learning cycle becomes hybrid: part predictive, part empirical. Learning is no longer exclusively ex post relative to the market, but incorporated into the inferential capacity of the models. This does not eliminate uncertainty, but it modifies its management, shifting the focus from sequential experimentation to the combination of algorithmic simulation and real feedback. The Lean paradigm thus evolves toward a model of augmented experimentation

Fourth, the study contributes to the reflection on the nature of entrepreneurial risk. In the Schumpeterian and Kirznerian tradition, the entrepreneur acts under conditions of uncertainty and information asymmetry. The analysed cases show that AI reduces some forms of informational uncertainty (through prediction and pattern identification), but introduces new forms of design uncertainty (related to bias, model opacity, algorithmic drift, and data infrastructure dependence), as evidenced in the governance dimension. The risk does not disappear, but it is redistributed: it decreases in the analytical phase and increases in the design and supervision phase of the algorithmic architecture. Entrepreneurial agency thus shifts from decision-making under uncertainty to systemic responsibility for the design of probabilistic decision-making architectures.

Finally, the results enrich the debate on algorithmic governance in business contexts. The operational autonomy of intelligent systems coexists with a concentrated organisational responsibility. The human-in-the-loop and human-on-the-loop configurations highlighted in the cases show that AI does not replace human agency, but rather reconfigures it in terms of architectural

control and systemic supervision. Governance is not an external constraint, but a constitutive dimension of hybrid entrepreneurial architecture.

Taken together, these implications support the conceptualisation of Hybrid Entrepreneurial Agency as a distinctive configuration of AI startups. The difference compared to a traditional digital startup lies not only in the technological intensity but also in the distributed nature of cognition, the algorithmic mediation of execution, the computational logic of scalability, and the architectural centrality of governance. Artificial intelligence must therefore be interpreted not as an enabling technology, but as a constitutive element of entrepreneurial action in the era of AI transformation.

6. Managerial Implications

The comparative analysis of the cases highlights that the integration of artificial intelligence is not merely a technological choice, but an architectural decision that profoundly impacts the four dimensions revealed in the results: cognitive function, executive function, computational scalability, and algorithmic governance.

Firstly, on a cognitive level, the cases show that AI actively participates in the generation and evaluation of strategic hypotheses (*e.g.*, Agrobit, Vaimee, Bandit, Audacia). For founders, this implies the need to decide from the early stages whether AI represents the core of the competitive advantage or a mere support tool. When AI is core (as in data-intensive models), the entire decision-making architecture must be designed around data quality, predictive capability, and continuous model validation. When AI instead performs an optimisation function, organisational and investment choices can be less radical. The distinction influences cost structure, dependence on proprietary datasets, exposure to technological risk, and the composition of internal skills.

Secondly, on the executive level, the evidence shows a drastic compression of decision latency and an increasing automation of operational processes (*e.g.*, Liqex, EV Field Service, EZ Lab). However, the reduction in decision-making times does not eliminate the need for critical interpretation. Startups must design a decision-making architecture consistent with the presence of intelligent systems, defining intervention thresholds, levels of algorithmic autonomy, and human override mechanisms. Founding teams must develop data literacy skills and the ability to interpret models, avoiding both algorithmic overconfidence and the a priori rejection of recommendations generated by the systems.

Thirdly, regarding scalability, the cases show that growth in AI startups is not linear with respect to human resources, but depends on the system's ability to learn cumulatively through the accumulation of data (e.g., YourBes, Snappel, Longeviva, Audacia). This implies that managers must invest early in robust data infrastructures, consistent tracking systems, and structured information collection processes. Without a solid data architecture, the potential for algorithmic learning diminishes and the promise of asymmetric scalability weakens. The system's learning speed becomes a central strategic variable, analogous to product-market fit.

Fourthly, in terms of governance, it clearly emerges that the operational autonomy of intelligent systems does not eliminate organisational responsibility. In regulated or socially sensitive sectors (healthtech, legaltech, pharma supply chain), the design of auditability, traceability, and continuous supervision mechanisms becomes an integral part of the business model. Managers must integrate validation protocols, monitoring procedures, and explicit definition of responsibilities from the outset. AI does not reduce risk; rather, it redistributes itfrom the decision-making phase to the design phase: governance becomes a strategic competence and not just a legal one.

An additional implication concerns the redefinition of the founder's role. In the analysed cases, the entrepreneur tends to evolve from a central decision-maker to an orchestrator of hybrid intelligences. The value no longer resides exclusively in the ability to make decisions under uncertainty, but in the ability to design the architecture within which probabilistic decisions are generated and supervised. The composition of the team, therefore, cannot be limited to the traditional distinction between

technical and commercial skills, but must integrate the ability to translate strategic parameters into computational terms and to systematically control models.

Finally, for investors and policymakers, the results suggest that the evaluation of an AI startup should not focus exclusively on the idea or the product, but on the robustness of the data infrastructure, the quality of the decision-making architecture, and the maturity of the governance mechanisms. The sustainability of the competitive advantage appears closely linked to the system's ability to learn over time and to responsibly manage its algorithmic autonomy.

Taken together, these implications show that the integration of artificial intelligence transforms the very nature of entrepreneurial design. Startups that manage to coherently integrate the human dimension and the algorithmic dimension—along the four directions that emerged in the results—are more capable of converting AI from a tool of efficiency to a lever of sustainable growth and structural competitive advantage.

7. Conclusions

This study has analysed how the integration of artificial intelligence as an operational component of entrepreneurial architecture modifies the nature of entrepreneurial action in contemporary startups.

Empirical evidence suggests that AI does not merely represent a factor of efficiency or a tool for automating pre-existing processes. Rather, it intervenes in the internal distribution of cognition, execution, scalability, and governance, redefining the very configuration of entrepreneurial agency. This is illustrated, for instance, by the predictive execution logic observed in Liqex, where algorithmic orchestration transforms financial flows from reactive to anticipatory processes, or by the epistemic governance infrastructure emerging in Longeviva and Geen, where AI mediates clinically sensitive decision pathways while maintaining concentrated organisational responsibility.

In this perspective, the startup can no longer be interpreted merely as a temporary organization in search of a scalable business model, but as an adaptive system in which the competitive advantage increasingly depends on the quality of the cognitive-computational infrastructure and the ability to orchestrate algorithmic learning processes over time. This results in a reinterpretation of dynamic capabilities: no longer just the ability to integrate and reconfigure resources, but also the ability to design, supervise, and evolve intelligent systems embedded in decision-making processes.

Artificial intelligence, therefore, does not replace human agency, but redefines its locus and modes of operation. The founder progressively assumes the role of architect and orchestrator of hybrid decision-making systems, in which responsibility remains human, while action is partially mediated by computational infrastructures.

Within the limits arising from the qualitative nature of the study and the ecosystem-specific nature of the cases analysed, the concept of Hybrid Entrepreneurial Agency offers a theoretical basis for further empirical and longitudinal insights into AI-intensive startups. The reliance on secondary data represents the primary methodological boundary of this work: future research should incorporate primary data through in-depth interviews with founders and key decision-makers, enabling a more granular reconstruction of the cognitive and governance mechanisms identified here. Longitudinal designs would further allow for the observation of how hybrid agency evolves as AI systems mature and accumulate data over time. Quantitative extensions, including survey-based studies on larger samples of AI-startups across different ecosystems, would contribute to assessing the generalisability of the theoretical framework proposed.

Il marketing imprenditoriale come percorso di apprendimento multilivello per imprenditori emergenti

NORA ANNESI, DANIELA CORSARO

Abstract

Frame of the research. *Il marketing imprenditoriale (EM) si è evoluto in un ambito di ricerca distinto, caratterizzato da proattività, innovazione, attenzione al cliente, assunzione di rischi calcolata, attenzione alle opportunità, sfruttamento delle risorse e creazione di valore (Morris et al., 2002; Hisrich & Ramadani, 2017). A differenza del marketing tradizionale, l'EM si sviluppa in condizioni di incertezza e vincoli di risorse, emergendo attraverso l'azione e l'interazione piuttosto che attraverso una pianificazione formale (Stokes, 2000; Sarasvathy, 2001).*

Purpose of the paper. *Questo studio mira a esplorare come le difficoltà iniziali nel marketing imprenditoriale inneschino processi di apprendimento e influenzino l'evoluzione dei comportamenti strategici, con particolare attenzione ai professionisti che passano da un impiego tradizionale a ruoli imprenditoriali.*

Methodology. *La ricerca adotta un approccio interpretativo qualitativo basato sull'analisi di dati secondari di natura narrativa, costituiti da 60 storie di vita professionale raccolte da piattaforme web dedicate alla transizione lavorativa. L'analisi è stata condotta tramite codifica tematica garantendo il rigore nel passaggio dai concetti di primo livello alle dimensioni teoriche aggregate. L'analisi raccoglie e analizza le esperienze vissute dai professionisti in transizione di carriera per catturare le dimensioni cognitive, relazionali, strategiche ed emotive delle loro prime attività di marketing imprenditoriale.*

Results. *I risultati delineano un modello di apprendimento in cui l'EM emerge come processo di ri-negoziazione identitaria. I principali temi emersi includono il superamento del 'comfort della pianificazione' (tipico del lavoro dipendente) a favore di una proattività relazionale. Vengono identificati tre livelli di adattamento: cognitivo (nuovi schemi mentali), relazionale (legittimazione sociale) e comportamentale (sperimentazione tattica). I risultati mostrano inoltre che l'ambiguità cognitiva, le sfide legate alla costruzione di legittimità, l'incertezza strategica e le tensioni emotive agiscono da catalizzatori per l'apprendimento esperienziale e sociale (Kolb, 1984; Lave & Wenger, 1991).*

Research limitations. *Il design qualitativo e l'attenzione rivolta ai professionisti in transizione potrebbero limitare la generalizzabilità. Ricerche future potrebbero adottare approcci longitudinali o quantitativi per convalidare ed estendere il quadro proposto.*

Managerial implications. *Lo studio evidenzia l'importanza di abbracciare la sperimentazione, la riflessione e la creazione di reti nell'EM in fase iniziale. Considerare le difficoltà come fattori scatenanti dell'apprendimento può supportare pratiche di marketing più adattive e resilienti.*

Originality of the paper. *L'articolo integra difficoltà, apprendimento e strategia all'interno di un quadro unificato e introduce la transizione di carriera professionale come una nuova prospettiva nella ricerca di marketing imprenditoriale.*

Keywords: *entrepreneurial marketing; ricerca qualitativa; apprendimento;*

1. Introduzione

Il marketing imprenditoriale è generalmente definito come il marketing svolto da imprenditori o solopreneur all'interno del proprio business. A partire dalla sua introduzione nei primi anni '80, i contributi accademici hanno progressivamente perfezionato e ampliato il costrutto, culminando nell'identificazione di sette dimensioni fondamentali del marketing imprenditoriale: (1) proattività, (2) innovazione, (3) intensità del cliente, (4) assunzione di rischi calcolati, (5) focalizzazione sulle opportunità, (6) sfruttamento delle risorse e (7) creazione di valore (Morris et al., 2002; Hisrich & Ramadani, 2017).

La letteratura sul tema ha focalizzato l'attenzione su come le attività di marketing in contesti imprenditoriali differiscano dal marketing tradizionale per la loro natura informale, adattiva e orientata all'azione, spesso sviluppata in condizioni di elevata incertezza e scarsità di risorse (Stokes, 2000; Fillis, 2002). In tali contesti, le strategie di marketing non sono infatti completamente definite ex ante, ma emergono progressivamente attraverso l'interazione con il mercato e l'esperienza diretta, assumendo la forma di processi dinamici piuttosto che di piani formali (Mintzberg, 1987; Sarasvathy,

2001). Le fasi iniziali del percorso di marketing imprenditoriale sono quindi particolarmente critiche, poiché i nuovi imprenditori devono contemporaneamente sviluppare una comprensione del mercato e le relazioni con gli stakeholder e devono definire una direzione strategica ancora instabile.

Le sfide incontrate in queste fasi iniziali sono multidimensionali. Dal punto di vista cognitivo, i marketer imprenditoriali alle prime armi operano in condizioni di razionalità limitata e ambiguità informativa, incontrando difficoltà nell'interpretare i segnali di mercato, valutare le opportunità e comprendere le reazioni dei clienti (Simon, 1955; Mitchell et al., 2002). I processi decisionali sono frammentati e fortemente influenzati da schemi interpretativi in continua evoluzione, rendendo il marketing un'attività esplorativa piuttosto che pianificata.

Queste sfide sono accompagnate da dimensioni relazionali, poiché il marketing imprenditoriale è profondamente radicato nelle interazioni sociali e nelle reti informali. Costruire relazioni con i primi clienti e partner richiede la continua negoziazione di fiducia, credibilità e legittimità, spesso in assenza di una reputazione consolidata (Granovetter, 1985; Stokes, 2000). Queste dinamiche influenzano la capacità di ottenere risorse, feedback e supporto esterno, con un impatto diretto sulle pratiche di marketing emergenti (Fillis, 2002; Cope & Watts, 2000). Le difficoltà assumono anche una dimensione strategica, poiché l'assenza di obiettivi chiari e di mercati definiti complica la formulazione di strategie coerenti nel tempo. L'approccio efficace sottolinea come gli imprenditori tendano ad agire entro i limiti delle risorse disponibili, adattando le proprie azioni alle contingenze emergenti piuttosto che seguire piani strategici formalizzati (Sarasvathy, 2001). Ciò si traduce in una strategia emergente, sviluppata attraverso l'azione e l'apprendimento progressivo, che può generare incertezza riguardo alle priorità e all'allocazione delle risorse (Mintzberg, 1987).

Oltre alle dimensioni cognitive, relazionali e strategiche, la letteratura riconosce il ruolo delle componenti emotive nei percorsi imprenditoriali. Emozioni come ansia, frustrazione o entusiasmo accompagnano le fasi iniziali del marketing imprenditoriale e influenzano il giudizio, la perseveranza e la capacità di apprendimento degli individui (Shepherd, 2003; Cope, 2011). Quando l'identità personale e quella imprenditoriale si intrecciano, le sfide emotive possono amplificare la percezione di incertezza e influenzare le successive scelte strategiche. Piuttosto che rappresentare semplici ostacoli, queste sfide sono importanti fattori scatenanti per i processi di apprendimento imprenditoriale. L'apprendimento è concepito come un processo dinamico attraverso il quale l'esperienza si trasforma in conoscenza, soprattutto in contesti caratterizzati da incertezza e cambiamento (Kolb, 1984; Politis, 2005). Nel marketing imprenditoriale, questo apprendimento assume prevalentemente una forma esperienziale, emergendo dall'interazione diretta con il mercato e dalla sperimentazione di pratiche di marketing.

L'apprendimento si sviluppa anche attraverso processi sociali e riflessivi. Le interazioni con clienti, partner e altri stakeholder consentono la condivisione di significati e l'elaborazione collettiva delle difficoltà incontrate (Lave & Wenger, 1991; Cope & Watts, 2000), mentre la riflessione sulle esperienze vissute consente di attribuire significato a errori e fallimenti, favorendo forme di apprendimento più profonde (Schön, 2017; Mezirow, 1991). Attraverso questi processi, le difficoltà contribuiscono allo sviluppo di comportamenti strategici adattivi, caratterizzati da sperimentazione, flessibilità e capacità di rispondere a stimoli contestuali (Fillis, 2002; Sarasvathy, 2001).

Nel loro insieme, questi contributi suggeriscono che le difficoltà incontrate nelle prime fasi del marketing imprenditoriale modellano i processi di apprendimento e influenzano anche l'evoluzione dei comportamenti strategici nel tempo. Tuttavia, la letteratura esistente ha spesso trattato separatamente difficoltà, apprendimento e strategia, offrendo una visione frammentata del fenomeno. Pertanto, la comprensione di come queste dimensioni interagiscono rimane limitata.

In questo contesto, la ricerca ha individuato un gap di letteratura relativo allo scollamento tra la teoria del marketing imprenditoriale come 'pratica' e la comprensione di come tali pratiche vengano interiorizzate da soggetti con imprinting cognitivo manageriale/esecutivo. Sebbene la letteratura abbia ampiamente descritto le dimensioni dell'EM, sappiamo ancora poco su come avvenga la transizione mentale e operativa per chi proviene da percorsi di lavoro dipendente, dove le logiche di marketing sono spesso governate da pianificazione formale e risorse pre-allocate. Questo studio

colma tale lacuna distinguendo tre piani analitici: (1) l'apprendimento come meccanismo di acquisizione; (2) l'identità come driver di cambiamento del ruolo; (3) il comportamento di marketing come esito strategico osservabile.

Basandosi sulla concettualizzazione del marketing imprenditoriale come processo non lineare, basato sulla pratica e fondato sull'esperienza (Stokes, 2000; Fillis, 2010) e su prospettive efficaci che enfatizzano l'apprendimento attraverso l'azione in condizioni di incertezza (Sarasvathy, 2001), questo studio affronta il marketing imprenditoriale come un percorso di apprendimento situato in cui conoscenza e strategia emergono dall'esperienza piuttosto che da una pianificazione preventiva. In termini di originalità: qualifica l'EM come un processo di 'unlearning' (disapprendimento) dei modelli di marketing tradizionale. Il contributo specifico consiste nel mappare come la 'resistenza' ai modelli appresi nel lavoro dipendente inneschi una transizione verso l'EM non solo per necessità economica, ma come evoluzione del sé professionale.

2. Letteratura

L'analisi della letteratura sul marketing imprenditoriale (EM) evidenzia un campo di studio ampio e frammentato, caratterizzato da una pluralità di approcci teorici e da una forte eterogeneità metodologica. I contributi analizzati si basano su framework consolidati come l'orientamento imprenditoriale e l'orientamento al mercato (Covin & Slevin, 1988; Morris et al., 2002), la teoria dell'effettuazione (Sarasvathy, 2001; Read et al., 2009), la Resource-Based View (Barney, 1991), la teoria delle reti (Hoang & Antoncic, 2003) e, più recentemente, prospettive relative alla sostenibilità, alla digitalizzazione e alla creazione di valore sociale. In questo scenario, la revisione sistematica di Breit e Widlok (2023) offre una mappatura tematica fondamentale del campo post-2010, confermando come l'EM si sia evoluto verso una dimensione più dinamica e multidimensionale.

La letteratura si concentra principalmente sul marketing imprenditoriale come insieme di pratiche strategiche orientate alla performance aziendale. Numerosi studi empirici dimostrano l'impatto positivo dell'EM su crescita, performance finanziaria, brand equity, innovazione e internazionalizzazione, soprattutto nel contesto di PMI e start-up (Hills et al., 2008; Becherer et al., 2012; Whalen et al., 2016; Manigandan, 2025). In questo filone, l'attenzione è principalmente focalizzata sui risultati organizzativi, mentre il ruolo dell'individuo è spesso ridotto a quello di un attore funzionale nell'implementazione di strategie efficaci. Tuttavia, come suggerito dagli studi longitudinali di Belchior e Castro-Silva (2023), l'identità imprenditoriale emerge proprio attraverso queste transizioni di carriera, rendendo l'esperienza individuale un elemento centrale e non meramente accessorio della strategia.

Un secondo filone riguarda il ruolo delle risorse relazionali, cognitive e simboliche nella pratica dell'EM. La letteratura sottolinea l'importanza delle capacità di networking, della legittimità, della conoscenza del mercato e dell'uso dei social media come leve chiave per superare la scarsità di risorse e la vulnerabilità della novità (Hoang & Antoncic, 2003; Amjad, 2025; Fillis & Telford, 2020). Studi recenti mostrano come il coinvolgimento degli stakeholder e la gestione del network siano centrali nei processi di costruzione di credibilità e accesso alle risorse (Amjad, 2025). Tuttavia, questi contributi tendono a dare per scontata la capacità degli attori di mobilitare efficacemente queste risorse, trascurando le difficoltà iniziali legate all'apprendimento, all'incertezza e alla mancanza di esperienza.

Una terza serie di studi concettualizza il marketing imprenditoriale come un processo creativo, non convenzionale e adattivo, in contrasto con il marketing tradizionale. In quest'ottica, il marketing imprenditoriale è descritto come basato sull'intuizione, la sperimentazione, il bricolage, la narrazione e le pratiche informali (Fillis, 2002; Gilmore et al., 2001; Fillis & Rentschler, 2010). Alcuni contributi recenti ampliano questa prospettiva per includere dimensioni identitarie, culturali e simboliche, ad esempio in contesti femminili, artistici o postcoloniali (Fillis, 2015; Saxena, 2025). In questo quadro, il concetto di 'Possible Selves' (Markus & Nurius, 1986) fornisce una chiave di lettura cruciale,

suggerendo che le difficoltà incontrate non siano solo ostacoli operativi, ma parte di un processo di negoziazione tra ciò che l'imprenditore è e ciò che teme di diventare o aspira a essere. Tuttavia, questi studi tendono anche a descrivere il marketing imprenditoriale come una pratica consolidata, piuttosto che come un processo progressivamente costruito.

Nel complesso, l'analisi di letteratura mostra una lacuna relativa alla scarsità di studi che analizzano esplicitamente le difficoltà incontrate da coloro che intraprendono una carriera come marketer imprenditoriali. In particolare, i processi di apprendimento iniziale, la gestione dell'incertezza decisionale, la tensione tra sperimentazione e legittimazione, il carico cognitivo ed emotivo, il rapporto con l'errore e il fallimento, nonché la costruzione dell'identità professionale nei contesti imprenditoriali in fase iniziale sono scarsamente esplorati (Weick, 1995; Shepherd et al., 2011). Per affrontare questa lacuna, è necessario un approccio metodologico rigoroso che, seguendo le recenti indicazioni di Leick e Tuitjer (2025), valorizzi la ricerca qualitativa come strumento elettivo per decodificare la complessità dei processi imprenditoriali emergenti.

Questa lacuna ha portato i ricercatori a considerare il marketing imprenditoriale come un processo esperienziale in cui gli imprenditori emergenti incontrano una serie di difficoltà che, se condivise, possono aiutare le iniziative future a ridurre l'incertezza e a prepararsi meglio agli ambienti che dovranno affrontare.

In questa prospettiva, la ricerca condotta punta a rispondere alla RQ: quali difficoltà incontrano gli imprenditori durante le prime fasi del loro percorso di marketing imprenditoriale e in che modo queste sfide influenzano i loro processi di apprendimento e i loro comportamenti strategici nel tempo?

3. Metodo

La ricerca ha utilizzato un approccio qualitativo per analizzare la storia di 60 persone che hanno cambiato il loro percorso di carriera per diventare imprenditori (Van Burg et al., 2022). Le storie sono state raccolte da una piattaforma web[1] che pubblica resoconti di transizione di carriera di persone provenienti da tutto il mondo. Le narrazioni, originariamente raccolte attraverso interviste semi-strutturate condotte da job coach professionisti, forniscono approfondimenti sulle motivazioni dei partecipanti, sulle sfide e sugli ostacoli incontrati e sulle strategie adottate per affrontare e sostenere la transizione. Chiunque, indipendentemente dal fatto che abbia acquistato servizi dalla piattaforma, può contattare la redazione e raccontare la propria esperienza di transizione di carriera. In particolare, su oltre 400 storie pubblicate, i ricercatori si sono focalizzati sul tipo di transizione di carriera coerente con gli obiettivi di ricerca e avvenuto nel più recente lasso temporale corrispondente agli ultimi 5 anni. Le storie personali sono state analizzate dai ricercatori per identificare qualsiasi riferimento al loro approccio al marketing nella loro nuova impresa. In particolare, i ricercatori hanno raccolto tali informazioni concentrando l'attenzione su tre serie di domande: (1) "Cosa hai imparato durante il processo?", (2) "Cosa non è andato bene? Quali svolte sbagliate hai preso? Qual è stata la cosa più difficile del cambiamento?" e (3) "Cosa consiglieresti ad altri di fare nella stessa situazione?". I dati sono stati analizzati utilizzando un approccio di analisi qualitativa del contenuto diretto basato su un framework di codifica definito esternamente (Hsieh e Shannon, 2005). Data la molteplicità dei casi, abbiamo seguito la logica di Eisenhardt (1989) del confronto tra casi per identificare pattern ricorrenti. Le macrocategorie sono state derivate dalla struttura editoriale incorporata nei protocolli di intervista semi-strutturata (Schreier, 2012).

La solidità del campione analizzato è supportata dall'autorevolezza dell'organizzazione di riferimento, attiva nel settore da oltre vent'anni con un network di oltre 180.000 utenti. L'impresa, inoltre cura e pubblica narrazioni di carriere individuali con continuità ventennale, garantendo così una prospettiva diacronica e una base empirica consolidata nel tempo. Nonostante le interviste non esplicitino direttamente la provenienza dei soggetti, secondo i bilanci di impatto dell'impresa, il

[1] https://www.careershifters.org/

dataset integra testimonianze raccolte su scala globale ed in particolare provenienti da 21 paesi distribuiti in Nord America, Europa, Medio Oriente, Africa, Asia-Pacifico. Il processo di codifica è stato implementato, perfezionato manualmente da un ricercatore e poi convalidato da un secondo (Miles et al., 2014). A ciascuna intervista sono stati assegnati un codice identificativo e un numero sequenziale per garantirne la tracciabilità. Infine, un totale di 169 porzioni di testo sono stati codificati e classificati come apprendimento esperienziale, riflessivo o sociale. I ricercatori hanno discusso i pattern emersi e li hanno rivisti in temi, insieme in un approccio iterativo. In particolare, il processo di codifica ha portato all'identificazione di sei macro-temi che riflettono le dimensioni della transizione; questi sono stati ulteriormente declinati in 16 sottocategorie e 42 codici analitici (tab. 1).

Macro-Tema (Livello 1)	**Sottocategoria (Livello 2)**		**Codici Analitici (Livello 3)**
		Frequenza assoluta e %	
1. Identity work & ricostruzione del sé	Crisi dell'identità precedente	14 12%	Perdita dello status sociale; Sensazione di "scissione" interna; Nostalgia della stabilità professionale passata; Paura del giudizio altrui.
	Sperimentazione Identitaria	*12* *10%*	*Identity Play* (testare nuovi ruoli); Età come valore aggiunto (maturità vs giovinezza); Ricerca di coerenza tra valori personali e lavoro.
	Validazione e Legittimazione	18 15%	Superamento della sindrome dell'impostore; Necessità di certificazioni formali; Feedback positivi come ancora identitaria.
2. Marketing strategico individuale	Posizionamento e Pricing	*16* *13%*	*Underpricing* iniziale (svendita); Passaggio a tariffe basate sul valore (*Value-based*); Identificazione della nicchia di mercato.
	Networking e Capitale Relazionale	15 12%	Uso strategico di LinkedIn; *Pay-it-forward* (chiedere aiuto e ricambiare); Networking proattivo vs passivo; Mentorship.
	Comunicazione del Brand Personale	9 7%	Storytelling della trasformazione; Pitching dei servizi; Gestione della reputazione online e offline; Visibilità vs Introversione.
3. Gestione del rischio e risorse	Sostenibilità Finanziaria	11 9%	Gestione del "cuscinetto" economico (6+ mesi); *Bootstrapping* (fai-da-te burocratico); Gestione dei periodi a reddito zero.
	Sistemi di Supporto	7 6%	Supporto emotivo della famiglia/amici; Community di settore (gruppi FB/associazioni); Uso della tecnologia per scalare l'attività.
	Pianificazione d'Emergenza	5 4%	Definizione del *Worst-case scenario*; Valutazione della reversibilità (possibilità di tornare al vecchio settore).
4. Psicologia della transizione	Dinamiche Emotive Negative	13 11%	Paura della paralisi decisionale; Stress da incertezza (*Liminality*); Senso di solitudine del freelance; Ansia da feedback.
	Risorse Cognitive ed Emotive	19 8%	Resilienza e *Resourcefulness*; Mindset proattivo (Roosevelt); Fiducia nell'intuito e nella "pancia"; Accettazione del fallimento.
5. Esecuzione tattica e metodologia	Benessere e Self-Care	6 *5%*	Rifiuto della *Hustle Culture*; Camminare/Attività fisica come problem solving; Gestione dei confini casa-lavoro.
	Apprendimento e Sviluppo	14 12%	Acquisizione rapida di nuove *Hard Skills*; *Trial & Error* (imparare dagli errori); Ricerca metodologica sull'industria target.
	Gestione Operativa	8 7%	Pro-bono strategico (lavorare gratis per portfolio); Gestione del tempo e dei carichi di lavoro; Selezione qualitativa dei clienti.
	Adattamento al Contesto	10 8%	Transizione da ufficio a *Remote/Solo work*; Gestione delle nuove gerarchie (essere "junior" da adulti); Risposta a shock esterni (es. Pandemia).
6. Etica e valore sociale	Impatto e Scopo	*6* *5%*	*Purpose-driven work* (lavoro con significato); Contributo alla comunità; Trasformazione del dolore personale in servizio agli altri.

4. Risultati

Il disegno di ricerca implementato ha portato all'identificazione delle pratiche marketing adottate nelle prime fasi del processo imprenditoriale. Gli imprenditori emergenti imparano a creare, comunicare e generare valore credibile sul mercato, costruendo contemporaneamente identità professionali, offerte, relazioni e routine operative. In termini di marketing imprenditoriale (EM), le esperienze raccolte mostrano il passaggio dal marketing "organizzativo", tipico di contesti strutturati e ruoli definiti, al marketing "imprenditoriale", caratterizzato da incertezza, risorse limitate, sperimentazione continua e ricerca di legittimità. Un tema chiave emerso è la centralità della dimensione relazionale nella costruzione di una strategia di marketing così destrutturata che caratterizza gli imprenditori emergenti: "*Mi sono reso conto che non si tratta necessariamente solo del settore in sé, ma anche del team più ampio, dell'ambiente*" (CS_1).
L'apprendimento esperienziale è il motore principale del comportamento di marketing imprenditoriale per gli imprenditori emergenti. L'ingresso nel mercato avviene spesso prima che l'offerta sia completamente definita o che l'identità professionale sia consolidata. Errori come la sottovalutazione dei prezzi, l'accettazione di incarichi al di fuori della propria area di competenza o la sottovalutazione della complessità dei progetti non sono visti come semplici errori, ma come momenti di apprendimento generativo: "*All'inizio mi sottovalutavo... col tempo, ho imparato il valore di ciò che so fare e ho più che raddoppiato i miei compensi*" (CS_26). In termini di processo di apprendimento, molti intervistati hanno appreso il significato del pricing solo dopo aver sottovalutato il proprio lavoro e aver sperimentato stress, sovraccarico o insoddisfazione finanziaria. Una successiva riflessione consente loro di reinterpretare il pricing come un segnale strategico di valore e professionalità: "*Non bisogna vergognarsi di chiedere ciò che si vale*" (CS_34).
Da una prospettiva di marketing imprenditoriale, questo passaggio evidenzia come il pricing funzioni come variabile economica e come segnale di valore e leva di posizionamento, appreso attraverso l'interazione diretta con il mercato. L'apprendimento sul campo produce anche una progressiva capacità di valutare clienti, progetti e i confini dell'offerta. Esperienze stressanti o infruttuose diventano criteri operativi per il futuro: "*È stata una lezione preziosa su come concentrarsi su ciò che si sa di poter offrire. Ho ignorato i segnali d'allarme e mi sono scottato*" (CS_25). Da questa prospettiva, l'esperienza diventa il principale strumento di indagine del mercato.
Accanto alla dimensione esperienziale, l'apprendimento riflessivo gioca un ruolo centrale nel trasformare l'esperienza in direzione strategica. Le interviste mostrano come la paura, la sindrome dell'impostore e il disorientamento iniziale vengano progressivamente rielaborati in modelli decisionali che guidano il posizionamento e la selezione delle opportunità di marketing: "*Ho imparato a lasciar andare il perfezionismo, a convivere con il disagio e ad accettare che la mia attività si evolverà*" (CS_2). Tale riflessività consente agli imprenditori di passare da una fase esplorativa a una maggiore coerenza strategica, elemento chiave del marketing imprenditoriale in contesti di incertezza.
L'apprendimento riflessivo si traduce anche in un lavoro sull'identità. In termini di posizionamento, gli imprenditori descrivono la difficoltà di "dare un nome" a ciò che fanno, di restringere il loro focus o di rendere tangibile la loro proposta. Attraverso la riflessione, gli imprenditori sviluppano una narrazione credibile e comunicabile che converte l'identità personale in una proposta di valore percepita come legittima dal mercato: "*Mi sono posizionato in modo troppo generico... mi ci è voluto un po' per scegliere una nicchia*" (CS_15).
L'apprendimento sociale emerge come il terzo pilastro del processo di marketing imprenditoriale. Networking, mentoring e community sono descritti non solo come supporto emotivo, ma come veri e propri meccanismi di accesso al mercato e legittimazione: "*Solo per essere stato invitato, ti apprezzano già"* (CS_7). Da una prospettiva di marketing imprenditoriale, le relazioni funzionano come infrastrutture di marketing poiché generano lead, creano fiducia e riducono l'incertezza informativa tipica delle fasi iniziali. Il networking favorisce anche l'apprendimento implicito delle regole di mercato, delle aspettative dei clienti e delle norme del settore. Le interazioni sociali diventano così luoghi di apprendimento strategico, dove il feedback non è formalizzato ma continuo:

"*Se non chiedi, non ottieni*" (CS_29). Questi risultati evidenziano la centralità del comportamento di coinvolgimento del mercato tipico del marketing imprenditoriale, basato sull'iniziativa e sull'attivazione di relazioni. Gli imprenditori emergenti apprendono attraverso l'interazione con altri attori (es. clienti, colleghi, reti, comunità professionali), scoprendo che il mercato è un'entità tangibile fatta di reti di relazioni. I comportamenti strategici associati implicano la capacità di attivare, mantenere e interpretare le relazioni come fonti di opportunità. Per questo tipo di imprenditore, il marketing non è pianificato ex ante, ma emerge dall'azione relazionale e dalla visibilità sociale. Queste affermazioni dimostrano come l'acquisizione di clienti venga appresa come pratica relazionale, piuttosto che come tecnica formale.

Le evidenze raccolte mostrano inoltre come il posizionamento e il personal branding rappresentino il punto di convergenza più evidente tra processi di apprendimento e comportamenti strategici. Costruire una nuova identità professionale richiede sperimentazione, riflessione e validazione sociale: "*Sto ancora lavorando alla creazione di una nuova narrazione che rappresenti ciò che mi interessa e dove sono diretto*" (CS_45). In questo senso, il posizionamento non è un atto comunicativo isolato, ma un comportamento strategico che si affina nel tempo attraverso il feedback del mercato.

In linea con l'evidenza che il marketing imprenditoriale è plasmato da un processo relazionale e dialogico piuttosto che da una strategia pianificata, l'acquisizione di clienti e l'interazione con il mercato emergono come pratiche di apprendimento continuo. Inviare pitch, discutere le proprie ambizioni, accettare incarichi iniziali o fare volontariato sono descritti come modi per impegnarsi con il mercato.

La dimensione della sperimentazione e dell'adattamento riflette pienamente la logica efficace del marketing imprenditoriale. I partecipanti descrivono percorsi fatti di piccoli passi, tentativi reversibili e continui aggiustamenti. La sperimentazione diventa una vera e propria epistemologia del marketing imprenditoriale, in cui l'apprendimento precede la previsione e l'azione genera conoscenza: "*Tutto ciò che facciamo è un esperimento*" (CS_45). Da una prospettiva strategica, questo si traduce in comportamenti adattivi: testare le offerte, cambiare direzione, riformulare servizi e obiettivi: "*Il fallimento è ciò che ti avvicina al successo*" (CS_23).

La fase di consolidamento emerge quando identità, offerte e routine iniziano ad allinearsi. Nelle fasi più avanzate, il processo di apprendimento diventa prevalentemente riflessivo. Gli intervistati dimostrano una maggiore capacità di guardare retrospettivamente al proprio percorso, riconoscendo modelli, priorità e direzioni strategiche: "*Sto imparando a dire di no alle opportunità che non sono allineate*" (CS_45). Questo dimostra come il processo di apprendimento porti gli imprenditori a passare da un marketing reattivo a uno strategicamente consapevole. La stabilizzazione avviene attraverso una maggiore selettività, una gestione più consapevole delle risorse e la costruzione di una continuità relazionale. Tuttavia, i dati mostrano anche che il consolidamento include una riflessione sulla sostenibilità personale: "*Abbiamo bisogno di tempo solo per distrarci... il cervello si libera per pensare alle soluzioni*" (CS_1). In termini di marketing imprenditoriale, il rifiuto della cultura del trambusto è esplicito e la sostenibilità individuale diventa una condizione per la continuità strategica dell'azienda.

Nel complesso, le prove suggeriscono che il marketing imprenditoriale nelle transizioni di carriera è un processo di apprendimento multilivello che produce comportamenti di mercato strategici. Le sfide cognitive, emotive e relazionali non sono esterne al marketing, ma ne costituiscono piuttosto la forza trainante: innescano riflessione, sperimentazione e relazioni, plasmando progressivamente posizionamento, prezzi e marketing. interazione. Il marketing emerge quindi come lo spazio in cui identità e mercato vengono co-costruiti, evidenziando il contributo specifico del marketing imprenditoriale alla comprensione delle carriere imprenditoriali nascenti.

5. Discussione e conclusioni

La ricerca presentata ha portato a identificare il marketing imprenditoriale come un processo di apprendimento multilivello in cui gli imprenditori emergenti muovono i primi passi fino al consolidamento del loro comportamento imprenditoriale. I risultati mostrano che le difficoltà svolgono un ruolo fondamentale nell'attivazione dei processi di apprendimento imprenditoriale. Piuttosto che rappresentare semplici ostacoli, le sfide fungono da fattori scatenanti critici che stimolano la riflessione e, successivamente, l'evoluzione.
Questi processi di apprendimento, a loro volta, plasmano i comportamenti strategici degli imprenditori. Man mano che gli individui si confrontano con l'incertezza e i vincoli di risorse, affinano progressivamente le proprie logiche decisionali, riposizionano la propria offerta e adattano i propri approcci al mercato. La strategia emerge quindi non come un piano predefinito, ma come il risultato di dinamiche di apprendimento iterative. Infine, lo studio dimostra che il marketing si apprende come una pratica situata, incarnata e progressiva. Si sviluppa attraverso l'azione e l'interazione in contesti specifici, si fonda sull'esperienza e sull'identità personale e si evolve gradualmente nel tempo. La competenza di marketing si acquisisce quindi attraverso la pratica imprenditoriale vissuta. In teoria, le voci dei professionisti che hanno compiuto la transizione dal lavoro tradizionale all'imprenditorialità assumono un valore particolare, colmando il gap individuato da Fillis (2015). Le testimonianze analizzate, focalizzate sulla fase iniziale dell'esperienza imprenditoriale, forniscono un "kit informativo" in grado di orientare i futuri imprenditori verso pratiche di marketing più consapevoli. In particolare, il marketing imprenditoriale emerge come il risultato di un processo di apprendimento in cui azione, riflessione e relazioni si intrecciano per plasmare comportamenti strategici adattivi e progressivamente più coerenti.
In linea con la letteratura che descrive il marketing imprenditoriale come informale, adattivo e orientato all'azione (Stokes, 2000; Fillis, 2002), le narrazioni raccolte dimostrano come le pratiche di marketing non siano definite ex ante, ma emergano attraverso l'esperienza, l'interazione e la riflessione, configurandosi come strategie emergenti nel senso di Mintzberg (1987) e come processi efficaci nel senso di Sarasvathy (2001). Le difficoltà incontrate dagli imprenditori nella fase nascente (incertezza sul posizionamento, ambiguità nella valutazione delle opportunità, incertezza nel prezzo, mancanza di risorse finanziarie e reputazionali) non si limitano a ostacoli contingenti. Esse attivano processi di apprendimento che trasformano progressivamente l'esperienza in conoscenza operativa, confermando la prospettiva di Kolb (1984) e Politis (2005), secondo cui l'apprendimento imprenditoriale è un processo dinamico di trasformazione dell'esperienza.
A livello cognitivo, le testimonianze riflettono le condizioni di razionalità limitata e ambiguità informativa descritte da Simon (1955) e Mitchell et al. (2002). I partecipanti descrivono momenti di disorientamento interpretativo, in cui comprendere il mercato e attribuire significato al feedback ricevuto risulta complesso. È proprio in questi momenti che si attivano forme di apprendimento riflessivo (Schön, 2017; Mezirow, 1991): rallentare, prendersi del tempo per "pensare" e rifiutare la logica della produttività incessante diventano pratiche strategiche. La riflessione consente di riformulare il problema, ridefinire le priorità e costruire una visione più coerente. In questo senso, comportamenti come la pianificazione strategica, il ritmo strategico, la determinazione dei prezzi o il rafforzamento dell'impegno a lungo termine emergono non come il risultato di un piano formale, ma come la sedimentazione di processi riflessivi attivati dall'incertezza.
Allo stesso tempo, le difficoltà stimolano l'apprendimento esperienziale. In condizioni di risorse scarse e in assenza di una reputazione consolidata, gli imprenditori agiscono entro i limiti di ciò che è disponibile, adattando le proprie scelte alle contingenze emergenti, in linea con la logica effettuale (Sarasvathy, 2001). La sperimentazione precoce, l'accettazione di opportunità imperfette e la costituzione di riserve finanziarie prima di assumersi rischi maggiori rivelano una strategia che si sviluppa attraverso l'azione, confermando il concetto di strategia emergente (Mintzberg, 1987). L'apprendimento avviene attraverso l'azione, la correzione e la ricalibrazione. Il marketing diventa quindi un'attività esplorativa, piuttosto che pianificata, in cui l'interazione diretta con il mercato

produce progressivi aggiustamenti nelle scelte di posizionamento, allocazione delle risorse e gestione del rischio.
La dimensione relazionale, ampiamente riconosciuta nella letteratura sul marketing imprenditoriale (Granovetter, 1985; Hoang & Antoncic, 2003; Fillis, 2002), emerge con forza anche nei nostri risultati. Le reti non sono semplici canali di acquisizione clienti, ma spazi di apprendimento sociale (Lave & Wenger, 1991; Cope & Watts, 2000). Attraverso il coinvolgimento di clienti, partner e colleghi, gli imprenditori negoziano significati, ridefiniscono le proprie competenze e costruiscono credibilità in assenza di una legittimazione pregressa. Il pitching proattivo, la valorizzazione delle raccomandazioni e la riformulazione delle proprie competenze diventano pratiche attraverso le quali la reputazione si consolida progressivamente. In questo processo, l'identità professionale si intreccia con gli sforzi di marketing, confermando come le dimensioni simboliche e relazionali siano centrali nella fase nascente. Dal punto di vista teorico, lo studio contribuisce alla letteratura sull'Entrepreneurial Marketing (EM) spostando l'attenzione dall'efficacia delle tattiche organizzative al processo di costruzione identitaria e cognitiva dell'individuo (Breit & Widlok, 2023). La ricerca estende la comprensione delle transizioni di carriera (Belchior & Castro-Silva, 2023) dimostrando che il marketing, in contesti nascenti, non è una funzione predefinita ma una competenza adattiva che emerge dalla rinegoziazione dei propri 'sé possibili' (Markus & Nurius, 1986). Il passaggio da un'identità professionale tradizionale a una imprenditoriale richiede un profondo processo di 'unlearning' dei modelli di marketing convenzionale a favore di logiche effettuali e dell'adozione di identità provvisorie (Ibarra, 1999) utili a testare il nuovo ruolo sul mercato. In questo senso, il lavoro rafforza il legame tra apprendimento e strategia emergente (Mintzberg, 1987), teorizzando che le difficoltà iniziali agiscano come meccanismi di apprendimento riflessivo indispensabili per la sedimentazione della conoscenza operativa (Politis, 2005).
In termini di implicazioni manageriali, chiarendo come le difficoltà attivino processi di apprendimento che plasmano i comportamenti di marketing strategico, i risultati hanno portato alla definizione di linee guida per supportare gli imprenditori emergenti nell'impegno in azioni di marketing imprenditoriale più consapevoli e ponderate.
In termini di implicazioni manageriali, l'apprendimento esperienziale emerge come una leva essenziale per la gestione del rischio e la sperimentazione di mercato. Creare riserve finanziarie prima di assumersi rischi più significativi è considerata una pratica cruciale: come sottolinea un intervistato, "*Avere un piano e una certa stabilità finanziaria per almeno i primi sei mesi*" (CS_19). Questi dati, supportati dall'alta frequenza del codice 'Sostenibilità Finanziaria'. suggeriscono che per l'imprenditore emergente la prudenza fiscale non è un freno, ma un abilitatore del marketing: solo con una base economica solida è possibile evitare l'"Underpricing' permettendo una negoziazione del prezzo basata sul valore reale e non sulla necessità immediata di liquidità.
Allo stesso tempo, dire "sì" alle opportunità e sperimentare in anticipo consente di imparare facendo: "*Non aspettare di essere perfetto... Il modo migliore per imparare è semplicemente dire 'sì'*" (CS_26). Per manager o mentor, ciò significa che i programmi di formazione o supporto dovrebbero incoraggiare la sperimentazione guidata e l'apprendimento attivo, creando ambienti in cui gli errori non vengono stigmatizzati ma diventano opportunità di crescita e adattamento.
L'apprendimento sociale gioca un ruolo altrettanto centrale, soprattutto nella costruzione di relazioni e legittimità di mercato. La capacità di mobilitare la rete per ottenere credibilità e accesso alle opportunità emerge chiaramente dalle testimonianze. Un partecipante ha osservato che "*Le persone che si raccomandano a vicenda sono un fattore assolutamente positivo*" (CS_128), mentre un altro ha sottolineato l'importanza del networking e del pitching: "*Invia il pitch, contatta le persone e crea una connessione"* (CS_17). Il successo del 'Networking Relazionale' dimostra che il ruolo del mentor deve evolvere da consulente tecnico a 'connettore sociale'. I coach dovrebbero incoraggiare la costruzione di micro-community per mitigare il senso di 'Isolamento', trasformando il networking da attività ansiogena a pratica di apprendimento collettivo e legittimazione reciproca. Questi esempi inoltre dimostrano come la costruzione di relazioni e la negoziazione della fiducia siano pratiche strategiche, non solo tattiche, e suggeriscono che gli interventi manageriali dovrebbero aiutare gli

imprenditori emergenti a sviluppare competenze narrative e relazionali, nonché capacità di riformulazione del valore, come evidenziato da un partecipante che ha osservato: "*Se osservate con occhi nuovi, le vostre competenze attuali potrebbero essere il trampolino di lancio verso qualcosa di nuovo*" (CS_20). Alla luce della pervasività della 'Sindrome dell'Impostore', l'implicazione per mentor e coach è la necessità di spostare il focus dalla mera acquisizione di hard skills alla validazione dell'identità. I programmi di mentoring devono integrare strumenti di 'riflessività guidata' per aiutare i soggetti a ricodificare il proprio passato professionale, trasformando il senso di inadeguatezza in una proposta di valore distintiva e autentica.

Infine, la gestione del valore e della direzione strategica richiede una combinazione di apprendimento riflessivo e pianificazione consapevole. Sentirsi sicuri nella determinazione dei prezzi "*Trova la fiducia in te stesso per far pagare ciò che vali*" (CS_13), pianificare strategie coerenti e garantire segnali di qualità "*Avere una strategia e una visione... assicurarsi che la qualità sia davvero buona*" (CS_127), nonché impegnarsi pienamente e definire obiettivi a lungo termine: "*Lavoraci ogni giorno... poi aumenta la posta in gioco nei tuoi obiettivi"* (CS_SOLO_161) sono comportamenti che emergono dall'integrazione di riflessione, esperienza e relazioni sociali. Da una prospettiva manageriale, ciò implica che il supporto agli imprenditori emergenti non può limitarsi a fornire strumenti operativi: è essenziale supportare la costruzione di fiducia, visione strategica e capacità di pianificazione, affinché le decisioni operative siano coerenti con la loro identità professionale e il loro posizionamento di mercato.

Limiti della ricerca sono legati all'utilizzo esclusivo di dati secondari, alla consultazione di una sola piattaforma e quindi di un solo dataset e all'autoselezione delle persone che hanno deciso di raccontare la loro storia. In questo senso un ampliamento della ricerca su nuovi database o l'integrazione dell'analisi con dati primari potrebbe rafforzare una futura ricerca. Sulla base di tali evidenze, si delineano diverse traiettorie per la ricerca futura. In primo luogo, appare prioritario approfondire il fenomeno attraverso l'integrazione di dati primari e studi longitudinali che, seguendo i più recenti orientamenti metodologici (Leick & Tuitjer, 2025), permettano di monitorare l'evoluzione delle pratiche di marketing in tempo reale. In secondo luogo, sarebbe opportuno indagare come variabili culturali o motivazionali (imprenditorialità per necessità vs. opportunità) influenzino la velocità del processo di 'unlearning' e la capacità di gestire l'incertezza del pricing. Infine, futuri approfondimenti potrebbero esplorare il ruolo delle tecnologie digitali nel facilitare la costruzione di legittimità relazionale, fornendo una visione ancora più granulare dei percorsi di consolidamento del comportamento imprenditoriale.

The King's Speech: How Entrepreneurs' Family Social Capital and Risk Aversion Shape New Venture Financing

LUCIA LUDOVICI, PIETRO TARAGONI

Abstract

Frame of the research. *Traditionally, the entrepreneurial function has been conceptualized as closely related to the entrepreneur's personal wealth. Despite the expanding supply of equity-based funding and the fact that venture capitalists (VCs) usually provide managerial and value-added contributions critical to new ventures success, VCs continue to account for only a modest share of overall entrepreneurial finance, especially when quantitatively compared to commercial banks. This phenomenon raises a fundamental question: what are the factors that systematically shape the propensity of entrepreneurs to choose between venture capital and bank financing?*

Purpose of the paper. *The primary objective of the paper is to advance our understanding of when a rational entrepreneur would seek venture capital rather than bank financing by developing a more comprehensive framework that incorporates two practically salient factors: family social capital and risk aversion of the entrepreneur.*

Methodology. *We propose a theoretical model of entrepreneurial financing in which preferences are characterized alternatively by a mean-variance framework and CARA utility, linking family social capital and risk aversion to show how their interaction shapes the financing choice.*

Results. *Family social capital affects utility under bank financing through two channels: it improves borrowing conditions by lowering the cost of debt, but it also increases effective risk aversion. The net impact of social capital on utility therefore depends on the relative strength of these two forces.*

Under venture capital, equity-based financing exposes the entrepreneur to full payoff variability, so that risk aversion directly reduces the attractiveness of venture capital.

As a result, there exists a threshold level of effective risk aversion such that venture capital is preferred to bank financing.

Research limitations. *The impact of family social capital on borrowing conditions and risk aversion is modeled in a linear form, but potentially nonlinear relationships may generate richer dynamics and alternative threshold effects.*

Managerial implications. *Venture capital financing is likely to be most beneficial when the new venture lies squarely within the venture capitalists' domain of expertise, enabling meaningful managerial value-added, when entrepreneurs pursue ambitious growth objectives, and exhibit lower risk aversion. Venture capitalists are more likely to achieve favorable outcomes when the entrepreneur's family social capital is limited.*

Originality of the paper. *While past research has focused almost exclusively on the central trade-off in venture capital financing – the profit motive versus the control motive – characterizing this trade-off as a "double moral hazard" problem, we advance the idea that entrepreneurial risk aversion and family social capital jointly shape the choice between bank debt and venture capital. Abstracting from these factors sharpens analytical tractability, yet it limits the understanding of a phenomenon that remains widely underexplored despite its practical relevance for new venture success.*

Keywords: *family social capital; risk aversion; venture capital; entrepreneurship; double moral hazard; entrepreneurial finance*

1. Introduction

Traditionally, the entrepreneurial function has been conceptualized as closely related to the entrepreneur's personal wealth (Evans and Jovanovic, 1989). With the transition to a system increasingly grounded in equity rather than debt (Lerner and Leamon, 2023; Cumming et al., 2023), the creation of new ventures is no longer necessarily limited by the endowment of the entrepreneur's resources. Despite this paradigmatic shift and the fact that venture capitalists (VCs) usually provide managerial and value-added contributions critical to new ventures success, VCs continue to account for only a modest share of overall entrepreneurial finance, especially when quantitatively compared to commercial banks (Honjo and Yoshida, 2025; Miglo, 2022). The coexistence of equity and debt financing sources, coupled with the persistent dominance of the latter, raises a fundamental question: what are the factors that systematically shape the propensity of entrepreneurs to choose between

venture capital and bank financing?

Prior research on resource assembly has explained entrepreneurial finance decisions primarily in terms of entrepreneurs' preferences among alternative financing sources (Shepherd et al., 2018). For example, this stream of work has examined entrepreneurs' propensity to rely on lower levels of debt (e.g., Huyghebaert, Gucht, and Hulle, 2007), their choice between debt and venture capital (e.g., de Bettignies and Brander, 2007), between venture capitalists and business angels (e.g., Fairchild, 2011), among different venture capital investors (e.g., Drover, Wood, and Payne, 2014), as well as preferences for other financing mechanisms such as crowdfunding (e.g., Miglo, 2022) and additional emerging forms of entrepreneurial finance. This literature has often conceptualized the fundamental financing decision around the central trade-off in venture capital financing: the profit motive – linked to the benefits of VCs' value-adding managerial contributions (e.g., Kirzner 1999; Schumpeter 1934) – versus the control motive – linked to the costs associated with effort dilution and loss of control when entrepreneurs cede substantial equity to a VC (e.g., Sapienza, Korsgaard, and Forbes 2003).

The current theory of venture financing is grounded in agency-based considerations that characterize this trade-off. Models of entrepreneurial finance highlight adverse selection outcomes, whereby high-quality entrepreneurs – who possess superior information about their startups relative to potential investors (Venkataraman, 1997) – are less inclined to rely on equity financing due to ownership dilution and the higher opportunity costs associated with relinquishing control rights (Meza and Webb, 1987; Stiglitz and Weiss, 1981). This trade-off also highlights a "double moral hazard" problem inherent in venture capital finance. Specifically, de Bettignies and Brander 2007 argue that under equity financing, both the entrepreneur and the VC supply non-observable (or at least non-verifiable) effort that is critical to venture performance. Allocating a larger equity stake to the VC strengthens the VC's incentives to exert effort but weakens effort incentives for the entrepreneur. By contrast, bank financing preserves the entrepreneur's full ownership, thereby avoiding effort dilution and loss of control, but it deprives the venture of the VC's managerial value-added.

While prior studies have advanced our understanding of entrepreneurs' preferences among alternative financing sources, academic understanding remains limited regarding a range of additional factors that shape these preferences. These factors – that include entrepreneurs' behavioral traits and social processes – are both theoretically and practically relevant for systematically explaining how the core trade-off varies when considering the choice between different forms of financing, beginning with the fundamental one between debt and equity (de Bettignies and Brander, 2007). First, scholars have paid limited attention to entrepreneurs' risk aversion. Much of the research on entrepreneurial firms has focused on access to credit, whereas comparatively little is known about the role of risk preferences (Hvide and Panos, 2014). Willingness to take risks has long been recognized as a salient attribute of successful entrepreneurs (Arteaga-Fonseca et al., 2025; Herranz, Krasa, and Villamil, 2015; Forlani and Mullins, 2000). Risk aversion can shift the preferences of entrepreneurs between debt and equity by altering the relative importance of the benefits of the managerial contributions of VCs versus the costs of effort dilution. Second, research in strategy and entrepreneurship has underscored the role of entrepreneurs' family social capital in shaping new-venture financing choices (Stasa and Machek, 2022; Shepherd et al., 2018; Chua et al., 2011)[1]. However, this line of research has indicated that the relationship between social capital and the capital structure of new ventures still remains poorly understood (Dudley, 2021). Conceptualized as the goodwill and resources available through reciprocal, trust-based relationships (Adler and Kwon, 2002; Hitt, Lee, and Yucel, 2002; Lin, 2001), social capital is often argued to be valuable, rare, difficult to imitate, and non-substitutable (Barney, 1991) and thus to contribute positively to firm outcomes (Nahapiet and Ghoshal, 1998).

To advance our understanding of when a rational entrepreneur would seek venture capital rather than bank financing, we build on previous agency considerations and retain the core feature of the double–moral hazard problem of the model presented by de Bettignies and Brander (2007) but

[1] Social capital was originally defined as "the aggregate of the actual or potential resources which are linked to possession of a durable network of more or less institutionalized relationships of mutual acquaintance and recognition" (Bourdieu 1986).

develop a more comprehensive framework that incorporates two practically salient factors: the risk aversion and family social capital of the entrepreneur. First, focusing on the entrepreneur's risk aversion, we theorize that an entrepreneur's willingness to take risks shifts the equilibrium of the core venture-capital financing trade-off by altering both the benefits of venture capital value-added and the costs of entrepreneurial effort dilution when equity is ceded to the venture capitalist. A dominant view holds that entrepreneurs are less risk-averse than the general population (Knight 1921; Kihlstrom and Laffont, 1979). However, this view largely assumes time-invariant risk aversion and, consequently, that less risk averse individuals are more likely to found new ventures. Subsequent research relaxes this assumption, showing that risk aversion is not time invariant and documenting heterogeneous pathways into self-employment (e.g., Brändle et al., 2025; Carroll and Mosakowski, 1987) and new venture creation (e.g., Urbano et al., 2022; Kacperczyk, 2012). Consistent with this evidence, we assume that entrepreneurs' risk aversion can vary, especially contingent upon different levels of family social capital, and dynamically reweighs the relative importance of venture capital benefits and the costs of incentive dilution, thereby shifting the balance toward (or away from) VCs participation. More risk-averse entrepreneurs tend to operate with higher leverage and face a greater likelihood of negative-equity positions than their less risk-averse counterparts, leading them to value more the retention of the full ownership of the business. By contrast, less risk-averse entrepreneurs are more willing to forgo current consumption and bear the costs of effort dilution, placing greater value on the upside exposure associated with venture capital financing (Herranz, Krasa, and Villamil, 2015).

Second, focusing on family social capital, we theorize that it is a crucial determinant of entrepreneurs' propensity to resort to debt rather than venture capital. Previous work shows that social capital is central to increasing access to outside financing reducing reliance on owner equity to finance the new venture (e.g., Dudley, 2021), and mitigating agency conflicts with lenders (e.g., Bosse, 2009; Petersen and Rajan, 1994; Uzzi, 1999). Whereas managers and employees in large firms benefit from established organizational reputations and broad recognition, entrepreneurs are often "unknown quantities" to customers, suppliers, investors, and other potential partners because they have yet to accumulate organizational social capital (Stinchcombe, 1965; Kwon, Heflin, and Ruef, 2013). Financial institutions therefore face particular difficulty in assessing the creditworthiness of nascent ventures (Wiklund, Baker, and Shepherd, 2010). As a result, entrepreneurs must rely on their own personal social capital or, if it is insufficient, attempt to "borrow" the social capital of others (Arregle et al., 2007). Yet, entrepreneurs cannot credibly leverage the social capital of others absent trust-based relationships or mutual obligations with their owners; moreover, the social capital of third parties may be exposed to opportunistic use or reputational erosion if the venture fails, further complicating access. Family involvement helps overcome this constraint. Only when family involvement enables the entrepreneur to draw on the family's social capital does the new venture's access to bank debt improve (Chua et al., 2011). When the entrepreneur successfully leverages this capital, access to debt is facilitated through three key benefits of family involvement: i) by reducing borrower–lender agency costs due to a lower likelihood of managerial opportunism (Fama and Jensen, 1983; Jensen and Meckling, 1976); ii) by making entrepreneurs more risk averse (McConaughy, 1999; Ward, 1997), and iii) more long-term oriented (Arregle et al., 2007; Chua, Chrisman, and Sharma, 1999; Smith and Warner, 1979). Specifically, family ties mitigate agency problems in external financing through information transfer (Uzzi, 1999) and social obligation (Saparito, Chen, and Sapienza, 2004). The former arises when the lender has observed the borrower's behavior over an extended period and, as a result, develops trust in the borrower's character and judgment. The latter occurs when the lender's decision is influenced by loyalty or by a perceived need to reciprocate favorable treatment received in other transactions or contexts. Additionally, family ties, reduce firms' propensity to pursue risky growth objectives. Higher risk aversion reduces lenders' exposure and should increase their willingness to extend credit to firms with family involvement. Post-loan, family ties associated with heightened entrepreneurial risk aversion, mitigate a key moral-hazard concern for lenders. Finally, in family firms the desire for control and "dynastic

stability" shifts their priorities toward long-term survival rather than growth (Arregle et al., 2007). Accordingly, the core mechanism is that when the family has social capital with lenders, more risk averse entrepreneurs can draw on that capital, agency frictions with lenders are alleviated and access to debt financing is facilitated.

In sum, we advance the idea that entrepreneurial risk aversion and family social capital jointly shape the choice between bank debt and venture capital. While related contributions have separately emphasized either entrepreneur's risk preferences or the family social processes underpinning legitimacy with lenders, these elements are rarely integrated into the canonical debt-equity trade-off. Abstracting from them sharpens analytical tractability, yet it limits the understanding of a phenomenon that remains widely underexplored despite its practical relevance for new venture success (Honjo and Yoshida, 2025, de Bettignies and Brander, 2007). In our framework, entrepreneurial risk aversion affects the financing trade-off through the relative valuation of upside exposure and incentive costs. More risk-averse entrepreneurs assign greater weight to the downside risk and effort-related costs associated with venture capital, whereas less risk-averse entrepreneurs value more strongly the upside potential generated by VCs value-added and growth opportunities. At the same time, family social capital operates as a relational asset that relaxes credit frictions, improves borrowing conditions, and mitigates the perceived downside risk associated with bank financing. The interaction between these two dimensions generates a threshold structure in the entrepreneur's financing decision. The model predicts the existence of a switching level of risk aversion that separates regions in which venture capital or bank debt is optimal. Moreover, this threshold is endogenous to social capital: higher family social capital shifts the switching point toward higher levels of risk aversion, delaying the transition from venture capital to bank financing and highlighting the interaction between relational advantages and prudential behavior.

Overall, our study makes several contributions. By integrating insights from agency theory on entrepreneurial financing choices with research on entrepreneurial risk aversion and social capital, we advance all three literatures. First, we contribute to entrepreneurial finance, and specifically to the canonical debt–equity choice (Honjo and Yoshida, 2025; Lerner and Leamon, 2023; Cumming et al., 2023; Miglo, 2022; de Bettignies and Brander, 2007; Winton and Yerramilli, 2006). Building on the suggestions of de Bettignies and Brander (2007), we develop a comprehensive theoretical model that incorporates adverse selection and moral hazard. We further include additional mechanisms shaping financing choices, rooted in practically salient factors such as entrepreneurs' risk aversion and social processes, that have thus far been largely overlooked in the literature. Second, we contribute to the social capital literature by theorizing how family social capital reshapes the central debt–equity trade-off rather than mechanically tilting it toward bank financing. While prior work has largely noted that social capital facilitates access to credit (Stasa and Machek, 2022; Dudley, 2021; Chua et al., 2011; Arregle et al., 2007), we explain how such facilitation alters a rational entrepreneur's financing choice between bank debt and venture capital. Finally, we contribute to research on entrepreneurial risk aversion (Arteaga-Fonseca et al., 2025). While prior studies have examined risk aversion in relation to foundational entrepreneurial choices – such as venture creation (e.g., Urbano et al., 2022; Kacperczyk, 2012) or entry into self-employment (e.g., Brändle et al., 2025; Carroll and Mosakowski, 1987) – our analysis demonstrates its relative importance in determining the equilibrium between the benefits of VC value-added and the costs associated with effort dilution.

The paper proceeds as follows. Section 2 introduces the model and develops testable propositions. Section 3 shows numerical simulations that illustrate the main mechanisms and comparative statics of the model. Section 4 assesses the robustness of the results by including adverse selection, considering an alternative specification of the entrepreneur's utility function, and non-linear effects of family social capital. Section 5 concludes, reports directions for future research, and discusses managerial and policy implications.

2. The model

Consider an entrepreneur seeking external financing to develop a new venture. The entrepreneur can obtain financing from either a competitive bank or a competitive venture capitalist (VC).

The project has a positive return R with probability $p \in (0,1)$. Conditional on success, gross revenue R depends on both entrepreneurial effort e and VC managerial input i (de Bettignies and Brander, 2007):

$$R(e,i) = \alpha e + \beta i \text{ [1]}$$

where $\alpha > 0$ and $\beta > 0$ capture the marginal productivity of entrepreneurial and VC effort, respectively.

Efforts are not verifiable and entail costs $c(e) = \frac{e^2}{2}$ and $c(i) = \frac{i^2}{2}$.

This setting generates the standard trade-off in entrepreneurial finance: venture capital provides managerial value-added but dilutes entrepreneurial incentives, whereas bank financing preserves incentives but offers no managerial contribution.

We assume the entrepreneur evaluates financing regimes using mean-variance preferences, so that for any payoff X, utility is given by:

$$U = \mathbb{E}[X] - \frac{\rho_0}{2}\mathrm{Var}(X) \text{ [2]}$$

where ρ_0 captures the entrepreneur's risk.

We introduce family social capital (SC) as a relational and reputational asset capturing the entrepreneur's embeddedness in the local financing environment. Family social capital improves access to bank financing by facilitating more favorable borrowing terms. At the same time, stronger family social capital raises the reputational and socioemotional stakes associated with entrepreneurial failure. Because failure may jeopardize family reputation, relational networks, and the preservation of family wealth, entrepreneurs embedded in dense family-based networks perceive risky outcomes as more costly. Accordingly, family social capital operates through two complementary channels: a price channel, improving borrowing conditions, and a preference channel, increasing the entrepreneur's effective aversion to payoff variability.

2.1 Bank financing

Under bank financing, the entrepreneur retains full ownership and provides effort e, while the bank acts purely as a financier. If the project succeeds, the entrepreneur produces αe and repays $\theta_0 = 1 + r$, where r is the bank risk-free rate.

The entrepreneur's payoff under bank financing, X_{Bank}, is therefore:

$$X_{Bank} = \begin{cases} \alpha e - \theta_0 & \text{with probability } p \\ 0 & \text{with probability } 1-p \end{cases} \text{ [3]}$$

The expected payoff net of effort cost:

$$\mathbb{E}[X_{Bank}] - c(e) = p(\alpha e - \theta_0) - \frac{e^2}{2} \text{ [4]}$$

And the variance:

$$\mathrm{Var}(X_B) = p(1-p)(\alpha e - \theta_0)^2 \text{ [5]}$$

Access to debt is shaped by the entrepreneur's family involvement and thus social capital: SC improves lending conditions by reducing agency frictions but increases risk aversion. We capture the price channel by allowing the effective cost of bank finance to depend on family social capital (SC):

$$\theta(SC) = \theta_0 - \gamma\, SC \qquad \gamma > 0 \text{ [6]}$$

so that higher social legitimacy relaxes credit frictions and increases the attractiveness of bank financing (Chua et al., 2011; Anderson et al., 2003). This means that the family social capital acts as an incentive to bank debt.

In addition, family social capital affects the entrepreneur's perception of risk by increasing the costs associated with failure. Entrepreneurs embedded in strong family-based networks may face greater losses in terms of reputation and perseveration of family wealth, leading them to adopt more conservative attitudes toward risky outcomes. We capture this mechanism through an effective risk-aversion parameter that increases with social capital:

$$\rho(SC) = \rho_0 + \kappa SC, \qquad \kappa > 0 \text{ [7]}$$

The entrepreneur's utility under bank financing is therefore:

$$U_{Bank}(\rho, SC) = p(\alpha e - \theta(SC)) - \frac{\rho(SC)}{2} p(1-p)(\alpha e - \theta(SC))^2 \text{ [8]}$$

This specification highlights the interaction between family social capital and risk aversion. Higher family social capital improves borrowing conditions by lowering the cost of debt $\theta(SC)$, thereby increasing expected returns from bank financing. At the same time, stronger family ties and reputational concerns increase the entrepreneur's effective exposure to potential losses, and thus his risk aversion. When financial outcomes affect not only individual wealth but also family reputation and socioemotional endowment, the entrepreneur behaves more prudently and assigns a greater weight to payoff variability.

The entrepreneur chooses effort e to maximize [8], yielding the first-order condition:

$$\frac{\partial U_{Bank}}{\partial e} = p\alpha - e - \rho(SC)\, p(1-p)\alpha\big(\alpha e - \theta(SC)\big) = 0 \text{ [9]}$$

which defines the optimal effort under bank financing e^*_{Bank}:

$$e^*_{Bank} = \frac{p\alpha - \rho(SC)\, p(1-p)\alpha\, \theta(SC)}{1 - \rho(SC)\, p(1-p)\alpha^2}, \text{ [10]}$$

provided $1 - \rho(SC)\, p(1-p)\alpha^2 > 0$.

Proposition 1. *Utility is affected by family social capital through two channels: it improves borrowing conditions by lowering the cost of debt, but it also increases effective risk aversion. The net impact of social capital on utility therefore depends on the relative strength of these two forces.*

2.2 Venture capital financing

Under venture capital financing, the VC provides funding and managerial input i in exchange for an equity share $s \in (0,1)$. The entrepreneur retains the residual share $(1-s)$ and chooses effort e. Both the entrepreneur and the VC exert unverifiable effort.

If the project succeeds, the entrepreneur obtains $(1-s)(\alpha e+\beta i)$, while payoff is zero if the project fails.

The entrepreneur's payoff under venture capital financing, X_{VC}, is:

$$X_{VC}=\begin{cases}(1-s)(\alpha e+\beta i) & \text{with probability } p\\ 0 & \text{with probability } 1-p\end{cases} \quad [11]$$

The expected payoff net of effort cost:

$$\mathbb{E}[X_{VC}]-c(e)=p(1-s)(\alpha e+\beta i)-\frac{e^2}{2} \quad [12]$$

Variance:

$$\mathrm{Var}(X_{VC})=p(1-p)(1-s)^2(\alpha e+\beta i)^2 \quad [13]$$

Let $\rho \geq 0$ capture the entrepreneur's risk aversion under VC financing. The entrepreneur evaluates the VC regime according to mean-variance preferences with effective risk aversion as in equation [7]:

$$U_{VC}(\rho,SC)=p(1-s)(\alpha e+\beta i)-\frac{e^2}{2}-\frac{\rho(SC)}{2}\,p(1-p)(1-s)^2(\alpha e+\beta i)^2 \quad [14]$$

The VC's payoff is:

$$\Pi_{VC}=sp(\alpha e+\beta i)-\frac{i^2}{2}-\theta \quad [15]$$

so that the VC chooses i to maximize Π_{VC}, yielding:

$$\frac{\partial \Pi_{VC}}{\partial i}=sp\beta-i=0 \quad \Rightarrow \quad i^*=sp\beta \quad [16]$$

Given i^*, the entrepreneur chooses effort e to maximize [14], which implies the first-order condition:

$$\frac{\partial U_{VC}}{\partial e}=p(1-s)\alpha-e-\rho(SC)\,p(1-p)(1-s)^2\alpha(\alpha e+\beta i^*)=0 \quad [17]$$

and thus the optimal entrepreneurial effort under venture capital:

$$e_{VC}^*=\frac{p(1-s)\alpha-\rho(SC)\,p(1-p)(1-s)^2\alpha\beta i^*}{1+\rho(SC)\,p(1-p)(1-s)^2\alpha^2} \quad [18]$$

Proposition 2. *Since family social capital enters the VC regime only through $\rho(SC)$, higher SC reduces the entrepreneur's utility under venture capital. Equity-based financing exposes the entrepreneur to full payoff variability, so that risk aversion directly reduces the attractiveness of venture capital.*

2.3 Financing choice

The entrepreneur compares utilities across financing regimes. The choice of venture capital over bank financing occurs whenever:

$$\Delta U(\rho, SC) = U_{VC}(\rho, SC) - U_{Bank}(\rho, SC) > 0 \text{ [19]}$$

The utility gap depends on the relative exposure to payoff variability across financing regimes and on the effective level of risk aversion $\rho(SC)$. Since venture capital exposes the entrepreneur to full payoff variability while bank financing provides lower exposure to payoff variability, higher effective risk aversion reduces the relative attractiveness of venture capital.

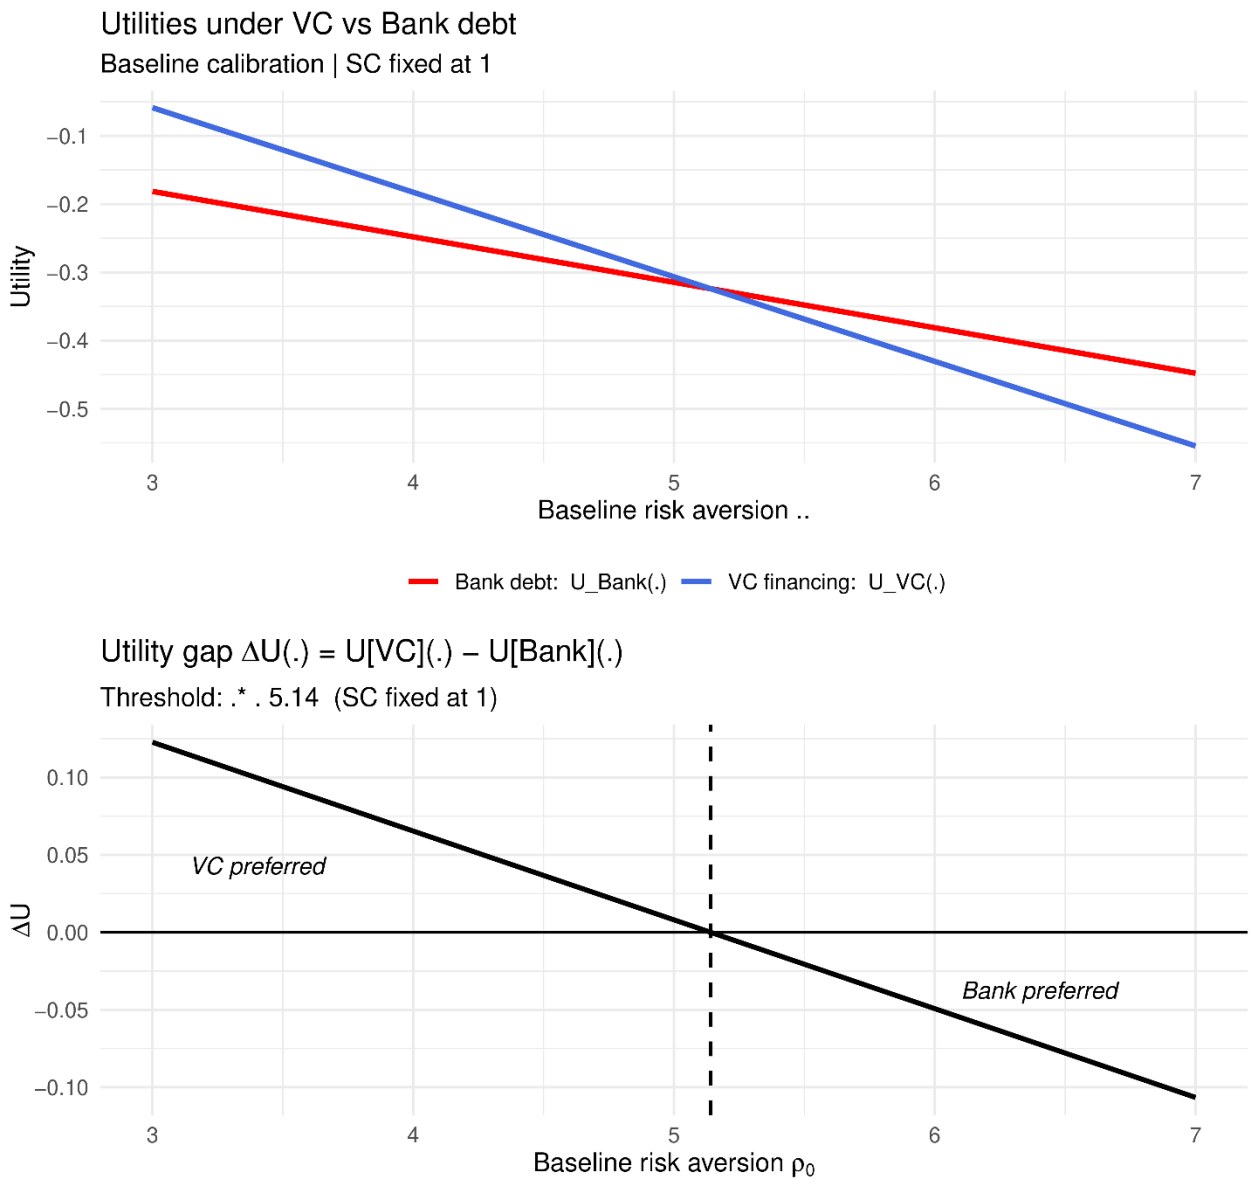
This monotonic relationship implies the existence of a threshold level of effective risk aversion separating the regions in which venture capital and bank financing are preferred.

Proposition 3. *There exists a threshold level of effective risk aversion $\rho^*(SC)$ such that venture capital is preferred for $\rho(SC) < \rho^*(SC)$, while bank financing is preferred for $\rho(SC) > \rho^*(SC)$. Family social capital affects this threshold through both borrowing conditions and prudential behavior, implying that $\rho^*(SC)$ is endogenous to social capital. In particular, higher social capital reshapes the switching point between financing regimes by modifying the trade-off between expected returns and exposure to downside risk.*

A proof of Proposition 3 is provided in Appendix A.

Proposition 3 highlights that family social capital does not mechanically tilt entrepreneurs toward bank financing; rather, it reshapes the risk tolerance frontier separating the two financing regimes. The financing decision therefore depends not only on entrepreneurial and VC productivity but also on underlying social processes and behavioral traits. In particular, family social capital increases the attractiveness of bank financing by reducing borrowing costs, while weaker risk aversion enhances the relative appeal of venture capital by increasing the value of upside exposure.

3. Numerical simulations



3.1 Utilities under bank and VC financing

To illustrate the mechanisms highlighted by the model, we perform a set of numerical simulations under a baseline calibration. The objective is to visualize how the entrepreneur's financing choice varies with risk aversion and family social capital. Unless otherwise stated, parameters are set as follows:

$$p = 0.5, \qquad \alpha = 1.6, \qquad \beta = 2.0, \qquad s = 0.35, \qquad \theta = 0.8, \qquad \gamma = 0.25 \text{ [20]}$$

Family social capital SC is initially held fixed at $SC = 1$ in order to isolate the effect of risk aversion on financing preferences. Effort levels are fixed at their interior benchmark values to keep the graphical analysis transparent and to focus on the interaction between payoff variability and financing regimes.

Fig. 1: Utilities under VC vs Bank financing

Source: Authors' own elaboration.
Note. Entrepreneurial utilities and financing threshold for fixed family social capital ($SC = 1$). The upper panel reports utilities under venture capital and bank financing as a function of family social capital and risk aversion. The lower panel plots the utility differential $\Delta U(\rho, SC)$ and highlights the threshold ρ^* separating the regions in which venture capital and bank financing are preferred.

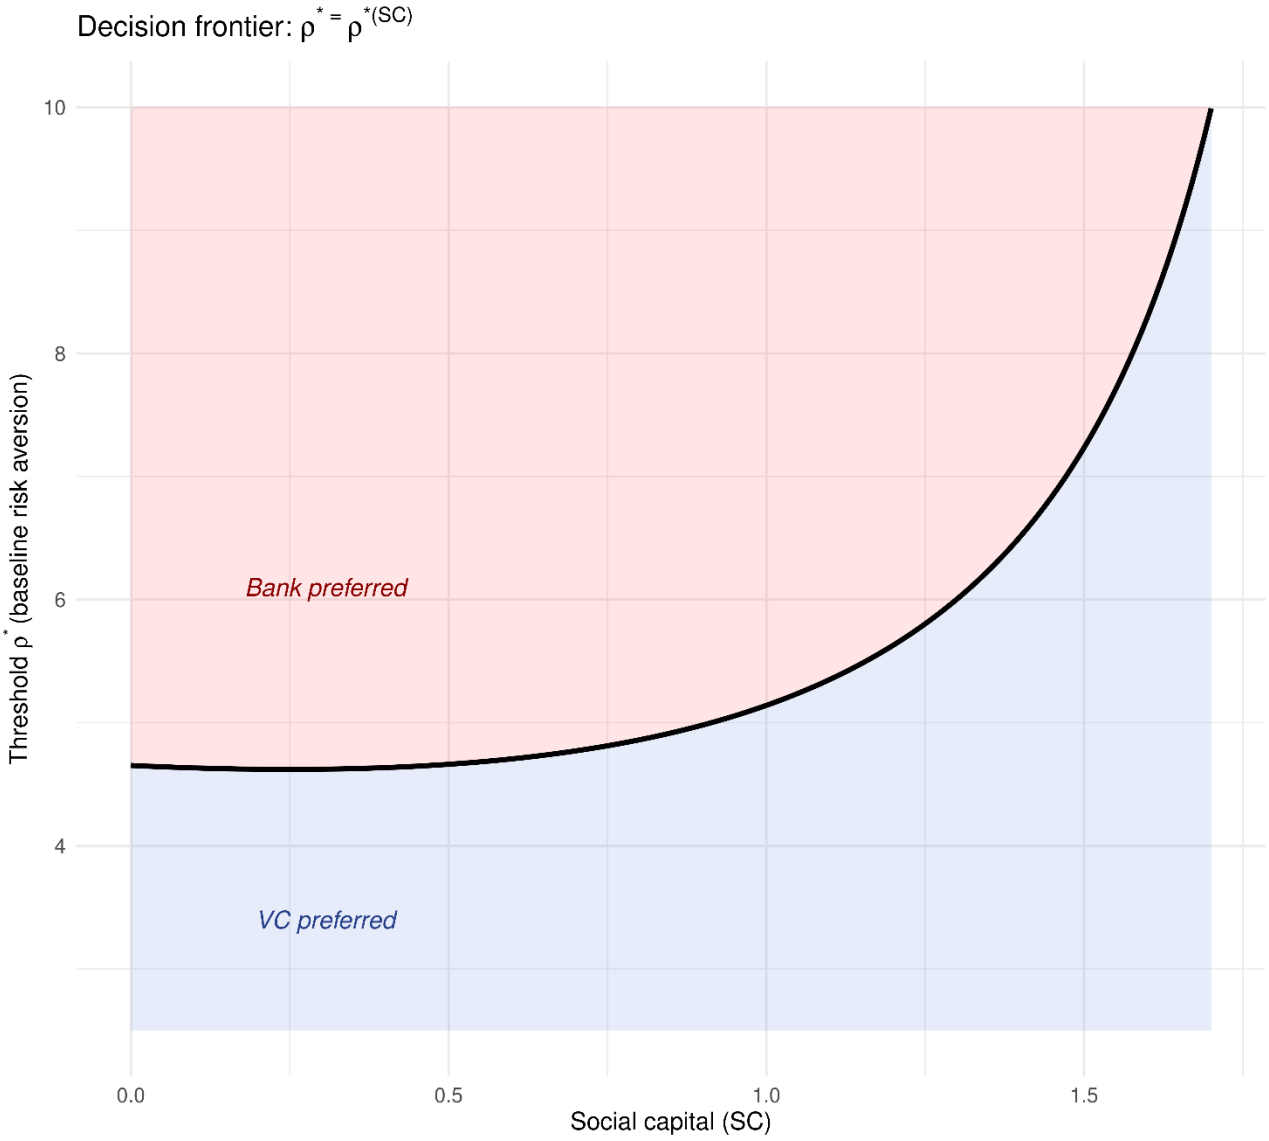
Figure 1 plots entrepreneurial utility under venture capital and bank financing as a function of family social capital and risk aversion. Consistent with the theoretical predictions, utility under venture capital declines more steeply as risk aversion increases, reflecting the entrepreneur's full exposure to payoff variability under equity financing. In contrast, utility under bank financing decreases more gradually because the entrepreneur is partially insulated from downside risk and benefits from improved borrowing conditions associated with family social capital. As a result, the utility differential $\Delta U(\rho, SC) = U_{VC}(\rho, SC) - U_{Bank}(\rho, SC)$ crosses zero at a threshold level $\rho^*(SC)$ separating the regions in which venture capital and bank financing are preferred. For low levels of risk aversion, the entrepreneur values managerial value-added and prefers venture capital, whereas for sufficiently high risk aversion the relative stability and lower cost of bank financing dominate.

3.2 The Social Capital–Risk Interaction and the Financing Threshold

To characterize how family social capital shapes financing choices, we compute the risk tolerance threshold $\rho^*(SC)$ implicitly defined by

$$\Delta U(\rho, SC) = U_{VC}(\rho, SC) - U_{Bank}(\rho, SC) = 0 \text{ [21]}$$

The threshold $\rho^*(SC)$ identifies the level of baseline risk aversion at which the entrepreneur is indifferent between venture capital and bank debt. For $\rho < \rho^*(SC)$, venture capital is preferred, whereas for $\rho > \rho^*(SC)$ bank financing becomes optimal.



Family social capital affects the threshold through two distinct channels: it enhances borrowing terms, captured by the decreasing function $\theta(SC) = \theta_0 + \gamma SC$ and it increases entrepreneurs' risk aversion, $\rho = \rho_0 + \kappa SC$. These two channels operate simultaneously; thus family social capital does not mechanically shift financing preferences toward bank debt. Instead, it modifies the mapping between risk preferences and financing choices. In particular, numerical simulations show that the threshold $\rho^*(SC)$ varies systematically with family social capital, highlighting an interaction effect between relational advantages and risk aversion: family social capital reshapes, rather than simply shifts, the boundary separating venture-capital oriented and bank-oriented entrepreneurs.

Figure 2 shows that while family social capital improves access to bank debt, it also alters the entrepreneur's risk aversion. As a result, bank financing becomes the preferred option only when risk aversion is sufficiently high. Family social capital therefore delays the point at which entrepreneurs switch from venture capital to bank debt, highlighting an interaction effect between relational advantages and risk perception.

This mechanism reflects the coexistence of the price and preference channels introduced in Equation [6]. On the one hand, lower borrowing costs increase the expected payoff from bank financing, strengthening its relative attractiveness. On the other hand, stronger family embeddedness raises the socioemotional stakes associated with entrepreneurial failure. When family reputation, relational networks, and intergenerational wealth are at risk, the downside state becomes particularly salient. In this sense, family social capital amplifies the perceived dispersion between success and failure outcomes. Even if the statistical payoff structure remains unchanged, entrepreneurs internalize the failure state as involving larger non-pecuniary losses, such as reputational damage or socioemotional wealth erosion. This perceived increase in downside exposure generates a stronger precautionary motive and translates into higher effective risk aversion.

The plot illustrates this interaction effect: as family social capital rises, risk considerations become more prominent, so that bank financing becomes optimal only at higher levels of risk aversion. In other words, greater social capital requires stronger prudential attitudes for the entrepreneur to prefer bank debt, emphasizing that social capital modifies, rather than mechanically shifts, the financing decision.

Fig. 2: Decision frontier

Source: Authors' own elaboration.
Note. Financing threshold $\rho^*(SC)$ separating venture capital and bank debt. The shaded regions identify the combinations of baseline risk aversion and social capital for which each financing regime is preferred. The figure illustrates how social capital reshapes the risk tolerance frontier through the interaction of relational advantages and risk attitudes.

4. Robustness checks

4.1. Adverse selection

The baseline model captures the effect of family social capital on borrowing conditions through a reduced-form function $\theta(SC)$. While this approach is analytically convenient, it abstracts from the informational frictions that characterize entrepreneurial finance. In this section we provide a micro-foundation for the borrowing channel by introducing adverse selection.

Suppose that project quality is not directly observable to outside financiers. The entrepreneur can be of type $q \in \{q_H, q_L\}$, $q_H > q_L$, where q_H denotes a high-quality project and q_L a low-quality one. Let $\mu \in (0,1)$ be the prior probability that the entrepreneur is of high quality. Before extending credit, the bank observes a signal $z \in \{G, B\}$\$, where G stands for a good signal and B for a bad signal. The precision of this signal depends on family social capital. In particular, let

$$P(G|q_H) = \phi_H(SC) \text{ [22]}$$

$$P(G|q_L) = \phi_L(SC) \text{ [23]}$$

with

$$\phi'_H(SC) > 0, \;\; \phi'_L(SC) < 0 \text{ [24]}.$$

These assumptions imply that higher family social capital improves the informativeness of the signal received by lenders. Defining

$$\Delta\phi(SC) = \phi_H(SC) - \phi_L(SC) \text{ [25]}$$

we assume $\Delta\phi'(SC) > 0$, so that family social capital mitigates adverse selection by increasing the separation between high and low-quality entrepreneurs.
Upon observing signal z, the bank updates its beliefs according to Bayes' rule.
After a good signal G, the posterior probability that the entrepreneur is high quality is

$$\mu_G(SC) = \frac{\mu\phi_H(SC)}{\mu\phi_H(SC) + (1-\mu)\phi_L(SC)} \text{ [26]}$$

while after a bad signal B it is

$$\mu_B(SC) = \frac{\mu[1-\phi_H(SC)]}{\mu[1-\phi_H(SC)] + (1-\mu)[1-\phi_L(SC)]} \text{ [27]}$$

Expected project quality conditional on the signal is therefore

$$\bar{q}(z, SC) = \mu_z(SC)q_H + [1-\mu_z(SC)]q_L \text{ [28]}$$

We assume that borrowing conditions depend on the bank's posterior assessment of project quality:

$$\theta = \theta\big(\bar{q}(z, SC)\big), \quad \frac{\partial\theta}{\partial\bar{q}} < 0 \text{ [29]}$$

Higher family social capital improves borrowing conditions indirectly, by increasing the precision of the signal and thereby raising expected project quality. This provides a structural interpretation of the reduced-form relationship between θ and SC used in the baseline specification.
Under this extension, the entrepreneur's payoff under bank financing is

$$X_{Bank} = \begin{cases} \alpha e - \theta\big(\bar{q}(z, SC)\big) & with\ probability\ p \\ 0 & with\ probability\ 1-p \end{cases} \text{ [30]}$$

And expected utility becomes

$$U_{Bank} = p(\alpha e - \theta\big(\bar{q}(z, SC)\big) - \frac{\rho(SC)}{2}p(1-p)(\alpha e - \theta\big(\bar{q}(z, SC)\big)^2 \text{ [31]}$$

4.1.1. Financing choice
The entrepreneur's financing decision is given by:

$$\Delta U(SC, z) = U_{VC} - U_{Bank} \text{ [32]}$$

The introduction of adverse selection does not alter the structure of the model. Family social capital continues to affect the financing choice through two channels: it improves borrowing conditions and increases effective risk aversion. The difference is that the borrowing advantage is no longer imposed exogenously, but arises endogenously from the reduction of informational asymmetries. This extension therefore provides a micro-foundation for the baseline specification and shows that the main qualitative results are robust to the presence of adverse selection.

4.2. Alternative specifications of the utility function

As a robustness check, we reformulate the entrepreneur's problem under constant absolute risk aversion (CARA) preferences. While the baseline mean-variance specification offers a reduced-form representation of prudential behavior, CARA preferences provide a fully micro-founded expected utility framework.

Preferences are defined as:

$$u(x) = -\exp(-\eta x), \qquad \eta > 0 \text{ [33]}$$

where η is the Arrow-Pratt (Pratt, 1976) coefficient of absolute risk aversion. Consistent with the baseline model, family social capital affects risk attitudes through a preference channel:

$$\eta(SC) = \eta_0 + \kappa SC, \qquad \kappa > 0 \text{ [34]}$$

4.2.1. Bank financing

Under bank financing, the entrepreneur's payoff is:

$$X_{Bank} = \begin{cases} \alpha e - \theta(SC) & \text{with probability } p \\ 0 & \text{with probability } 1-p \end{cases} \text{ [35]}$$

where borrowing conditions improve with social capital:

$$\theta(SC) = \theta_0 - \gamma SC, \qquad \gamma > 0 \text{ [36]}$$

Expected utility is:

$$\mathbb{E}[U_{Bank}(\eta, SC)] = -\,p \exp\Big(-\eta(SC)\big(\alpha e - \theta(SC)\big)\Big) - (1-p) \text{ [37]}$$

Since the constant term $-(1-p)$ does not affect optimization, we consider the normalized expected utility:

$$\widetilde{U}_{Bank}(\eta, SC) = -\,p \exp\Big(-\eta(SC)\big(\alpha e - \theta(SC)\big)\Big) - \frac{e^2}{2} \text{ [38]}$$

The entrepreneur chooses effort e solving:

$$\max_e \widetilde{U}_{Bank}(\eta, SC) \text{ [39]}$$

yielding the first-order condition:

$$p\,\eta(SC)\alpha \exp\Big(-\eta(SC)\big(\alpha e - \theta(SC)\big)\Big) - e = 0 \text{ [40]}$$

which implicitly defines the optimal effort $e^*_{Bank}(\eta, SC)$.

4.2.2. Venture capital financing

Under venture capital financing, the entrepreneur's payoff is:

$$X_{VC} = \begin{cases} (1-s)(\alpha e + \beta i) & \text{with probability } p \\ 0 & \text{with probability } 1-p \end{cases} \quad [41]$$

Expected utility is:

$$\mathbb{E}[U_{VC}(\eta, SC)] = -p\, exp\big(-\eta(SC)(1-s)(\alpha e + \beta i)\big) - (1-p) \quad [42]$$

Dropping the constant term and subtracting effort cost, normalized utility is:

$$\widetilde{U}_{VC}(\eta, SC) = -p \exp\big(-\eta(SC)(1-s)(\alpha e + \beta i)\big) - \frac{e^2}{2} \quad [43]$$

As in the baseline model, the VC chooses managerial effort i to maximize profits, yielding $i^* = sp\beta$. Given i^*, the entrepreneur solves:

$$\max_e \widetilde{U}_{VC}(\eta, SC) \quad [44]$$

which implies the first-order condition:

$$p\,\eta(SC)(1-s)\alpha \exp\big(-\eta(SC)(1-s)(\alpha e + \beta i^*)\big) - e = 0 \quad [45]$$

defining optimal entrepreneurial effort $e^*_{VC}(\eta, SC)$.

4.2.3. Financing choice

The entrepreneur compares utilities across regimes. Venture capital is preferred whenever:

$$\Delta\widetilde{U}(\eta, SC) = \widetilde{U}_{VC}(\eta, SC) - \widetilde{U}_{Bank}(\eta, SC) > 0 \quad [46]$$

Because CARA preferences penalize downside risk more strongly as $\eta(SC)$ increases, higher family social capital strengthens prudential behavior while simultaneously improving borrowing conditions. This interaction mirrors the price and preference channels of the baseline specification and implies the existence of a threshold level of effective risk aversion $\eta^*(SC)$ such that venture capital is preferred for $\eta(SC) < \eta^*$, while bank financing becomes optimal for $\eta(SC) > \eta^*$.

4.3. Nonlinear Effects of Family Social Capital

The baseline specification assumes that family social capital affects borrowing conditions and risk aversion in a linear way. While this reduced-form representation is useful for tractability and for highlighting the core trade-off of the model, it abstracts from potentially important nonlinearities in the way family social capital affects the two channels.

In this section, we relax the linearity assumption and allow family social capital to affect $\theta(SC)$ and $\rho(SC)$ in a nonlinear way. We assume that family social capital SC exhibits diminishing returns in reducing borrowing costs, and increasing marginal effects in shaping risk aversion.

4.3.1. Nonlinear Borrowing Conditions

Let $\theta(SC)$ be the parameter that captures the borrowing conditions, as in the baseline model. We posit now that $\theta(SC)$ is a decreasing and concave function of family social capital:

$$\theta'(SC) < 0, \quad \theta''(SC) > 0 \text{ [47]}$$

A convenient functional form consistent with these properties is:

$$\theta(SC) = \theta_0 - \gamma\left(1 - e^{-\phi SC}\right), \quad \gamma, \phi \text{ [48]}$$

where ϕ represents the sensitivity of borrowing conditions to family social capital: higher values of ϕ imply that even small increases in family social capital significantly reduce borrowing costs.
This specification captures diminishing marginal improvements in borrowing conditions as social capital increases. The economic intuition is that family social capital can facilitate access to bank credit enhancing the trust of the lender. However, once lenders have acquired sufficiently precise information about the borrower, additional increments in family social capital generate progressively smaller informational gains. As a result, the increase in family social capital generates decreasing marginal borrowing costs.

4.3.2. Nonlinear risk aversion
Let $\rho(SC)$ denote the risk aversion. We posit that:

$$\rho'(SC) > 0, \quad \rho''(SC) > 0 \text{ [49]}$$

A simple functional form satisfying these properties is:

$$\rho(SC) = \rho_0 + kSC^v, \quad k > 0, v > 1 \text{ [50]}$$

where v controls the curvature of effective risk aversion with respect to family social capital. This convex specification reflects the idea that the socio-emotional and reputational costs associated with failure increase more than proportionally with family embeddedness. When family social capital is low, incremental increases have a limited effect on perceived downside risk, by contrast, for highly embedded entrepreneurs, additional increases in family social capital amplify reputational exposure and concerns, leading to a more pronounced increase in risk aversion.

4.3.3. Implications for the Financing Choice
The main qualitative predictions of the model remain unchanged. Family social capital continues to affect the financing choice through two distinct channels: a borrowing conditions channel and a preference channel. However, allowing for nonlinear effects highlights that the interaction between these two channels may generate richer comparative statics, including non-monotonic responses of the financing decision to social capital. In particular, the existence and uniqueness of a switching threshold between bank financing and venture capital are preserved under standard regularity conditions. However, the position of this threshold and its sensitivity to model parameters depend on the relative curvature of $\theta(SC)$ and $\rho(SC)$. Overall, this extension shows that the baseline linear specification can be interpreted as a first-order approximation of a more general nonlinear relationship, and that the core insights of the model are robust to more flexible and economically grounded functional forms.

5. Discussion and conclusion

This paper examines the choice of the entrepreneur between venture capital and bank financing. This decision remains theoretically and practically consequential: although equity financing offers entrepreneurs greater scope to pursue high-growth objectives (Lerner and Leamon, 2023; Cumming et al., 2023; Evans and Jovanovic, 1989), a substantial body of research shows that venture capital continues to account for only a modest share of overall entrepreneurial finance relative to commercial bank lending (Honjo and Yoshida, 2025; Miglo, 2022). Prior work has largely framed the debt–equity choice as a core trade-off between the profit motive (e.g., Kirzner, 1999; Schumpeter, 1934) and the

control motive (e.g., Sapienza, Korsgaard, and Forbes, 2003). However, relatively little research has considered additional factors with both theoretical and practical relevance to explain the variation in this trade-off. We focus on two such factors – entrepreneurial family social capital and risk aversion – and theorize how they impact the choice between debt and equity within well-known agency settings.

We advance the idea that distinct mechanisms influence the balance between the benefits of VC value-added (managerial contributions) and the costs of entrepreneurial effort dilution when equity is ceded to the VC. Absent these mechanisms, higher levels of VC productivity direct the choice toward venture capital; accordingly, VC financing is more likely where VCs can provide substantial managerial value-added (de Bettignies and Brander, 2007). These mechanisms involve family social capital and risk aversion. Family social capital reduces borrower–lender agency frictions, thereby improving access to credit. We refer to this mechanism as the price channel. At the same time, family involvement is associated with higher entrepreneurial risk aversion. Because failure can jeopardize family reputation, relational networks, and family wealth, entrepreneurs who draw on family social capital perceive un-certain outcomes as more costly. Family social capital therefore signals to banks not only lower tolerance for risk but also greater prudence in corporate governance and managerial decision-making. We refer to this mechanism as the preference channel. As a result, the positive effect of family social capital on debt operates through both channels: reduced agency conflicts and higher risk aversion, therefore, facilitating access to bank credit. Ultimately, there exists a threshold level of effective risk aversion such that venture capital is preferred over bank financing. Family social capital affects this threshold through both borrowing conditions and prudential behavior, implying that effective risk aversion is endogenous to social capital.

5.1. Directions for future research

Our model also yields a set of empirically testable propositions concerning the role of entrepreneurial family social capital and risk aversion in shaping financing choices. The model predicts a negative relationship between risk aversion and the preference for venture capital financing, as well as an interaction effect between family social capital and risk attitudes. In particular, family social capital simultaneously improves access to bank debt through more favorable borrowing conditions and strengthens prudential behavior by increasing effective risk aversion. As a consequence, social capital reshapes the risk-aversion threshold separating the two financing regions rather than mechanically shifting financing preferences toward bank debt. These predictions can be tested using proxies for entrepreneurs' risk preferences, relational lending intensity, and observed financing structures. For example, prior studies have operationalized risk aversion using survey-based measures (Kan and Tsai, 2006) or proxies grounded in individual asset allocation theory. The latter approach approximates risk aversion based on individuals' investment histories, such as stock market participation, among other indicators (e.g., Hvide and Panos, 2014). With respect to family social capital, because it is not directly observable and its benefits depend on the degree of family involvement, the literature has relied on measures that capture this involvement. Family involvement, which enables entrepreneurs to draw on family social capital, is commonly operationalized through indicators of family ownership, family governance, and family management (e.g., Chua et al., 2011). Family ownership is measured as the percentage of equity held by family members. Family governance is measured by the number of family members serving on the venture's board of directors or advisors. Family management captures the number of family members involved in managerial roles.

5.2. Managerial implications

Our analysis also yields several managerial implications. First, from the entrepreneur's standpoint, venture capital is most valuable when the new venture lies squarely within the VC's domain of expertise, enabling meaningful managerial value-added. Crucially, however, the effectiveness of VC contributions depends on the entrepreneur's growth orientation. It is not sufficient for the VC to have strong incentives to contribute; the entrepreneur must also be willing to accept equity dilution in

exchange for more variable future payoffs. In other words, VC financing is likely to be most beneficial when entrepreneurs pursue ambitious growth objectives and exhibit lower risk aversion. Second, VCs are more likely to achieve favorable outcomes when the entrepreneur's family social capital is limited. Where family social capital is high, the entrepreneur's role is decisive not only for the venture's performance but also for the financing choice. For VC investments to succeed, VCs typically require a sufficiently large equity stake to sustain their effort incentives. Yet such stakes necessarily dilute the entrepreneur's incentives and may trigger conflicts associated with reduced control. When entrepreneurs possess substantial family social capital, these costs loom larger than in cases where entrepreneurs are pivotal to the venture but lack family social capital.

5.3. Policy implications

Finally, our study also has implications for policy makers. The start-up ecosystem is widely regarded as a major engine of economic growth and job creation. At the same time, a well-developed venture capital industry is critical for fostering the emergence and scaling of successful start-ups (Gallo et al., 2025). Our findings can inform policymakers seeking to unlock the growth potential of start-ups by acting through distinct levers that encourage entrepreneurs to solve the traditional control–profit dilemma in favor of the latter, thus generating broad societal benefits.

In entrepreneurial ecosystems in which family capital is highly prevalent, the model predicts a systematic underutilization of venture capital due to both easier access to debt financing and greater risk aversion among entrepreneurs. Policymakers should therefore pursue targeted interventions aimed at unlocking the growth potential of startups that remains constrained by the traditional control–profit trade-off, often resolved in favor of control. Such interventions should focus on improving the institutional conditions for entrepreneurship, on programs directly targeting entrepreneurs, and on policies oriented towards the creation of entrepreneurial ecosystems (OECD, 2020).

With respect to the interventions aimed at improving the institutional conditions for entrepreneurship, policies should primarily emphasize the promotion of favorable attitudes and motivations among prospective entrepreneurs, as well as the removal of administrative and regulatory barriers to entrepreneurial activity (e.g., taxation, competitive practices, regulation). In this context, policies aimed at increasing awareness of the societal importance of new entrepreneurial ventures, the resources available to entrepreneurs, and the growth potential of startups are particularly critical. These efforts can foster an entrepreneurial culture oriented toward growth and innovation rather than toward dynastic stability.

Regarding the development of programs directly targeting entrepreneurs, contexts char-acterized by the systematic underutilization of venture capital require initiatives designed to address this "equity gap". Because entrepreneurs endowed with family social capital tend to be more risk averse and enjoy easier access to debt financing, the rationale for equity-oriented interventions is to stimulate the growth potential of startups that is often constrained by entrepreneurs' desire to retain control. In this respect, possible policy measures include the establishment of public sector venture capital funds; "hybrid" funds (Murray 2007), in which public resources are used to leverage private investment into funds managed by private-sector investment professionals—thereby reducing risk for private investors while increasing their expected returns; co-investment funds that invest alongside both venture capital funds and business angels; and the development of the fintech sector to facilitate alternative sources of finance.

Finally, the context in which entrepreneurship unfolds shapes entrepreneurial intentions, the entrepreneurial process, and firm growth (Stam, 2018; Spigel, 2017; Mason and Brown, 2014; Audretsch and Fritsch, 1994). Policies aimed at supporting the development of entrepreneurial ecosystems thus seek to promote a favorable, comprehensive, and well-integrated environment for venture creation and growth.

Appendix A – Proof of Proposition 3

Under mean-variance preferences, utility in each regime takes the form

$$U = \mathbb{E}[X] - \frac{\rho(SC)}{2}\mathrm{Var}(X), \quad [51]$$

where $\rho(SC)$ denotes effective risk aversion. Hence, higher effective risk aversion reduces utility whenever the entrepreneur is exposed to payoff variability.

Since venture capital financing leaves the entrepreneur with an equity claim on project returns, it involves greater payoff variability than bank debt. Therefore, an increase in $\rho(SC)$ reduces U_{VC} more than U_{Bank}, implying that the utility difference $\Delta U(\rho(SC))$ is decreasing in effective risk aversion:

$$\frac{\partial \Delta U}{\partial \rho(SC)} = -\frac{1}{2}\left(\mathrm{Var}(X_{VC}) - \mathrm{Var}(X_{Bank})\right) < 0 \ [52].$$

For low levels of effective risk aversion, the entrepreneur values upside exposure and venture capital may be preferred, implying $\Delta U(\rho(SC)) > 0$. For sufficiently high effective risk aversion, the disutility from payoff variability dominates and bank financing becomes more attractive, implying $\Delta U(\rho(SC)) < 0$.

Since $\Delta U(\rho(SC))$ varies with $\rho(SC)$ and decreases monotonically, there exists a threshold level ρ^* such that

$$\Delta U(\rho(SC)) \begin{cases} > 0 & \text{if } \rho(SC) < \rho^*, \\ < 0 & \text{if } \rho(SC) > \rho^*. \end{cases} \quad [53]$$

This establishes the existence of a cutoff level of effective risk aversion separating the regions in which venture capital and bank financing are preferred. Because $\rho(SC)$ increases with social capital, higher social capital anticipates the switch toward bank financing.

From Compliance to Purpose: Governance Models for Sustainability Innovation

MARIA CRISTINA LONGO [1□] ROSARIA FERLITO[2] ROSARIO FARACI[3*] PAOLA LA PORTA[4∞]

Abstract

Frame of the research. *Sustainable Corporate Governance research has mainly focused on ESG performance and board characteristics. Limited attention has been given to how governance supports sustainable innovation in SMEs, particularly in purpose-driven firms.*

Purpose of the paper. *This study aims to understand which Sustainable Corporate Governance models enable purpose-driven SMEs to develop sustainable innovation.*

Methodology. *The study adopts a multiple case study methodology involving three Italian purpose-driven SMEs. Data were collected through semi-structured interviews and triangulated with secondary sources. Cross-case analysis was conducted to compare governance structure and functioning and related innovation patterns.*

Results. *The findings show that sustainable innovation in purpose-driven SMEs is supported by the combination of founder leadership and governance formalization. Purpose-driven leadership provides strategic direction, while higher levels of formalization contribute to greater stability and a more long-term orientation.*

Research limitations. *The qualitative nature of the study limits the generalizability of the findings. Moreover, the governance configurations identified reflect conditions at a specific moment in time.*

Managerial implications. *This research provides insights for SMEs seeking to strengthen their governance systems to better support sustainable innovation. The study helps managers assess whether their current governance system enables or hinder innovation efforts and identify areas where formalization or purpose alignment may be required.*

Originality of the paper. *This study advances sustainable innovation and Sustainable Corporate Governance research by shifting attention from ESG outcomes to how governance supports innovation in founder-driven SMEs. It introduces a purpose-centred perspective and highlights the role of decision coherence as a central outcome of governance formalization for sustainable innovation.*

Keywords*: Sustainable corporate governance, sustainable innovation, governance structure, governance functioning, SME, purpose-driven organizations.*

1. Introduction

In recent years, corporate governance research has shown a growing interest in sustainability. Environmental and social challenges increasingly require firms to move beyond short-term financial logics and peripheral corporate social responsibility initiatives, calling instead for governance mechanisms capable of long-term orientation. Within this perspective, Sustainable Corporate Governance (SCG) has emerged as a central lens through which scholars examine how sustainability considerations are integrated into firms' core decision-making processes. This shift is reinforced by the recognition that sustainable innovation is a systemic and long-term organizational process, characterized by high uncertainty and short-term economic trade-offs (Seebode et al., 2012; Silvestre & Țîrcă, 2018; Ferlito & Faraci, 2025). Far from being manageable through peripheral CSR activities, sustainable innovation requires strategic coherence, continuity of resources, and firm-wide commitment, conditions that corporate governance is uniquely positioned to support (Boons et al.,

[1♦] Professoressa Ordinaria di Economia e Gestione delle Imprese – Università degli Studi di Catania – Dipartimento di Economia e Impresa. e-mail: mclongo@unict.it

[2·] Ricercatrice di Economia e Gestione delle Imprese – Università degli Studi di Enna "Kore" – Dipartimento di Scienze Economiche e Giuridiche. e-mail: rosaria.ferlito@unikore.it

[3*] Professore Ordinario di Economia e Gestione delle Imprese – Università degli Studi di Catania – Dipartimento di Economia e Impresa. e-mail: faraci@unict.it

[4∞] Dottoranda in Economia e Gestione delle Imprese – Università degli Studi di Catania – Dipartimento di Economia e Impresa. e-mail: paola.laporta@phd.unict.it

2023; Sarpong et al., 2022). Governance thus serves as the infrastructure that enables firms to respond effectively to environmental shifts while maintaining a consistent sustainability trajectory.

The SCG literature has increasingly examined how governance mechanisms incorporate sustainability objectives into firms' decision-making systems (Mazaj et al., 2022). Prior studies emphasize the role of board composition (e.g. independence, diversity, size, workload), ownership structures (e.g. CEO/Chair separation), and formalization (e.g. committees, procedures, metrics) in shaping long-term orientation (Ludwig & Sassen, 2022). Some contributions further highlight that formalization is particularly critical in SMEs (Brunninge et al., 2007; Daily, & Dalton, 1992; De Massis et al., 2015), where ownership and control often overlap and rapid decision-making may become a vulnerability without appropriate counterbalances and codified rules (Chrisman et al., 2025).

Despite this growing attention, a significant gap persists regarding how SCG concretely supports sustainable innovation development, especially in SMEs. Much of the existing literature has focused on sustainability performance, reporting, and ESG practices (Michelon et al., 2015), whereas less attention is devoted to how governance models, rather than isolated governance practices, enable or hinder sustainable innovation (Scherer & Voegtlin, 2020). Yet sustainable innovation requires firms to re-design products, processes, and organizational solutions in ways that align economics, environmental and social objectives (Longo & Cardillo, 2024). Understanding how governance configurations facilitate this process remains an open question.

This gap becomes even more salient when firms adopt a purpose-driven orientation. A growing research stream conceptualizes corporate purpose as a firm's explicit aim to address societal challenges; positioning sustainability as a guiding principle embedded in corporate governance (George et al., 2023; Hollensbe et al., 2014). When authentically embedded, purpose guides investment priorities and helps manage stakeholder tensions, ensuring strategic coherence, resource continuity, and legitimacy; when merely symbolic, it risks inconsistency and loss of credibility.

Starting from these considerations, our research aimed to understand which SCG models enable SMEs to develop long-term sustainable innovations.

To address this question, we conducted an exploratory multiple case study, involving three SMEs characterized by strong sustainability orientation, but different levels of governance system and rules formalization.

This study provides several insights into how SMEs govern sustainable innovation. First, it reveals that governance supports sustainable innovation through the interaction between founder's leadership and governance structures. Second, sustainable innovation is shown to rely on structured processes that ensure consistency in decision-making. Third, legitimacy is found to be pivotal for maintaining continuity and credibility.

This paper consists of six sections. After the introduction in Section 1, we present the theoretical background in Section 2. Section 3 describes the research design, while Section 4 presents the findings. Section 5 is dedicated to discussion and Section 6 concludes by highlighting contributions, limitations and future research directions.

2. Theoretical Background

2.1 Sustainable Innovation

Sustainable innovation is conceptualized as a socially grounded process in which innovators engage with multiple stakeholders to ensure the ethical acceptability and societal relevance of innovation processes and outcomes (Mazaj et al., 2022; Ferlito, 2024). Within this broad perspective, corporate governance plays a foundational role (Xu & Bai, 2019). It operates as a form of meta-responsibility that creates the conditions under which social, environmental and technological initiatives can emerge, develop and persist over time (Voegtlin & Scherer, 2017).

Strategically, sustainable innovation entails reorienting corporate strategy so that environmental and social objectives influence resource allocation decisions and long-term competitive aims (Hart,

1995; Longo & Cardillo, 2025; Porter & Kramer, 2011). For example, this strategic shift includes adopting sustainable business models that decouple value creation from resource use and developing low-carbon strategies supported by investments in clean technologies (Bocken et al., 2014; Ferlito & Faraci, 2022; Geissdoerfer et al., 2017).

At organizational level, sustainable innovation manifests through changes in internal structures, routines, and learning processes (Damanpour, 1991). It involves revising managerial processes, coordination mechanisms, and internal arrangements so that environmental and social considerations become embedded in everyday organizational activities (Du Plessis, 2007).

At product level, it entails modifying product architectures, production technologies, and material choices to reduce environmental and social impacts across the life cycle (Hallstedt et al., 2013).

Taken together, these dimensions indicate that sustainable innovation cannot be developed through isolated managerial initiatives, but requires governance arrangements capable of aligning strategic intent, organisational processes and technological choices.

2.2 Board of Directors' structure and functioning in Sustainable Corporate Governance

SCG refers to the governance structures and processes through which sustainability objectives are embedded in firms' strategic decision-making and control systems (Berrone et al., 2023).

Within this perspective, a first stream of SCG research examines how board structure influence ESG performance and practices. Among structural attributes, board independence is the most widely investigated as the presence of non-executive directors presumed to exercise objective monitoring functions (Kang et al., 2007). Studies show that board independence is positively associated with higher ESG performance and more extensive sustainability disclosure (Ludwig & Sassen, 2022; Yang et al., 2024; Brogi & Lagasio, 2025).

Board size, represented by the number of directors serving on the board, is another frequently examined attribute (Correa-García et al., 2020). Larger boards provide broader expertise, more diverse professional backgrounds and stronger external connections, which enhance firms' capacity to address sustainability issue (Chatjuthamard et al., 2022). Consistently, board size correlates positively with higher-quality sustainability disclosure and more consolidated CSR reporting practices (Ludwig & Sassen, 2022). However, research also finds that such benefits hold only up to an optimal threshold, beyond which coordination and communication problems reduce board effectiveness (Treepongkaruna et al., 2024).

Board diversity has also as a critical determinant of sustainability orientation. Boards with higher gender diversity tend to exhibit greater stakeholder sensitivity, ethical orientation, and engagement with sustainability issues (Chen et al., 2016; Konadu et al., 2022). A larger proportion of women directors is associated with higher ESG performance (Terjesen et al., 2009; Mensi-Klarbach, & Seierstad, 2020). Similarly, nationality diversity, represented by the presence of foreign directors, enhances ESG reporting quality and rigorous by broadening the board's cultural and institutional perspective (Ellili, 2023).

A second stream of SCG research focuses on board functioning in pursuing sustainability. Ownership concentration is a key structural mechanism influencing managerial discretion over sustainability strategies. Concentrated control tends to limit stakeholder-oriented decisions, reinforcing short-term pressures (Correa-García et al., 2020; Ludwig & Sassen, 2022; Yang et al., 2024). Block holder ownership is negatively associated with both environmental performance and CSR orientation (Shaukat et al., 2016). Conversely, dispersed ownership supports more stakeholder-oriented behaviours. Leadership structure also matters: CEO duality, when the same individual occupies both the CEO and chair positions, reduce board monitoring capacity and is negatively associated with environmental performance; while leadership separation, when the roles of CEO and board chair are attributed to different individuals, promotes a more balanced long-term stakeholder orientation (Shaukat et al., 2016; Naciti, 2019).

Founder leadership, in this context, reflects the entrepreneur's values, vision, and discretion in shaping strategic priorities, including sustainability-oriented choices (He, 2008). However, when

governance structures remain informal, strategic direction tends to be enacted through personalized decision-making processes, limiting the development of stable organizational routines (Brunninge et al., 2007). Conversely, when founder leadership and governance are treated as overlapping, sustainability-oriented decisions risk being interpreted as outcomes of governance, even if they primarily reflect individual discretion. This makes it difficult to establish whether strategic orientation is anchored in organizational arrangements or remains contingent on the founder's influence, raising the question of how such orientation can be sustained beyond the founder level.

Finally, SCG effectiveness depends on the degree of formalisation of governance mechanisms. Formalisation refers to the codification of roles, procedures and accountability structures that reduce discretion (Pugh et al., 1968). Applied to sustainability, it captures the extent to which ESG responsibilities are institutionalised through formal policies, charters and documented processes, rather than delegated to informal practices or left to managerial discretion (Hamad et al., 2024; Brogi & Lagasio, 2025).

Overall, existing SCG literature highlights how board structure and board functioning contribute to firms' sustainability orientation. However, a key research gap remains. Current studies rarely investigate how the governance mechanisms affect firms' capacity to pursue sustainable innovation through a purpose purpose-driven approach. This gap opens the way for examining how boards can enable sustainability not only through oversight and disclosure but through the strategic alignment of purpose, innovation, and sustainability objectives.

2.3 Purpose-driven Sustainable Corporate Governance

Corporate purpose has progressively shifted from a symbolic expression of organizational identity to a governance principle that shapes how firms interpret their role in society (George et al., 2023). Across the managerial literature, purpose is conceptualized as the reason why a firm exists: a guiding logic that goes beyond profit maximization and seeks to align economic goal with social and environmental needs (Jimenez et al., 2021). Unlike mission and vision, which describe what a firm does or aspires to do, purpose clarifies why it acts, thereby influencing stakeholder relationships and governance arrangements (Hollensbe et al., 2014).

Recent studies (Cucino et al., 2025) highlight the difference between firms that merely declare a purpose and those that are genuinely purpose-driven. Purpose-driven firms integrate pro-social objectives into their core business logic, ensuring that purpose is not confined to rhetorical statements but permeates strategic decision-making and organizational processes (George et al., 2023). This orientation is often grounded on internal factors such as managerial values, ethics and pro-social attitudes. In SMEs, particularly the founder's personal values, ethical beliefs, and cultural background play a pivotal role in shaping the firm's purpose, which tends to be deeply rooted in the entrepreneurial identity and strongly aligned with community-oriented and relational logics (Mariani et al., 2023; De Massis et al., 2018; Aguinis & Glavas, 2019).

The rise of corporate purpose is also interpreted as a response to external pressures and institutional tensions that challenge traditional business models. Purpose is framed as a reaction to systemic grand challenges, rising inequality, declining trust, technological disruption, and environmental degradation, that render conventional shareholder-oriented strategies insufficient (Jimenez et al., 2021; Longo & Cardillo, 2025). These pressures are reinforced by global institutional frameworks such as the Sustainable Development Goals (SDGs), which increasingly shape expectations regarding firms' societal contributions (Mahajan et al., 2024).

Overall, the SCG literature suggests that both governance structures and purpose orientation shape how firms interpret their economic, social and environmental role. Yet, while purpose clarifies why firms act, corporate governance determines how such intentions are translated into strategic and operational choices. Existing research has not yet clarified how purpose interacts with sustainable corporate governance mechanisms and, specifically, how purpose-driven governance supports sustainable innovation. To better understand the relationship between purpose and sustainable innovation, it is therefore relevant to examine how governance mechanisms influence

firms' ability to develop and prioritize sustainability-oriented innovation. This provides the basis for the final research stream: the link between corporate governance, purpose determination and sustainable innovation.

2.4 Corporate Governance and Sustainable innovation

SCG can be understood as a set of governance dimensions that create the conditions under which sustainable innovation is prioritised and supported over time. These dimensions concern how boards define innovation priorities, allocate resources, and legitimize sustainability-oriented projects within the organization.

A first SCG dimension concerns how boards set priorities for sustainability-oriented innovation. Boards that are independent, inclusive and heterogeneous are more likely to promote sustainable innovation, as they can challenge short-term managerial biases and integrate stakeholder perspectives into strategic decision-making (Xu & Bai, 2022; Cek & Ercantan, 2024). This priority-setting ability is closely connected to the decision quality, understood as the extent to which boards base their evaluations and judgments on systematic information processing rather than intuitive or short-term oriented assessments (Martínez-Ferrero & García-Meca, 2020).

A second dimension concerns resources allocation. SCG influences how financial, human and organisational resources are deployed to support sustainability-oriented innovation. As governance mechanisms become more structured, firms are better able to channel resources toward innovation initiatives that ehnance organisational resilience and environmental stewardship (Helfaya & Aboud, 2023; Martínez-Ferrero & García-Meca, 2020). By formalising sustainability criteria through tools such as impact assessments and ESG risk indicators, governance ensure that sustainability systematically informs budget decisions and innovation portfolio choices (Aras & Crowther, 2008; Kayikci et al., 2022).

A third dimension concerns the institutional legitimisation of sustainability-oriented innovation. Governance contributes by strengthening transparency and accountability, reducing the risk of stakeholder contestation (Cek & Ercantan, 2024; Mocciaro Li Destri et al., 2024). Governance practices that promote more reliable disclosure of environmental and social performance enable stakeholders to assess firm's conduct more effectively, reinforcing trust and organisational legitimacy (Xu & Bai, 2022; Saeed et al., 2024).

Taken together, these dimensions show that sustainable innovation also depends on the governance mechanisms that prioritise, resource, and legitimise sustainability-oriented initiatives. However, existing literature has not yet integrated these mechanisms into a coherent governance perspective, particularly in purpose-driven firms.

Three main research gaps emerge: (1) the lack of a governance perspective on how specific mechanisms shape sustainable innovation; (2) Limited understanding of how purpose orientation modifies or strengthens the governance mechanisms over time, particularly in purpose-driven firms; and (3) limited understanding of how sustainable corporate governance and purpose orientation interact to steer long-term sustainable innovation.

Addressing these gaps is particularly relevant to assess whether and how purpose drives the alignment of governance systems and sustainability-oriented innovation, thereby motivating the following research question: *How do sustainable corporate governance mechanisms interact with founder-driven purpose to support long-term sustainable innovation in SMEs?*

3. Research Design

3.1 Methodology

Case selection. The study adopts a multiple case study approach (Yin, 2009), focusing on Italian SMEs within the biomaterials, biotechnology, and wine sectors. In line with a purposive sampling strategy (Suri, 2011), the sample was selected to reflect the specific aims of the study, which focus

on sustainable innovation. Only firms recognized as top-tier performers in sustainability innovation were considered eligible for inclusion. Accordingly, firms were intentionally selected based on their demonstrated excellence and strong commitment to sustainable innovation, as documented in sustainability reports, investor-oriented disclosures, and sustainability-related awards received.

Firm 1 develops a sustainable, high-end leather alternative by transforming recycled orange and cactus waste into durable textiles. Firm 2 is a biotech Benefit Corporation and a spin-off of a family-owned plastics firm. It specializes in the extraction and production of microalgae compounds. Firm 3, a family-owned winery, has launched sustainable Sicilian wine by reinterpreting tradition practices through high-quality viticulture.

In all cases, these are founder-led SMES, where leadership is vested in the entrepreneur, who also serves as CEO.

Data collection and Triangulation. The analysis focuses on the following dimensions: Founder/CEO leadership; Board structure and functioning; Corporate purpose; Degree of governance formalization; Patterns of sustainable innovation.

The data collection followed a multi-step process involving primary and secondary sources, data analysis and findings.

Primary data were collected through semi-structured interviews with founders (or one of them)/CEOs. They were complemented by secondary sources, including official corporate websites, sustainability and impact reports, certifications, press releases and institutional documents, economic databases (AIDA Bureau Van Djik, 2026). The interview protocol was aligned with the study's objectives and the aforementioned literature-derived dimensions.

Interviewees were contacted by email and mobile to introduce the research goals and clarify in advance the content of the questions. Each engagement began with a two-hour recorded presentation. Following the transcription of these presentations, semi-structured interviews featuring open-ended questions were conducted in a subsequent phase. Interviewees were also asked to provide supporting documentation and sources for their answers.

Table 1 reports the interview structure adopted and the main topics.

Table 1. Interview Framework

Leadership & Purpose ● Number of co-founders ● Company overview ● Sustainability purpose & strategy alignment
Board Structure ● Board mechanisms: ➢ Size ➢ Gender diversity ➢ International diversity ➢ Independence ➢ Board workload ● Ownership: ➢ Ownership concentration ➢ Leadership separation ➢ ESG-linked Incentives ● Degree of board formalization: ➢ Charters, regulatory obligations, ESG reporting, ESG or sustainability Committees ➢ Climate and sustainability risk management ➢ Motivation to codification (normative or voluntary)
Board Functioning ● Board orientation and coordination on sustainability: ➢ Inclusiveness ➢ Sustainability expertise in the board ● Assessment of the Sustainability-related decision making

➢ Sustainability performance monitoring ● Resources allocation to sustainability ● Strength of external validation mechanisms: ➢ Interaction with Chief Sustainability Officer ➢ Stakeholders' relationship ➢ Institutional legitimacy ➢ Certifications
Purpose-driven Sustainable Corporate Governance ● Corporate Governance's purpose and values ● Motivation of key actors: ➢ Mission-driven, Opportunistic, Reactive, or Rule-based motivation ➢ Hybrid motivations (strategic + ethical) ● Internal factors and managerial tensions: ➢ Balancing economic vs. sustainability tensions ● External factors and institutional tensions: ➢ Stakeholder-driven ➢ Market-based ➢ Sustainability regulatory based ● External innovation enablers (technology hubs, innovation ecosystem)
Sustainable Innovation/ Solution ● Circular innovation process and circular economy practices ➢ Eco-design approach ➢ Sustainable materials selection ➢ Environmental impact ➢ Energy efficiency ➢ Waste reduction ● Digitalization ➢ Digital technologies enabling sustainability (AI, IoT, LCA tools) ● KPIs and measures of sustainable innovation performance

Source: our elaboration

To ensure empirical consistency, primary data were triangulated with secondary data, covering the period 2022-2025. The analysis was conducted by each sustainability dimension and cross-checked with secondary data, before final case results were elaborated. The table 2 reports the triangulation activity.

Table. 2. Integration between primary and secondary data

Company overview ● Official firms' websites ● Italian Business Register official website ● Italian Chamber of Commerce (CCIAA) ● Italian Trade Agency Official Website (ICE) ● Annual Financial Statements ● Press releases (2022-2025)
Board structure and functioning ● Corporate governance disclosure on official websites ● Sustainability/ESG Committee charters ● ESG-linked compensation ● Third-party ESG ratings ● National Corporate Governance Code references
Purpose-driven Sustainable Corporate Governance ● Interviews with corporate leadership (CEO/Founders) ● Mission, purpose and values statements on corporate websites ● Codes of Ethics and Codes of Conduct ● Stakeholder engagement documents ● Impact Valuation Report 2024 (*Firm 2*) ● Sustainability Report (*Firm 3*)
Sustainable Innovation ● Innovation & Technology Hubs (Intesa Sanpaolo Innovation Center)

- Awards & Institutional recognition (Eni Award 2023 - *Firm 2*)
- Start-cup ecosystem (*Startup Italia 2025 - Firm 1*)
- Accredia/DNV GL Certification Reports (2025 Firm 3)
- University–industry collaborations and Partnership (MUSA Scarl – *Firm 2*)

Source: our elaboration

Data Analysis. The data analysis followed a structured and iterative process. First, detailed case overviews were developed for each firm by integrating primary interview data with secondary sources, including corporate documents, sustainability reports, and institutional materials. This step enabled the construction of contextualized accounts of each case, capturing governance configurations, purpose orientation, and sustainable innovation practices (Eisenhardt, 1989).

The analysis was conducted in two sequential stages. In the first stage, a within-case analysis was performed for each firm. Each case was examined along the three core analytical dimensions identified in the research design: board structure and functioning, corporate purpose, and sustainable innovation. Pattern matching methods were used to compare empirical observations with the theoretical dimensions derived from the literature (Yin, 2009).

In the second stage, a cross-case analysis was conducted to identify similarities and differences across cases. This comparative analysis enabled the identification of recurring patterns and the development of more generalizable insights regarding the role of Sustainable Corporate Governance in supporting sustainable innovation in purpose-driven SMEs. Following an iterative approach, cases were systematically compared (Eisenhardt & Graebner, 2007). Specifically, the results are presented in comparative tables (Table 3-6), placing firms in relation to the specific dimensions of their governance system and sustainable innovation.

To enhance the robustness of the analysis, interpretation process was conducted independently by the authors and subsequently compared. The convergence of interpretations across researchers strengthened the reliability of the findings (Miles & Huberman, 1994).

3.2 Company Overview

Firm 1 - Innovative Sustainable Leather from Agro-Industrial Waste

Firm 1 produces a bio-based alternative to animal leather, which is also sustainable and cruelty-free. It uses by-products of Sicilian oranges and cactus as raw materials. Through a patented circular-economy process, it converts agro-industrial waste, such us orange peels and cactus leftovers, into a high-performance treated material using recycled polymers. The resulting product is soft, durable, and visually comparable to luxury leather. The material serves several industries, primarily luxury fashion (apparel, footwear and accessories), interior design, automotive, and occasionally nautical furniture. The founder is a textile designer woman and pioneer in sustainable materials. The Co-founders are respectively an engineer specializing in development and operations with experience in the automotive sector and a chemist, who contributed to the development of the material.

The innovation lies in patenting a material derived from citrus pulp and prickly pear cladodes. Unlike other bio-based materials, it is designed for industrial scale production and aims to transform the landscape of vegan material. In 2023, the company reported revenues of €48.150,00. In 2024, revenues increased to €77.291,00. Through a partnership with the Italian Trade Agency (ITA), firm 1 has gained international visibility as representative of "Made in Italy" innovation.

It also collaborates with the Municipality of Milan to position its material as a sustainable market alternative. These achievements are recognized by certifications and awards such as the VVV+ label (to guarantee that products are 100% animal-free), and the Eni Award, granted by the President of Italy for contributions to environmental research and decarbonization.

Firm 2 - Innovative Sustainable Microalgae-based Biotechnology

Firm 2, registered as a Benefit Corporation, is an innovative startup operating in experimental research and development in the biotechnology sector. It specializes in producing and extracting compounds from microalgae, integrating CO_2 into its processes as part of a circular-economy model.

Production employs eco-friendly solvents for the industrial-scale cultivation of microalgae such

as Chlorella and Spirulina. Its innovation lies in the use of advanced technologies for indoor cultivation under controlled environmental conditions, enabling the production of high-value compounds with a level of purity unattainable through outdoor systems The extracted and formulated microalgae-based compounds target various sectors, including agriculture and nutraceuticals. In 2024, the firm reported revenues of €281,762, reflecting a 3.67% increase from the 2023 figure of €271,786.

This improvement demonstrates an enhanced ability to generate margins from its core business. The firm received Scientific Approval from an Italian university, whose researchers provided chemical and physical validation confirming the sustainability of the production process. It was also recognized with the Start Cup competition award, a prestigious regional competition for high-tech entrepreneurship.

Firm 3 - Innovative Sustainable Viticulture and Wine Production

Firm 3 is a family-owned business founded in 1983 in Italy and has played a key role in revitalizing local wine production. It shifted from standardized methods to a model of high-quality, sustainable viticulture, characterized by low yields (approximately 50 hectoliters per hectare). Its commitment to environmental stewardship is exemplified by the practice of "heroic viticulture" in a small island, where grape cultivation occurs under extreme geographical conditions, performed entirely by hand, without chemical fertilizers, and with systematic monitoring of carbon and water footprints. Firm 3 aligns its operations with the EU Green Deal and published its first Sustainability Report in 2025. It has expanded its presence to 65 countries, transitioning from local sales to a wide digital e-commerce, which grew by 400% in 2020.

A multi-year partnership with a leading fashion brand has further elevated its market positioning, particularly through the launch of the 2024 limited-edition wine, which strengthened the brand's identity as a model of local innovative and sustainable craftsmanship. The firm has been recognized by UNESCO for its commitment to the environmental protection and landscape conservation. Additionally, it holds the Bio Suisse organic certification, valid in both the EU and Swiss markets, and the ISO 50001 certification, which attests to the presence of an energy management system.

4. Findings

The multiple-case analysis reveals a relationship between founder-driven purpose and governance system in developing sustainable innovation. Following we report the results for each firm and then a comparative analysis.

Firm 1, operating in the bio-materials sector, is characterized by a founder-controlled and low-formalized board. The three founders compose a small, non-independent board and retain full ownership. Although governance is concentrated, external financial support comes from accelerators and Italian institutional investors: the former strengthens sustainability-oriented innovation capabilities, while the latter focus on early-stage financing.

The firm is led by a female CEO, and all board members share the same nationality. The company is not legally required to adopt sustainability governance mechanisms and lacks a dedicated sustainability committee, confirming low formalization.

Nevertheless, governance remains limited in formal mechanisms, while sustainability orientation is primarily driven by the founder's leadership style formally acknowledged through the "Women's Enterprise Recognition," listing the firm among the top 100 Italian women-led excellence cases.

Decision-making quality is supported by a Life Cycle Assessment (LCA) conducted with an independent partner, which monitors the carbon footprint while ensuring material durability. The LCA sets thresholds for carbon footprint and durability that determine whether a material can be adopted. The screening process excludes conventional materials that fail to meet sustainability targets

and directs experimentation toward bio-based alternatives derived from agricultural waste. As a result, material selection becomes a structured decision process that channels innovation toward circular solutions.

Resource allocation follows the same logic. Governance directs investments toward bio-based materials, stabilization processes, and performance testing. Concentrated ownership places evaluation and funding decisions in the same decision locus, allowing founders to commit resources directly to selected projects without additional approval layers. The coupling between funding decisions and technical development shortens experimentation cycles and supports the advancement of sustainable material solutions. A similar approach governs production and value-chain decisions. Value-chain traceability is ensured through digital tools such as QR codes and dedicated platforms. Each production output is verified against predefined compliance requirements before moving forward. The verification step filters out suppliers and processes that do not meet sustainability standards and directs sourcing and production toward certified inputs. As a result, traceability operates as a selection mechanism that stabilizes decisions.

External validation emerges through the firm's ability to build high-quality partnerships, participate in sustainability-oriented networks, and obtain public funding. Access to these relationships depends on meeting predefined requirements, so decisions on materials, suppliers, and production processes must be validated externally before being confirmed.

Its purpose is anchored in circular-economy principles, value-chain transparency, and cruelty-free production. This orientation stems from the CEO's educational and professional background—combining fashion studies, chemistry-lab experience, and deep knowledge of the local context—and is reinforced by industry-level pressures such as the environmental impact of leather production and opportunities for collaboration with fashion, furniture, and automotive companies.

Despite operating under limited mandatory sustainability requirements (e.g., REACH, PROP65, VVV+), the firm voluntarily adopts practices that exceed regulatory obligations. Motivation is primarily driven by self-realization and the strategic use of the CEO's prior experience, reflecting an opportunity-oriented purpose logic.

A combination of mechanisms explains these outcomes: LCA-based evaluation defines viable options, concentrated governance enables rapid resource allocation, purpose establishes stable decision criteria, and external validation reinforces their consistent application, leading to circular material innovation. It follows a bio-circular model that uses agricultural waste (orange peels and prickly pear residues) combined with recycled polymers. Solar panels installed in partnership with an energy provider improve energy efficiency. QR-code-based traceability, a zero-waste approach, and carbon and water footprint monitoring further strengthen the firm's bio-circular and traceability-driven innovation model.

Firm 2, active in biotechnology and centered on microalgae-based solutions, has a one-member board, with the founder serving as both sole director and owner. Governance is therefore non-independent, and ownership is fully concentrated in the Italian CEO. The firm reports no external financial investors. As a Benefit Corporation, it is legally required to disclose sustainability practices and publishes an Impact Valuation. It also has a Scientific Advisory Board composed of external academic researchers, contributing to a high level of governance formalization.

Governance functioning is influenced by inclusive female leadership and supported by an interdisciplinary team of engineers, agronomists, and business specialists, which also promotes local talent retention. Technical competences are brought into the same decision process, allowing the firm to assess whether each innovation choice is scientifically feasible, operationally manageable, and economically viable.

Decision-making follows a value-creation logic that directly links environmental resources to economic outcomes. CO_2 and biological inputs are treated as productive resources, and investment decisions are evaluated based on their ability to generate both environmental and economic value. Resource allocation prioritizes patenting sustainable extraction processes and developing carbon-

neutral logistics with local farmers.

External validation comes from university-based scientific approval and recognition through the regional competition. Scientific validation operates as a selection mechanism: only processes that meet academic standards of reliability and replicability are pursued. This reduces experimentation based on unverified assumptions and directs development toward solutions with proven scientific grounding.

The firm's purpose centers on creating sustainable economic and social value, particularly through CO_2 valorization in production. This orientation stems from the CEO's multidisciplinary background, architecture studies, entrepreneurial family experience, and business expertise, and is reinforced by external drivers such as a research center partnership and application of the 231 Organizational Model. Regulatory and institutional requirements introduce formal constraints that structure decision-making, requiring documentation, and accountability in project development. Each project must satisfy these conditions before proceeding, which limits the range of feasible options and directs investment toward processes that are compliant. Innovation therefore concentrates on solutions that can be validated and scaled within a regulated environment. The firm's recent financial turnaround further shapes its purpose logic, resulting in a family-driven, reactive orientation.

Therefore, three mechanisms explain the findings: scientific validation selects technically viable solutions, formal governance requirements restrict the range of feasible options, and resource allocation concentrates efforts on scalable applications of biological inputs, leading to circular and zero-landfill innovation. The sustainability innovation derived follows a circular model with end-of-life disassembly principles, using biological raw materials from recycled plastics and industrial residues. Energy efficiency is supported by a temperature-monitoring system that minimizes thermal impact. Real-time material-flow monitoring ensures process traceability. Given its emphasis on waste reduction, disassembly, and recovery, the firm's sustainability innovation can be characterized as zero-landfill and circular-design oriented.

Firm 3, active in viticulture and wine production, has a four-member board, two of whom are founders and co-CEOs. The board shows medium independence, and ownership is concentrated in the two founder-directors, who share the same nationality. The firm reports no external financial investors. Although not legally required to provide sustainability reporting, it published its first Sustainability Report in 2024. It also has an agronomic committee composed of internal specialists and external consultants, including an entomology expert, indicating a medium level of governance formalization.

Governance functioning reflects inclusive, gender-balanced leadership: one out of four board member is a woman, and the organizational culture emphasizes valuing individual contributions. Decision-making is supported by a formal management and control model based on the firm's ethical code, supplemented by a whistleblowing system for internal oversight. The presence of both formal control systems and specialized committees introduces multiple decision checkpoints, requiring production choices to be justified against ethical, environmental, and technical criteria before implementation. Choices that do not meet these criteria are not pursued, which directs innovation toward practices that preserve environmental quality and meet certification standards.

Resource allocation focuses on "heroic viticulture," a chemical-free cultivation method carried out in challenging environmental conditions. Investment decisions prioritize practices that preserve soil integrity and adapt to local environmental constraints, even when these choices increase operational complexity. The directs resources toward cultivation techniques, monitoring systems, and inputs that maintain long-term land productivity.

External validation comes from several certifications and recognitions, including a partnership with a leading fashion brand, UNESCO acknowledgment for sustainable practices, Bio Suisse certification, and ISO 50001 for energy management. Access to and maintenance of these certifications require compliance with strict environmental and production standards.

The firm's purpose is expressed through the idea of acting as "Guardians of the Earth,"

emphasizing local production, territorial value, and minimizing anthropogenic impact to preserve soil fertility for future generations. A key driver of this purpose orientation is the view of sustainability as a value-generating investment. The purpose logic is shaped by external forces such as pressure from Northern European markets requiring quality certifications and alignment with EU Green Deal guidelines. The purpose introduces long-term decision criteria: production and investment choices must preserve soil fertility, maintain ecosystem balance, and sustain territorial value.

Sustainability innovation reflects the combined effect of the governance mechanisms described above. It includes lightweight, chemical-free material design, monitoring of carbon and water footprints, and soil-preservation practices. Energy efficiency is supported by solar panel systems enabling both self-production and energy selling, complemented by precision-viticulture techniques. The firm also employs satellite monitoring and field sensors for process traceability.

These solutions are selected and developed because they satisfy multiple decision conditions: they preserve soil fertility, comply with certification requirements, and meet technical and environmental evaluation criteria. Its waste-reduction policy is based on circular viticulture, transforming organic waste into soil-restorative fertilizers, characterizing its sustainability innovation as preservation-based.

In order to highlight similarities and differences we compare the three case studies according to governance model (board structure and functioning and corporate purpose) and sustainable innovation dimensions. The following four tables (Table 3-6) report the comparative results.

Table 3. Corporate Governance Structure

Board Structure	**Firm 1**	**Firm 2**	**Firm 3**
Board Size	3 members	1 member	4 members
Gender Diversity ***(% women/ total members)***	1 woman out of three	1 woman	1 woman out of four
International Diversity	Absent (100% Italians)	Absent (100% Italians)	Absent (100% Italians)
Independence ***(#independent directors/total directors)***	Zero outsider directors	Zero outsider directors	Two outsider directors
Ownership Concentration	High, split among three owners	Maximum (the unique Director is the owner)	High, split among two owners
Leadership separation	Low separation – founder-controlled board; CEO is also founder; no independent chair.	No separation – single-member board; founder is sole director, CEO, and owner.	Low separation – dual leadership concentrated in two founder-CEOs; no independent chairperson.
Degree of board formalization	Absence of sustainability report, regulatory obligation, or sustainability committee	High: Benefit Corporation status; mandatory "Impact Valuation" (annual report) and Preventive Plans	"2024 Sustainability Report" Absence of regulatory obligation; Whistleblowing system.
Sustainability Committees	Absent	Scientific Advisory Board including external academic researchers	Agronomic committee with external consultants and one agronomist specialized in entomology
Key Highlights of Corporate Governance Structure	**Small-sized board, high-concentrated ownership, low degree of formalization**	**Maximum ownership and board concentration, high degree of formalization**	**High ownership and board concentration, medium degree of formalization**

Table 5. Purpose-driven sources

Corporate Purpose	Firm 1	Firm 2	Firm 3
Purpose and values	Circular economy, transparency, and cruelty-free/animal-free production.	Sustainable economic and social value creation; CO_2 valorisation.	Being "Guardians of the earth"; Promoting local production and territory value while minimizing the anthropogenic footprint; Leaving fertile soil for future generations
Motivation of key actors	Self-realization; Strategic leverage of past experiences	Family-business financial turnaround	Commitment to future generations; Research on strategic differentiation factors
Internal factors and tensions	Sustainability-focused background (fashion studies, chemical lab experience); Strong local knowledge	Sustainability-focused background (architecture studies); Second-generation entrepreneur with family business background; Business knowledge	Sustainability as value - creating investment
External factors and institutional tensions	Alternative to leather industry pollution; Partnership with fashion, furniture, and automotive industries; Low compliance (REACH, PROP65, and VVV+ Animal-Free labels)	Research Center partnership; 231 Model	Pressures from northern European markets demanding quality certifications; Alignment with the EU Green Deal.
External innovation enablers	Accelerators and institutional investors	University partnership. Local recognition.	Industry partnership
Key Highlights of Purpose-driven Sources	**Self-oriented, opportunistic purpose with low compliance commitment**	**Family-driven, reactive purpose aligned with high compliance commitment**	**Future-oriented purpose with high compliance commitment**

Source: our elaboration

Table 6. Circular Sustainable Innovation

Sustainable Innovation/Solution	Firm 1	Firm 2	Firm 3
Circular innovation process and practices: *Eco-design*	Circularity-oriented design Durable and flexible packaging	Disassembly based end-of-life design	Lightweight material design
Circular innovation process and practices: *Sustainable materials selection*	Bio-based and recycled raw materials from agricultural sources; Recycled polymers	Bio-based raw materials from recycled plastics and industrial residues	Chemical-free raw materials
Circular innovation process and practices: *Environmental impact*	Carbon-footprint reduction; Water pollution reduction	Carbon circularity model	Carbon-footprint reduction Water-footprint reduction Soil fertility preservation
Circular innovation process and practices: *Energy efficiency*	Solar cells implementing partnership	Thermal minimization impact: temperature monitoring	Solar panels; Energy self-production and sell; Precision viticulture technicals
Circular innovation process and practices: *Waste reduction*	Zero Waste: circular processes	Zero-waste-to-landfill: circular processes	Circular viticulture: Organic waste valorization through composting to soil-restorative fertilizer
Digitalization	Product-level QR-code traceability	Digital platforms for real-time material-flow monitoring	Satellite monitoring and field sensors
Key Highlights of Circular Sustainable Innovation	**Bio-circular and traceability based**	**Disassembly and zero-landfill based**	**Preserving-based**

Source: our elaboration

5. Discussion

This study advances the SCG literature by explaining how governance supports sustainable innovation in purpose-driven SMEs, a context largely overlooked compared to large corporations. While prior research has examined governance structures, sustainability reporting, and board characteristics in established firms, little is known about how governance systems interact with entrepreneurial leadership to support long-term sustainable innovation in SMEs. In detail, the findings clarify the mechanisms through which governance influences sustainable innovation, showing how decision processes, resource allocation, and validation practices connect governance configurations to innovation outcomes.

Findings reveal that sustainable innovation is supported by the interaction between founder-driven purpose and corporate governance. This interaction effect operates at different levels: founder leadership defines the initial sustainability orientation, while governance outlines whether such orientation is translated into consistent and organization-wide decision-making. Without a clear separation, sustainability outcomes may be attributed to governance, while they are still driven by the founder's decisions.

Consistent with prior research, in resource-constrained SMEs, effective progress depends less on technology adoption and more on early design choices that embed sustainability principles into core processes (Maxwell & Van der Vorst, 2003; Ferlito & Faraci, 2022).

Evidence indicates that sustainability orientation originates from founder-driven purpose. It legitimizes sustained investment despite short-term financial pressures (Bhattacharya et al., 2023), making sustainability a constitutive element of corporate identity (Jones-Khosla & Gomes, 2023; Longo & Cardillo, 2025). While purpose-driven orientation allows rapid action and experimentation, it does not ensure consistent decision-making when initiatives scale or financial constraints intensify. This refines existing research on purpose-driven organizations (George et al., 2023). Although internalized purpose strengthens intrinsic motivation and cooperation (Bhattacharya et al., 2023), our evidence shows that, without appropriate governance formalization, purpose can inadvertently increase dependence on individual leaders. As a result, sustainable innovation remains tied to individual decisions rather than being sustained through organizational processes. Thus, this study extends SCG research by identifying a non-traditional role for governance formalization. Previous

studies typically associate formalization with compliance, monitoring, and reporting (Pugh et al., 1968).

Our evidence suggests instead that appropriate level of formalization supports stabilizes sustainable innovation paths, by translating the founder's purpose into consistent organizational practices. Even "light-touch" mechanisms, such as independent advisors, help limit selective participation (Michelon & Parbonetti, 2012) by establishing procedural discipline and standardized routines (Peters & Romi, 2014). Furthermore, external pressures (investor scrutiny in Firm 1; customer expectations in Firm 3; environmental-industry requirements in Firm 2) also reinforce governance formalization, consistent with Cui and Wang (2022), and Nazari et al. (2015). Collectively, these findings reveal that purpose orientation and governance formalization are mutually reinforcing, enabling sustainable innovation without constraining entrepreneurial initiative.

A second theoretical insight concerns decision-making processes. Prior SCG research stresses how boards improve decision quality on sustainability through deliberation, information processing, and structured evaluation (Berrone et al., 2023).

Our findings extend this perspective by showing that, in the context of sustainable innovation, the primary challenge is not only to make good decisions at discrete points in time, but to preserve coherence across successive decisions.

In particular, sustainability-oriented innovation requires organizations to remain consistently aligned with shared sustainability criteria and long-term objectives across strategic, technological, and resource allocation choices. We conceptualize this capability as decision coherence, defined as the ability to maintain consistency among interdependent decisions when sustainability goals are characterized by uncertainty, trade-offs, and delayed returns.

Formalized governance structure, as observed in our case studies, play a critical role in sustaining decision coherence by providing stable reference criteria and shared standards against which decisions are evaluated (Galbreath, 2018).

Formal reporting practices, advisory bodies, ethical codes, certifications, and control systems emerge as institutionalized decision anchors that guide sustainability-oriented innovation and help ensure its continued alignment with long-term goals. By contrast, when governance structures are weakly formalized, decision-making tends to rely more heavily on situational and ad hoc assessments. This may preserve the quality of individual decisions while simultaneously generating fragmentation and drift across the innovation trajectory.

These findings invite a shift in the SCG literature from the focus on decision quality toward greater attention to decision coherence as a distinct and largely overlooked governance dimension. Whereas decision quality refers to the soundness and robustness of a specific choice, decision coherence captures the continuity and alignment among multiple decisions over time that collectively sustain sustainable innovation pathways. As such, decision coherence represents a promising theoretical contribution for understanding how governance mechanisms shape long-term sustainability outcomes beyond isolated decision episodes.

A third theoretical insight concerns legitimacy for ensuring continuity and credibility to sustainable innovation pathways. Existing SCG literature examines legitimacy as an outcome of transparency, accountability, and stakeholder alignment with their expectations. Authors (Cek & Ercantan, 2024; Saeed et al., 2024) mainly emphasize legitimacy in reducing contestation and enhancing organizational credibility. Legitimacy is primarily associated with disclosure quality, compliance, and formal accountability mechanisms.

Our findings show that, in purpose-driven SMEs engaged in sustainable innovation, legitimacy is not merely a reputational asset; it is an enabling condition for innovation continuity. Certifications, scientific partnerships, awards, and institutional recognitions reduce perceived risk and facilitate access to strategic resources, such as external finance, knowledge sharing, and market access, which are essential for sustaining capital-intensive sustainable innovation. This insight complements studies emphasizing the board's role in mediating between external pressures and long-term strategic objectives (Kavadis & Thomsen, 2022; Mocciaro Li Destri et al., 2024). It extends SCG research by

showing that governance-generated legitimacy not only enhances accountability but also enables access to critical resources, allowing SMEs to pursue long-term innovation pathways.

6. Conclusion, Contributions and Future Research

This study fills a key gap in the sustainable corporate governance (SCG) literature by showing how governance supports sustainable innovation in purpose-driven SMEs.

The study advances SCG research in several ways. First, it links board orientation and governance formalization to sustainable innovation pathways. Second, it shifts attention from ESG outcomes to the processes through which governance supports innovation. Third, it introduces a purpose-centered view of governance, where purpose acts as a strategic compass and formalization provides the operational map. Finally, it proposes SCG models specific to founder-driven SMEs, showing how purpose-driven leadership, ownership concentration, and governance formalization interact.

Empirically, the three cases illustrate distinct governance models. Firm 1, a biomaterials start-up, combines low formalization with strong purpose-driven leadership, enabling experimentation and ecosystem partnerships. Tools such as Life Cycle Assessment and digital traceability enhance innovation coherence.

Firm 2, active in biotechnology, pairs concentrated ownership with a more formalized governance system, including a scientific advisory board, mandatory impact reporting, and codified procedures. This configuration reduces mission drift and stabilizes decision-making. Firm 3, a family-owned wine producer, exhibits a hybrid model integrating a partially independent board, formal governance instruments, third-party certifications, an ethical organizational model, and a strong purpose orientation centered on environmental stewardship. Its innovation pathway is preservation-based, focused on reducing environmental footprints, protecting soil, and adopting digital monitoring systems. These elements position the firm between purpose-driven and compliance-driven governance archetypes.

Across all three cases, however, a common pattern emerges: governance mechanisms, regardless of their level of formalization, serve to translate the founder's purpose into coherent, long-term sustainability-oriented decisions.

The study offers several practical implications. For entrepreneurs and SME leaders, introducing light touch formalization (e.g., sustainability committees, ESG linked incentives, clear board selection criteria) can strengthen resilience in informal, purpose driven firms. In compliance driven contexts, promoting inclusive leadership and reinforcing purpose internalization help avoid box ticking behaviors.

For policy makers and investors, establishing minimum formalization standards can enhance accountability while preserving entrepreneurial agility. Overall, the study highlights the importance of aligning corporate purpose with governance formalization to sustain sustainable innovation.

This research has several limitations. It examines three purpose-driven SMEs, while broader cross-industry or cross-country comparisons could reveal different governance–purpose interactions. The qualitative data capture governance models at a single point in time; longitudinal studies could examine how such models evolve as firms grow. Moreover, stakeholders beyond founders and boards also warrants deeper investigation.

Future research could investigate how purpose–governance interactions vary across institutional contexts, whether specific combinations of ownership concentration, board composition, and formalization lead to distinct SCG archetypes, and how founders' identities, values, and socioemotional wealth shape long-term sustainable innovation pathways.

Heuristic shortcuts in Technology Acceptance Model: The cognitive architecture of perceived usefulness in the zero-emission vehicle market

VITTORIO MARIA GARIBBO, ELEONORA ANNUNZIATA, FRANCESCO RIZZI, MARCO FREY

Abstract

Frame of the research. *Consumers' evaluations of emerging sustainable technologies are shaped by uncertainty, complexity, and limited familiarity. Although TAM research has extensively examined predictors of Perceived Usefulness (PU), little is known about how consumers cognitively assemble PU when faced with multiple interdependent attributes typical of sustainability-oriented innovations.*

Purpose of the paper. *The study investigates the structure of the utility function underpinning PU in zero-emission mobility, comparing Battery Electric Vehicles (BEVs) and Fuel Cell Electric Vehicles (FCEVs), and assessing how attribute hierarchies evolve across technologies and information frames.*

Methodology. *We conduct a rank-ordered logit (Rologit) experiment using vignette scenarios that vary five attributes capturing product-level, ecosystem-level, and policy-driven features. The design is implemented across four groups (BEV vs. FCEV; explicit vs. blind) to test whether attribute weights shift with technological labels or information structures.*

Results. *Findings reveal a highly stable and recurrent utility structure across all groups. Four of the five attributes remain consistently significant, with robust coefficient signs across conditions. This stability suggests reliance on satisficing heuristics rather than analytical evaluation. The hierarchy, dominated by use-phase savings, charging/refueling time, and infrastructure-related range anxiety, persists even when misaligned with the actual technology.*

Research limitations. *The vignette-based design may simplify real-world decision complexity, and results are limited to zero-emission mobility in a single national context.*

Managerial implications. *Consumers appear to "delegate" technical trade-offs to firms and policymakers, focusing instead on pragmatic, experiential attributes. Competitive advantage will depend on infrastructure robustness, pricing models, and support services rather than technology-centric narratives.*

Originality of the paper. *The study extends TAM's cognitive foundations by revealing how bounded rationality shapes PU formation and demonstrates the value of cross-sample Rologit designs to uncover stable consumer heuristics.*

Keywords: *Technology acceptance model; Perceived usefulness; Green mobility; Sustainable technology; Heuristics and Bounded Rationality; Rank-Ordered Logit Model (Rologit)*

1. Introduction

The imperative to transition global production and consumption paradigms toward sustainable, low-carbon models has catalysed a fundamental reconfiguration of carbon-intensive industries. While firms have to assume the role of eco-innovators, developing radical alternatives that must reconcile emission reductions with evolving market expectations (McMeekin and Southerton, 2012; Rizzi et al., 2014), consumers now confront a landscape populated by pioneering and often immature innovations, marked by heightened technological complexity and "fluctuating market conditions" (Ziegler and Abdelkafi, 2023).

The automotive sector epitomizes these dynamics. As a primary contributor to global GHGs (IEA, 2016; Larson et al., 2014; Wang et al., 2017), transportation has become a central target for policymakers (Lane and Potter, 2007; Ajanovic, 2015; Liao et al., 2017). A prominent example is the European Union's mandate to phase out internal combustion engine (ICE) production by 2035, a regulatory shock that has fundamentally altered the industry's strategic trajectory. Manufacturers, accordingly, have spent the past years developing and commercializing alternative vehicle technologies aimed at reducing carbon emissions (De Santiago et al., 2011), exploring a portfolio of technological pathways that must jointly ensure environmental compliance, maintain competitiveness, and meet consumer preferences. However, the systemic success of this transition is ultimately contingent upon consumer adoption (Chorus et al., 2013; Junquera et al., 2016), who face significantly higher uncertainty and cognitive load when evaluating innovative sustainable mobility technologies than when making conventional purchases (Calabrese and Tang, 2023; Du et al., 2024; Garibbo et al., 2025).

This evaluative ***uncertainty*** stems from the fact that sustainable mobility solutions - whether Battery Electric Vehicles (BEVs), hydrogen fuel cells (FCEVs), or synthetic fuels - cannot be appraised as "stand-alone" products. Rather, they are ecosystem-dependent innovations. Their market diffusion is inextricably linked to exogenous factors, including an evolving regulatory framework, the maturity of refuelling and charging infrastructures, and national investment strategies that dictate dominant technological trajectories. This systemic uncertainty is compounded by the ***technology's inherent complexity***, which requires users to engage in sophisticated trade-off analyses involving product performance metrics, long-term cost-benefit ratios, access to public subsidies, and prospective usage constraints. Consequently, although understanding the cognitive processes that foster consumer engagement is vital to accelerating the diffusion of sustainable mobility models, unpacking how consumers navigate a volatile, uncertain, and highly complex evaluative context remains profoundly challenging.

Within the broader landscape of behavioral theories, the Technology Acceptance Model (TAM) (Davis, 1989) offers a particularly suitable framework for examining the adoption of emerging technologies, especially in contexts where multiple technology-specific features and exogenous factors jointly shape consumers' decision processes (FakhrHosseini et al., 2024). At the core of the Technology Acceptance Model (TAM) lies the **Perceived Usefulness** (PU), which represents a key predictor of behavioral intention (Venkatesh, 2000) and describes the degree to which a person believes that "*using a particular technology will enhance his or her performance"* (Davis, 1989). However, in a context characterised by substantial technological complexity and high environmental uncertainty, the capacity of consumers to effectively assess the extent to which such technology will "*enhance his or her performance*" becomes severely constrained. Given that consumers must assess alternatives that are deeply technical, unevenly mature, and embedded in fluid regulatory and infrastructural ecosystems, the construction of Perceived Usefulness cannot be assumed to follow a linear or fully rational process.

Although numerous studies have applied TAM to green technologies and, more specifically, to the automotive domain (Yuen, 2021; Jaiswal et al.,2021; Shanmugavel, 2022; Lakshmanan et al., 2024), existing research predominantly employs the model in a straightforward, structural fashion, estimating relationships among established constructs through structural equation models (SEM).

While these contributions offer valuable insights into the antecedents of adoption, they leave a critical gap regarding the underlying cognitive synthesis through which consumers construct PU. Specifically, current literature fails to explicate the internal evaluative logic by which disparate, often conflicting inputs are weighted and integrated to shape PU when consumers are confronted with emerging, uncertain, and unfamiliar sustainable technologies. This study seeks to "open the black box" of PU by shifting the focus from static predictors to the dynamic hierarchical construction of utility, leading to the following research question:

RQ1. *How do consumers construct perceived usefulness when evaluating emerging green technologies under conditions of complexity and uncertainty?*

To address this research question, we employ a **discrete-choice experimental** design, utilizing a **Rank-Ordered Logit (ROLOGIT)** model. While traditional survey-based instruments often capture static, stated preferences, choice experiments simulate the trade-off environments inherent in real-world decision-making (Hyman and Steiner, 1996). By requiring respondents to rank attribute-based scenarios, the ROLOGIT model does not merely elicit latent preferences; it maps the hierarchical structure of the consumer's utility function, providing an empirical proxy for the internal logic used to construct Perceived Usefulness.

The experimental architecture adopts a **cross-sample comparative approach** across four treatment groups: Battery Electric Vehicles (BEV) and Fuel Cell Electric Vehicles (FCEV), each presented in both **explicit** and **"blind" (unlabelled)** formats. This multi-cohort design is specifically engineered to test the stability of the evaluative logic. By comparing the emerging utility functions across these four samples, we can determine whether consumers adapt their cognitive construction to the specificities of each technology (contextual rationality) or whether, faced with high uncertainty, they retreat to **standardized decision heuristics** that prioritize a consistent set of attributes regardless of the technological features. In doing so, the methodology directly addresses the identified gap by shifting from a measurement of *what* is preferred to an analysis of *how* usefulness is cognitively synthesized.

Our findings "open the black box" of Perceived Usefulness (PU) by demonstrating that, under conditions of profound uncertainty and evaluative complexity, consumers rely on **stable cognitive heuristics** to navigate the decision-making process. The identification of consistent PU construction patterns across all four experimental cohorts suggests that when consumers are unable to ascertain an objective optimum, they adopt systematic simplifications to mitigate cognitive load.

This study extends the TAM literature by demonstrating that beyond the identification of incremental predictors, it is essential to explicate the generative processes through which core constructs are formed. By revealing how individuals resolve decision trade-offs through simplification strategies, the study identifies the specific product attributes and informational cues that consumers prioritize when navigating unfamiliar technological landscapes advancing our understanding of decision-making under technological and contextual volatility. Managerially, these insights offer actionable guidance for firms and policymakers, pinpointing the critical levers required to alleviate cognitive barriers and foster the widespread diffusion of sustainable mobility innovations.

2. Theoretical Background

2.1. Evolution and Architecture of the Technology Acceptance Model

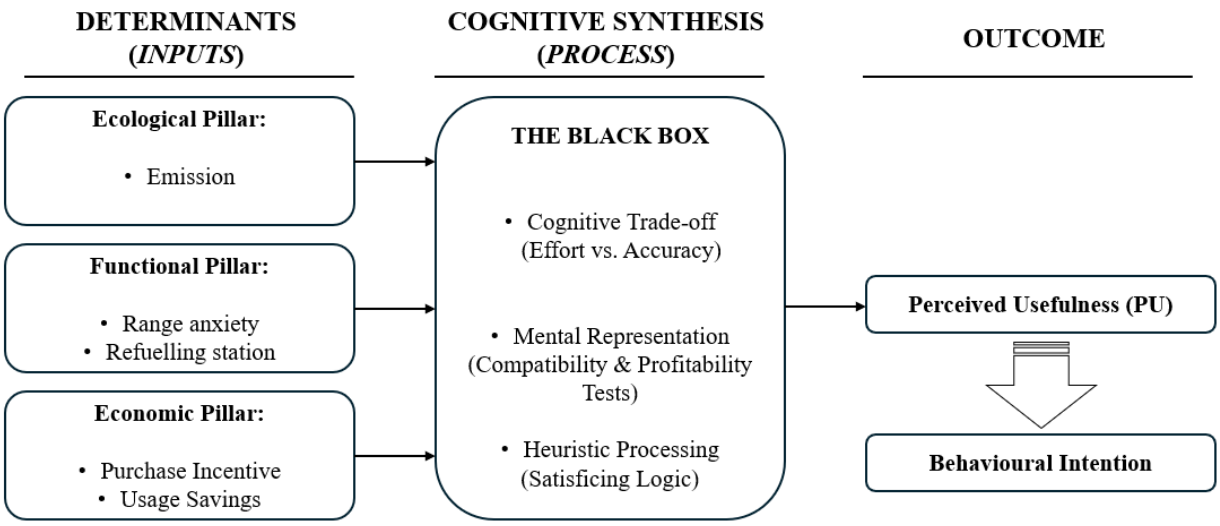
Among the various behavioral theories, a distinction is commonly drawn between theories that explain technology acceptance and adoption at the individual user level and those that conceptualize these phenomena at societal or cultural levels (FakhrHosseini et al., 2024). TAM is positioned as a holistic paradigm that transcends this dichotomy by synthesizing multifaceted dimensions of the adoption process. By integrating the heterogeneous characteristics of users, technical systems, and broader environmental and task-specific contexts, TAM provides a comprehensive analytical lens (FakhrHosseini et al., 2024). This integrative capacity is essential for capturing the nuanced interplay between consumer perceptions and the structural complexities inherent in modern socio-technical transitions.

Originally proposed by Davis (1989), TAM is rooted in cognitive-behavioral traditions, specifically the Theory of Reasoned Action (Fishbein and Ajzen, 1975) and the Theory of Planned Behavior (Ajzen, 1991). It conceptualizes adoption as a sequential process where cognitive beliefs shape intentions, which subsequently determine usage behaviour. Initially developed to examine IT adoption in organisational settings, TAM's foundational architecture relies on two primary belief constructs: **Perceived Ease of Use (PEOU)** and **Perceived Usefulness (PU)**. While early formulations included "attitude" as a mediator between these beliefs and intentions, subsequent

research demonstrated that attitude offered limited explanatory power (Legris et al., 2003). Consequently, refined versions of the model positioned PEOU and PU as direct predictors of behavioural intention.
Over time, the model has been extensively applied, tested, refined, and, crucially, expanded, particularly shifting attention toward unpacking the antecedents of TAM's two central belief constructs. **TAM2** (Venkatesh and Davis, 2000) incorporates social influence processes (subjective norms, voluntariness, and image) and cognitive instrumental processes (job relevance, output quality, and result demonstrability) as determinants of PU, alongside PEOU, which also functions as an antecedent of PU. A further elaboration came with **TAM3** (Venkatesh and Bala, 2008), designed to deepen understanding of the drivers of PEOU. In this extended model, PEOU is shaped by anchor variables, including computer self-efficacy, perceptions of external control, computer anxiety, and computer playfulness, and adjustment variables, such as perceived enjoyment and objective usability. Experience and voluntariness operate as moderating conditions influencing behavioural intention.
Despite these extensive refinements, PU remains the central driver within the framework. As noted by Venkatesh and Davis (2000), because PU is the fundamental determinant of usage intentions, it is critical to understand its underlying components, especially since PEOU often exhibits less consistent effects across different contexts. However, a significant distinction must be made between identifying the predictors of PU and understanding the cognitive process through which PU is constructed. While the existing literature has successfully isolated a wide range of predictors, the mechanism by which consumers weigh and integrate these diverse and often conflicting information inputs remains a distinct area of inquiry. This study shifts the focus from the identification of external drivers to the internal evaluative logic used by individuals to synthesize these inputs into a final judgment of utility. Understanding this integrative process is essential for explaining how perceived usefulness is formed in complex and uncertain technological environments.

2.2. The Cognitive Construction of Perceived Usefulness

Building on the extensive refinements of TAM and its emphasis on belief formation, an important next step is to unpack how individuals actually form judgments of PU. Perceived usefulness is defined as "*the degree to which a person believes that using a particular system would enhance his or her job performance. This follows from the definition of the word useful: capable of being used advantageously*" (Davis, 1989, p. 320). This definition underscores a performance-oriented cognitive evaluation: individuals assess whether a system/technology is *advantageous* relative to their work goals, implicitly engaging in a forward-looking judgment of expected utility. While originally applied to workplace productivity, in the context of broader technological innovation, this translates to the consumer's belief that adopting a new technology will effectively meet their needs while offering relative advantages over incumbent alternatives.
Understanding how this evaluation is constructed requires acknowledging the cognitive constraints under which individuals operate. Davis (1989) and Venkatesh & Bala (2008) explicitly note that usefulness assessments involve a cognitive trade-off between the effort required to employ the strategy and the quality (accuracy) of the resulting decision. This insight resonates with foundational work on bounded rationality (Simon, 1955) and dual-process models of judgment (Tversky and Kahneman; 1976; Kahneman, and Frederick 2002), which show that decision makers seldom engage in fully exhaustive analytical processing. Instead, when task complexity increases or information becomes difficult to integrate, individuals gravitate toward satisficing strategies, seeking an intermediate point between a computationally costly optimal analysis and a sub-optimal heuristic assessment. PU judgments therefore emerge from a cognitively efficient compromise: people evaluate potential performance gains while minimizing unnecessary mental effort.
From this starting point Venkatesh and Davis (2000) clarify the deeper cognitive mechanism by which individuals build a sense of usefulness. People form PU judgments partly by comparing what a system *can* do with what they *need* to accomplish. This comparison is grounded in a broader cognitive architecture that links actions to goals. Across work motivation theory, action theory, and



behavioral decision theory, research converges on the idea that behavior is guided by mental representations connecting higher-level goals to the instrumental actions believed to achieve them. For example, **work motivation theory** (Vroom 1964) highlights task-specific plans (Locke & Latham, 1990), which cognitively map sequences of acts to desired goals. Similarly, **action identification theory** (Vallacher & Wegner, 1987) posits identity structures that connect lower-level action descriptions to higher-level purposes, enabling individuals to regulate behavior toward meaningful ends. **Image theory** (Beach & Mitchell, 1996, 1998) provides an even clearer account of this process: individuals first screen alternative actions for "*compatibility*" with their standards and goals, and then, if multiple viable options remain, evaluate them in terms of their expected "*profitability*," that is, the extent to which they maximize desired outcomes. Both stages rest on assessing the match between one's goals and the perceived consequences of available action paths.
These converging theoretical streams support the core of TAM: individuals form PU judgments by evaluating how well using a system aligns with and advances important work goals. In other words, PU emerges from a cognitive assessment of the *use–performance contingency*: whether the action of using a technology is instrumentally suited to achieving valued outcomes. This perspective not only clarifies the internal process of usefulness evaluations but also provides the conceptual mechanism for modelling their formation as a systematic process of decision-oriented cognition, setting the stage for the analytical choices developed in the next section.

2.3. Zero emission vehicles and perceived usefulness formation

Building on the general cognitive mechanisms underlying the formation of PU in TAM, the next step is about contextualizing this process in the domain of zero-emission mobility by identifying which evaluations consumers actually mobilize when constructing the utility of adopting a zero-emission vehicle (ZEV). While the original TAM predictors, such as job relevance, output quality, or result demonstrability, were formulated within organizational and task-oriented contexts, consumer decisions involving technologically complex durable goods, such as electric and hydrogen-powered vehicles, hinge on a different set of considerations. Here, usefulness pertains not to work performance but to mobility performance, energy system integration, and the broader environmental implications of transport choices.
A substantial body of literature has examined the determinants and barriers shaping consumer adoption of electric and zero-emission vehicles across different geographical contexts. Although country-specific variations exist, studies consistently point to a common constellation of factors. For instance, Prakash et al. (2018) identified regulatory incentives and consumer traits as critical determinants of EV adoption in India, while Noel and Sovacool (2016) highlighted the interplay among social, technical, political, and environmental constraints in Denmark and Israel. Similarly, large cross-country reviews (Biresselioglu et al., 2018; Sierzchula et al., 2014; Berkeley et al., 2017) converge on a set of recurring barriers such as infrastructural limitations, economic costs, technological concerns, and attitudinal predispositions. Other studies further refine these dimensions by emphasizing financial factors, charging infrastructure, and vehicle performance issues (She et al., 2017), while stressing the importance of adopting an ecosystem perspective given the interdependencies among these barriers (Tarei et al., 2021).
Taken together, these studies reveal marked redundancy among the factors shaping consumer evaluations of ZEVs, suggesting an emerging consensus on the main determinants of PU in this domain. Recent TAM-based studies on electric mobility identify three overarching dimensions that structure consumers' assessments of usefulness: ecological performance, functional performance, and economic performance. These dimensions capture how consumers weigh environmental implications, operational capabilities, and cost-related considerations when evaluating ZEVs.
Ecological performance is salient because electric and hydrogen vehicles are positioned as eco-innovative solutions to mitigate transport-related emissions (Wu et al., 2020). Empirical work shows that environmental performance can rival or even outweigh price considerations in shaping purchase intentions (Degirmenci & Breitner, 2017), and that environmental knowledge influences perceptions

of the usefulness of green technologies (Masukujjaman et al., 2021). Consistent with this evidence, we incorporate the variable **Emissions**, which reflects the perceived environmental impact of ZEVs, a factor linked to the energy source used for charging or refuelling the vehicles.
The second major dimension, *functional performanc*e, captures the operational attributes consumers expect from a mobility product. The literature consistently identifies recharging/refuelling time (Carley et al., 2013; Chen et al., 2021; Degirmenci & Breitner, 2017), driving range and (Eccarius et al., 2023; Chen et al., 2021), and the availability of charging infrastructure (Wiedmann et al., 2011) as critical determinants of adoption. These concerns reflect users' attempts to minimize the risk and inconvenience associated with mobility disruptions. Drawing on this stream of research, we include two variables: **Range Anxiety**, capturing the discomfort associated with limited range and sparse charging options; and **Recharging Time**, representing the time required to replenish the battery or hydrogen tank, which is often perceived as inferior relative to traditional refuelling processes.
Finally, the *economic performance* represents a third foundational aspect, reflecting the monetary trade-offs consumers consider when comparing ZEVs to internal combustion engine vehicles (Harvey, 2020). Economic value is shaped by both upfront costs, often still higher than conventional vehicles, and operational savings derived from lower energy costs. National subsidies, tax exemptions, and infrastructure investments have played a decisive role in accelerating adoption in countries such as China, Norway, the Netherlands, and the United States (Bunsen et al., 2018). Accordingly, our model includes **Incentives**, capturing the role of public financial support in reducing the cost gap, and **Savings**, reflecting expected economic benefits during vehicle use due to lower charging or refuelling costs compared to fossil fuels.
Together, these five variables (Emissions, Range Anxiety, Recharging Time, Incentives, and Savings) represent the core determinants through which consumers in the ZEV domain construct the perceived usefulness providing a robust theoretical foundation for modelling how consumer build PU in the context of zero-emission mobility.
As illustrated in **Figure 1**, the construction of Perceived Usefulness in the ZEV context is conceptualised as a dynamic integration process rather than a linear summation of attributes. The model suggests that consumers do not evaluate the five identified determinants in isolation. Instead, these inputs enter a 'cognitive black box' where individuals perform a mental trade-off between the effort required to process technical complexities and the desired accuracy of their utility judgment. This evaluative logic, shaped by prevailing uncertainty in the transition environment, determines how these ecological, functional, and economic dimensions are weighted to form a final assessment of usefulness, which ultimately drives the intention to adopt.

Figure 1: Conceptual Framework of PU Construction in ZEV Adoption

3. Research methodology

3.1 Vignette-based method

Given this study's objective of uncovering how consumers construct PU of zero-emission vehicles, we adopted a vignette-based experimental methodology, specifically the constant-variable-value vignette (CVVV) approach (Cavanagh & Fritzsche, 1985). This method represents an advanced and widely applied refinement of the general vignette framework introduced by Alexander and Becker (1978).

In this experimental design, all respondents are presented with identical sets of vignettes, short descriptive scenarios of mobility, and are required to rank them according to their preference. Each vignette is defined by a unique configuration of the five attributes identified in the theoretical background (emissions, range anxiety, charging times, incentives, and savings). By ranking these scenarios, respondents generate consistent intra-respondent data that reveal their relative desirability, and, by extension, the latent salience assigned to each underlying attribute (Wason et al., 2002).

Vignette methodologies are particularly well suited to studying complex evaluative processes because they approximate real-world decision-making conditions and preserve contextual richness. As Hyman and Steiner (1996, p. 1) observe, vignettes "*offer a range of situational or contextual factors that approximate real-life decision-making situations*", enabling respondents to engage with multifaceted trade-offs more naturally than in abstract survey items.

This methodological choice is especially appropriate for our research aims for several reasons. First, the mitigation of **evaluative bias**. As a choice-based model, this methodology does not ask respondents to rate individual attributes in isolation. Instead, preferences are revealed through the ranking of scenarios. This is critical in the context of sustainable products, where traditional survey methods often suffer from social desirability and self-image biases. By focusing on relative ranking rather than absolute ratings, we effectively bypass these distortions to uncover more authentic latent preferences.

Second, the activation of **cognitive trade-offs**. The vignettes are carefully constructed so that no single scenario is objectively superior to the others across all attributes. This design forces respondents to engage in the cognitive trade-off described previously, balancing the effort required to evaluate complex information against the accuracy of their decision. This compels the consumer to navigate the space between an analytically exhaustive optimal analysis and a heuristic-driven sub-optimal assessment, thereby revealing their true decision-making "shortcuts."

Third, the alignment with **PU construction mechanisms**. Unlike binary choice models that merely identify a single "winner," the ranking process closely mirrors the dual-stage construction of Perceived Usefulness. As respondents order scenarios from most to least preferred, they implicitly replicate the compatibility test (screening out scenarios that violate their standards) and the profitability test (ordering viable options based on their perceived benefits). This procedural isomorphism ensures that the methodology is a direct empirical reflection of the theoretical process it seeks to measure.

Finally, we analysed the ranking data using a **Rank-Ordered Logit (ROLOGIT)** model, which estimates a utility function defined over the attributes embedded in the vignettes. Because these attributes were selected to represent the core determinants of perceived usefulness (i.e. the 5 variables), the resulting utility function serves as a **proxy for PU**. The ROLOGIT estimation enables us to derive the **hierarchy of attribute importance** and to uncover the underlying cognitive structure through which individuals organize information and resolve decision trade-offs. This hierarchy reflects the pattern by which respondents exclude undesirable options (compatibility) and prioritize promising ones (profitability), thereby illuminating the mental representation of usefulness that guides their evaluations of zero-emission mobility options.

In summary, by simulating the informational density and multi-dimensional trade-offs inherent in the transition to sustainable mobility, this methodology provides a controlled yet realistic lens through which to observe how consumers navigate **complexity and uncertainty**. It enables the identification

of the stable cognitive patterns and hierarchical simplifications that individuals employ to maintain evaluative agency in a volatile, technologically opaque landscape.

3.2 Survey design and sample

To investigate the formation process of PU, we chose not to restrict the analysis to a single technological product. Instead, we examined two distinct low-emission vehicle technologies: battery electric vehicles (BEVs) and hydrogen fuel-cell electric vehicles (FCEVs). Furthermore, to assess whether respondents' evaluations were influenced by prior predispositions, for example, those shaped by national policies, media narratives, or public discourse, we implemented a blind experimental condition for each technology. In these blind conditions, respondents evaluated the same set of scenarios as their non-blind counterparts, but without being informed of the specific technology under assessment. As a result, **the empirical analysis is based on four samples**: BEV, BEV-Blind, FCEV, and FCEV-Blind.

Two core elements of the research design deserve emphasis. The BEV and BEV Blind groups were subjected to an identical set of vignettes. The only experimental manipulation was the presence or absence of a technological identifier at the start of the survey (a stimulus stating that the survey was about BEVs vehicles). This ensures that any variance in the resulting utility functions between these two groups can be attributed solely to the influence of the "BEV" label and its associated pre-conditioned beliefs. The same logic was applied to the FCEV and FCEV Blind groups. Second, when comparing vignettes across the broader BEV and FCEV conditions, the content of the scenarios were qualitatively differentiated to reflect the intrinsic technological differences between BEVs and FCEVs. For instance, current BEV models typically require charging times that may reach up to eight hours, whereas commercially available FCEVs can refuel significantly faster. To ensure realistic and meaningful scenario evaluations, these differences were incorporated into the vignette designs. Nonetheless, the structural logic of the vignettes, i.e. the ways in which scenarios differ from one another, was held constant across all four samples. This means that if the variation between Scenario 1 and Scenario 2 involved, for example, an improvement in charging/refueling time and a deterioration in emissions performance, the magnitude and direction of these attribute changes were kept identical in all four experimental groups[1].

This architecture offers a distinct methodological advantage: it allows us to examine whether the cognitive mechanisms underlying PU are technology-specific or technology-general, and whether individuals rely on similar or different evaluative criteria when assessing emerging sustainable technologies. By observing patterns of reasoning across two technologies that differ in maturity, visibility, and public familiarity, we gain analytical leverage to disentangle whether PU arises from stable cognitive structures or from technology-related priors, expectations, and mental models.

Therefore, a pivotal stage of the experimental design is the rigorous construction of the scenarios. Following the established methodological framework proposed by Contini et al. (2020), the vignette development process was operationalized through four distinct phases: (i) attribute identification, (ii) specification of variation levels, (iii) the synthesis of attributes into coherent scenarios, and (iv) the elicitation of respondent preferences.

The identification of attributes (**Step 1**) aligns with the five variables discussed in the theoretical background: *emissions, range anxiety, charging times, purchase incentives, and operational savings*. For the definition of variation levels (**Step 2**), each attribute was operationalized across three distinct tiers (Levels 1, 2, and 3), representing a trajectory from current technological constraints to an idealized future state: Level 1 (Baseline Performance), which reflects the current technological and infrastructural landscape as of 2024. For instance, charging durations and driving ranges were calibrated to match the performance of existing mid-range electric vehicles. Level 2 (Projected Advancements) incorporates anticipated short-to-medium-term improvements. These values are derived from official industry roadmaps and policy frameworks, such as the European Hydrogen

[1] This is evident in table 3, where the column levels are exactly the same in the 2 group sets of scenarios, while the contents (i.e. the descriptions) change according to the respective technology.

Strategy, which outlines specific targets for refuelling infrastructure density. Level 3 (Technological Frontier) represents an optimal or "ideal" state for each technology. This level includes frontier solutions such as battery-swapping systems capable of replenishing energy in under 10 minutes that reflect the ultimate objectives of manufacturers and policymakers.

While the values at Level 3 may represent an aspirational rather than a current reality, their inclusion is theoretically motivated. The primary objective of this design is not to mirror the present market accurately, but to observe how systematic improvements across the variable levels impact the consumer's ranking of alternatives. By forcing respondents to evaluate these increments, the model can isolate the relative salience of each attribute, revealing which factors are most influential in the internal construction of Perceived Usefulness. The specific values for both BEV and FCEV samples are detailed in **Tables 1 and 2**, respectively.

Step 3, concerning the combination of attributes into coherent scenarios, represented both a delicate and essential phase of the research design. The guiding principle was to construct scenarios that simultaneously exhibited strengths and weaknesses, ensuring that none of them dominated the others across all variables. Each scenario was developed by assuming a different strategic emphasis among manufacturers and policymakers, thereby simulating how alternative national interventions and automaker investment priorities might plausibly shape future mobility landscapes. To avoid overwhelming respondents with excessive cognitive load during the ranking task, we limited the final design to seven scenarios. Six of these reflected distinct strategic trajectories, whereas the seventh acted as a deliberately inferior "dummy" configuration, set at the lowest possible level across all variables. This benchmark scenario functioned as a reliability check to confirm respondent attentiveness. The resulting design prevented the emergence of a clear optimal choice and required respondents to evaluate genuine trade-offs among competing mobility scenarios, thereby mirroring the complex decision environments characteristic of emerging sustainable technologies. **Table 3** presents the full set of scenarios.

Step 4 involved asking respondents to rank the seven scenarios from most to least desirable. These ordered evaluations generated quantitative evidence on the relative salience of each attribute and enabled us to infer the underlying hierarchical logic governing how individuals resolve complex trade-offs. This approach reveals the pattern of informational prioritisation that consumers employ when forming their judgments of Perceived Usefulness during the transition toward sustainable mobility solutions.

Table 1: BEV (labelled and blind) attributes, modalities of variation and associated weights

Attribute	Modalities of variation	Level
Range anxiety	450 km range; charging stations primarily located in urban centres.	1
	650 km range; charging stations available in urban centres and expanding along motorways.	2
	850 km range; infrastructure density equivalent to conventional fuel stations.	3
Charging times	~7 hours (Standard overnight/workplace charging).	1
	~5 hours (Accelerated charging).	2
	8-minute battery swapping or ultra-fast tank replacement.	3
Savings	2% reduction in running costs compared to petrol/diesel vehicles.	1
	30% reduction in running costs compared to petrol/diesel vehicles.	2
	60% reduction in running costs compared to petrol/diesel vehicles.	3
Emissions	40% of the energy consumed is derived from renewable sources.	1
	60% of the energy consumed is derived from renewable sources.	2
	80% of the energy consumed is derived from renewable sources.	3
Incentives	Government eco-incentives up to €7,000.	1
	Government eco-incentives up to €11,000.	2
	Government eco-incentives up to €15,000.	3

Table 2: FCEV (labelled and blind) attributes, modalities of variation and associated weights

Attribute	Modalities of variation	Level
Range anxiety	600 km range; refuelling stations limited to a few urban hubs.	1
	800 km range; refuelling stations available in urban hubs and developing along motorways.	2
	1,000 km range; infrastructure density equivalent to conventional fuel stations.	3
Charging times	~5 minutes; exclusively available at dedicated refuelling stations.	1
	~5 minutes; includes domestic refuelling/recharging services in urban areas.	2
	~5 minutes; includes domestic refuelling/recharging in both urban and rural areas.	3
Savings	+20% cost premium compared to petrol/diesel counterparts.	1

3.3. Data collection

We conducted our study using an online survey developed in Qualtrics and administered in May 2024 via a professional survey provider. To ensure the relevance of responses, we targeted only potential vehicle buyers within the Italian market, restricting participation to individuals who held a valid driving license and either owned a car or intended to purchase one within the following year.

The survey followed a streamlined structure. At the outset, respondents were exposed to a stimulus informing them of the type of vehicle they would be evaluating: BEVs, FCEVs, or a generic reference to "zero-emission vehicles" in the case of blind conditions. This was followed by a set of demographic questions designed to ensure balanced distributions across age, gender, and educational background. In the final section, respondents were presented with the vignette scenarios. Before beginning the ranking task, they were clearly instructed to read each scenario carefully and to order the seven configurations from the most to the least desirable. To ensure data reliability, several attention and quality checks were incorporated. First, because the distinction among BEV, FCEV, and blind labelling was central to the study design, we included a closing verification question assessing whether respondents correctly recalled the type of vehicle they had evaluated; only those who answered correctly were retained. As an additional safeguard, we applied an opt-out criterion to respondents who did not place the dummy scenario last. Failure to do so was interpreted as evidence of inattentive or random ranking. Finally, we excluded respondents who completed the entire questionnaire in less than five minutes, considered the minimum reasonable threshold given the number of items and the need for reflective scenario evaluation.

After applying these exclusion criteria, the final dataset consisted of 399 valid respondents: 102 in the BEV group, 112 in the BEV Blind group, 95 in the FCEV group, and 90 in the FCEV Blind group. The average of c.a. 100 respondents per sample is fully adequate for the purposes of our analysis. The rank-ordered logit (ROLOGIT) model operates on individual rankings rather than aggregate responses, meaning that each ranked scenario represents an observation. Given seven scenarios per respondent, the dataset includes 2793 observations (399 valid respondent × 7 ranked scenario), which provides a sufficient basis for robust estimation and inference. **Table 4** reports the demographic composition of the sample. Gender distribution was balanced across all groups, with each comprising approximately 50% male and 50% female participants. The majority of respondents were over 35 years of age and in higher education, consistent with the demographic profile of car owners in Italy (ISTAT, 2023). Random sampling procedures ensured comparability across groups with respect to age, gender, and education, thereby supporting robust cross-sample analyses.

3.4 Data analysis

To analyze the data elicited from the ranking tasks, we employed a Rank-Ordered Logit (ROLOGIT) model, executed via Stata 15. This approach is specifically designed to handle data in which respondents provide a complete preference ordering of alternatives, as it estimates the relative contribution of each attribute to the perceived desirability of a given scenario (StataCorp, 2005).

The model is grounded in the Random Utility framework, which posits that an individual's preference for an alternative is a function of its perceived utility (Guimarães et al., 2016). In this study, the ROLOGIT estimation utilizes the respondents' full rankings as the dependent variable. This allows us to express consumer preferences not just as a single choice, but as a systematic evaluation of various technological and economic configurations. Crucially, by leveraging the complete ranking information rather than focusing solely on the most preferred option, the model captures the exhaustive pattern of trade-offs that consumers perform among competing attributes (Contini et al., 2020). Each ranked vignette constitutes an observation that contributes to reconstructing the underlying utility structure.

Formally, it is assumed that each respondent r assigns a latent utility U_{jr} to scenario j (where $j = 1, \dots, 7$) in order for the model to calculate the overall utility $\boldsymbol{U_j}$ as:

$$\boldsymbol{U_j = \beta_0 + \beta_1 X_{1j} + \beta_2 X_{2j} + \cdots + \beta_k X_{kj} + \varepsilon_j}$$

where:

- $\boldsymbol{X_{1j}, \dots, X_{kj}}$ are the **explanatory variables**, namely the specific levels of the five attributes (emissions, range anxiety, charging times, incentives, and savings) defining scenario j,
- $\boldsymbol{\beta_0, \dots, \beta_k}$ are the **estimated coefficients**, which indicate the relative influence and "weight" of each attribute on the overall perceived utility,
- and $\boldsymbol{\varepsilon_j}$ is an idiosyncratic error term.

The ROLOGIT estimation provides more than a simple preference list; it reveals the latent hierarchy of attributes through which consumers organize information to construct Perceived Usefulness. Rather than focusing on individual coefficients in isolation, our analysis reveals the relative rankings and statistical weights of these parameters to map respondents' underlying cognitive architecture. This approach treats the resulting utility function as a direct empirical window into the consumer's evaluative logic. Crucially, the multi-sample design allows for a comparative analysis of these hierarchies across the four experimental groups. By comparing the utility functions of BEV and FCEV groups and their respective "blind" controls, we can identify whether the construction of PU is driven by a stable, technology-agnostic cognitive model or is significantly reshaped by technology-specific features, providing a rigorous assessment of how consumers navigate complexity and uncertainty in the ZEV transition.

4. Results

4.1. Rologit results

The results of the Rank-Ordered Logit (ROLOGIT) estimation, detailed in **Table 5**, provide the statistical significance and beta coefficients for each of the five attributes across the four samples.
A primary finding is that four out of the five variables, Range anxiety, Charging Time, Purchase Incentives, and Savings, are **statistically significant** at the $p < 0.05$ level in all samples. This consistent significance underscores the robustness of the model, confirming that these attributes effectively explain the variance in the utility function, which is defined in this study as a proxy for Perceived Usefulness (PU).

Table 5: Rologit Results

Savings	2,793	0,301	9,270	0,000	2,202	3,384

Regarding the **directionality of the coefficients**, which indicate the marginal utility and relative weight of each variable, the data reveals a *uniform pattern across the groups*. Range anxiety, Charging Time, and Savings exhibit positive beta coefficients. In contrast, Incentives yields a negative coefficient across all samples. Although environmental performance did not reach statistical significance, it showed a positive trend in three of the four groups. Crucially, the stability of these signs across the experimental groups suggests that the impact of these variables on marginal utility is independent of the specific technology (BEV vs. FCEV) and remains consistent across both explicit and "blind" conditions.
The **negative sign** associated with *Incentives* warrants further clarification, helpful to better clarify the interpretation of the rologit results. A negative beta should not be interpreted as in traditional regression models (e.g., SEM), because the Rologit model operates on a ranked set of closed scenarios rather than on independently rated items. As such, *coefficients capture the trade-offs* that respondents make when ranking scenarios. In general, a positive coefficient implies that higher levels of attribute *xj* increase the likelihood that a scenario is placed higher in the ranking, while a negative coefficient indicates that increases in *xj* tend to push the scenario lower. However, because each scenario

comprises a bundle of attributes, a negative sign may reflect compensatory effects. From this perspective, the negative coefficient for *Incentives* becomes interpretable. Respondents appear willing to sacrifice higher incentive levels to avoid decreases in attributes with stronger positive utility contributions, such as *Savings*, *Charging Time*, or *Range Anxiety*. Conversely, scenarios that offered substantial gains in these positively valued attributes were prioritized, even when accompanied by lower incentive levels.

This logic underscores the key value of the Rologit framework, which forces respondents to navigate competing priorities in a manner analogous to real-world decision-making. It does not estimate the absolute importance of each attribute in isolation, but rather its importance **relative to the others**, within a constrained choice environment

4.2 Cross-sample analysis

Table 6 consolidates the beta coefficients and associated p-values across all groups, allowing for a direct comparison of the underlying preference structures. A central finding of this research is that the **hierarchy of attributes** remains remarkably constant across all four groups. This structural consistency indicates a universal evaluative logic among consumers when assessing zero-emission mobility solutions. Specifically, the results identify Savings as the most critical attribute with the highest beta coefficient, followed in descending order of importance by Charging/Refuelling Time, Range Anxiety, and Incentives (the latter maintaining its negative coefficient). Environmental Performance consistently failed to reach statistical significance across all groups. This suggests that consumer preferences are not only resilient to "technological bias" as the "Blind" and "Explicit" groups exhibit nearly identical utility structures, but are also independent of the specific technological platform. Both BEV and FCEV respondents appear to employ the same decision-making approach. The interpretation of this outcome suggests that regardless of the ZEV technology, consumers prioritize a pragmatic value proposition: they seek significant operational cost reductions, rapid energy replenishment, and the elimination of range anxiety through high autonomy and a mature refueling ecosystem. Notably, the "greenness" of the energy source (percentage of renewable energy used) does not yield a statistically significant improvement in utility. Furthermore, the findings confirm that purchase incentives are viewed as a "tradable" asset; they are willingly sacrificed by respondents to prioritize improvements in more impactful functional or economic dimensions.

Table 6: Cross-sample analysis

	BEV		**Bev Blind**		**FCEV**		**FCEV Blind**	
Variables	**BETA**	**P>|z|**	**BETA**	**P>|z|**	**BETA**	**P>|z|**	**BETA**	**P>|z|**
Range anxiety	0,779	0,000	0,779	0,000	0,836	0,000	0,934	0,000
Charging times	2,012	0,000	2,178	0,000	2,179	0,000	2,329	0,000
Emissions	0,066	0,425	0,104	0,189	-0,151	0,087	0,009	0,924
Incentives	-0,892	0,000	-1,037	0,000	-1,101	0,000	-1,095	0,000
Savings	2,440	0,000	2,793	0,000	3,273	0,000	3,089	0,000
Observation	**714**		**784**		**665**		**630**	

To further validate the robustness of these findings, we analysed the probability that each scenario would be ranked first, following ROLOGIT guidelines (Stata, 2005). These results, presented in **Table 7**, show the scenarios ordered by their probability of being most preferred within each sample. As expected, Scenario 7 (the dummy control) consistently ranks last, reflecting the effectiveness of our respondent screening and the sample's logical consistency. In contrast, the top three positions, those with the highest probability of being ranked first, are consistently occupied by Scenarios 5, 1, and 4. While this probability analysis does not offer the same depth as the ROLOGIT beta derivation (as it focuses only on the top rank and omits information regarding the lower-tier preferences), it provides strong secondary evidence for our utility model. Specifically, Scenarios 5 and 4, which

dominate the first-choice rankings, both feature Savings at Level 3 (the attribute with the highest beta). Scenario 1, also a frequent top choice, represents a balanced configuration where both Savings and Range Anxiety are at Level 2. The fundamental takeaway from this secondary analysis is the high degree of coherence in preference levels across the entire sample. The fact that the same scenarios emerge as leaders across BEV and FCEV group, as well as their blind counterparts, confirms that the preference for specific strategic "packages" is robust and cross-sample stable.

Table 7: Scenarios probabilities to be selected as first choice

5. Discussion

5.1 Theoretical Contribution

This study sets out to understand how consumers construct perceived usefulness (PU) when evaluating technologies characterized by high uncertainty and substantial cognitive complexity. Rather than identifying which predictors of PU matter most, the objective was to illuminate how consumers process multiple attributes when forming their utility judgments. Two main contributions emerge from this investigation.

The central contribution of this study is to show that, when confronted with complex technological choices, consumers do not follow the fully analytical, sequential evaluation process commonly assumed in PU formation. Instead, across all four experimental samples, respondents relied on a highly stable, recurring structure of the utility function, which strongly suggests the adoption of a robust heuristic rather than a detailed, attribute-by-attribute assessment.

This finding extends the theoretical foundations of the Technology Acceptance Model (TAM). The classical PU formation process, as articulated by Venkatesh and Davis (2000) and rooted in work motivation theory (Vroom 1964), action identification theory (Vallacher & Wegner 1987), and image theory (Beach & Mitchell 1996, 1998), assumes that individuals first screen relevant inputs (compatibility test) and then prioritize alternatives through a profitability evaluation. Such a framework assumes a largely rational, functional decision-making process.

However, our results challenge this assumption in contexts where technologies are unfamiliar, multi-dimensional, and cognitively demanding. For example, charging time emerged as a highly influential attribute not only for BEVs, where long recharging times are a known barrier, but also for FCEVs, despite hydrogen vehicles offering refueling times comparable to conventional combustion engines (one of the main strength of this technology). Similarly, although the lack of refueling infrastructure is the primary constraint on hydrogen mobility uptake, range anxiety did not emerge as the dominant attribute in the FCEV samples, ranking below savings and, unexpectedly, below charging time.

These patterns indicate that respondents did not analytically differentiate between technology-specific constraints. Instead, they anchored their judgments around a limited subset of attributes

directly associated with expected user experience (e.g., savings, time requirements, and infrastructure support). The stability of attribute hierarchies across all group samples, therefore, does not imply that "consumers know exactly what they want"; rather, it reveals that they do not discriminate among nuanced technological differences. They simplify the decision problem by resorting to a satisficing strategy consistent with Simon's (1955) notion of bounded rationality.

This insight answers our research question: in contexts characterized by uncertainty and technological complexity, consumers shift from an analytical decision process to a heuristic one. Consequently, studies employing TAM or similar behavioral models in sustainability transitions should pay greater attention to the cognitive shortcuts that structure decision-making. These heuristics provide crucial insights into what consumers consider salient and what they systematically overlook when evaluating emerging technologies.

The second contribution of this study pertains specifically to the automotive domain and concerns the attribute hierarchies that shape perceived usefulness (PU) in the context of zero-emission mobility. Prior research consistently emphasizes that these products cannot be evaluated in isolation. Instead, they require an ecosystemic lens, as adoption depends on the simultaneous alignment of multiple interdependent conditions. Tarei et al. (2021) and Berkeley et al. (2018) argue that the barriers hindering the diffusion of sustainable mobility solutions are intertwined, and that understanding consumer evaluations requires moving beyond single-attribute or individual-level analyses.

Our study explicitly adopts this ecosystemic perspective. The experimental design integrates product-specific attributes (e.g., charging time, driving range), system-level conditions (e.g., availability of charging infrastructure), policy-driven factors (e.g., purchase incentives and energy mix), and hybrid attributes that arise from the interaction of product and system characteristics (e.g., use-phase savings, which depend both on vehicle features and electricity prices). By jointly modelling these dimensions, the study directly addresses the gap identified by Tarei et al. (2021) regarding the limited empirical evidence on how consumers rank, prioritize, and trade off interconnected barriers and strengths in sustainable mobility.

The results reveal patterns that are empirically distinctive and detectable only through a methodology grounded in trade-offs, such as the rank-ordered logistic framework employed here. A notable first finding is that the *emissions* attribute is not statistically significant in any of the four samples. This result should not be interpreted as contradicting the extensive evidence showing that pro-environmental values and sustainability orientations are strong predictors of interest in green mobility (Garibbo et al., 2025; Lakshmanan et al., 2024). Rather, it reflects the deliberate choice made in this study to focus on the *actual environmental determinant of vehicle sustainability,* namely, the energy source used for charging, an aspect expected to influence PU through environmental knowledge (Masukujjaman et al., 2021).

The non-significance of this variable indicates that highly abstract and system-external factors, which are distant from direct usage experience, exert limited influence on PU, particularly once consumers already know they are evaluating zero-emission vehicles. In other words, respondents were operating within a pre-established "green product frame (i.e., the stimuli we provided)" and marginal improvements or deteriorations in upstream emissions were not sufficiently salient to affect their utility judgments. This finding advances prior evidence on the role of environmental knowledge (Degirmenci & Breitner, 2017) by showing that, in zero-emission mobility, environmental performance becomes secondary to more experiential attributes when consumers form PU.

A second and integrative relevant finding concerns the role of incentives. Previous research consistently highlights financial incentives as key levers to offset the green premium and accelerate adoption (Berkeley et al., 2017; Bunsen et al., 2018; Biresselioglu et al., 2018; Harvey, 2020). In contrast, the negative sign of the *incentives* coefficient in our model must be interpreted within the logic of forced trade-offs. It does not imply that incentives are undesirable, but that, when ranking complete scenarios, respondents consistently prioritize other attributes, such as use-phase savings, driving range, and charging infrastructure. The finding resonates with recent work (Liu et al., 2021;

Setiawan, 2022) calling for a recalibration of the weight attributed to state subsidies and highlights that PU in complex technological transitions is primarily guided by pragmatic, usage-oriented considerations rather than by financial optimization alone.

Taken together, with the emergent utility functions, these findings reveal that *use-phase savings*, *charging time*, and *range anxiety* constitute the core drivers of PU. Beyond indicating bounded rationality (given that some prioritizations, especially in the FCEV samples, are not fully aligned with technological realities), this pattern reinforces the idea that consumers anchor their evaluations to tangible, easily assessable, experience-proximal attributes. This is consistent with the foundational definition of PU as "*the degree to which a person believes that using a particular system would enhance his or her job performance*." In complex, and interdependent ecosystems such as zero-emission mobility, consumers simplify the evaluation by focusing on what most directly signals a smooth, predictable, and convenient usage experience: fuel costs, charging time, and the perceived ease of refuelling.

These results deepen our understanding of how consumers process ecosystem-level information when forming PU judgments. They demonstrate that, even in contexts requiring advanced systemic reasoning, consumers gravitate towards concrete, experience-linked dimensions and struggle to incorporate abstract, upstream, or policy-driven features into their evaluations. This contributes to the literature by showing that PU in sustainable mobility emerges from a boundedly rational, ecosystem-filtered trade-off process in which only a subset of attributes meaningfully enters the cognitive calculus.

A final contribution concerns the methodological approach used to interpret the Rank-Ordered Logit (ROLOGIT) results. While this study does not aim to propose a formal extension of the ROLOGIT technique, it demonstrates a more nuanced way of leveraging choice-based vignette designs to explore consumer cognition. Traditionally, choice models are employed to estimate the relative importance of attributes within a specific product configuration (Contini et al., 2020). In such analyses, the beta coefficients indicate which factors contribute most to utility in a given moment. However, our research design employs a cross-sample experimental design (BEV vs. FCEV; explicit vs. blind conditions) to assess the **stability** of these utility functions across different technological and informational contexts.

By comparing these four distinct cohorts within the same product category (zero-emission vehicles), we move beyond a simple "list of preferences." The finding that attribute hierarchies remain invariant across all groups (regardless of the technology or the presence of a label) suggests that the ROLOGIT model can be used to detect **latent decision heuristics**. From this perspective, the value of the model lies in its ability to reveal not only *what* is important but also whether the consumer's *evaluative logic* is stable or context-dependent. This approach enriches the interpretation of choice models by shifting the focus from individual attribute weights to the **consistency of the cognitive architecture** used by consumers to navigate complex transitions. This level of analysis provides a more robust foundation for predicting consumer behavior in emerging markets than traditional, single-sample attribute analyses.

5.2 Managerial Implication

The empirical evidence from this study provides a clear strategic roadmap for automakers and policymakers, shifting the focus from technological advocacy to a user-centric ecosystemic strategy. The implications revolve around three fundamental pillars:

The finding that consumers apply a standardized decision heuristic regardless of technology suggests a "**Delegation Effect".** Consumers appear to ignore the underlying technological trade-offs (e.g., differences between batteries and fuel cells) and implicitly delegate the responsibility for addressing adoption issues of technical solutions to firms and policymakers. By adopting a satisficing approach, they seek a "package" that meets their minimum requirements for cost saving, absence of range

anxiety, and quick charging time. For managers, this means that marketing efforts should move away from explaining technical complexities and instead emphasize the reliability of the deriving service (sustainable mobility), positioning the ZEV as a worry-free utility rather than a technological breakthrough.

Secondly, the stability of the attribute hierarchy suggests a **dual strategic path for firms**: in communication, brands must emphasize the most salient attributes identified by the model: operational savings and refueling infrastructure and charging time. These are the primary drivers of Perceived Usefulness that trigger the purchase intention. In development (mirroring the operational reality) given that consumers may de-prioritize certain technical constraints - factors that ultimately dictate the real-world performance - firms should continue to innovate in these "under-the-radar" areas to ensure that the user experience matches the initial promise, thereby preventing long-term dissatisfaction and negative word-of-mouth.

Finally**,** because technological labels (BEV vs. FCEV) do not significantly alter consumers' cognitive hierarchies, basing a competitive position solely on "**technological superiority**" is likely to be ineffective. Competitive advantage in the ZEV market will no longer be determined by vehicle specs alone but by **ecosystemic attributes**: the maturity of the charging/refueling network, innovative pricing models (e.g., energy-as-a-service), and seamless support services. This implies that the path to ZEV adoption lies not in promoting the technology, but in demonstrating its seamless integration into the user's functional and economic life.

6. Limitations and further research

This study presents limitations that offer avenues for future research. First, the empirical setting is restricted to a single country. While this limits the generalizability of our findings, a cross-country design would have introduced substantial noise due to structural differences in energy prices, charging-infrastructure availability, and hydrogen mobility diffusion. We therefore recommend replicating the study in other national contexts rather than combining them ex ante, enabling meaningful cross-country comparisons without compromising internal validity.

Second, although the study investigates the construction of the utility function, data were collected through a survey completed in a relatively short time frame (approximately ten minutes). Vehicle purchase decisions, however, are typically extended, deliberative processes. Our findings should thus not be interpreted as a direct reflection of all the factors consumers consciously evaluate. For instance, we cannot infer that respondents were completely unaware of the lack of hydrogen refueling infrastructure. Rather, the results should be viewed as capturing the initial cognitive heuristics that shape early-stage evaluations of zero-emission vehicles. Such heuristics are highly informative for understanding instinctive reasoning patterns and for designing effective communication strategies.

Finally, the set of attributes included in the study reflects only a subset of the broader determinants of perceived usefulness. We did not incorporate value-based drivers (e.g., environmental identity), symbolic or self-image considerations, or brand-related variables. The selection was intentionally constrained to attributes tightly aligned with the functional core of perceived usefulness and to maintain a viable experimental design. Expanding the attribute space or the number of scenarios would have increased informational richness at the cost of excessive cognitive burden, potentially undermining task completion. Future research should therefore explore alternative scenario designs and include additional attributes, while preserving a feasible balance between experimental complexity and respondent capability.

Entrepreneurial agency and hybrid finance in post-globalization. Evidence from SMEs facing the twin transition

FILOMENA IZZO[1], DOMENICO GRAZIANO[2], MARIO MUSTILLI[3]

Abstract

Objective. The paper analyzes how hybrid regional financial instruments reshape entrepreneurial agency and strategic decision-making processes in small and medium-sized enterprises (SMEs) engaged in the twin transition of digital transformation and environmental sustainability. Moving beyond a purely financial perspective, the study interprets finance as an active governance mechanism capable of influencing entrepreneurial decisions in contexts of post-globalization and structural uncertainty.

Methodological design The study adopts a qualitative, theory-driven case study approach. The empirical evidence derives from the analysis of the *Garanzia Campania Bond* program, a hybrid regional financial instrument that combines market-based minibonds and public portfolio guarantees. The analysis relies on a triangulation of sources, including institutional documentation, aggregated financial data, reports from financial intermediaries and independent evaluations, as well as a semi-structured interview with a key institutional actor involved in the instrument's design and governance.

Findings. The results show that GCB operates not only as a mechanism for alleviating financial constraints, but also as an agentic governance device capable of recalibrating entrepreneurs' risk perception, extending the time horizon of investment decisions, and steering entrepreneurial choices toward digital and sustainable transformation pathways. The instrument supports investments with a high intangible intensity, such as digitalization, organizational innovation, and energy efficiency.

Theoretical implications. The paper contributes to the literature on entrepreneurship and SME finance by conceptualizing hybrid financial instruments as drivers of entrepreneurial agency rather than neutral financing tools. It also enriches the debate on the twin transition by highlighting the role of financial architectures in shaping the directionality of digital transformation and sustainability-oriented entrepreneurship in post-globalization contexts.

Practical implications. For entrepreneurs, the findings emphasize the importance of using structured financial instruments to support transformative, long-term investment strategies. For policymakers and financial intermediaries, the study highlights the need to design hybrid instruments that do not merely reduce financial risk but actively accompany entrepreneurial decision-making processes, including through complementary capacity-building policies aimed at strengthening inclusiveness.

Originality. The originality of the work lies in integrating the research streams on entrepreneurship, SME finance, and the twin transition, showing how hybrid regional financial instruments can operate as governance mechanisms capable of shaping entrepreneurial agency, thereby offering an innovative place-based perspective on entrepreneurial transformation in uncertain and fragmented economic contexts.

Keywords: *Entrepreneurial agency, Hybrid financial instruments, SMEs, Twin transition, Digital and sustainable transformation, Post-globalization*

1. Introduction

Access to adequate financial resources represents a strategic element for entrepreneurial action, innovation, and the transformation of small and medium-sized enterprises (SMEs). This relevance is intensified in contexts marked by high uncertainty, institutional fragmentation, and the reconfiguration of global value chains — conditions typical of the post-globalization phase — in which entrepreneurs are required to make complex strategic decisions in the presence of recurring shocks, geopolitical discontinuities, and increasing regulatory pressures. Under such circumstances, the entrepreneurial capacity to recognize opportunities, manage risk, and steer transformation depends not only on individual capabilities, but also on the financial and institutional architectures that frame entrepreneurial action (Berger & Udell, 2006; Hanedar et al., 2014; Udell, 2020).

[2] Senior Researcher in Management, University of Campania Luigi Vanvitelli, domenico.graziano@unicampania.it
[3] Full Professor in Management, University of Campania Luigi Vanvitelli, mario.mustilli@unicampania.it

In the Italian bank-centered system, SMEs' dependence on traditional credit tends to limit entrepreneurs' strategic discretion, with particularly pronounced effects in less developed regions, where financial constraints, information asymmetries, and a lack of collateral hinder innovative and intangible investments (Banca d'Italia, 2022; ISTAT, 2022; SVIMEZ, 2023).
The literature on SME finance has extensively documented these constraints, focusing on the effects of access to credit in terms of investment, growth, and financial stability (Berger & Udell, 2006; Hanedar et al., 2014; Udell, 2020). However, this stream tends to consider finance as a predominantly exogenous factor, devoting less attention to how financial configurations influence entrepreneurial decision-making processes and entrepreneurs' capacity to pursue long-term transformation trajectories.
At the same time, the literature on entrepreneurship and SMEs highlights that firms adopt proactive and flexible strategies in response to crises and uncertain environments, leveraging resilience, adaptation, and entrepreneurial competences to preserve competitive advantage (Pusceddu, 2022). Studies on the role of local innovation systems and collaborative networks further emphasize how innovation processes in SMEs are often the product of inter-organizational relationships, partnerships with knowledge actors, and territorial dynamics that integrate resources and capabilities (De Martino et al., 2012). These contributions show that entrepreneurial agency is expressed not only through individual choice but also through networks and local contexts that facilitate access to resources and knowledge.
The twin transition — understood as the joint transition toward digitalization and environmental sustainability — represents a central challenge for SMEs. The literature shows that digitalization and sustainability can reinforce each other, but such complementarities are not automatic: they depend on organizational capabilities, strategic choices, and the quality of contextual institutions (Faucheux & Nicolaï, 2011; Montresor & Vezzani, 2023; Aiello et al., 2025).
Recent research in the Italian context highlights how digital transformation, when strategically oriented, can enhance sustainability outcomes and generate resilient business models (Lanfranchi et al., 2025). However, the effectiveness of these trajectories depends on entrepreneurs' ability to make intentional decisions under conditions of uncertainty and to mobilize adequate resources for investments that are often intangible and characterized by delayed returns.
In light of this evidence, hybrid financial instruments — namely devices that combine market mechanisms with public guarantees or interventions — have emerged, designed to reduce perceived risk, extend the investment time horizon, and support projects with high intangible intensity (Zedda, 2019; Pampurini et al., 2024). These instruments have mainly been interpreted as mechanisms for capital access; less attention has been devoted to their potential role as governance devices capable of shaping entrepreneurial agency by influencing risk perception, strategic discretion, and entrepreneurs' capacity for experimentation along twin transition pathways

1.2 Literature gap

Overall, the reviewed streams provide important but partial contributions. Studies on SME finance analyze credit access constraints without fully considering how such constraints and financial solutions may reshape entrepreneurs' decision-making practices; the literature on entrepreneurship and local systems emphasizes capabilities and networks but tends to treat financial architectures as a given context; research on the twin transition often focuses on technological or environmental outcomes without systematically analyzing the financial mechanisms that enable (or constrain) sustainability-oriented entrepreneurial choices. Consequently, a gap emerges: there is a lack of an integrated analysis showing how hybrid financial instruments may act as agentic devices, recalibrating entrepreneurial action and the strategic decision-making process of SMEs in the twin transition, especially in regional contexts characterized by structural fragilities and post-globalization.

In light of the identified gap, this study interprets hybrid regional financial instruments not merely as mechanisms of capital access, but as governance devices capable of affecting entrepreneurial action.

Specifically, the paper analyzes how particular financial architectures can recalibrate the decision-making processes of SMEs engaged in the twin transition in contexts marked by post-globalization and structural uncertainty. To this end, the research is guided by the following questions:

*RQ1***.** How do hybrid regional financial instruments recalibrate SMEs' entrepreneurial agency by influencing risk perception, strategic discretion, and the time horizon of investment decisions?

*RQ2***.** How do such instruments shape the directionality of entrepreneurial choices toward trajectories consistent with the twin transition, fostering the integration of digital transformation and environmental sustainability?

*RQ3***.** To what extent do territorial and institutional contexts condition the effectiveness and inclusiveness of hybrid financial instruments and, consequently, the limits of SMEs' entrepreneurial agency?

From this perspective, the case of the *Garanzia Campania Bond* program allows observation of how specific financial architectures may operate as agentic devices, influencing not only access to resources but also the quality and direction of entrepreneurial action.

The remainder of the article is organized as follows. Section 2 describes the methodological design and the case study analyzed; Section 3 develops the theoretical framework by integrating the literature on entrepreneurship, SME finance, and the twin transition; Section 4 presents the empirical findings; Section 5 discusses the evidence in light of the research questions and theoretical contributions; finally, Section 6 concludes by highlighting theoretical, managerial, and policy implications, as well as limitations and directions for future research.

2. Methodology

2.1 Research design

This study adopts a qualitative, theory-driven case study approach, consistent with the methodological literature on theory building through case studies (Eisenhardt, 1989; Eisenhardt & Graebner, 2007; George & Bennett, 2005; Yin, 2018). Such an approach is particularly appropriate for analyzing complex and underexplored phenomena in which the boundaries among context, actors, and causal mechanisms are blurred, as in the interaction between hybrid financial instruments and entrepreneurial agency in SMEs.

Consistent with the gap identified in the literature, the case study is not used to test predefined hypotheses but to investigate in depth the mechanisms through which specific financial architectures influence entrepreneurial decision-making processes, risk perception, and the time horizon of strategic choices in the twin transition. The theory-driven approach makes it possible to connect empirical evidence to a conceptual framework that integrates entrepreneurship, SME finance, and the governance of digital and sustainable transformation.

2.2 Case selection

The *Garanzia Campania Bond* (GCB) program was selected following a logic of theoretical relevance and an information-rich case (Siggelkow, 2007). The case is particularly suitable for observing how hybrid regional financial instruments — combining minibonds, market mechanisms, and public portfolio guarantees — can reorganize SMEs' financial constraints and affect entrepreneurs' decision-making processes.

GCB represents an emblematic case for at least three reasons. First, it operates in a regional context characterized by structural fragilities, where financial and institutional constraints amplify

entrepreneurial difficulties. Second, the instrument is explicitly oriented toward supporting medium- to long-term investments, often intangible, typical of digitalization and sustainability processes. Third, GCB involves a plurality of actors — entrepreneurs, financial intermediaries, institutional investors, and public institutions — allowing observation of entrepreneurial agency within a complex financial and institutional ecosystem.

2.3 Data sources and data collection

The analysis relies on a triangulation of primary and secondary sources (Denzin, 1978) in order to strengthen the internal validity of the study and enable a comprehensive understanding of the instrument's operating mechanisms.

First, institutional and administrative documents from the Campania Region and Sviluppo Campania were analyzed, including public calls, monitoring reports, technical materials, documentation related to ERDF programming for 2014–2020 and 2021–2027, and independent evaluation reports. These sources made it possible to reconstruct the instrument's design, stated objectives, selection criteria, and governance mechanisms.

To complement these sources, a semi-structured interview was conducted with a key actor involved in the design and management of the program (the President of Sviluppo Campania). The interview aimed to explore qualitative aspects that are difficult to observe through documentary sources alone, such as the decision-making processes underlying the instrument's design, the risk-sharing logic, the modes of interaction with SME entrepreneurs, and the strategic choices related to the orientation of investments. In line with the literature on elite interviews, the interview played an interpretative and contextualizing function (Patton, 2002; Harvey, 2011).

2.4 Data analysis strategy

The data analysis was conducted following a theory-guided logic, consistent with the conceptual framework developed. The empirical material was organized along three analytical dimensions, corresponding to the research questions:

1. Financial and governance mechanisms through which GCB mitigates SMEs' financial constraints;
2. Effects on entrepreneurs and decision-making processes, in terms of risk perception, time horizon, and types of investments undertaken;
3. Territorial and institutional conditions influencing the effectiveness and inclusiveness of the instrument.

3. Literature Review

3.1 Entrepreneurial agency

The concept of entrepreneurial agency has assumed a central role in entrepreneurship studies, as it allows the firm to be interpreted not as a purely adaptive response to market constraints, but as the outcome of intentional action capable of influencing the economic context. Research defines entrepreneurship as the study of the processes through which opportunities are identified, evaluated, and exploited by specific economic actors (Shane & Venkataraman, 2000). From this perspective, the entrepreneur is not simply a rational decision-maker reacting to given incentives, but an actor who actively contributes to the configuration of opportunities and the transformation of markets.

The theoretical debate has progressively distinguished two main interpretations. The opportunity discovery perspective assumes that opportunities exist independently of economic actors and can be identified in the presence of informational imperfections. The opportunity creation approach, by contrast, maintains that opportunities emerge from entrepreneurial action and from interactions among actors, resources, and interpretations, framing entrepreneurship as a constructive process developed under conditions of non-probabilistic uncertainty (Alvarez & Barney, 2007). Subsequent

studies have reinforced this view by highlighting how economic opportunities are the product of interpretive and social processes rather than pre-existing objective entities (Wood & McKinley, 2010).

Within this debate, the opportunity-based entrepreneurship perspective proposes an integrative position, emphasizing that opportunities are neither entirely given nor entirely constructed, but emerge from the interaction between external conditions and entrepreneurial action. Entrepreneurship can therefore be interpreted as a process in which actors attribute economic meaning to potentially profitable situations through judgments, decisions, and experimentation (Davidsson, 2015). This approach reconciles the structural and agentic dimensions, showing how entrepreneurial action depends simultaneously on contextual conditions and on entrepreneurs' capacity to interpret and modify them.

Entrepreneurial agency manifests itself particularly in the ability to act under conditions of radical uncertainty. Entrepreneurial action occurs when an individual commits resources without being able to probabilistically calculate future outcomes, accepting the risk of failure while simultaneously contributing to market formation (McMullen & Shepherd, 2006). In this perspective, entrepreneurship is explained not only by the availability of opportunities or resources, but also by the willingness to act amid ambiguity and by the capacity to construct shared expectations.

A complementary contribution derives from effectuation theory, according to which entrepreneurs do not plan action on the basis of predetermined objectives and market forecasts; rather, they progressively build the competitive context through sequential decisions based on available means and interaction with other actors (Sarasvathy, 2001). The market, therefore, is not merely anticipated but co-evolves with stakeholders.

Organizational literature has also highlighted that entrepreneurial agency is embedded, meaning incorporated within social and institutional structures that simultaneously constrain and enable action. Entrepreneurs may modify practices, rules, and organizational arrangements, thereby contributing to the transformation of the economic fields in which they operate (Garud, Hardy & Maguire, 2007). Entrepreneurial agency should therefore be interpreted as a multilevel phenomenon emerging from the interaction among individual characteristics, organizational capabilities, and institutional conditions.

This dimension is particularly relevant in small and medium-sized enterprises. In SMEs, the concentration of strategic decisions in the entrepreneur or owner-manager makes entrepreneurial action directly sensitive to contextual conditions. In the presence of financial constraints, informational asymmetries, and limited access to resources, the possibility of undertaking innovative investments depends not only on individual competences but also on the institutional architecture within which the firm operates. Financing conditions influence investment propensity and the time horizon of decisions, indirectly affecting entrepreneurial action (Brown, Martinsson & Petersen, 2012; Kerr & Nanda, 2015).

Consequently, entrepreneurial agency cannot be interpreted as an exclusively individual property. Rather, it represents a situated capability shaped by the interaction among entrepreneurs, organizations, and institutional contexts. From this perspective, financial architectures do not merely constitute an enabling factor or an external constraint; they can directly influence risk perception, strategic discretion, and the time horizon of decisions. Financial instruments may therefore be interpreted as governance devices capable of recalibrating entrepreneurial action, affecting not only access to capital but also the very quality of SMEs' strategic decision-making processes.

3.2 Entrepreneurial processes and decision-making under uncertainty

Entrepreneurship literature has progressively moved away from a static view of the entrepreneur as a set of individual traits, adopting instead a processual perspective on entrepreneurial action. From this standpoint, entrepreneurship does not coincide with a single decision-making act, but with a dynamic sequence of interpretations, evaluations, and reallocations of resources that unfolds over time and under conditions of uncertainty (Shane & Venkataraman, 2000). Entrepreneurial action emerges

through continuous cognitive and strategic adjustments, in which the entrepreneur combines incomplete information, expectations, and operational constraints in order to guide firm choices.
This interpretation is consistent with studies emphasizing the role of radical uncertainty in entrepreneurial decision-making processes. Entrepreneurial action takes shape when an individual commits resources despite the absence of calculable probabilities regarding future outcomes, assigning economic meaning to still-indeterminate situations (McMullen & Shepherd, 2006). In this context, entrepreneurs frequently rely on heuristics and cognitive schemas different from those of managers in large organizations, adopting faster and more experimental decision modes typical of highly ambiguous environments (Busenitz & Barney, 1997). The entrepreneur therefore does not merely react to given opportunities, but contributes to constructing them through judgment, experimentation, and progressive learning (Davidsson, 2015).
A complementary contribution derives from effectuation theory, according to which entrepreneurs do not plan action on the basis of market forecasts and rigidly defined objectives; rather, they develop strategies through sequential decisions grounded in available resources and interaction with other actors (Sarasvathy, 2001). Entrepreneurial action thus assumes an iterative nature: decisions are continually revised in light of environmental feedback and operational possibilities, configuring the entrepreneurial process as an evolutionary path rather than a predetermined plan. In this perspective, entrepreneurship can also be interpreted as a dynamic mindset that develops through experience, interaction, and continuous learning rather than as a simple individual endowment (Ali et al., 2023).
The processual perspective also highlights the relevance of the temporal dimension of entrepreneurship. Recent studies describe the entrepreneurial path as an entrepreneurial journey characterized by sequences of decisions, strategic revisions, and progressive reorientations (McMullen & Dimov, 2013). Beliefs about opportunities arise through learning-by-doing, in which the entrepreneur reduces initial uncertainty and progressively constructs shared expectations (Shepherd et al., 2007). Technological and environmental changes may further reshape entrepreneurial trajectories, affecting attainable opportunities, business models, and firm performance (Foisal et al., 2023).
Within this framework, institutional context and access to resources play a decisive role. The entrepreneur does not operate in isolation but interprets opportunities and risks in light of mobilizable resources, social relationships, and available organizational configurations. Relational networks facilitate access to information, capabilities, and opportunities, helping compensate for the size limitations of smaller firms (Urbano et al., 2011). In particular, access to entrepreneurial resources is often mediated by personal and relational networks, increasingly integrated through digital tools (Bidart & Ibrahim, 2023).
An important implication is that conditions of access to resources directly affect entrepreneurial decision-making processes. The availability or scarcity of financial resources does not only determine the volume of feasible investments; it also modifies how entrepreneurs evaluate risk, time, and the scope of opportunities they pursue. From this perspective, institutional and financial architectures are not external elements to the firm but components of the entrepreneurial process itself, as they contribute to defining perceived opportunities and feasible strategies.
Financial instruments therefore do not operate exclusively as funding mechanisms but as factors that influence the formation of entrepreneurial decisions and the configuration of SMEs' development trajectories. By reducing perceived uncertainty and expanding the range of mobilizable resources, hybrid financial instruments can be interpreted as devices intervening in the micro-foundations of entrepreneurial action, recalibrating the process through which entrepreneurs evaluate opportunities, risks, and time horizons.

3.3 Financial constraints, hybrid instruments and entrepreneurial decision-making

A substantial body of research analyzes SMEs' financial constraints, highlighting how information asymmetries, lack of collateral, and dependence on bank credit limit access to capital and shape investment decisions (Berger & Udell, 2006; Hanedar et al., 2014; Udell, 2020). In particular, in

bank-centered systems these constraints are especially severe for intangible and long-term investments, typically associated with innovation and transformation processes.
More recent literature has begun to explore alternative and hybrid financial instruments, such as minibonds, basket bonds, and public guarantee schemes, emphasizing their potential to mitigate SMEs' financial constraints and mobilize private capital (Zedda, 2019; Pampurini et al., 2024). These studies show that "second-generation" instruments, based on risk-sharing mechanisms and multilevel governance, can improve access to credit without substituting for the market.
However, much of this literature adopts a predominantly financial or policy perspective, assessing the effectiveness of such instruments in terms of volumes disbursed, financial leverage, or system stability. By contrast, analysis of how these instruments affect entrepreneurial decision-making processes — influencing risk perception, investment propensity, and the time horizon of strategic choices — remains marginal. In other words, finance is often treated as an exogenous input rather than as an active element capable of shaping entrepreneurial agency (Ceglia et al., 2025).
This gap is particularly relevant in the case of SMEs, where investment decisions are strongly concentrated in the hands of the entrepreneur or owner-manager and are therefore highly sensitive to financial conditions and to the incentive structures embedded in financing instruments.

3.4 Twin transition, digital transformation and entrepreneurial directionality
Another relevant stream of literature concerns the **twin transition**, understood as the integration between digital transformation and environmental sustainability. Theoretical studies distinguish between forms of digitalization aimed at reducing the environmental impact of technologies (*Green IT*) and the use of digital technologies as enablers of broader sustainable innovations (*IT for Green*), emphasizing that environmental benefits depend on the directionality of digital transformation (Faucheux & Nicolaï, 2011).
Empirical contributions show that digitalization and eco-innovation can mutually reinforce each other, but only in the presence of adequate organizational capabilities, investments in intangible capital, and supportive institutional contexts (Montresor & Vezzani, 2023; Aiello et al., 2025; Checchinato et al., 2025). Management research further highlights that sustainability-oriented digital transformation requires intentional strategic choices and advanced managerial capabilities, especially in SMEs (Lanfranchi et al., 2025).
However, much of this literature focuses on the technological and environmental outcomes of the twin transition, devoting less attention to the financial mechanisms through which such entrepreneurial choices become feasible. In particular, the ways in which specific financial instruments may shape the directionality of digital transformation — influencing entrepreneurs' decisions and fostering (or hindering) the integration of digitalization and sustainability — remain underexplored.

3.5 Synthesis and research gap
Taken together, the reviewed streams provide complementary but fragmented contributions. The entrepreneurship literature highlights the central role of entrepreneurial agency and strategic capabilities in SMEs; studies on SME finance analyze constraints in access to capital and the effectiveness of alternative instruments; research on the twin transition emphasizes the non-automatic nature of the integration between digitalization and sustainability.
What is missing is a systematic integration of these perspectives. In particular, the literature has not yet clarified how hybrid financial instruments may act as governance devices capable of shaping entrepreneurial agency, influencing SMEs' strategic decision-making processes and directing digital transformation toward trajectories compatible with environmental sustainability, especially in regional contexts characterized by structural fragilities and post-globalization.
This study addresses this gap by analyzing a hybrid regional financial instrument as an empirical case, interpreting it not only as a mechanism for capital access but as an institutional architecture capable

of recalibrating SMEs entrepreneurs' risk perception, time horizon, and strategic discretion within the twin transition.

4. Results

The *Garanzia Campania Bond* (GCB) is a regional financial instrument designed to facilitate small and medium-sized enterprises' access to market financing through the issuance of medium- to long-term debt securities (minibonds) backed by a public guarantee. Unlike traditional subsidy schemes, the program does not provide direct grants or public loans to firms; rather, it relies on a public–private collaboration mechanism aimed at activating private capital and reducing SMEs' dependence on bank credit. The initiative is promoted by the Campania Region and operationally managed by Sviluppo Campania S.p.A., the in-house regional company responsible for coordinating selection, eligibility, and guarantee administration procedures.

The operation of the instrument unfolds through several stages. First, interested firms submit an application including an investment project and financial documentation. After a preliminary verification of formal and size requirements, firms undergo a creditworthiness assessment conducted by institutional investors and financial intermediaries involved in the transaction. Firms deemed eligible then issue a minibond, a corporate debt security that commits the firm to periodic interest payments and principal repayment at maturity.

The minibonds issued by different firms are not individually placed on the market but aggregated into a portfolio. Each security is transferred to a Special Purpose Vehicle (SPV), established to acquire the firms' bonds and transform them into a single financial instrument. The SPV subsequently issues an overall security, known as a *basket bond*, subscribed by institutional investors (investment funds, investment banks, or other financial operators). Through this structure, risk is no longer linked to a single firm but distributed across the entire portfolio, allowing greater diversification.

The public actor provides a direct first-demand guarantee covering a predetermined share of potential losses of the overall portfolio. The guarantee therefore operates at the basket-bond level rather than at the level of individual firms: in the event of default by some firms, the Region intervenes to cover the guaranteed portion, reducing investors' exposure. This mechanism does not eliminate the economic risk of the operation but redistributes it between public and private actors according to a risk-sharing logic. Investors retain a significant share of risk and therefore continue to perform screening and monitoring activities, while the presence of the public guarantee makes the investment viable even for relatively small firms or those with limited credit history.

The resources raised through the subscription of the basket bond are transferred by the SPV to the issuing firms, which use them for development programs, technological innovation, digitalization, productive investment, and organizational strengthening. Repayment of the minibonds occurs over time through cash flows generated by business activity. In this way, GCB introduces a financing channel alternative to traditional bank lending and allows SMEs to obtain resources with longer time horizons and greater flexibility than standard loans.

Overall, the instrument does not merely expand liquidity availability but modifies the structure of the financial conditions under which firms operate, enabling capital market access even for actors normally excluded. The program thus functions as a regional financial market activation intervention in which public action does not replace private capital but reduces its perceived risk, making investment projects financeable that would otherwise struggle to obtain coverage through traditional credit channels.

By reducing exposure to loss risk and making medium- to long-term resources available, the instrument alters the conditions under which entrepreneurs evaluate investment opportunities. It therefore not only increases accessible capital but also affects decision-making processes, extending the time horizon and the propensity to undertake innovative and transformative initiatives, thereby concretely influencing the exercise of entrepreneurial agency.

From a quantitative perspective, GCB mobilized approximately €200 million in financing for 90 SMEs, against a regional public endowment of €37 million provided in the form of a portfolio guarantee (Sviluppo Campania, 2024; Regione Campania, 2023). This results in financial leverage close to 4:1, indicating a substantial capacity to attract private capital.
A further relevant aspect concerns the instrument's temporal and adaptive dimension. The articulation of the program into multiple successive phases (first edition in 2019, second in 2023) has transformed the intervention into an evolutionary process capable of incorporating institutional learning and adapting to macroeconomic changes following the pandemic shock.

Examination of the portfolio composition shows a sectoral distribution consistent with regional development trajectories. Beneficiary firms mainly belong to manufacturing, agri-food, ICT, and advanced services sectors, characterized by a high incidence of investments in digitalization, organizational innovation, and energy efficiency. From a geographical perspective, however, a significant territorial concentration emerges: most firms are located in the province of Naples, followed by Salerno, while inland areas are only marginally represented.

Another finding concerns the type of investments financed. Available information indicates that the mobilized resources were allocated primarily to capital-intensive tangible investments but also to intangible investments — such as software, research and development activities, patents, and ICT platforms — as well as technological upgrades and energy-efficiency interventions (Sviluppo Campania, 2024). Overall, initiatives aimed at modernizing production processes and strengthening firms' digital capabilities prevail.

These elements suggest that GCB does not operate solely as a tool for closing a financing gap but also contributes to orienting firms toward projects consistent with the twin transition. In particular, the financed digital investments support optimization of production processes, reduction of energy consumption, and improvements in environmental monitoring and reporting, configuring applications of *IT for Green* rather than mere technological adoption. Moreover, the nature of the supported interventions appears aligned with the European regulatory framework, including the objectives of the EU Taxonomy and the Green Deal, strengthening the program's coherence with supranational policy priorities (European Commission, 2019; 2020).

5. Discussion

*RQ1 – Hybrid financial instruments and the recalibration of entrepreneurial agency***.** With reference to the first research question, the findings show that GCB helps mitigate SMEs' financial constraints not only by expanding access to capital, but by qualitatively transforming the conditions under which entrepreneurs make investment decisions. The combination of the basket-bond structure and the public portfolio guarantee reduced the perceived risk associated with medium- to long-term and high-intangible-intensity investments, thereby expanding entrepreneurs' strategic discretion.
This result enriches the SME finance literature, which traditionally interprets financial constraints in terms of the quantity of available resources. The evidence instead suggests that financial architectures also affect the quality of entrepreneurial agency, influencing entrepreneurs' ability to plan over the long term, to experiment, and to undertake more ambitious transformation paths. In this sense, GCB confirms that "second-generation" financial instruments can perform a crowding-in function not only of capital but also of entrepreneurial agency.

RQ2 – Directionality of entrepreneurial choices in the twin transition. The second research question concerns GCB's contribution to aligning digital transformation with environmental sustainability.

The findings show that the instrument does not merely finance generic adoption of digital technologies but indirectly steers entrepreneurial choices toward transformation trajectories consistent with the twin transition. The prevalence of investments in process digitalization, software, R&D, and energy efficiency suggests that entrepreneurs used the resources to strengthen productive and organizational capabilities oriented toward long-term objectives.
This result is consistent with the literature on the directionality of digital transformation, which emphasizes that complementarities between digitalization and sustainability are not automatic but depend on intentional strategic choices. In this sense, GCB operates as an orienting mechanism, creating financial and temporal incentives that make sustainability-aligned entrepreneurial decisions more likely, even in the absence of stringent ex ante environmental constraints.
However, the evidence also suggests that such orientation strongly depends on the organizational capabilities of beneficiary firms. This implies that financial instruments, while capable of favoring the directionality of transformation, cannot substitute for entrepreneurial agency and the competences required to systematically integrate digitalization and sustainability.

RQ3 – Territorial context, selectivity, and limits of entrepreneurial agency. The third research question situates the findings within a broader territorial perspective. Analysis of the portfolio composition reveals a sectoral concentration consistent with regional development trajectories, but also a significant geographic concentration in the economically stronger areas of the region. This result confirms that entrepreneurial agency is deeply conditioned by context, in line with the literature on local innovation systems and territorial inequalities.
On the one hand, territorial selectivity may be interpreted as an outcome of the market discipline embedded in the instrument, which favors firms with more manageable risk profiles and stronger organizational capabilities. On the other hand, it highlights the limits of sophisticated financial instruments in reaching firms located in more fragile contexts, where financial and institutional gaps reduce entrepreneurs' ability to access and benefit from such tools.
This evidence suggests that GCB's impact on entrepreneurial agency is heterogeneous and depends on the interaction between financial architectures and territorial contexts.

6. Conclusions and implications

This study analyzed the *Garanzia Campania Bond* program as a case study to understand how hybrid regional financial instruments may affect SMEs' entrepreneurial action, contributing to the governance of the twin transition in contexts characterized by post-globalization and structural uncertainty. Adopting a theory-driven case study approach, the paper shows that the twin transition is not the automatic result of technological adoption or the availability of financial resources, but a deeply entrepreneurial process in which financial architectures play an active role in shaping entrepreneurs' strategic decisions.

Theoretical contributions
From a theoretical perspective, the paper's main contribution lies in repositioning finance at the center of the entrepreneurship debate, interpreting it not as a simple enabling factor but as a device of entrepreneurial agency. The GCB case shows that hybrid financial instruments can recalibrate risk perception, expand strategic discretion, and extend the time horizon of entrepreneurial decisions, making possible the intangible and transformative investments typical of the twin transition.
Second, the paper contributes to the twin transition literature by highlighting the directional and governed nature of digital transformation. The findings suggest that alignment between digitalization and environmental sustainability does not emerge spontaneously, but depends on the interaction between entrepreneurial agency and financial architectures that orient investment choices. In this sense, the study enriches existing research — which mainly focuses on technological or

environmental outcomes — by showing that the direction of transformation results from specific financial and decision-making mechanisms.
Finally, the study contributes to the literature on entrepreneurship and territorial contexts by showing that the impact of financial instruments on entrepreneurial agency is heterogeneous and strongly conditioned by institutional and regional environments. This result reinforces the interpretation of entrepreneurship as a situated phenomenon emerging from the interaction among entrepreneurs, instruments, and local systems rather than as an exclusively individual expression.

Implications for entrepreneurship research
The paper opens several avenues for future research. First, it suggests the need to integrate more systematically the literature on entrepreneurship and SME finance, shifting attention from capital-access outcomes alone to entrepreneurial decision-making processes and the mechanisms through which financial architectures shape agency.
Second, future studies could further investigate the role of financial instruments as agentic devices through comparative approaches across regions, sectors, or types of instruments, as well as through longitudinal research designs capable of capturing the evolution of entrepreneurial agency over time. In particular, integrating micro-level qualitative data — for example, interviews with entrepreneurs — would allow more direct observation of the underlying cognitive and decision-making processes.
Finally, the study suggests further exploration of the interactions among entrepreneurship, sustainability, and digital transformation in post-globalization contexts, with attention to the role of institutions and place-based policies in creating favorable conditions for inclusive and long-term-oriented entrepreneurial transformation.

Managerial and policy implications
From a managerial standpoint, the findings indicate that SME entrepreneurs can benefit significantly from structured financial instruments that reduce perceived risk and enable planning over longer investment horizons. However, such benefits are not automatic: they require adequate organizational capabilities and entrepreneurial competences to integrate digitalization and sustainability into coherent long-term strategies. Entrepreneurs are therefore called to develop a strategic vision that goes beyond mere technological adoption, using financial instruments as levers for transformation.
For financial intermediaries and policymakers, the GCB case highlights the importance of designing instruments that do not merely fill financial gaps but actively accompany entrepreneurial action throughout the transformation process. This implies particular attention to instrument governance, risk-sharing arrangements, and adaptive capacity over time. Moreover, the findings suggest that sophisticated financial instruments, if not accompanied by complementary capacity-building and entrepreneurial support policies, risk favoring already structured firms and limiting their inclusive impact.

Limitations and future directions
This study presents several limitations. The analysis is based on a single case study and therefore does not allow statistical generalization. In addition, the availability of data on the long-term outcomes of the financed investments — particularly regarding environmental and digital performance — is still limited. As noted, the absence of direct data on entrepreneurs' decision-making processes represents an additional limitation.
Despite these constraints, the paper offers a meaningful analytical generalization, showing how hybrid regional financial instruments may operate as governance architectures capable of shaping entrepreneurial agency in contexts of uncertainty and post-globalization. Future research may extend and test these insights through comparative and quantitative approaches, contributing to a deeper understanding of the role of finance in entrepreneurial transformation.

Humanistic Enterprise and Reputational Vulnerability: Evidence from the Brunello Cucinelli Case

DAVIDE ALFIERI[1], MARIA ROSARIA NAPOLITANO[2]

Abstract

This paper examines how public accusations become intelligible as brand transgression episodes when a brand has built its legitimacy around an explicitly humanistic and morally charged identity. Focusing on Brunello Cucinelli, the study analyzes two recent episodes that challenged the symbolic coherence of the brand: the September 2025 accusations concerning the company's operations in Russia and the February 2026 testimony-based allegations regarding employees' experiences and organizational practices. Adopting an embedded single-case study design, the paper relies on a diversified set of documentary sources, including official corporate materials, investor-facing documents, public statements, journalistic coverage, observable market-facing signals, and academic papers. The findings show that, although both episodes challenged the same symbolic core of the brand, they generated markedly different public trajectories. The Russia-related accusations produced stronger media visibility, market reaction, and explicit organizational engagement, whereas the employee-related allegations, while symbolically more corrosive to the brand's humanistic promise, remained less institutionally amplified and less visibly addressed. The paper interprets this asymmetry by suggesting that the public salience of brand transgression depends not only on the symbolic seriousness of an accusation, but also on its public legitimacy, amplifiability, and the degree of organizational engagement it elicits. The study contributes to brand transgression research by showing how heterogeneous accusations may converge on the same moral brand promise while diverging in their post-event trajectory.

Keywords: *humanistic enterprise; brand transgression; brand promise; reputational vulnerability; public legitimacy*

1. Introduction

The relationship between consumers and brands is often compared to interpersonal relationships because similar relational dynamics may develop over time (Alvarez & Fournier, 2016; Fournier, 1998). Within this perspective, brand transgressions, understood as violations of implicit or explicit norms within the relationship with consumers, can significantly affect the bond established with consumers. Such dynamics are especially relevant for brands that present themselves as sincere, human-like, and responsible, since these brands build their legitimacy not only on product or service quality, but also on a strong identity, enduring values, and perceived coherence across consumer interactions and institutional communication (Aaker et al., 2004). When public accusations circulate, these brands may become particularly exposed to reputational erosion and face negative behavioral responses, with repercussions for their symbolically and emotionally rich brand promise (Aaker, 1996, 2014).

Although brand transgression research has advanced our understanding of norm violations, stakeholder reactions, and recovery processes, more insights are needed to understand how acts of transgression unfold for those brands whose public legitimacy rests on explicit moral and humanistic promises. This limitation is especially relevant when such legitimacy is strongly personified in the founder, so that public accusations potentially challenge not only the organization itself, but also the symbolic authenticity given to the brand by the founder's values (Hamby et al., 2019). As a result, we still know relatively little about how heterogeneous public accusations may converge in destabilizing the symbolic core of a stakeholder-oriented brand.

This paper addresses this issue through a single embedded case study of Brunello Cucinelli, an Italian luxury brand in the fashion industry. The company is internationally known for its so-called

[2] University of Naples Parthenope, e-mail: mariarosaria.napolitano@uniparthenope.it.

humanistic management philosophy and socially responsible identity, both strongly embodied in the figure of its founder. Recently, the company has faced two public accusation episodes that are analytically relevant to brand transgression theory: first, the accusations concerning its market operations in Russia in September 2025; second, the public allegations published in February 2026, based on reported testimonies by current and former employees, which challenged the coherence of the brand's corporate social responsibility narrative. While different in nature, the two episodes are analytically comparable because both called into question the alignment between brand promise and publicly attributed conduct. The empirical reconstruction relies on multiple sources, namely corporate identity documents, official company statements, investor-relations materials, and reputable journalistic coverage and academic literature. The paper's contribution is primarily analytical: it shows how different public accusations may converge in destabilizing the symbolic core of a humanistic brand, thereby extending the empirical readability of brand transgression theory in a contemporary setting.

The paper proceeds as follows. First, we introduce brand transgression through a theoretical lens and its implications for brands characterized by moral and humanistic claims. Second, we present the methodology and the case background. Third, we analyze the two episodes and discuss the findings in light of the literature. Finally, we conclude by outlining limitations and directions for future research.

2. Theoretical Background

A brand transgression is defined as an "act of violation of the implicit or explicit rules guiding consumer-brand relationship performance and evaluation" (Aaker et al., 2004, p. 2). This conceptualization is rooted in a view of brands not merely as transactional entities, but as relationship partners with whom consumers may develop meaningful bonds over time (Fournier, 1998). Interpersonal processes in consumer-brand relationships are often activated through brand anthropomorphism, whereby consumers attribute mindfulness, morality, and human-like qualities to brands (Alvarez & Fournier, 2016; Puzakova et al., 2013). Within this perspective, brands are not evaluated only in terms of product and service quality. Consumers may also rely on relationship norms when evaluating whether a brand has acted appropriately, coherently, or disappointingly (Aggarwal, 2004; Aggarwal & Law, 2005). Brand transgressions therefore concern specific relational ruptures, insofar as they call into question the trust, coherence, and accountability expected from the brand as a relationship partner (Aaker et al., 2004).

Subsequent literature has positioned brand transgressions within the broader discipline of negative events in marketing, namely significant negative incidents capable of triggering a reappraisal of the relationship between consumers and firms, brands, or offerings. This broader perspective is especially useful when the focal issue is not simply substandard performance, but the perceived violation of norms or standards. Brand transgressions should therefore not be understood as isolated episodes, but as temporally extended relational processes that unfold along the customer journey (Khamitov et al., 2020). Since transgressions occur within an already established relationship, their meaning and consequences are shaped by prior promises and relational configurations, which can be framed as the pre-event phase of the transgression process. In these terms, the transgressive incident represents the core event and subsequent brand and stakeholder responses belong to the post-event phase. This view implies that the same negative episode may be interpreted differently depending on the relationship that preceded it, including its strength, trust, commitment, and relational expectations (Grégoire et al., 2009; Su et al., 2022). This explains why prior research has frequently relied on experimental, survey-based, and in some cases longitudinal designs to examine how negative brand episodes unfold in the presence of different relational types and across different phases of the customer journey.

Prior research has also shown that the outcomes of brand transgressions are not homogeneous. Post-transgression forgiveness, for example, depends on the interaction between relationship strength

and controllability attributions, while also being shaped by consumers' self-construal and their orientation toward justice or relationship maintenance (Sinha & Lu, 2016). Severity also matters, since more serious transgressions tend to reduce forgiveness and weaken downstream behavioral intentions, including repurchase intentions (Tsarenko & Tojib, 2015). More recent work has further shown that consumer responses differ depending on the type of transgression involved. In particular, a relational perspective distinguishing between performance-related and performance-unrelated transgressions suggests that the impact of brand transgression on consumer choice is also moderated by moral identity, thereby highlighting the relevance of morality-based individual differences in shaping responses to negative brand episodes (Rosendo-Ríos et al., 2025).

A particularly important implication of this literature is that strong consumer–brand bonds do not automatically protect brands from adverse reactions. As a matter of fact, previous studies showed that when failure occurs, customers who had a strong prior relationship with the firm react more negatively in the long run, especially in terms of disaffect and avoidance (Grégoire et al., 2009). In some cases, firms even face direct and indirect avengers (Grégoire et al., 2018). Thus, when the transgression is ethically charged or personally relevant, close brand relationships may lose their buffering effect and, under some conditions, intensify the significance of the violation (Trump, 2014). In a similar vein, betrayal should not be treated as a mere extension of dissatisfaction. It represents a qualitatively deeper response, associated with psychological loss, rumination, indignation-focused anger, and self-castigation, all of which indicate that the transgression has affected not only evaluations of the brand, but the meaning of the relationship itself (Reimann et al., 2018).

Brand characteristics further shape how transgressions are interpreted and amplified. Sincere brands appear especially vulnerable because they elicit stronger partner-quality expectations, while anthropomorphized brands tend to be judged more harshly when wrongdoing occurs, as consumers are more likely to attribute intentionality, responsibility, and stable traits to them (Aaker et al., 2004; Puzakova et al., 2013). Related work suggests that brands perceived as more agentic and cognitively capable are also more likely to elicit blame, anger, and punishment in the face of transgressive conduct (Huang et al., 2020). At the same time, post-event outcomes depend not only on stakeholder interpretations, but also on how firms respond. Apologies, denials, and remedial actions may influence forgiveness and repurchase intentions, although their effectiveness varies depending on transgression severity and prior awareness of the brand's socially responsible behavior (Tsarenko & Tojib, 2015). Corporate social (ir)responsibility itself represents an expanding platform on which acts of transgression can take place, threatening a specific dimension of brand credibility (Lock & Seele, 2017; Riera & Iborra, 2017). These transgressions acquire broader significance through public circulation, newsworthiness, and media amplification. Negative events linked to corporate irresponsibility are more likely to become economically consequential when they attract wider media coverage, and stronger brands may be particularly exposed because their salience increases the probability of public attention (Stäbler & Fischer, 2020). These insights are especially important for qualitative case-based research, because they suggest that brand transgression may be examined not only through direct measures of consumer response, but also through observable traces such as public accusations, organizational responses, media attention, and market-facing consequences.

The overall theoretical lens supported by this body of literature is particularly useful when the brand's legitimacy rests on explicit moral and humanistic promises, since accusations of inconsistency may challenge not only organizational conduct but also the coherence of the brand's symbolic core. It becomes even more salient when such legitimacy is strongly personified in the founder, so that public accusations potentially affect the overlapping authenticity between founders and brands (Hamby et al., 2019). In this sense, brand transgression provides an appropriate interpretive lens for examining the Brunello Cucinelli case as a contemporary and publicly unfolding challenge to brand coherence.

3. Methodology

3.1. Research design

We adopted a single embedded case study design to investigate how recent public accusation episodes involving a stakeholder-oriented Italian luxury brand can be interpreted through the lens of brand transgression. Case study research is particularly appropriate when the research objective is to develop a detailed understanding of "how" and "why" (Yin, 2018). According to previous literature, brand transgression is a phenomenon that depends on specific contextual elements related to brand attributes and behavior, along with stakeholders' responses. This makes the case study approach methodologically suitable, since the phenomenon is not independent and detachable from its setting. Given the nature of the phenomenon, with the present study we do not aim at generalization, but rather advance a theory-informed interpretation of a contemporary brand case in its specific real-life circumstances (Stake, 1995). The overall case is Brunello Cucinelli, while the two accusation episodes examined in the paper are treated as embedded units of analysis. Although the two episodes are different in content, consequences and sources for data collection, the adopted design allowed us to preserve the integrity of the brand case while analytically comparing distinct transgressions that challenged the brand's symbolic core dimension in different ways (Yin, 2018).

3.2. Case selection

We selected Brunello Cucinelli as an information-rich and theoretically relevant case because of the strong moral, humanistic, and founder-centered identity that characterizes the brand. Its stakeholder orientation, humanistic business ethics, and corporate social responsibility efforts have already been the subject of multiple studies (Donato et al., 2019; Napolitano & Fusco, 2019), which collectively portray the company as a value-laden and symbolically distinctive business case. The heritage-infused identity and territorial embeddedness of the brand further reinforce theoretical relevance, as these characteristics contribute to a public image strongly grounded in continuity, authenticity, and moral coherence, enriching also the well-discussed stakeholder orientation (Napolitano et al., 2018; Rindell & Santos, 2021; Riviezzo et al., 2021; Urde et al., 2007). Our choice was therefore motivated by analytical potential: two recent accusation episodes, different in nature yet directed at the same symbolic core of the brand, make Brunello Cucinelli especially suitable for examining how brand transgression may unfold in a humanistic and founder-personified brand.

3.3. Data collection

We based data collection on the construction of a documentary case study database aimed at reconstructing both the pre-event brand identity context and the two accusation episodes analyzed in the study. For the sake of credibility and reliability, we selected multiple types of materials to reconstruct the case. These sources comprised academic papers, corporate identity documents, official company statements, official visual communication materials, investor-relations materials, high-reputation journalistic coverage, and, where available, publicly observable market-facing signals. Official visual communication materials included selected campaigns published on the company's corporate website and used to reconstruct the visual and narrative articulation of the brand promise. Since the company released an official documentary film in December 2025, we also considered it as an official source for reconstructing the brand promise in the pre-event phase. Although this occurred between the two transgression episodes, we decided to include it in the collected materials since the brand narrative antecedent to the first episode (September 2025) was reinforced and not changed.

Our approach was not intended to establish judicial certainty regarding the facts under dispute, but to compare different narrative positions to get a complete understanding of the case. The database ensured traceability, comparability, and analytical consistency across the two embedded episodes. For each source, the database recorded the link or document reference, source type, publication date, relevance to the two episodes and to the three brand transgression phases, and notes concerning its

content and potential analytical contribution. For journalistic sources we assessed credibility based on national and international relevance and resonance, maintaining an objective approach. Our final corpus included 14 web pages from the official main and investor relations websites, 4 official corporate documents, 1 corporate documentary film, 19 corporate campaigns, 18 non-scientific national and international publications and 5 academic sources.

3.4. Data analysis

We conducted data analysis through a comparative interpretive reconstruction of the two embedded accusation episodes. In line with the three-phase perspective adopted in the study, we classified all materials according to pre-event, core event, and post-event. This phase-based organization made it possible to reconstruct not only the focal episodes, but also the relational and symbolic conditions that preceded them and the observable developments that followed them.

More specifically, in the pre-event phase we included materials used to reconstruct the brand promise and public identity of Brunello Cucinelli before the emergence of the accusations (e.g., official website communications, past visual campaigns). In the core event phase we included materials directly related to the accusations themselves (e.g., the Morpheus Research report and related journalistic articles, Lucarelli's article). Finally, in the post-event phase we included materials documenting the organizational response, the public development of the episode, and any observable reputational or market-facing signals (e.g., press release). We first reconstructed each episode individually and then compared them to identify similarities and differences in the way they challenged the symbolic core of the brand.

4. Case background

Brunello Cucinelli is an Italian luxury fashion company whose origins date back to 1978, when its founder launched the business around what the company itself presents as a then-innovative idea: colored cashmere knitwear for women. Over time, this entrepreneurial initiative developed into a globally recognized luxury brand, while maintaining a strong symbolic and productive anchorage in Italy. A crucial stage in this trajectory was the move to Solomeo, the small medieval hamlet near Perugia that progressively became one of the most distinctive elements of the company's public identity. In the company's own narrative, Solomeo is not simply a location but part of a broader moral and aesthetic project linking craftsmanship, beauty, place, and work («The company continued to grow in step with my love for this village, to the point that I began to imagine a sort of rebirth», from the company website). Today the company's economic relevance is reflected in its recent financial performance: Brunello Cucinelli closed 2025 with a net profit of €142 million and proposed a dividend of €1.04 per share, confirming its solid market position.

Official corporate materials consistently frame the company through the language of "humanistic capitalism" and "human sustainability", presenting economic activity as inseparable from human dignity, fair work, respect for privacy, and responsibility toward communities and places. In this view, profit is not denied, but morally framed, as Brunello Cucinelli stated in his speech at the G20 in Rome in 2021: «I wanted a company that made healthy profits, but did so with ethics, dignity and morals». This orientation is also rooted in the founder's autobiographical narrative, where he explicitly recalls learning «the great theme of life: the balance between profit and giving» from his childhood experience in the countryside. This means that the brand promise extends well beyond product quality or luxury performance and incorporates explicit ethical and relational expectations, consistent with a shared value model (Porter & Kramer, 2011) and a corporate humanistic responsibility view (Arnaud & Wasieleski, 2014). Official visual campaigns also reinforce this promise over time, repeatedly mobilizing themes such as humanism, beauty, harmony, privacy, truth, and respect for nature. In institutional communication the company always presents craftsmanship, manual skills, and Made in Italy know-how as central dimensions of its ethos. The territorial

embeddedness of the brand therefore does not function merely as a heritage cue or as a backdrop for storytelling, but as part of a wider claim to authenticity and coherence. Here again, the founder's self-narrative is meaningful: recalling his early life, he writes that «we lived in harmony with Creation», linking work, order, beauty, and respect for the natural world within a single moral horizon. In this sense, the company's self-presentation suggests that commercial success, organizational conduct, and moral legitimacy should appear aligned.

A further reason why the case is analytically significant lies in the centrality of the founder himself. The public image of Brunello Cucinelli is deeply intertwined with the identity of the firm. The official corporate narrative explicitly associates his entrepreneurial path with the moral and economic dignity of human beings, as well as with a broader philosophy of work and life. As a result, the legitimacy of the brand appears to rest not only on organizational claims, but also on a strong symbolic overlap between founder identity and brand identity.

Against this background, the relevance of the case lies in the fact that the two recent accusation episodes examined in this paper concerned a brand whose legitimacy had long been built around moral coherence, human dignity, organizational responsibility, and founder personification. This makes Brunello Cucinelli a particularly suitable case for examining how public accusations may challenge the symbolic core of a humanistic brand.

5. Findings

5.1. Episode 1: The accusations on operations in Russia

On 25 September 2025 Morpheus Research, a short-selling and investigative platform founded by financial analysts, published a report (morpheus-research.com/cucinelli) accusing Brunello Cucinelli of continuing to operate in Russia inconsistently with EU sanctions and of misleading investors about the scope of its Russian business. The report was presented as the result of more than three months of investigation, involving interviews with former Cucinelli employees and partners, an extensive analysis of trade data, and visits to Cucinelli's Russian stores.

The allegations rapidly moved beyond the originating report and acquired immediate public visibility through both financial and general news coverage. On the same day, trading in Brunello Cucinelli shares was suspended pending a company statement, and the stock recorded a double-digit decline, with reports indicating a fall of 17.28% on 25 September 2025. Italian and international media framed the case not only as a financial controversy, but also as a reputational shock affecting one of the most symbolically distinctive Italian luxury brands.

Brunello Cucinelli responded immediately through an official statement released on 25 September 2025. In that statement, the company firmly rejected the accusations and reaffirmed full compliance with EU rules. More specifically, it stated that its continued presence in Russia was limited to activities considered lawful, including the maintenance of local structures, the payment of salaries and rents, and the management of shipments within the applicable regulatory framework. The statement also rejected the claim that the Russian market had been used to dispose of excess inventory, emphasized the sharply reduced economic relevance of Russia for the group, and announced that the company was evaluating possible legal action to protect its reputation and stakeholders. In the days that followed, this line was reiterated in public reporting and investor-facing communication. The episode quickly evolved from an accusation originating in a report produced by a financially interested actor into a public challenge to the consistency between the brand's declared values and its attributed conduct in Russia.

5.2. Episode 2: The employee-related allegations

Against a pre-event promise centered on the dignity of work, respect for the person, and a humanistic vision of enterprise, the employee-related episode publicly challenged the internal credibility of the brand's organizational self-presentation. The episode emerged on 10 February 2026,

when the Italian journalist Selvaggia Lucarelli published on Substack an extended version of an inquiry released the same day in *Il Fatto Quotidiano*. The article was explicitly framed as a challenge to the widely circulated image of Brunello Cucinelli as an exemplary employer and was based on reported testimonies from current and former employees.

The allegations did not concern a single isolated incident, but a broader pattern of perceived inconsistency between the company's humanistic narrative and everyday organizational experience. Some reported testimonies described a work environment marked by pronounced asymmetries of status and by interactional rules experienced as degrading rather than respectful. Others referred to episodes of verbal aggression, public reproach, and managerial conduct perceived as inconsistent with the image of a human-centered enterprise. Additional claims concerned organizational control and pressure, including the perception that the public narrative of balance, beauty, and civilized working conditions did not correspond to the everyday reality experienced by at least some workers.

The allegations acquired secondary public visibility through other online outlets and social media posts, but in a rather limited way. The available materials do not indicate a broad institutional amplification of the episode through major financial or general news outlets, nor do they show clearly identifiable market-facing consequences.

Regarding the organizational response, Lucarelli stated that she attempted to contact Cucinelli before publication, but that the press office reportedly indicated there was no interest in further addressing the matter. Beyond this, no visible formal public response of comparable prominence was identified in the materials collected for this study. This shows how the episode did not unfold through an explicit and structured organizational rebuttal. Nevertheless, it remains relevant because it strikes directly at the organizational and relational core of the brand promise.

5.3. Cross-episode comparison

Although different in sources, content, and public trajectory, the two episodes can be analytically compared because both activated a perceived incongruence between Brunello Cucinelli's pre-event brand promise and publicly attributed conduct. Table 1 summarizes the main empirical dimensions through which the two episodes were reconstructed and compared.

Tab. 1: Cross-episode comparison

	Episode 1	**Episode 2**
Content of the promise	Fair profit, responsible economic conduct	Dignity of work, respect for the person
Trigger	Investigative report (short seller)	Journalistic investigation
Type of accusation	Inconsistency between declared values and market operations	Inconsistency between humanistic philosophy and organizational reality
Threatened credibility	External	Internal
Media coverage	Extensive	Limited
Organizational response	Immediate formal response	No formal response
Immediate repercussions	Temporary suspension of the stock and decline in share price	None clearly identifiable in market terms

Source: authors' own elaboration

The comparison highlights both convergence and asymmetry. In both cases, the accusations became relevant because they challenged a brand publicly grounded in moral coherence, dignity, and founder-personified legitimacy. At the same time, the two episodes differed significantly in accusation domain, public visibility, organizational response, and evidentiary robustness. The Russia-related case developed into a highly visible market-facing controversy accompanied by an immediate formal denial, whereas the employee-related allegations remained less amplified and were not followed by a comparably visible public rebuttal.

6. Discussion

In this study we examine two accusation episodes related to the Italian luxury brand Brunello Cucinelli through the lens of brand transgression. The brand is internationally known for its humanistic responsibility view and its stakeholder-oriented organizational conduct, which enhances the theoretical relevance of the case (Napolitano & Fusco, 2019).

Both episodes challenged the brand promise and the relational norms established over years with stakeholders, but in different ways and with different trajectories in the public space. The Russia-related accusations concerned Cucinelli's market conduct, which pertains to the economic pillar of sustainability (Elkington, 1997), more than the most intimate organizational dimension of the brand promise. Yet these accusations generated the strongest public transgression trajectory, with direct financial consequences and amplification from general news outlets. By contrast, the employee-related allegations appear symbolically more corrosive to the company's humanistic promise, because they targeted the internal credibility of its organizational narrative and the integrity of the founder himself. Nevertheless, they remained less institutionally amplified and unanswered by the organization.

This asymmetry suggests a useful distinction between symbolic severity and public claim legitimacy. Symbolic severity refers here to the extent to which an accusation appears to strike the core meaning of the brand promise. Public claim legitimacy, by contrast, refers to the extent to which an accusation appears publicly plausible, documentable, amplifiable, and therefore difficult for the organization to ignore. Thus, the Russia-related accusations seem to have possessed greater public claim legitimacy, not in the sense of being established as truer, but in the sense of being more easily translated into a publicly actionable controversy. This interpretation is coherent with conceptualizations of claims' perceived legitimacy advanced in the growing historical brand transgression literature (Pecot et al., 2025; Schrempf-Stirling et al., 2016).

Seen from this angle, the organizational response becomes theoretically meaningful and reflects contextual elements. Denial does not function merely as a defensive move. It can also be read as an indicator that the accusation had already reached a level of public legitimacy and visibility that made non-engagement too costly. The company's immediate rebuttal, reaffirmation of compliance, and consideration of legal action all suggest that the accusation had become a public challenge requiring explicit organizational engagement. In the employee-related episode, by contrast, the absence of a visible formal public response of comparable prominence may indicate either that the accusation did not achieve the same degree of institutional legitimacy or that a strategy of non-amplification was preferred. In both cases, no compensatory actions emerged in the materials analyzed. However, in this paper we provide a short-term reading of the case. The literature reviewed above underlines that brand transgressions are temporal phenomena whose consequences may unfold over time (Khamitov et al., 2020). Not only can consumers "hold a grudge" (Grégoire et al., 2009) with a desire for revenge or avoidance, but companies that rely on collective forgetting in the long run may also create additional layers of historical irresponsibility and generate a compounded liability (Coraiola & Derry, 2020). This means that the case could become more significant in terms of its future consequences and the company may be held accountable for past alleged or perceived wrongdoings.

Overall, the findings suggest that brand transgression trajectories should not be inferred from accusation content alone, but from the entire process. From this perspective, the main contribution of the paper is to refine the empirical readability of brand transgression in a specific but revealing setting. The case shows that, in a humanistic and founder-personified brand, heterogeneous accusations can converge in challenging the same symbolic core while diverging sharply in their public trajectory. It also suggests that studying brand transgression in such contexts may require attention not only to stakeholder reactions in the narrow sense, but also to the public legitimacy of accusations, the form of organizational engagement they provoke, and the post-event signals through which they become consequential.

Managerially, the case suggests that explicit moral and humanistic promises increase both symbolic strength and vulnerability to accusations of inconsistency. It also indicates that different accusation types may require different response strategies, depending on their public legitimacy and amplifiability. For such brands, managers should pay particular attention to both employees' lived experience and the informational flows through which internal organizational conditions may become publicly visible.

7. Limitations and future research

This study examines two brand transgression episodes within a contemporary time frame. Because the analysis focuses on recent and still unfolding public episodes, consumer perceptions are not investigated directly through primary data. This represents an important limitation of the study, as the analysis relies on documentary and public materials rather than on direct evidence of stakeholder interpretation. Future research could complement this perspective through survey-based, experimental, or interview-based designs capable of capturing how different audiences interpret and respond to such episodes. The two episodes also differ in evidentiary robustness, with the second requiring greater caution because it is primarily grounded in testimony-based public allegations. These limitations do not invalidate the analysis but define the scope of its contribution as mainly analytical and interpretive (Patton, 1999; Yin, 2018). Future research could also examine other cases involving multiple subsequent transgressions in high-moral-identity brands, adopting a more explicitly theory-building approach.

Brand Awareness as a Threshold Condition: How Attitudes Translate into Willingness to Pay for the Mountain Product Label

GIADA SALVATORE[1], ELENA SARTI[2], FRANCESCA DE CANIO[3]

Abstract

Frame of the research. *Despite its institutional value, the EU optional quality label "Mountain Product" suffers from an awareness gap among consumers and this may limit its effectiveness as a market signal. Moreover, little is known about the psychological mechanisms that translate label recognition into economic commitment.*

Purpose of the paper. *Drawing on signaling, this study investigates whether Brand Awareness activates a structured evaluative process leading to Willingness to Pay through Brand Attitude.*

Methodology. *Primary research data were gathered through a survey based on the administration of a questionnaire to a sample of Italian consumers. SEM is employed for two sub-samples segmented by self-reported awareness levels of the Mountain Product label.*

Results. *Brand Attitude drives monetary evaluation in both sub-samples, but the consumer is inclined to pay a premium price not only because of his/her degree of recognition of the label, but because there is an affective evaluation that play a role within the relationship.*

Research limitations. *Generalizability is limited by the use of a convenience sample and its cross-sectional nature.*

Managerial implications. *Results provides insights for policymakers and agri-food stakeholders enhancing the economic value of mountain-origin products. Strategic priority should be given to establish a cognitive baseline for consumers through educational contents. Afterwards, managers must focus on Brand Attitude, which serves as critical mediator for translating label recognition in economic commitment.*

Originality of the paper. *This study contributes to the consumer behaviour literature, highlighting the role of Brand Attitude in the relationship between label awareness and price premium.*

Keywords*: Mountain Product Label, Brand Awareness, Brand Attitude, Willingness to Pay, SEM.*

1. Introduction

In the contemporary food market, there is an escalating consumer demand for products characterized by authenticity, local provenance, and a well-defined geographical identity (Feldmann & Hamm, 2015). This trend is exceptionally prominent for foodstuffs originating from mountainous regions, which are widely recognized for their high-quality artisanal production that mirrors the unique biodiversity, traditional landscapes, and rich cultural heritage of these territories. Despite this prestige, mountain areas represent a paradox of high ecological value coupled with extreme socio-economic vulnerability (Duglio et al., 2022; Sturaro et al., 2013). These regions face systemic challenges, including harsh climatic conditions, complex topography, and persistent phenomena such as depopulation and land abandonment. Such adverse factors not only hinder market competitiveness but also threaten the maintenance of traditional farming methods and the survival of the socio-ecological systems they support (Dax et al., 2021).

To address these challenges and safeguard the livelihoods of mountain communities, the European Union introduced the Mountain Product optional quality term under the Regulation 1151/2012 on quality schemes for agricultural products and foodstuffs. This represented a significant evolution in the European regulatory landscape, shifting the institutional focus toward the enhancement of mountain-origin foodstuffs through a powerful valorization tool.

The Mountain Product label is exclusive to products intended for human consumption originating

[3] University of Modena and Reggio Emilia, Email: francesca.decanio@unimore.it

from mountain areas, distinguishing itself from traditional certification schemes, since it operates within the broader regulatory framework of food labeling, without technical production specifications and certifications.

The Mountain Product label serves a dual strategic purpose: supporting the local economy, particularly the agri-food sector, while providing consumers with assurances regarding the origin and authenticity of these goods. By promoting unique characteristics and traditional production methods, the label allows producers to differentiate their products in a crowded marketplace, offering consumers verified indicators of quality, authenticity, and sustainability.

However, despite the strategic potential of the label, empirical evidence raises questions about its market effectiveness. Recent studies consistently highlight a pervasive awareness gap, showing that a vast majority of European consumers remain unfamiliar with the designation (Oliveira et al., 2021; Staffolani et al., 2023). Research suggests that while the label embodies attributes highly desired by consumers, such as healthiness, safety, and environmental stewardship, its signaling function is often compromised by the lack of cognitive salience (Oliveira et al., 2021; Staffolani et al., 2023). Moreover, the existing literature has confirmed a general positive Willingness to Pay (WTP) for mountain-labeled goods (Stiletto and Trestini; 2022; Bentivoglio et al. 2020) but the internal psychological mechanisms that translate initial signal recognition into an economic premium remain insufficiently explored. Specifically, there is a lack of research on how Brand Attitude (ATT) plays a role within the relationship between Brand Awareness (AWA) and Willingness to Pay.

This study addresses this gap by proposing a model where Brand Attitude acts as a pivotal bridge between awareness and economic commitment. Furthermore, acknowledging that the consumer base is not monolithic, we provide an original contribution by investigating the heterogeneity of this signaling process. More specifically, we test whether the behavior mechanism operates differently across segments with different levels of prior knowledge. This approach allows us to determine if high awareness not only increases the likelihood of purchase, but also fundamentally alters the strength and coherence of the Attitude-WTP nexus, offering a more granular understanding of how institutional labels can be effectively leveraged in complex food markets.

The paper is organized as follows: Section 2 develops the theoretical background; Sections 3 and 4 detail the hypotheses, sample and methodology; Section 5 reports the empirical results; and Sections 6 and 7 discuss conclusions and implications for policy-makers and stakeholders.

2. Theoretical Background

This section establishes the theoretical foundation for investigating the market value of the Mountain Product optional quality term. It employs Signaling Theory to explain the cognitive mechanisms, specifically Brand Awareness (AWA) and Brand Attitude (ATT), that translate into Willingness to Pay (WTP), used to determine consumers' economic commitment. A conceptual model is then proposed to test how these structural relationships vary across different levels of consumer awareness.

2.1 The Mountain Product Label to Support Resilience in Mountain Areas

In the last decades, the European agri-food system has undergone a radical transformation, shifting its focus to territorial specificities and differentiated quality. Within this context, the Common Agricultural Policy (CAP) has played a pivotal role, evolving from an economic support mechanism into a vital driver of resilience for marginal territories like mountainous regions, which hold immense significance, as they cover over a third of the total European territory and house approximately 20% of its population. However, despite their importance, these regions have faced a severe process of deruralization, resulting in the widespread abandonment of mountainous land, the decline of traditional farming activities and significant depopulation. Consequently, this led to the breakdown of the economic, cultural, and social systems that are traditionally unique to these territories (Bucci, 2017). Unsurprisingly, mountain areas have been historically identified by the European Union as

Less Favoured Areas (LFAs) under Article 18 of EC Regulation No. 1257/1999. This designation is specifically attributed to regions characterized by high costs of agricultural activity due to unfavorable climatic conditions related to altitude and complex morphological constraints, such as steep slopes, which make the mechanization of production processes challenging or even infeasible, and the typical lower soil fertility compared to lowland counterparts.

To address these systemic challenges, the European Union's regulatory landscape underwent a significant evolution with the introduction of Regulation 1151/2012 on quality schemes for agricultural products and foodstuffs, marked by the incorporation of Optional Quality Terms. Within this framework, the Mountain Product designation stands out, representing a powerful tool for the enhancement of mountain-origin foodstuffs. To qualify, the label requires that products are intended for human consumption, with both the raw materials, animal feedstuffs and the processing stages strictly located within defined mountain territories.

Unlike Protected Designations of Origin (PDO) and Protected Geographical Indications (PGI), which safeguard specific names linked to strict production specifications, the Mountain Product label serves as a more transversal and optional indication, designed to emphasize the unique characteristics of products originating from areas where challenging natural and production conditions prevail, leveraging the rich traditions and local knowledge related to food processing. The flexibility and simplified nature of the label is reflected by the absence of technical complex production specifications, certifications, and the lack of involvement of certification bodies typical of formal certification schemes. These characteristics make the label a more accessible instrument for local producers to leverage authenticity as a competitive advantage.

The underlying policy objective of the label extends far beyond simple consumer protection, representing an institutional territorial branding strategy. By promoting the distinctiveness, the label aims to generate added value for local producers, thereby compensating for the diseconomies of scale typical of these agricultural systems. Ultimately, the label acts as an instrument of resilience: the goal is to effectively transform geographical disadvantages into competitive advantages and support the socioeconomic resilience of mountain communities, counteracting critical phenomena such as land abandonment, loss of biodiversity, and rural depopulation (Gragnani, 2013).

2.2 The Mountain Product Label in Consumer Research

The literature on the topic and the empirical research conducted over the last decade reveals a complex and often contradictory market landscape. A shared consensus on the existence of a significant awareness gap with respect to the label is present among scholars: despite its institutional status, the label remains partially unknown to the general public, posing a substantial barrier to the label's effectiveness as a quality signal (Oliveira et al., 2021; Staffolani et al., 2023), with limited understanding of its existence and the certification process. However, insights from Staffolani at al. (2023) suggest that once consumers become aware of the label, their perception of it is comparable to that of the Protected Designation of Origin (PDO).

Interestingly, the literature highlights that consumers consider mountain food products as intrinsically associated with highly positive attributes, such as naturalness, environmental sustainability, healthiness, and the preservation of traditional cultural heritage (Bassi et al., 2021; Bassi et al., 2022). Consumers perceive these goods as premium items, often evoking idyllic and pure imagery of mountain landscapes (Stiletto and Trestini, 2022). This positive image translates into a generally favorable attitude once the consumer is exposed to the label, because they tend to perceive the Mountain Product label as a hallmark of authenticity, safety, and traditional craftsmanship (Bassi et al., 2022). Moreover, factors such as personal attachment to mountain regions, tourism experiences, and a general green consumption orientation have been found to significantly strengthen these positive attitudinal dispositions (Bassi et al., 2021; Staffolani et al., 2023).

Academic literature also focused on the relationship between these perceptions and economic behavior, with a large portion of studies investigating consumers' Willingness to Pay. Despite the aforementioned low awareness, consumers consistently demonstrate a readiness to pay a price

premium for products bearing the Mountain Product designation compared to unlabeled alternatives. This premium has been empirically quantified in various food categories and it is consistently driven by the perceived added value of sustainable and traditional production methods (Stiletto and Trestini, 2022; Bentivoglio et al., 2020). Notably, the Mountain Product label has shown a capacity to generate utility levels comparable to more established schemes like the Protected Designation of Origin (PDO), suggesting its potential as a strategic differentiation tool for producers who do not fall under PDO specifications (Staffolani et al., 2023).

However, the efficacy of this value-creation chain, from recognition to price premium, is not uniform. Existing research points to significant heterogeneity in consumer responses based on socio-demographic factors and levels of cognitive engagement (Stiletto and Trestini, 2021; Bentivoglio et al., 2020). This variability underscores the complex interplay between consumer perceptions, product attributes, and label regulations in shaping the effectiveness of the Mountain Product scheme.

2.3 Decoding Quality: The Role of Labels in Food Consumption

In the contemporary food market, characterized by an escalating demand for quality and authenticity, Signaling Theory provides a robust framework for understanding how quality labels and quality schemes can act as extrinsic cues. Within this paradigm, labels can serve as strategic instruments to mitigate market and information asymmetry between producers, who possess full knowledge about the intrinsic quality of a product, and consumers, who would have to face prohibitive costs in verifying such attributes, that, as credence qualities, remain largely unobservable even post consumption (Javeed et al., 2022; Mardumyan et al., 2023).

This theoretical lens is particularly relevant for mountain food products, which are fundamentally defined by their credence attributes, namely qualities that remain unverifiable even post-consumption. Consequently, Geographical Indications (GIs) and the *Mountain Product* act as institutional proxies for *terroir* and provenance, transforming unobservable production standards into market signals (Artencio et al., 2022; Aprile et al., 2022; Proi et al., 2025).

The Mountain Product label encapsulate a multidimensional array of credence attributes to remain credible, functioning as a proxy for complex socio-ecological dimensions. By synthesizing these qualities into a single extrinsic cue, quality schemes act as potent instruments for product differentiation, effectively isolating mountain-origin foodstuffs from generic alternatives (Staffolani et al., 2023; Bispini et al., 2025; Mazzocchi and Sali, 2022).

Empirical evidence indicates that the successful transmission of these signals can catalyze a significant increase in Willingness to Pay. Specifically, consumers often exhibit a propensity to accept a price premium for certified mountain products compared to unlabeled counterparts, as the label mitigates the perceived risk associated with unobservable quality (Staffolani et al., 2023; Mazzocchi and Sali, 2022). This premium is particularly pronounced among psychographic segments characterized by high green involvement or a strong territorial attachment, where the label aligns with the consumer's internal value system (Staffolani et al., 2026; Schäufele-Elbers et al., 2024).

However, the efficacy of the signal is fundamentally moderated by the consumer's cognitive engagement and prior knowledge. Despite the inherent *halo* of tradition and purity associated with the mountain quality scheme (Mazzocchi and Sali, 2022), the role as value-drivers is compromised by asymmetries in consumer awareness (Staffolani et al., 2023; Bispini et al., 2025). When awareness is deficient, the signal remains undecoded, failing to activate the evaluative frameworks necessary to justify a premium price (Staffolani et al., 2026). This highlights a critical challenge, because poorly understood claims erode institutional trust (Hemar-Nicolas et al., 2024; Ray et al., 2022; Hasan et al., 2024). Such limitations underscore that the signal's ultimate impact is highly contingent upon the heterogeneous interpretive frameworks and awareness levels of the target audience (Xu, 2025).

2.4 From Cognitive Recognition to Economic Valuation: The Role of Brand Attitude

Building upon the framework of signaling theory, the effectiveness of a quality scheme is fundamentally rooted in a hierarchical cognitive process where Brand Awareness acts as a

foundational and functionally necessary precursor to the formation of any evaluative judgement. From a cognitive perspective, for a signal such as the *Mountain Product* designation to exert any influence over consumer evaluative processes, it must first be perceived and recognized. Within this hierarchical process, Brand Awareness ensures that the consumer not only notices the label but also processes it as a credible extrinsic cue; otherwise, without this initial cognitive salience, the signal remains latent and fails to trigger the mental associations necessary to shape a structured Brand Attitude (Menzel and Teubner, 2024; Lee et al., 2022).

The logical necessity of awareness is explained by the role of quality labels as heuristics in markets defined by information asymmetry. As discussed in the previous paragraph, brands and quality schemes serve as mental shortcuts that reduce the complexity of evaluating unobservable credence qualities (Jain et al., 2022; Seonbo et al., 2026). In this sense, the Brand Awareness of the label represents the essential entry point for these heuristics to operate: only once a label is recognized and its presence is cognitively validated, the consumer can proceed to form specific beliefs and affective evaluations (attitudes) based on the perceived credibility and symbolic meaning of the cue.

However, signaling theory alone does not fully account for the internal psychological mechanisms that translate a signal into a behavioral or economic response. In the agri-food sector, empirical evidence identifies Brand Attitude as the critical mediating variable linking the recognition of external quality cues to final purchase outcomes and pricing strategies (Di Domenico et al., 2022), bridging the gap between signal recognition and Willingness to Pay.

As underscored by Di Domenico et al. (2022), Brand Attitude represents a pivotal variable in marketing research, serving as a reliable predictor of purchasing preferences and a frequently employed mediator in the analysis of consumer buying behavior.

The *Signal-Attitude-Behavior* nexus is expected to exhibit significant heterogeneity based on the depth of the consumer's cognitive engagement, that is the level of Brand Awareness with respect to the *Mountain Product* label. In instances of low awareness, the signal's diagnostic capacity is attenuated, leading to fragmented or superficial attitude formation that may fail to translate into economic commitment. Conversely, high awareness facilitates a more coherent alignment between the label's values and the consumer's belief system, potentially strengthening the predictive power of Brand Attitude on Willingness to Pay. This theoretical heterogeneity necessitates to investigate how value creation differs fundamentally between low-awareness and high-awareness segments.

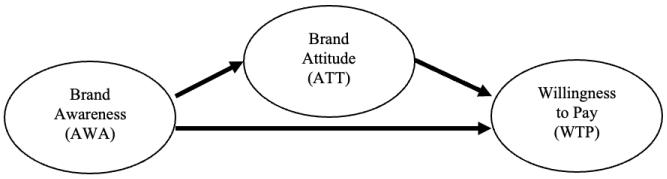
3. Hypotheses Development and Conceptual Model

Based on the theoretical framework and the empirical evidence previously discussed, this study explores the cognitive-evaluative path that leads consumers to valorize mountain-origin products. While Brand Awareness is a fundamental prerequisite for signal recognition, we posit that its impact on Willingness to Pay is not only potentially direct but is significantly processed through the consumer's evaluative framework. In the agri-food sector, quality labels act as cues that foster trust and positive perceptions. These perceptions merge into a Brand Attitude, which serves as a psychological bridge. A consumer accepts a price premium (WTP) because the label has successfully shaped a positive attitude that justifies the higher expenditure.

In addition, the literature emphasizes a persistent awareness gap regarding the Mountain Product label. This heterogeneity suggests that the signaling mechanism may not function uniformly. In high-awareness segments, the signal is decoded more effectively, potentially strengthening the link between attitude and economic commitment. Conversely, for consumers with low awareness, the signal may remain ambiguous, leading to a weaker attitudinal impact on WTP. To test this structural difference, we propose a model in which the sample is divided into two different and separated groups: one with low levels of knowledge of the Mountain Products and the other one with high levels of familiarity.

Consequently, we test the following hypotheses for both sub-samples separately:

H_1: Brand Awareness (AWA) has a positive effect on Brand Attitude (ATT), therefore AWA is an antecedent of affective evaluations.



H_2: Brand Attitude (ATT) has a positive effect on Willingness to Pay (WTP), therefore we expect that ATT drives monetary evaluation.

H_3: Brand Awareness (AWA) has a positive and direct effect on Willingness to Pay (WTP).

H_4: Brand Attitude (ATT) positively affects the relationship between AWA and WTP, therefore we expect the consumer being inclined to pay a *premium price* (WTP) for Mountain Products not only because of his/her degree of recognition of the label (AWA), but because there is an affective evaluation (ATT) that play a key role within the relationship.

Figure 1 illustrates the proposed theoretical framework.

Figure 1. Theoretical model

4. Data and Empirical Strategy

A survey was performed administering a structured questionnaire to a convenience sample of consumers. People have been approached just after the entry of a hypermarket in Italy and a total number of 317 questionnaires were collected on different days/weeks.

The final sample consists of 317 respondents, that are found being mainly women (68.1%), born between 1931 and 2005, and living in families composed mainly of two (37.9%), three (20.8%) or four (20.5%) members. Finally, around 40.1% of the sample states a family monthly income between 1,301 and 2,600 euro.

Measurement items included in the questionnaire were derived from the extant literature and adapted to the context of the study, assessed using a 7-point Likert scale anchored by *strongly disagree - 1* and *strongly agree - 7*.

Finally, Structural Equation Modeling (SEM) has been employed to test the forementioned hypotheses for two different sub-samples: one with very-low/low self-reported levels of brand awareness (i.e., all the three items of the latent variable ATT with a score lower than 4), and one with high/very-high self-reported levels of brand awareness (i.e., all the three items of ATT with a score higher than 4).

5. Empirical analysis and findings

Standardized loadings and p-values demonstrate that the measurement model provide evidence of robust convergent validity and internal reliability. Factor loadings are higher the threshold of 0.70 (Hair et al., 2010). We found statistically significant coefficients and this demonstrate a robust relationship between the items and their corresponding latent constructs (Table 1).

For all the three latent constructs (AWA, ATT, WTP) the convergence validity is assessed by the Average Variance Extracted (AVE) across all items associated with a construct. The AVE is higher than the recommendation of 0.5 for all latent variables, meaning that they explain more than 50% of the variance of their items (Hair et al., 2017a, 2017b).

For what concerns Cronbach's alpha and McDonald's omega, they always exceed the threshold, denoting a very good level of internal consistency of the chosen indicators (Hair et al., 2017a).

Table 1. Measurement Models Results

		Low AWA (1-2-3) N. 88		**High AWA (5-6-7) N. 110**	
Latent Constructs	Items	Standardized Factor Loadings		Standardized Factor Loadings	
Brand Awareness (AWA)	**AWA1**: I know the *Mountain Product* label. **AWA2**: I can distinguish the *Mountain Product* label. **AWA3**: I believe to be an expert of the *Mountain Product* label.	1.00*** 0.87** 0.80***	AVE: 0.80 Cronbach's alpha: 0.92 McDonald's omega: 0.92	0.90*** 0.94*** 0.74***	AVE: 0.75 Cronbach's alpha: 0.89 McDonald's omega: 0.90
Brand Attitude (ATT)	How do you consider buying food products with the *Mountain Product* label? **ATT1**: 1 negative – 7 positive **ATT2**: 1 very bad – 7 very good **ATT3**: 1 useless – 7 useful	 0.96*** 0.98*** 0.97***	AVE: 0.94 Cronbach's alpha: 0.98 McDonald's omega: 0.98	 0.94*** 0.97*** 0.97***	AVE: 0.92 Cronbach's alpha: 0.97 McDonald's omega: 0.97
Willingness to Pay (WTP)	**WTP1**: I buy *Mountain Products* even though they are more expensive. **WTP2**: I am willing to pay more to buy *Mountain Products*. **WTP3**: I believe it is fair to pay a higher price to buy *Mountain Products*.	0.92*** 0.99*** 0.92***	AVE: 0.89 Cronbach's alpha: 0.96 McDonald's omega: 0.96	0.88*** 0.91*** 0.90***	AVE: 0.80 Cronbach's alpha: 0.93 McDonald's omega: 0.93

Switching to the structural models, we find acceptable fit indices for both models (Hu and Bentler, 1999):

- Model 1 for low self-reported levels of knowledge of the label: CFI=1.00, TLI=1.00, SRMR=0.052 and CD=0.999[4];
- Model 2 for high self-reported levels of knowledge of the label: CFI=0.968, TLI=0.951, SRMR=0.061 and CD=0.932.

Starting from the sample of consumers reporting a low level of knowledge of the Mountain Product label, results show that the only statistically significant relationship is the one from affective evaluations (ATT) and Willingness to Pay (WTP) with a β coefficient equals to 0.68. Therefore, self-reported low AWA leads to not significant relationships, despite the direct one ATT WTP.

Conversely, for those consumers' who are aware of knowing very well the Mountain Product label, all hypotheses are supported. Table 2 reports the relationships at work for the structural models.

Table 2. Structural Models Results

	Low AWA (1-2-3)		**High AWA (5-6-7)**	
Relations	β	Hypotheses	β	Hypotheses
H_1: AWA → ATT	-0.11 (n.s.)	Not supported	0.47***	Supported
H_2: ATT → WTP	0.68***	Supported	0.34***	Supported
H_3: AWA → WTP	0.07 (n.s.)	Not supported	0.30**	Supported
H_4: AWA → ATT → WTP	-0.15 (n.s.)	Not supported	0.21**	Supported

Note: *p < 0.05, **p < 0.01, ***p < 0.001

[4] Such a well-fitted model may be due to the small sample size or small correlations.

6. Discussion and Implications

This study investigates how Brand Awareness (AWA) and Brand Attitude (ATT) interact to generate Willingness to Pay (WTP) for the EU optional quality term *Mountain Product*. By distinguishing between low- and high-awareness consumers, we uncover a stage-dependent decision architecture that refines existing models of brand signaling.

The empirical findings reveal two structurally distinct decision regimes.

In the low-awareness segment, Brand Awareness does not significantly influence either Brand Attitude or Willingness to Pay. The only robust relationship observed is the direct effect of ATT on WTP. This suggests that when the *Mountain Product* label is not cognitively salient, it does not function as a diagnostic quality signal. Instead, economic commitment appears to be driven by general affective evaluations rather than by structured interpretation of the institutional cue.

On the contrary, in the high-awareness segment, the signaling mechanism becomes fully operative. Brand Awareness positively influences Brand Attitude and exerts both direct and indirect effects on WTP. This indicates that once awareness surpasses a minimum familiarity threshold, the label activates a coherent cognitive–evaluative process.

These findings suggest that AWA does not operate as a simple linear predictor of WTP. Rather, it functions as a threshold condition enabling the transformation of institutional recognition into economic value. Three main theoretical contributions can be derived from our findings.

First, we demonstrate that in markets defined by high-complexity credence attributes, the effectiveness of institutional signals is contingent upon consumer cognitive maturity. Awareness acts as a structural activation mechanism, without which the signal remains economically inert. By identifying ATT as a pivotal variable, the study contributes to the literature by proving that a quality signal must undergo an evaluative transformation into an attitudinal disposition before it can generate a price premium. In doing so, this study extends Signaling Theory by demonstrating that a signal's effectiveness depends not only on its credibility but also on its cognitive accessibility. A signal that is not recognized cannot reduce information asymmetry.

Second, identifying awareness thresholds enable us to prove that the diagnostic power of a quality signal is basically influenced by the recipient's prior cognitive engagement. The divergence between low- and high-awareness segments is also consistent with dual-process theories (Petty & Cacioppo, 1986). In low-awareness conditions, decision-making appears peripheral and affect-driven. In high-awareness conditions, the evaluative process becomes more central and cognitively elaborated, integrating awareness into price justification. Thus, awareness does not merely amplify attitudes, it alters the decision architecture underlying WTP.

Third, ATT acts as a pivotal mediator, transforming signal recognition into economic value. In fact, the findings confirm that Brand Attitude is not merely a byproduct of awareness, but the central mechanism translating recognition into monetary commitment. In high-awareness conditions, ATT partially mediates the relationship between AWA and WTP, reinforcing its role as a value-conversion engine.

Regarding implications, our findings may be particularly insightful for policymakers and institutional actors. In fact, our results indicate that the Mountain Product label cannot generate price premiums autonomously: without sufficient awareness, the signal fails to activate structured consumer evaluation. Thus, awareness-building initiatives should be considered a foundational investment rather than a complementary marketing activity. Policy-makers should fund large-scale institutional campaigns to help the label cross the cognitive threshold identified in the analysis: without public support to increase basic awareness, the label fails to activate its potential as a tool for territorial resilience, as consumers with low awareness are less likely to translate positive attitudes into an economic premium. Educational marketing strategies are required, focused on the emotional and symbolic attributes associated with mountain farming (emotional branding, storytelling, etc.). Policy-makers must understand that promoting the label is not just a matter of origin transparency, but of building an institutional reputation. As a consequence, one-size-fits-all communication

strategies are very much likely to be ineffective and require a different approach depending on the territories. In geographical areas where awareness is high, policies can support more sophisticated valorization schemes. In regions where the label is still unknown, institutional efforts must prioritize signal salience to ensure that the label becomes a diagnostic tool for consumers.

Last but not least, assessing periodically the reached level of awareness after the communication campaign is key. If the path between ATT and WTP remains weak in certain segments, the institutional signal is not reaching its objective of creating added value for producers, requiring a recalibration of promotional investments.

For agri-food firms, the findings suggest that collective communication strategies and coordinated territorial branding are essential to unlock the economic potential of optional quality schemes. Moreover, in low-awareness markets, producers should complement the *Mountain Product* logo with clear explanatory cues on packaging (e.g., short descriptions of the label's guarantees, QR codes, or concise origin claims), as the symbol alone is unlikely to activate WTP. In high-awareness markets, instead, producers should invest in premium packaging and territorial storytelling that emphasize authenticity and tradition, leveraging positive attitudes to justify higher prices. Moreover, pricing strategies should be adjusted across regions and channels, avoiding aggressive price premiums in areas where awareness of the label remains limited.

7. Conclusions, Limitations and Future Research

This study demonstrates that the economic effectiveness of the Mountain Product label depends not only on positive consumer attitudes, but on the presence of a minimum awareness threshold that activates structured evaluative processes. Awareness is therefore not simply a communication metric, but a strategic precondition for territorial value creation.

However, beyond the contribution of this work, some limitations should be acknowledged.

The survey was undertaken in one hypermarket only; this may limit generalizability of the results. In addition, the study is cross-sectional in nature, and this does not allow to capture causal dynamics. Therefore, future research should consider a longitudinal approach to verify causality and to examine whether awareness transitions from low to high states alter decision regimes over time.

Next steps may also investigate additional mediators such as perceived authenticity or trust and can extend the analysis cross-nationally.

Missing the Social in Entrepreneurial Team Research: A Systematic Literature Review of Social Entrepreneurial Teams

FATIMA ZAHRA BADGAOUI, MARIAROSA SCARLATA

Abstract

Social entrepreneurial teams (SETs) create and manage social ventures and need to balance economic and social objectives, traditionally competing and diverging. We conduct a systematic literature review of 49 research articles specifically focused on SETs implementing an input-mediator-output (McGrath 1964, Mathieu 2008) framework to identify research areas, and key research gaps: First, we identify that despite social entrepreneurship literature focus studied organizational dynamics, teams are not properly scrutinized. In particular, studies on SETs mostly focus on established social enterprises with lack of studies on team dynamics at the team formation stages, secondly outcomes measures are considered at organizational level leading lacking focus on team related measures. We suggest prospective research avenues that combine socio-economic research approaches (longitudinal qualitative studies) with quantitative studies using larger samples to enable a holistic system perspective on SET.

***Keywords**: Social entrepreneurial teams, SET, literature review, new social entrepreneurial teams*

1. Introduction:

Social enterprises (SEs) are organisations that seek to address persistent social challenges, including poverty, exclusion, and marginalisation, through innovative, entrepreneurial business models (e.g., Peredo & McLean, 2006; Seelos & Mair, 2005; Thompson, 2002). Motivated by these issues, SEs conduct business with an embedded social mission (Huda et al., 2019; Doherty et al., 2014) and employ revenue-generating strategies to support it (Bedi and Yadav, 2019; Pless, 2012; Santos, 2012; Mair et al., 2012). The pursuit of both social and economic objectives makes SEs hybrid organisations (Battilana and Lee, 2014) that embed dual institutional logics, i.e., the socially constructed practices, assumptions, values, beliefs, and rules by which individuals and organisations exist, organise time and space, and provide meaning to their social reality (Thornton and Ocasio, 2008).

Similar to commercial ventures, SEs are the result of the collective effort of founders (Ben-Hafaïedh & Dufays, 2021; Wolf & Mair, 2021). Each founding member imprints the venture with her own personal experiences—such as managerial, sector-specific, or community-based working experiences—that shape how social problems and related available solutions are identified and framed (Becker 1964, Haugh, 2007; Lee & Battilana, 2020; Sahasranamam et al., 2024; Marquis & Tilcsik, 2013; Mathias, Williams, & Smith, 2015; Colombo & Piva, 2018; Niu, He, & Zhu, 2022; Kim & Aldrich, 2005). Beside human capital, founders also contribute heterogeneous assets and their own networks, including access to funds, stakeholder relationship, and other forms of social capital (Kim & Aldrich, 2005, Brinckmann and Hoegl 2011, Haugh, 2007; Wolf & Mair, 2021,). In this sense, early imprinting shapes both the composition and the internal dynamics of the founding team and, through the team, the emerging new venture (Fauchart & Gruber, 2011; Waguespack et al., 2018, Johson 2007). Individuals (self) select in but also out of the founding team based on homophily, i.e., similarity of team members' characteristics (Discua Cruz et al. 2013, Francis & Sandberg 2000), and heterogeneity, with particular emphasis on functional characteristics and the wider composition of the individual's social network (Martin et al., 2003; Beckman, 2006, Davidsson & Honig 2003, Mosey & Wright 2007), ultimately identifying "who should be part of us" (Ruef et al., 2003, Beckman 2006, Ben-Hafaïedh & Dufays, 2021; Sahasranamam et al., 2024). Once assembled, the team engages in collective sensemaking — shared interpretive work through which members negotiate how to understand their environment, the nascent team and future organisation, and its mission — and identity work which

seeks to construct and maintain answers to "who are we as a team?" and "what do we want to do?" type of questions (Weick, Sutcliffe, & Obstfeld, 2005; Cornelissen & Clarke, 2010; Battilana & Dorado, 2010; Powell & Baker, 2014; Lee & Battilana, 2020). In these early phases of team emergence, individual identity and value commitments are articulated, contested, and recombined into a shared team identity that both channels and constrains personal agency—founders' capacity to act in line with their own individual value. Subsequently, founders simultaneously guide the emergence of organisational arrangements such as role structures, decision-making routines, and patterns of coordination (Howard-Grenville 2005, Lin et al., 2017, Battilana & Dorado, 2010; Smith & Besharov, 2019).

However, individual contributions are not purely idiosyncratic to the single individual founder but are institutionally shaped: founders' interpretations of problems, solutions, "appropriate" ways of doing and organising are informed by and embedded in the broader institutional environment which shapes norms, guides behaviour and the interpretation of social reality (Thornton & Ocasio, 1999; Garud, Hardy, & Maguire, 2007; Battilana, Leca, & Boxenbaum, 2009). As such, individuals are both enabled and constrained by the institutional environment (Lounsbury, Steele, & Wang, 2023; Thornton & Ocasio, 1999; Garud, Hardy, & Maguire, 2007). Individuals are agents embedded in their institutional environment and act within but independently from it (DiMaggio, 1988).

As the venture-creation process unfolds, founders' human capital and individual characteristics - such as values, work practices, and role identities - are enacted and become stabilised and imprinted on the team through everyday interactions. These personal characteristics of the founders are subsequently imprinted on the nascent organisation by guiding early structural choices (e.g., governance forms, role configurations), routine practices (e.g., how decisions are made, how stakeholders are engaged), and claims of organisational identity (e.g., how the organisation presents "who we are" and "what we stand for") (Schein, 1983, Johnson, 2007, Fauchart & Gruber, 2011; Gioia et. al., 2013, Johansen & Waldorff, 2020). In this way, institutionally shaped interpretations and identities at the individual level are translated into relatively durable organisational-level patterns that remain embedded within—and interact with—the broader institutional field, reinforcing or sometimes contesting existing logics (Garud et al., 2007; Battilana et al., 2009).

SET are relevant to be studied since they are at the foundations of collective decision-making in hybrids; they may be the source and outcome of organisational deviations from its core values (Battilana & Lee, 2014; Besharov & Smith, 2014; Dufays, 2020; McPherson et al., 2001; Klotz, 2014). Current work on SET tends to be framed as a subset of mainstream social entrepreneurship research, which typically adopts a broad organisational-level perspective on how social entrepreneurship processes unfold (e.g., Bacq & Janssen, 2011; Servantie & Rispal, 2018). Extant studies examine how social ventures are created and managed, yet they rarely develop a clear and explicit focus on SETs, instead centring the debate on social entrepreneurship, social ventures, and social enterprises more generally (Bacq & Janssen, 2011; Dacin et al., 2010; Saebi et al., 2019). Only tangentially does this literature zoom in on, or explicitly acknowledge, the relevance of SETs and the ways in which they are formed (Ben-Hafaïedh & Dufays, 2021; Mai et al., 2022; Sahasranamam et al., 2024).

In addition, existing work views SETs as undistinguished/able entities that may include founders, senior and/or top managers but also more peripheral members such as employees and/or volunteers, often conceptualised through core–periphery structures (Ben-Hafaïedh, 2021; for traditional literature see Cattani & Ferriani, 2014; Roberto, 2003). However, conceptualising SET as an undifferentiated object of analysis is problematic because it obscures differences in roles, responsibilities and influence between founders and managers, thereby producing a fragmented and internally inconsistent understanding of SET.

Despite increasing interest in hybrid organisations, our understanding of SETs remains elusive, and scholars have called for more work on the topic (Short et al., 2009; Dufays, 2016; Saebi, 2019;

Dufays, 2022; Song, 2024). SETs must navigate heterogeneous and conflicting stakeholder demands associated with the dual social and commercial mission of the ventures they create (Smith et al., 2013; Costa et al., 2022). To maintain organisational legitimacy with the diverse set of stakeholders involved in hybrids, SEs must continuously respond to and reconcile expectations anchored in both the organisation's logics (Battilana & Lee, 2014; Greenwood et al., 2011). This requires adaptive leadership, inclusive decision-making, and resource-mobilisation strategies grounded in team-level attitudes, such as a shared commitment to the social mission and a shared perseverance in pursuing it (Doherty, 2014; Makhlouf, 2011). Against this background, we ask the following research question: What are the emerging topics, contributions, and shortcomings in extant literature on social entrepreneurial teams?

To answer this question, we conduct a systematic literature review (Snyder et al., 2019; Tranfield et al., 2003) of 31 articles published between 2006 and 2024 that explicitly examine SETs, and integrate these sources with an additional 35 research papers that mention and report relevant findings on SETs. The literature review was conducted using the Input–Mediator–Output (IMO) framework (McGrath, 1964), which enables us to identify emergent themes related to team composition of SEs, mediating mechanisms, and related outcomes.

First, we organise the extant literature and identify commonly discussed topics and findings, as well as inputs, mediators, and outputs, in the SET literature. Second, we shed light on and critically analyse inconsistent findings and imbalances in overall scholarly contributions. Thus, by developing conversations on SETs, we lay the groundwork for future theorising and establish a baseline for theoretical contributions (Patriotta, 2020). Third, we illustrate that the SET literature fails to address team dynamics, as current studies focus on established SEs. We propose avenues for future research, with specific methods, questions, and theoretical anchors, to encourage research on SETs.

Building on this, we identify specific avenues for future research and outline practical implications for social entrepreneurs and organisations. In particular, our findings inform the design of co-founding support programmes, such as founder-matching events and digital matchmaking platforms (Cohen, 2013; Cohen & Hochberg, 2014), and yield actionable recommendations for building, developing, and mentoring effective SETs.

SETTING AND METHOD

Scope of the review

Literature-based articles that examine social ventures emphasise the need for more clarity on the social entrepreneurship construct (Peredo and McLean, 2006; Dacin et al., 2010; Bacq 2011; Lehner and Kansikas, 2013), or engage in a broader review of such a literature (Saebi 2019; Gupta 2020; Klarin and Suseno, 2023). However, there is increasing interest in more specific aspects of social entrepreneurship and social venturing, such as how social and economic value is created (Rispal 2016), the analysis of well-being (Kummitha 2025), and social networks (Dufays and Huybrechts 2014). Through our review, we seek to bring to scholarly attention the relevance of SETs in the social entrepreneurship field, as well as, more broadly, in hybrid organising and how individual members contribute to the creation and growth of social ventures.

To answer our research question, we implement a systematic literature review process structured into multiple steps, including sampling, coding, synthesis, analysis, and interpretation of existing studies (Tranfield, Denyer, & Smart, 2003). We then employ content analysis to recognise key themes across the examined papers (e.g., Schad, Lewis, Raisch, & Smith, 2016; Schilke, Hu, & Helfat, 2018) and follow Duriau, Reger, and Pfarrer (2007) and Krippendorff (2013).

Database driven

We followed a two-step search strategy combining a database-driven and a journal-driven approach. To sample articles, Scopus database and Web of Science are used and to provide coverage on SET literature, keyword search is run including the following keywords in the title and abstract: "founding group*", "new venture team*", "start-up team*", "Entrepreneurial team*, founding team, co-founder, venture team, "top management team*", and "TMT", and keywords related to SE, including "social entrepreneurship*", "social enterprise*", "social venture*", AND "social entrepreneur*", "social entrepreneurial team*", social venture team*, mission-driven team*. We consider only peer-reviewed English articles and exclude news articles, reviews, comments, editorial notes, and grey literature (e.g., professional reports, conference papers, policy papers) (Adams et al., 2017). Were excluded 14 articles on chemistry, agriculture, nursing, dentistry, Chemical engineering. Resulting in an initial sample of 206 articles. Because the social entrepreneurship field is relatively recent, and because a substantial share of social entrepreneurship research appears in specialized outlets such as the Social Enterprise Journal (rated 1 in the ABS Academic Journal Guide 2024) and the Journal of Social Entrepreneurship (rated 2), rather than in mainstream 3–4* management and entrepreneurship journals, only journals ranked Association of Business Schools 2024 (Chartered Association of Business Schools, 2024) level 1, or above, are included in the search, leading to an initial sample of 80 articles.

Journal driven:

In a second step, we complemented the database-driven search with a journal-driven search strategy to ensure that no other articles were missed. Based on the preliminary sample of 70 articles, we identified the main subject areas based on the ABS list, in which the initial sample of articles on social entrepreneurial teams wew published (e.g., entrepreneurship – ENT-SBM-, strategy -STRAT, finance – FINANCE, and accounting - ACCOUNT. For each subject area, we relied on the ABS Academic Journal Guide to select all the journals under these categories. We then conducted a systematic search within these journals. For each outlet, we screened all fully published articles and run advanced searches in Scopus (and, where necessary, EBSCO), restricting the search to the selected journal titles (field "Source title" / "SO – Publication name"), and applying the same keyword string and inclusion/exclusion criteria used in the database-driven phase. This procedure ensured that we captured all articles published, including those that might not have been retrieved through the initial topic-based database search.

The journal-driven search yielded 10 additional articles that met our eligibility criteria, which were added to the preliminary sample, 3 on SETs and 7 with relevant findings on SETs. The relatively small number of additional studies indicates that the database-driven search was already highly comprehensive, while the journal-driven step increases the robustness and transparency of our sampling strategy.

Reading the 90 articles (10 form the journal driven search and 80 from the database driven), we identify 31 articles that directly focus on SETs and 35 studies with relevant empirical findings and/or theoretical insights on SETs, although SETs were not their primary object of analysis, published between 2014 and 2024, drawn from 21 ABS-listed journals. Table 2 lists the sampled articles considered in the literature review, indicating their typology (conceptual or empirical).

Table 1 reports the details of this step of the literature review process.

Insert Table 1 about here

DESCRIPTIVE FINDINGS

Research on SETs began in 2014 and has grown steadily over the past 10 years, with a peak of 4 research papers published in 2022 and 2023. Figure 1 shows the trend in the number of articles published over the sampled period and integrates this with the empirical research methods used.

Insert Figure 1 about here

The studies included in our review employ a heterogeneous set of research designs, spanning conceptual, qualitative, quantitative, and mixed-methods approaches.

Research on SETs tends to be empirical with 26 percent of the articles adopting qualitative methods, 55 percent relying on quantitative approaches, and 10 percent using mixed-methods designs and the remaining 10 percent are non empirical. Qualitative studies tend to rely on case studies (n=8), four single and four multiple case studies. Quantitative contributions heavily rely on survey data (n=10, on the overall quantitative studies, 60%) or archival datasets such as GALI (1, 6%) or EDP (3, 10%), 3 articles on web crowled data. Gali is The Global Accelerator Learning Initiative (GALI) dataset, led by Emory University and the Aspen Network of Development Entrepreneurs (ANDE), collects global data on social startups applying to accelerators, while EDP Entrepreneurship Database Program (EDP), involving surveys completed by founding team members. The remaining mixed-methods articles (n=3, 10%) combine these strategies to exploit the complementary strengths of qualitative depth and quantitative breadth. Last, 5 percent of articles are literature reviews whereas and the remaining 3 (10%) are conceptual.

RESEARCH TOPICS ON SOCIAL ENTREPRENEURIAL TEAMS

We draw on the input–mediator–outcome (IMO) framework, which extends McGrath's (1964) classic input–process–output model by distinguishing team processes from other mediating mechanisms, such as cognitive, motivational and affective states (Mathieu et al., 2008). This framework is well-suited to our review because it allows us to take a broad, system-level perspective on SETs by organising the literature around inputs, mediators and outcomes, rather than focusing solely on performance (Klotz, 2014). In team research, inputs typically include members' individual attributes and team composition, such as educational background, specialisation and functional background (Amason et al., 2006), prior company affiliation (Beckman, 2006), educational prestige (Lester, Certo, Dalton, Dalton, & Cannella, 2006) and prior start-up experience (Nelson, 2003), as well as social capital. At the team level, inputs also include members' diversity. Mediators capture the dynamic interactions (communication, coordination) and emergent states (trust, shared mental models) that link inputs to outcomes. Outcomes refer to results assessed at the team or organisational level, such as team learning, innovation and effectiveness, although some studies use organisational performance as a proxy for team outcomes. For each IMO dimension, we identify the key theories, methods, and empirical results emerging from the reviewed studies.

Inputs:

Key theoretical frameworks and theories. Research on inputs to SETs primarily examines how founding and top management teams differ in functional backgrounds and prior experiences, and how this heterogeneity shapes social venture outcomes. Within the SET literature, the main theoretical lenses employed are Human Capital Theory (2 articles), the Resource-based view (2 articles; e.g., Bojica et al., 2018; Cheng, 2022), Upper Echelons Theory (4 articles; e.g., Bojica et

al., 2018; Gauthier, 2019; Lucas, 2023; Song et al., 2024), Team Production Theory (Crucke, 2021) and the Attention-based view (Lin, 2024). These 22 SET-focused articles are published mainly in 22 business and management journals, many of which are in the fields of entrepreneurship, organisation studies and innovation.

Research that draws on Human Capital Theory (Becker, 1964) conceptualises team members' backgrounds, skills and experiences as stocks of capital that can be invested in and leveraged to enhance venture outcomes. In this literature, HC theory is mainly used to theorise how specific team inputs—such as founding teams' prior entrepreneurial, sectoral or non-profit experience—translate into the social and commercial performance of social enterprises. For example, Sahasranamam et al. (2024) apply the theory to discuss that different types of founding team entrepreneurial experience constitute distinct forms of human capital whose value depends on how they align with external financing conditions and institutional logics.

Key methods.

Regarding key methods, 27 studies on inputs comprise 8 qualitative (30%), 16 quantitative (60%) and 2 mixed-methods designs (7%), and 1 conceptual (3%). Quantitative work predominantly relies on survey data collected directly from SEs through surveys (e.g., Crucke, 2021; Lin et al., 2024; Romero, 2023; Scarlata, 2016) or on data drawn from the EDP survey (Entrepreneurship Database Program) (e.g., Sahasranamam et al., 2023; Song et al., 2024; Chandler et al., 2022). Analysing research design, most quantitative articles adopt cross-sectional designs and rely on self-reported measures, often from a single informant within the social enterprise, as in Lin et al. (2024), who survey 17 social-investment experts. Such designs are particularly vulnerable to social desirability response bias — especially when assessing socially valued constructs such as social impact, mission orientation or inclusive leadership — and may therefore overestimate positive impact (Brutus et al., 2013). Single-informant data also risk masking intra-team differences in perceptions, power and role interpretations that are central to understanding collaboration, conflict and emergent states in diverse SETs (Song et al., 2024; Sahasranamam et al., 2023). The widespread use of perception-based indicators of social impact and team or enterprise effectiveness further complicates comparability across studies, as different scales and operationalisations tend to capture different performance indicators rather than a common construct. Among the 8 qualitative approaches, most use single- or multiple-case study designs based on semi-structured interviews (in European contexts or in low-income settings in Africa and Asia), complemented by archival analysis. The 2 mixed-methods studies combine archival or survey data with interviews and/or longitudinal case studies of WISEs, providing richer insight into team dynamics over time but remaining rare in the current evidence base (e.g., Almandoz, 2014; Battilana et al., 2015).

Human Capital in Social Entrepreneurial Teams

Consistent with the broader conceptualisation of human capital in economics, strategy, and management literature (Becker, 1964), the studies analysed focus on how combinations of education and experience within SETs shape problem-solving capacity, strategic vision, and the ability to address the complex dual goals typical of SEs (Sánchez, 2023). Human capital has been conceptualised as functional background, entrepreneurial and sector-specific experience, and education. Moreover, team heterogeneity and gender composition have been studied in terms of both resource acquisition and dual social–economic performance.

A first group of studies examines the functional background and prior experience of SET members. Human capital is identified as a central input for attracting external finance, gaining legitimacy, and achieving dual organisational objectives, even when key expertise is concentrated among a subset of team members (Scarlata et al., 2016; Sahasranamam et al., 2023). Non-profit entrepreneurial experience in SETs enhances SE performance, particularly when there is a strong

fit between the team's human capital and the institutional logic of external finance providers (Sahasranamam et al., 2023). Similarly, research on philanthropic venture capital (PhVC) shows that commercial experience in founding teams supports economic performance, whereas social experience supports social performance. Maximising overall performance is easier when teams combine high commercial experience with relatively lower social experience, suggesting that excessive social orientation at the top may harm financial outcomes (Scarlata et al., 2016). Complementary studies using structural equation modelling indicate that prior entrepreneurial and professional experience is among the key determinants of social entrepreneurs' success—measured by growth, profitability, and sustained financial returns—alongside environmental and psychological factors (El Chaarani, 2022).

A second set of studies examines SET's heterogeneity and human capital diversity, often drawing on Upper Echelons Theory (Hambrick & Mason, 1984) to link observable demographic and professional attributes — including functional background, organisational tenure, and education — to financial and social performance. Quantitative studies show that diversity in prior experience at the top management team (TMT) level is associated with greater and more stable social impact, as heterogeneous TMTs engage in sophisticated strategic decision-making and integrate multiple stakeholder perspectives into social value creation (Gauthier et al., 2019; Song, 2024). Heterogeneous teams provide richer cognitive resources and multiple frames of reference, which, when combined with high behavioural integration, reinforce the hybrid balance between social and economic objectives (Song, 2024). Ethnic diversity has also been identified as valuable in contexts involving refugees, as ethnically heterogeneous teams help overcome liabilities of foreignness, enhance opportunity identification and idea validation, and improve legitimacy within refugee communities and host societies, as well as access to key external stakeholders (Harima & Freudenberg, 2020). At the same time, qualitative work shows that the same heterogeneity that fosters innovation and stakeholder engagement can also generate coordination problems, communication breakdowns, and conflict, especially when underlying institutional logics differ (Bojica et al., 2018; Dufays, 2019).

A third stream considers gender composition and human capital. Studies of SETs indicate that teams with a higher proportion of women, younger members, and more highly educated founders are more strongly associated with the pursuit of social motives in new social enterprises, suggesting that founding teams with more women entrepreneurs, younger members, and greater education are positively associated with the pursuit of social motives in new ventures (Chandler, 2022). However, participation in accelerator programmes appears to attenuate the pursuit of social motives among female-dominated teams, while leaving the social orientation of younger or more educated teams largely unaffected (Chandler, 2022). Other studies show that female founders and female-led teams tend to attract less external funding than male or mixed-gender teams and are more likely to start non-profit rather than hybrid or for-profit social enterprises, highlighting gender disparities in access to finance and organisational structures (Compion et al., 2022). At the outcome level, studies of CEOs suggest that female chief executives are associated with higher social value creation but lower economic value creation relative to male CEOs, implying that gender diversity at the top is relevant in SEs (Compion et al., 2022; Lin, 2024). Taken together, this body of work highlights the importance of SETs' education and experience for social value creation, while contributing to the debate on whether heterogeneity or the presence of a particular set of experiences and backgrounds is more consequential for hybrid performance.

Finally, a conceptual strand within this stream draws on institutional logics and social imprinting to interpret how founders' initial emphasis on the organisation's social mission shapes recruitment, training, and operational processes. Beyond showing how founders initially imprint values and logics onto new organizations, recent work explains how these imprints evolve over time through processes of reinforcement, reforming, and coupling, creating 'sedimented imprints' that continue to guide action and identity even after founders' exit (De Cuyper, Clarysse, & Phillips, 2020). Building on the view of social enterprises as hybrids embedded in competing

social-welfare and commercial logics (Battilana & Lee, 2014), studies suggest that teams need exposure to both types of contexts to design and manage hybrid models effectively. Empirical studies show that logic diversity within teams can both enrich strategic innovativeness and create internal tensions: teams that successfully integrate multiple logics are better equipped to align social mission with financial viability, while unresolved differences fuel role ambiguity (uncertainty about who should prioritise which logic), decision-making issues (i.e. divergencies around investments, project choices, or growth strategies), and mission drift, where one goal progressively dominates the other (Battilana, 2015; Besharov & Smith, 2014; Pache & Santos, 2013). Complementary research grounded in value-based perspectives and stewardship theory identifies mechanisms — such as value fit, flexible structures, carefully designed partnerships, and intensive communication — that help SETs mitigate conflicts between social and commercial objectives (Eiselein & Dentchev, 2020). Overall, the composition and diversity of experiences, values, and logics within SETs are central to understanding both their capacity for innovation and their vulnerability to hybrid tensions.

Psychological Factors in SETs

Research on psychological constructs shifts attention to traits, values, and ideological orientations that shape individual behaviour, collective interpretation of the social mission, and how teams experience and manage tensions between social and commercial logics.

Entrepreneurial traits and motivational profiles, in particular the need for achievement, internal locus of control, self-efficacy, tolerance for ambiguity, risk-taking propensity, innovativeness, independence, autonomy, and optimism, are core psychological resources for social entrepreneurs because they help team members cope with the uncertainty and complexity inherent in addressing social problems through market-based mechanisms, sustain effort under resource constraints, and mobilise others around an ambitious mission. These traits are also relevant for reconciling long-term horizons for social impact with the shorter-term demands of financial performance (El Chaarani, 2022). Focusing on social imprinting and mission-related identity, and building on institutional logics and hybrid organisation research, Battilana and colleagues show that strong early imprinting around the social mission via founding values, initial recruitment criteria, and mission-centric routines enhances social performance but can damage economic productivity (Battilana, 2015). Teams that heavily privilege social related features in their early startup design choices tend to select staff, partners, and practices primarily for value alignment, which deepens mission fulfilment but may constrain efficiency, revenue generation, or scaling. To navigate this paradox, research recommends structural differentiation between social and commercial activities and the creation of "spaces of negotiation" in which team members openly discuss trade-offs and re-negotiate priorities over time (Battilana, 2015; Pache & Santos, 2013). Psychological commitment to the mission can have both positive and negative effects: it gives purpose and legitimacy but can also make the organisation rigid and resistant to changes needed for financial sustainability. A more recent line of inquiry investigates values and political ideology as foundations of team-level cognition and moral framing arguing that psychological and ideological characteristics of founding teams shape not only internal decision-making, including how the venture publicly defines what counts as "good" and "right." Drawing on Schwartz's value theory and related perspectives, Eiselein & Dentchev (2020) show that value fit within teams and between teams and stakeholders is critical for managing conflicts between social and commercial objectives and identify stewardship-oriented mechanisms—such as shared purpose, participatory structures, and open communication—that help teams to reconcile competing goals. Extending this idea, Lucas (2023) combines moral foundations theory with Upper Echelons Theory to study how founding team characteristics (i.e. political ideology), shape the moral narratives embedded in mission statements of US social enterprises. The study demonstrates that mission statements contain rich and heterogeneous moral discourse, drawing on foundations such as care, loyalty, fairness, authority, and sanctity, and that founding teams' ideological leanings systematically

predict which moral foundations are emphasised and whether missions span multiple foundations. Liberal-leaning teams are more likely to reference a broader set of moral foundations and to articulate multi-dimensional moral narratives, whereas conservative-leaning teams tend to emphasise Care and Sanctity and are more likely to omit explicit moral language (Lucas 2023).

These studies suggest that psychological factors—traits, values, and ideology—provide the deep cognitive and emotional endowments through which SETs interpret their hybridity. They influence resilience, opportunity framing, the management of paradoxical objectives, and the symbolic construction of mission, while also introducing potential fault lines, for example, when value or ideological differences remain unarticulated or unmanaged within the team.

Social Capital in SETs

Social capital is defined as "the sum of the actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or social unit" (Dean et al., 2007; Gedajlovic et al., 2013; Payne et al., 2010). Beyond the experience and education of team members, the external networks that team members bring play a pivotal role in identifying and implementing opportunities (Harima 2020), mobilising resources (Chen 2023, Crescenzo 2022, Sanchez 2023), and enhancing credibility (Crescenzo 2022).

A first set of studies focuses on network ties and access to external resources. In line with findings from traditional entrepreneurship (e.g., Baron & Tang, 2009; Zolin et al., 2011), research shows that social capital provides access to trusted external contacts who can offer strategic advice on both the business and social aspects of the venture, financial support, and even labour in the form of volunteer contributions. Strong ties to friends, family members, and former colleagues with business expertise are essential during the start-up phase, compensating for internal skill gaps and facilitating early experimentation (Lehner, 2014). In crowdfunding and impact-oriented financing settings, collaborative networks and inter-organisational partnerships act as powerful signals of legitimacy: endorsements from reputable partners, presence in professional networks, and visibility in the media substantially increase the likelihood of reaching funding goals and expanding the supporter base (Crescenzo 2022, El Chaarani 2022, Chen 2023).

A second stream highlights beneficiary proximity and co-creation as distinctive relational features of SETs. Close relational proximity to beneficiaries deepens teams' understanding of their needs and contexts, but can also heighten emotional stress and identity tensions as team members negotiate their roles against the communities they may also belong to (Dufays, 2019). In SEs involving refugees, for example, ethnically mixed teams comprising local and refugee entrepreneurs co-create opportunities through iterative phases of opportunity construction, evaluation, and pursuit, combining contextual knowledge, networks, and legitimacy from both sides (Harima & Freudenberg, 2020). This co-creation process enhances the opportunity's relevance, feasibility, and acceptance, while simultaneously revealing challenges related to communication, expectations, and power asymmetries. In the context of social crowdfunding, research shows that SC is central to success, and that funding outcomes are strongly shaped by cultural and symbolic capital—operationalised by narrative quality, signalling strategies, and media presence—because campaigns both create and test opportunities in real time through interaction with the crowd (Lehner, 2014).

A third line of work adopts a broader view of social capital. Studies show that financial support schemes, government policies, cultural norms, and professional infrastructure substantially affect the success and sustainability of social entrepreneurial initiatives (El Chaarani, 2022). Supportive ecosystems, particularly those near effective social incubators and accelerators, are crucial for achieving sustainable goals and for strengthening both social and economic performance (Sánchez, 2023). Such intermediaries provide finance and technical support, as well as relational capital through useful networks, mentoring relationships, and reputational endorsement. By embedding SETs in supportive networks, these ecosystems amplify teams' ability to access opportunities, scale impact, and withstand shocks.

SETs on social capital suggest that the relational embeddedness of social entrepreneurial teams is fundamental to understanding how they identify and develop opportunities, secure resources, and build and maintain legitimacy. Social capital operates at multiple levels—from intimate personal ties to beneficiaries, through professional and inter-organisational networks, to ecosystem-level support—each with its own benefits and tensions. High levels of social capital can compensate for internal resource constraints and enable co-creation with stakeholders, but they can also generate dependency, emotional overload, or unequal power dynamics if not carefully managed.

MEDIATORS:
Key theories adopted by scholars to study mediators are Input Process Output (IPO), Institutional theory (~2 papers), Paradox theory, Personal Values Theory (~ 1 paper), Resource-Based View (~ 2), Team Production Theory (~ 1) and UET (1), and Institutional Theory ~ (2).

Key methodologies
20 articles focuses on Mediators, and within these, 100 percent are empirical (n=20), with 2 articles applying a mixed-method quantitative and qualitative approach (Bojica, 2018, Almandoz 2014). The remaining 8 use a qualitative approach (%), including both multiple case studies (5), single case studies (3), and the remaining 10 articles are quantitative.

Research on SETs has increasingly examined the behaviour-based processes and emergent states that link team composition to outcomes. Behavioural processes include coordination, decision-making, conflict management, communication, and collective learning—activities through which members work together to transform inputs into meaningful outcomes (LePine et al., 2008). Emergent states refer to shared cognitive, affective, and behavioural properties, such as behavioural integration, cohesion, and shared understanding, that characterise the team at a given point in time and shape subsequent interaction (Marks et al., 2001). In SETs, these mediators are strongly influenced by the coexistence of social and commercial logics: heterogeneous professional and value backgrounds are a source of innovation and a generator of tensions that must be actively managed to preserve a balance between social and economic goals (Battilana & Lee, 2014; Dacin et al., 2011; Dufays, 2019).
In social enterprises, decision-making processes that allow time for deliberation and knowledge integration appear to be required. A first cluster of studies focuses on interpersonal processes in decision-making. Studies of top management teams (TMTs) show that creative decision-making, characterised by extensive information sharing and experimentation, fosters an environment conducive to employee-driven innovation, whereas very high decision speed risks sidelining employee input and constraining creativity (Cheng, 2022). Meanwhile, studies of how strategic decisions are made at the apex of hybrid organisations, Maine et al. (2024) show that in municipal hybrid corporations, the strategic apex aligns goals through iterative negotiation and compromise. Generally, SETs engage in collective sense-making to resolve ambiguities following stakeholder priorities, integrating relational and instrumental logics to remain adaptable to shifting stakeholder demands. The creation of sub-committees and dedicated strategic discussion arenas supports cohesion and provides structured spaces for addressing tensions. These findings resonate with earlier work showing that varied experiences among board and management members—for example, in politics, industry, or public organisations—facilitate acceptance of multiple underlying logics and encourage the design of team structures that promote cohesion and efficiency (Jansen et al., 2016).
A second stream examines team conflicts and their origins. In addition to macro-level tensions arising from hybridity, intrateam tensions emerge when members differ in their attraction to social versus financial logics, when their value systems diverge, or when they commit unequal efforts (Battilana & Lee, 2014; Besharov & Smith, 2014; Dufays & Huybrechts, 2016). Dufays (2019) shows that teams with overlapping professional and general interests experience identity-related

tensions, particularly when members' personal identification with the social mission clashes with organisational constraints. Larger teams, while richer in expertise, face more pronounced "performing" and "organising" tensions due to greater diversity and coordination challenges; these can be mitigated by stronger governance structures and clear role definitions, which enhance cohesion and enable more effective tension management (Dufays, 2019). Tensions that remain unmanaged can have severe consequences. Studies on impact investing relationships show that intrateam tensions and misalignment of priorities may result in unplanned termination of partnerships, changes in investee management, or non-achievement of intended social and financial goals (Agrawal & Hockerts, 2019; Alvi, 2021; Castellas et al., 2018; Glänzel & Scheuerle, 2016; Mogapi et al., 2019; Moore et al., 2012). Across these contributions, close collaboration, value and goal alignment, trust, and continuous fit-value assessment are critical to preventing tensions that could undermine the long-term mission team's attachment.
Research has identified team-level mechanisms that help balance dual missions. Eiselein and Dentchev (2020) highlight three core mechanisms: value fit, agile structures, and partnerships. First, recruiting individuals whose personal values align with organisational goals supports strategic and day-to-day decision-making and reduces the likelihood of deep conflicts. Second, agile structures—flexible hierarchies, adaptable roles, and responsive internal processes—enable teams to reconfigure responsibilities as hybrid demands evolve. Third, partnerships and strategic alliances with external stakeholders extend resource bases, enhance operational focus, and provide additional perspectives and accountability, thereby helping teams navigate conflicting objectives. These mechanisms are complemented by open and transparent communication, which bridges individual differences, aligns stakeholder expectations, and supports ongoing alignment and reflection processes, in which individual and team goals are periodically synchronised and strategies are recalibrated (Eiselein & Dentchev, 2020). A related set of studies identified external communication as a key process for engaging with the external environment. In social crowdfunding campaigns, frequent and substantive social-media updates increase backer engagement and improve funding outcomes (Chen, 2023). Moreover, communication is useful to demonstrate legitimacy by highlighting internal resources and capabilities, and maintaining consistent, credible communication, which in turn reduces information asymmetry and strengthens funders' confidence, leading to better fundraising performance (Chen, 2023). Such findings suggest that communication is both an internal coordination tool and an outward-facing mechanism for signalling quality and hybrid commitment.

Another process-level mediator examined is participation in accelerator and incubator programmes. Chandler (2022) finds that SETs' participation in accelerator programmes could diminish the positive effect of female representation in founding teams on the pursuit of social motives. Accelerators prioritise financial outcomes, weakening the influence of gender-based social role orientations on the pursuit of social objectives. By contrast, social incubators have been found to exert a strong positive impact on the efficiency and development of social start-ups, generating efficiency gains of over 35 per cent that extend beyond the start-ups' initial know-how (Sánchez, 2023). These programmes provide structured support, mentoring, and network access that enhance internal processes and accelerate capability building.
Uzuegbunam (2021) adds a cultural and gender-composition dimension to process-level dynamics. The study shows that all-male teams are most likely to pursue commercialisation, followed by mixed-gender teams. These gender-based differences are amplified in culturally tight societies, where mixed-gender teams, in turn, exhibit the highest adaptability and success in hybrid strategies. Cultural looseness reduces the predictability of gender effects on commercialisation, offering greater fluidity in team dynamics. Overall, cultural tightness moderates the effect of team composition, such that mixed-gender teams outperform homogeneous teams in balancing dual goals in tighter cultural contexts (Uzuegbunam, 2021). These findings indicate that team-level

processes cannot be fully understood without considering the broader cultural environment in which they unfold.

Beyond observable processes, studies increasingly analyse emergent team states that arise from interaction and, in turn, shape how SETs handle hybrid demands. One central construct is TMT behavioural integration, defined as the extent to which top team members engage in mutual and timely information exchange, collaborative decision-making, and joint involvement in key issues (Lubatkin et al., 2006; Hambrick, 2007). In hybrid contexts, Song (2024) shows that behavioural integration translates CEO traits into effective organisational outcomes by channelling ambition into shared, collectively vetted strategies. TMT heterogeneity also shapes the strength and direction of this effect, making the relationship between CEO personality and hybrid Organising is dynamic and context-dependent. The findings underscore the importance of building behaviourally integrated TMTs and actively managing their diversity through communication, collaboration, and inclusive decision-making. A second emergent state is bricolage behaviour. Bricolage is understood as "making do" by creatively recombining available resources and rejecting resource constraints as inherently limiting. Bojica et al. (2018) find that bricolage supports organisational growth primarily when social enterprises enjoy relatively high resource endowment and autonomy. Under these conditions, bricolage allows teams to adapt quickly to emerging challenges and overcome them in innovative ways. In contrast, in severe resource scarcity, adopting bricolage led to stagnation, especially when teams have little room to experiment. The study also reveals nuanced interactions: resource-rich settings and TMT tenure diversity reinforce the positive effects of bricolage on growth; gender diversity appears largely neutral; and diversity in prior for-profit experience can be detrimental in organisations that rely heavily on bricolage, likely because conflicting logics complicate prioritisation and compromise (Bojica et al., 2018).

A third emergent state concerns group cohesion and stewardship-like behaviour. Eiselein and Dentchev (2020) show that alignment between personal values and organisational goals is a key antecedent of cohesion in social enterprises. Through iterative processes—ensuring value fit in recruitment, maintaining effective communication, and adopting agile structures—teams build a shared sense of purpose that helps them manage conflicting objectives. Many SETs in their sample display stewardship behaviour: collective action, low power distance, high levels of trustworthiness, and shared responsibility. These attributes reinforce alignment between social and commercial goals and support long-term impact.

Across these streams, the evidence indicates that how team members interact and the emergent states they develop have substantial consequences for outcomes. Teams that address tensions openly, invest in behaviourally integrated and cohesive top teams, and develop mechanisms to align values and goals are more likely to maintain their dual mission and achieve sustainable impact over time (Dufays, 2019; Eiselein & Dentchev, 2020; Song, 2024). Conversely, when tensions rooted in divergent logics, values, or effort levels are left unaddressed, they can lead to role ambiguity, decision-making gridlock, mission drift, and ultimately relationship breakdowns or failure to reach either social or economic targets (Agrawal & Hockerts, 2019; Alvi, 2021; Castellas et al., 2018; Glänzel & Scheuerle, 2016; Mogapi et al., 2019; Moore et al., 2012). While the existing literature offers rich insights into individual mechanisms—such as creative decision-making, behavioural integration, bricolage, and stewardship—studies remain fragmented and rarely track how specific combinations of processes and emergent states unfold over time. This fragmentation suggests a clear agenda for future research: longitudinal and comparative designs that systematically link process configurations and emergent states to blended social and economic performance across the life cycle of social enterprises.

Outputs:

Of the 30 articles on outputs, 28 are empirical and 2 conceptual. Within the empirical ones, 8 qualitative – 3 single-case studies and 5 multiple-case studies, 3 apply mixed methodologies, and 17 studies are quantitative.

The articles draw on multiple theoretical lenses: 3 articles on the attention-based view and upper echelons theory link decision-makers' attention, human capital, and values to strategic choices; 4 articles on Bourdieu's forms of capital, Resource Based View, and Team Production Theory conceptualise resources and value creation; and 5 articles used Institutional Theory, Institutional Logics and imprinting, IPO, and legitimacy frameworks study ventures within broader normative and regulatory environments. Further, 4 articles adopt Gender and Social Role Theories, Personal Values Theory, Narrative Theory, and process models of opportunity recognition — highlighting how identities, values, and narratives shape which opportunities are perceived as legitimate and pursued.

Studies of SETs predominantly assess outcomes using firm-level indicators, which serve as proxies for team-level outputs and provide a comparable basis for cross-venture analysis of how team characteristics — such as Human and Social Capital — relate to performance. Revenues, employment levels, and employment growth capture both social and economic value creation, reflecting venture stability, credibility, and growth ambition (Battilana & Lee, 2014; Cassar, 2006; Pache & Santos, 2013; Sahasranamam, 2024).

However, performance is often conceptualised through aggregate constructs that do not systematically disentangle social from economic performance. As a result, the social component of value creation has been under-specified and subsumed within financial outcomes. This reflects the broader challenge of quantifying social value in a rigorous and comparable way (Ebrahim & Rangan, 2014; Emerson, 2003; Garcia-Castro et al., 2010; Hertel et al., 2022). These shortcomings have led to growing calls for integrated assessment frameworks that capture financial, social, and environmental dimensions in parallel, and for greater reliance on third-party and longitudinal data—such as certification schemes and external databases—to move beyond self-reported, perception-based performance measures. In this direction, Scarlata et al. (2016) provide a notable contribution by proposing a composite indicator of total value creation within a portfolio of venture-capital-backed social enterprises that combines economic sustainability and social experience, thereby demonstrating the feasibility of more objective, portfolio-level social return metrics.

A second cluster of research focuses on funds raised (i.e., in crowdfunding contexts) as a key output. Chen (2023) shows that team size and venture age are positively associated with the amount of funds raised in social crowdfunding campaigns, suggesting that larger, more mature teams can mobilise more internal resources, project greater legitimacy, and thereby attract more external capital. The same study finds that female-led social ventures perform worse than male-led ones in terms of pledge amounts, contradicting evidence from commercial crowdfunding and indicating that gendered perceptions and biases may operate differently in social venture settings. Complementary work by Crescenzo (2022) identifies entrepreneurial narratives as a driver of funding success. The study shows that narrative strategies deployed in crowdfunding campaigns—especially those that clearly showcase team expertise and professional alignment with the project—significantly enhance investors' perceptions of credibility and, in turn, funding outcomes. Personal attributes, such as team members' passions and interests, are effectively used to humanise the venture and deepen engagement from potential backers, while networks with stakeholders and institutions further bolster perceived legitimacy. Together, these findings suggest that funding success is not only a function of structural characteristics (e.g., team size, age), but also of how teams present and frame their human and social capital to external audiences.

Other studies examine social value creation. Lin (2024) investigates the effects of CEO gender on social and economic value creation in social enterprises and finds that social value creation tends to be higher under female CEOs, whereas economic value creation tends to be lower. Importantly, selective attention to economic goals—operationalised as shifts in the CEO's attentional focus—

mitigates the negative association between female leadership and economic value creation, suggesting that attentional strategies can partially rebalance dual goals. In this study, economic value creation is measured as perceived financial outcomes, while social value creation is measured as perceived non-financial outcomes benefiting the community or natural environment, thereby offering a more fine-grained operationalisation of dual performance.

Battilana et al. (2015) provide a complementary perspective in the context of work-integration social enterprises (WISEs). They operationalise social value as the proportion of beneficiaries who secure regular employment after exiting the programme, alongside indicators of economic productivity that capture the efficiency with which inputs are converted into economic outputs. Their results reveal a paradox in which strong social imprinting in founding teams—i.e. an early and pronounced emphasis on the social mission—enhances social value creation but is negatively related to economic productivity. This trade-off indirectly weakens the total social value created and underscores the tension between mission focus and economic sustainability that SETs must maintain over time. Lin (2024) also notes that SETs' human capital (age, education, work experience) and firm-level characteristics (i.e. firm age, mission type, prior social performance) condition social and economic value creation, reinforcing the idea that outputs are shaped by interactions between team attributes and organisational context.

Compared with firm-level indicators, team-level outputs are less often measured explicitly (1 study). One important exception comes from board-level research: Crucke (2021) finds that board service performance—reflecting how effectively boards fulfil their advisory and monitoring roles—significantly contributes to social outcomes, such as the employment of disadvantaged people. This effect is particularly strong when board members possess high stakeholder knowledge and when behavioural integration within the board is high. These findings show that high-quality team functioning at the governance level can translate directly into improved social performance, even when financial indicators are less sensitive.

More broadly, most SET studies conceptualise outcomes at the organisational level—using variables such as sales growth, profitability, number of employees, and funds raised (e.g., Crescenzo, 2022; Chen, 2023; Sahasranamam, 2024; Romero et al., 2024; Lin, 2024)—while team-level outcomes such as team effectiveness, viability, coordination quality, or psychological well-being remain underexplored. This gap is notable given evidence from research on entrepreneurial teams that team effectiveness and viability are critical precursors of sustained performance (Chowdhury, 2005; Foo et al., 2006).

Finally, some studies adopt composite or multi-dimensional measures of overall firm performance. Sahasranamam (2024), for example, uses revenues and the number of employees as key indicators of a social venture's stability and credibility, and as proxies for growth ambition, while differentiating between economic and social performance constructs. Song (2024), in examining the relationship between CEO narcissism and hybrid organising, conceptualises hybrid organising via survey items capturing the perceived social and commercial orientation of the organisation, and computes an overall hybrid organising index as the product of sociality and commerciality scores.

Across these contributions, SET outcomes extend beyond aggregate measures (to include social value creation, funding success, governance effectiveness, and hybrid organising capacity). At the same time, scholars continue the discussion of unresolved paradoxes and measurement challenges typical of SEs. Results show that strong social imprinting and female leadership, for instance, tend to enhance social outcomes but can harm economic performance unless attentional strategies or supportive structures are introduced (Battilana et al., 2015; Lin, 2024). Firm-level metrics are dominant, despite clear indications that team-level outputs—such as team effectiveness, viability, and resilience—are likely to be crucial mediators between team composition and hybrid performance. This points to a promising avenue for future research: the development and use of team-specific outcome measures that complement firm-level indicators and allow a more precise assessment of how SETs create and sustain blended value over time.

CRITICAL REFLECTIONS AND FUTURE RESEARCH PATHS

Inputs:

Our findings identify five critical research gaps in SET inputs that warrant systematic investigation. Much SE research remains founder-centric, focusing on the characteristics of individual entrepreneurs, and there is a need to deepen theoretical and empirical analysis of team formation processes in SEs. While the literature on traditional commercial ETs has developed richer frameworks to explain how entrepreneurial teams form, emerge and evolve, drawing on economic, psychological and sociological perspectives, we suggest that SETs could also yield insightful findings, given the SE hybridity that creates an interesting setting related to the mission being pursued: whereas in a traditional commercial enterprise the mission is economically centred, in SEs the mission is to pursue blended value. In this setting, an entrepreneur deciding to start a SE must navigate the decision to become a social entrepreneur, starting an enterprise with blended value purposes, and the decision to start it within a team. These complex decisions might open an interesting avenue for research. In the commercial literature, economic lenses, including human capital theory, agency theory, and resource- and capability-based views (Anton & Yao, 1995; Hellmann, 2007; Barney, 1991; Teece, 1986; Teece et al., 1997), have been used to model how founders with complementary resources and risk preferences come together, negotiate roles, and structure ownership. Applying these lenses to SETs could contribute to understanding how and why SETs are formed, the dynamics of team formation in such a hybrid context, how functional diversity and expertise are initially assembled to create social and economic value and then reconfigured over time as the start-up grows, and how these choices shape the capacity to create, scale, and sustain social impact under resource constraints and institutional complexity (Bolzani, 2019; Klotz, 2024).

Second, future work should examine how SETs balance specialised and generalist competencies across a start-up's developmental phases. This involves distinguishing between core human capital, such as experience aligned with the venture's core activities and difficult to outsource, and peripheral skills that can be acquired through external collaborations, advisors, or partnerships (Dufays, 2017; Camenzuli & McKague, 2015). Bricolage theory offers an applicable theoretical lens to explore how, in resource-constrained contexts like SEs, teams creatively combine internal and external resources. Through this lens, conceptualising the team's human capital as a resource that can be recomposed and re-skilled over time, longitudinal empirical designs would enable researchers to study how functional backgrounds, expertise, and role distributions within the team change as ventures negotiate shifting demands related to hybrid organising, scaling, and environmental turbulence typical of SEs (Sanchez-Robles et al., 2023; DeSantola & Gulati, 2017).

Finally, the discussion of SET inputs underscores the importance of integrating multiple theoretical perspectives and methodological approaches. UET and human capital theories provide robust starting points for studying team composition in relation to organisational and team outcomes. We argue that combining them with process-oriented and context-sensitive frameworks, such as bricolage, institutional logics, and hybrid organising, would capture the mechanisms and contingencies through which functional diversity and expertise shape social venture value creation. Methodologically, advancing the field will require longitudinal, multi-source, cross-cultural, and mixed-method research designs, together with more standardised measures of social and economic value creation. This can help explain how the inputs embodied in SETs contribute to the formation, evolution, and impact of SE value creation.

Inputs include age, which has been mainly used as a control variable, and ethnicity, which has been marginally considered. We argue that both age and ethnicity are significant in SEs because younger entrepreneurs might encounter significant issues linked to less experience, knowledge, or a smaller network, but they might be more flexible and innovative. However, if we

consider the team as a whole, an age gap could negatively affect the decision-making process. So we argue that age could be an interesting input influencing the value creation of such SEs.

Team processes and emergent states:

Future research on social entrepreneurial teams (SETs) should deepen understanding of how team processes and emergent states mediate the relationship between team composition and blended social–economic outcomes. Building on the input–mediator–output (IMO) framework (Marks et al., 2001), a promising first avenue concerns membership changes and evolving team composition. As social ventures grow, early founding members may no longer fit the venture's changing strategic and operational demands, due to increasing complexity, new capability requirements, or motivational decline (Boeker & Wiltbank, 2005; Clarysse & Moray, 2004). In SEs, these dynamics are exacerbated by financial constraints, which may limit the ability to offer competitive wages or undermine the retention of founders and employees, despite their strong social commitment (Gupta, 2020). At a certain point, this may be insufficient to retain them, leading to co-founder exit. Future studies should therefore examine how membership changes unfold in SETs over time, how they affect emergent states such as trust, cohesion, and shared identity, and which strategies SETs might adopt to retain or replace founders when social value alone is insufficient to keep them engaged (Mathieu et al., 2017).

A second line of inquiry concerns conflicts and tensions within SETs. Existing research has highlighted tensions arising from social and commercial objectives at the organisational level, yet there remains limited understanding of how these tensions manifest as task and relationship conflicts among team members across the pre-formation, formation, and post-formation stages of SE' development (Besharov & Smith, 2014). Future work could map the types of tensions that characterise SETs at different stages, for example, disagreements over mission priorities, resource allocation, or growth strategies, and investigate the strategies (e.g., role structuring, narrative reframing, or boundary spanning) that teams use to confront and transform these tensions. Integrating insights from social identity and social categorisation theories would enable researchers to explore how in-/out-group dynamics, status hierarchies, and gender- or ethnicity-based faultlines aggravate or mitigate such conflicts, particularly when members strongly identify with different logics or stakeholder groups.

Third, opportunity identification and implementation constitute a fertile yet underexplored domain for SET research. Although traditional entrepreneurship studies show that knowledge heterogeneity in teams can enhance opportunity recognition (Tang et al., 2012), it remains unclear how SETs collectively identify and shape opportunities amid the constraints and paradoxes of hybrid social missions. Future research could examine how team characteristics, such as prior social-sector experience, commercial expertise, or value orientations, influence the types of social entrepreneurial opportunities pursued, and how decision-making logics (e.g., effectuation versus causation) are enacted at the team level. Longitudinal designs would be particularly valuable for tracing how founding teams progress from opportunity recognition to implementation, how team composition adapts to evolving organisational needs, and how these changes feed back into emergent states and coordination quality over time.

Finally, systematic studies are needed on coordination-related emergent states and their antecedents in SETs. Prior research suggests that coordination involves not only task-related structures and routines but also alignment in values and vision, relational fit, and interpersonal cohesion (Discua Cruz et al., 2013; Francis & Sandberg, 2000; Jaskiewicz et al., 2017; Shah et al., 2019). In SEs, balancing social impact and financial viability amid evolving roles and responsibilities makes coordination particularly challenging, yet studies explicitly linking behavioural integration, shared perspectives, and trust to outcomes remain scarce. Future research could leverage behavioural integration (Hambrick, 2007; Lubatkin et al., 2006) and faultline theory to investigate how team size, diversity, and aligned attributes (e.g., function, age, nationality) shape subgroup formation, internal frictions, and communication patterns in early-

stage SETs. From a human capital perspective, it would also be valuable to identify which combinations of knowledge, skills, and abilities (KSAs) foster effective collaboration and coordination, clarifying, for instance, when background homogeneity enhances cohesion versus when heterogeneity is necessary for complex hybrid problem-solving (González-Cruz et al., 2020; Sanchez-Robles et al., 2023).

Output:

Measuring the value creation of SEs remains a central and open debate in the SE literature. Future research needs to refine both the object and the method of measurement. Existing studies rely heavily on self-reported survey data from founders and CEOs, which raises well-known concerns about overconfidence, social desirability bias, and non-response bias, as leaders may overestimate performance, answer in ways that project a favourable image, and differ systematically from those who do not respond, thereby skewing results (Cycyota & Harrison, 2006; Hirshleifer et al., 2012; Podsakoff et al., 2003). To enhance validity, future studies should systematically combine multiple data sources, such as administrative data, investor reports, certification databases, and impact ratings, with self-reported measures, and track outcomes longitudinally rather than through single cross-sectional snapshots (Ebrahim & Rangan, 2014; McMullen & Dimov, 2013; Rawhouser, Cummings, & Newbert, 2019; Zahra et al., 2009). Third-party assessments of social and environmental performance, including those associated with schemes such as the B Impact Assessment used for B Corp certification, offer particularly promising avenues for deriving comparable blended value indicators across organisations, sectors, and countries, and for detecting mission drift via events such as decertification (Hiller, 2013; Jackson & Harji, 2013; Rawhouser et al., 2019).

Another relevant concept that emerges in this review is the extensive reliance on firm-level measures. Future research on SET outcomes should adopt an explicit multilevel perspective that distinguishes between firm- and team-level indicators, as existing studies assess SET outcomes indirectly through organisational outcomes such as revenue growth, profitability, employee numbers, and fundraising success, thereby assuming that firm performance is a reliable proxy for team effectiveness (Chen, 2023; Crescenzo, 2022; Lin, 2024; Romero et al., 2024; Sahasranamam, 2024). However, organisational outcomes can be strongly influenced by environmental conditions, resource endowments, and institutional support, and may fail to capture how well teams function. Building on work in entrepreneurial and top management teams, future studies should incorporate explicit team-level performance metrics, such as team effectiveness, team viability, milestone attainment (e.g., incorporation, seed funding, first product launch, first sale), speed to market, innovativeness, and coordination quality, to provide a more fine-grained view of how SET dynamics translate into value creation (Barney et al., 1996; Chowdhury, 2005; Clarysse & Moray, 2004; Cohen, 2013; Foo et al., 2006; Francis & Sandberg, 2000; Knockaert et al., 2011; Perry-Smith & Coff, 2011; Shah et al., 2019; Vohora et al., 2004). Linking these micro-level indicators to firm-level blended value measures would allow scholars to unpack when and how strong team functioning is a necessary but not sufficient condition for social and economic performance in hybrid ventures.

At the same time, future work should broaden the outcome space to include psychological and contextual dimensions that are especially salient for SETs. Research increasingly suggests that meaningful work, subjective well-being, and work–life balance are central motives for engaging in SE and can influence both persistence and performance. However, the relationship between well-being and outcomes is complex, with evidence of burnout and weak or inconsistent links between satisfaction and performance under high growth and resource pressures (Brieger et al., 2020; Hmieleski & Corbett, 2008; Lerman, 2020; Tisu et al., 2023). SEs often operate under severe resource constraints, complex stakeholder demands, and value-laden conflicts, which can generate psychological strain for founders and team members and, in turn, influence organisational value creation. Future studies should therefore triangulate subjective well-being and meaningful work

measures with more traditional performance indicators to examine how the psychological health of SETs supports or undermines their capacity to sustain blended value over time (Kummitha, 2025). Additionally, cross-country studies might be undertaken to explore how cultural norms moderate the trade-offs between social and economic objectives, for example, by fostering more competitive orientations in highly market-driven contexts or more solidarity-based orientations in others (Mafico et al., 2021). Integrating decision-making theories, human and knowledge-based capital perspectives, and institutional logics/hybrid organising frameworks will be useful for theorising how diversity, competences, and the embedded logics of team members shape both the measurable outputs of SETs and the deeper, less tangible aspects of their value-creation trajectories. More specifically, inputs have been used to explain performance; for example, SEs with larger teams and greater age performed better on pledge amounts (Chen, 2023). However, it could also be useful to consider other outcome measures. Performance on a thorough questionnaire is vulnerable to social desirability bias, particularly when measuring socially valued constructs such as social impact, mission orientation, or inclusive leadership (Brutus et al., 2013). Single-informant designs also risk overlooking intra-team divergences in perceptions, power distributions, and role interpretations, which are central to understanding collaboration, conflict, and emergent states in diverse teams (Song et al., 2024; Sahasranamam et al., 2023). The predominance of perception-based measures of social impact and team effectiveness further complicates comparability across studies, as different scales and operationalisations may capture distinct facets of performance.

Capturing Brands and Consumer Voice. A Longitudinal Study of Online Discourse on Well-Being and Healthy Eating in the Italian Grocery Retail Sector

BEATRICE CECCOLI, DONATA TANIA VERGURA,
ANNA BONCOMPAGNI, CRISTINA ZERBINI, GUIDO CRISTINI

Abstract

Frame of the research. *The digital communication of grocery retailers on health, well-being, and healthy eating has been steadily increasing, reflecting both growing consumer interest in these topics and the strategic importance of promoting healthier lifestyles. These digital initiatives, ranging from social media content to targeted online campaigns, aim to shape consumer perceptions and encourage informed, health-oriented food choices.*

Purpose of the paper. *This study investigates how Italian grocery retailers (both discount and non-discount) address health, healthy eating, and well-being in their online communication, particularly through social media, and examines how these messages are interpreted and discussed by consumers.*

Methodology. *A longitudinal web listening methodology combining quantitative and qualitative textual analysis was applied to user-generated content and from six Italian leading retailers, collected from social media and web sources, covering the 2024-2025 period.*

Results. *Over the months considered, online conversations on health, well-being, and healthy eating grew markedly, revealing evolving consumer interests and retailer strategies. Healthy eating gained prominence, discount retailers improved communication, positive sentiment increased, negative sentiment shifted toward inflation and trust issues, and high-protein and sugar-free products dominated perceived health.*

Research limitations. *Limitations include the small retailer sample, lack of demographic data, and reliance on manual data cleaning.*

Managerial implications. *The results provide valuable insights into enhancing health-focused communication, monitoring partnership campaigns, leveraging distinctive brand strengths, and managing the trade-offs between affordability and quality.*

Originality of the paper. *This study proposes a longitudinal analysis of online-generated content, bridging retailers' digital communication strategies with consumer perception and sentiment analysis, while providing actionable insights for promoting healthier behaviors in grocery retail.*

Keywords: *digital communication; web listening; grocery retailers; well-being; health*

1. Introduction

The growing attention to health and well-being is significantly reshaping consumers' dietary behaviors and redefining the role of food retailing in promoting healthier lifestyles (Kumar et al., 2025; Scapin et al., 2025; Samoggia et al., 2019). The increasing awareness of the negative consequences associated with unhealthy eating habits has led to a rise in both the demand for and the supply of nutritionally balanced alternatives (Campo et al., 2020).

In this context, retailers are not merely commercial intermediaries, but key actors capable of concretely influencing consumers' food choices (Martinelli & De Canio, 2021; Cameron et al., 2016; Scapin et al., 2025). Through assortment decisions, product presentation, and in-store valorization strategies, they can shape individual preferences and either encourage or conversely, hinder, the adoption of healthier eating behaviours (Gaur et al., 2024; Machín et al., 2018).

Among the various levers through which retailers can influence consumers' food choices, communication shapes the meaning attributed to products and guides perceptions related to health and well-being (Dawson, 2013; Endres, 2016; Grandi et al., 2017). With the progressive diffusion of digital technologies, this capability has extended into the online context (Kumar et al., 2025), fundamentally transforming the ways in which retailers and consumers interact (Samoggia et al., 2019). Compared to traditional marketing approaches, digital communication enables real-time

interactions, message personalization, and detailed analysis of user-generated content (UGC), allowing retailers to adjust their strategies with greater precision and flexibility (Khwaja et al., 2020; Todor, 2016).

Despite extensive research on how digital communication influence consumers' attitudes toward healthy eating (e.g., Kumar et al., 2025; Dearlove et al., 2021; Zhang et al., 2023), limited attention has been devoted to the joint analysis of retailer-generated communication and consumer-generated discourse on health-related topics in grocery retailing. In particular, little is know about how grocery retailers communicate health, well-being, and healthy eatingand how consumers perceive and discuss retailers' nutrition-related marketing initiatives through digital channels (Samoggia et al., 2019; Ceccoli et al., 2025). This issue is particularly relevant, as communication influences consumer trust, brand reputation, and long-term engagement (Khamitov et al., 2024; Chierici et al., 2019; Kim, 2019), while the abundance of UGC offers an opportunity to better understand which communicative strategies are most effective in eliciting consumer engagement.

Previous studies have also highlighted that, despite a growing convergence in the reputation of different retail formats over recent years (Cardinali & Bellini, 2014; Anselmsson & Johansson, 2014), including both non-discount and discount retailers, discount formats are often penalized because their lower-priced products are perceived as less healthy (Ceccoli et al., 2025). It is therefore of interest to investigate whether such divergence persists over time and whether it is reflected in the online image of discount retailers relative to non-discount retailers, or whether the convergence between formats has mitigated this gap.

Importantly, existing research has largely overlooked the value of a longitudinal perspective in capturing how both retailer communication and consumer perceptions evolve over time.

To address these gaps, the present study adopts a longitudinal and exploratory design over two years (2024–2025), a period characterized by sustained inflationary pressures in the food sector (Statista, 2025), which may have shaped both retailers' communication strategies and consumers' online perceptions and discussions. By adopting an integrated perspective, the study jointly examines retailer-generated digital communication (across discount and non-discount formats) and the perceptions and conversations developed by consumers around health, well-being, and healthy eating. In light of this reasoning, the paper aims to fill these gaps by answering the following research questions:

RQ1: Which contents and communication strategies do Italian grocery retailers employ on health, well-being, and healthy eating in digital contexts?

RQ2: How are these messages perceived and discussed by online users?

RQ3: Do differences persist in user perception and sentiment between non-discount and discount retailers?

To answer these questions, the study adopts a web listening methodology, designed to comparatively explore online conversations generated by both Italian grocery retailers and consumers, analyzing first the data from 2024 and then from 2025 to identify temporal changes and trends. The contribution of this research is twofold. First, it advances the literature on online communication in the food retail sector by addressing a relatively underexplored domain: how Italian grocery retailers (discount vs. non-discount) leverage social media to promote healthier behaviors and how these efforts are perceived by consumers. Second, it provides actionable insights for optimizing communication strategies, enhancing consumer trust, and increasing the impact of health-related messaging, with recommendations directly derived from the patterns and dynamics observed in online conversations.

2. Theoretical background

Grocery Retailers and promotion of healthy, well-being, and healthy eating

Grocery retailers constitute a central component of the food value chain. They influence not only product availability but also consumers' choices and dietary habits (Dubowitz et al., 2015; Hillier et al., 2015; Chrisinger et al., 2018). Through assortment planning, in-store layout, promotional strategies, and product reformulation, retailers can steer consumers toward healthier options (Scapin et al., 2025; Martinelli & De Canio, 2021; Coyle et al., 2020; Jensen & Sommer, 2017). For instance, they may reduce the energy content of products or introduce healthier alternatives through private label. In this way, many retailers have expanded their assortment by including healthier alternatives or introducing entire product lines dedicated to health and well-being (Martinelli & De Canio, 2021). Packaging has also been redesigned to serve both aesthetic and informative purposes. Retailers increasingly use front-of-pack (FOP) labels, nutritional claims, and messages related to health and disease risk reduction (van't Riet, 2013; Cameron et al., 2016). These tools have been shown to influence perceived healthfulness and encourage consumers to choose healthier options (Asioli et al., 2017; Machín et al., 2018; Ballco & Gracia, 2022).

Retailers also shape consumers' access to healthy food. Pricing strategies, as well as store location, can significantly influence purchasing habits (Crawford et al., 2017; Cameron et al., 2016). In particular, discount policies and cashback mechanisms have been used to enhance the economic accessibility of healthier products (Ball et al., 2015; Cameron et al., 2016). This is especially relevant in the context of rising food prices due to inflation (Statista, 2025). Moreover, layout and display strategies play a key role. Retailers can position healthier products at eye level, place them in strategic locations, or create dedicated "health pathways" to guide consumers toward more informed choices (Van Kleef et al., 2012; Cameron et al., 2016).

Finally, communication represents one of the main levers through which retailers can promote healthier dietary habits and lifestyles (Cameron et al., 2016; Grandi et al., 2019; Graziano et al., 2025). These initiatives include in-store campaigns, traditional advertising, outdoor activities, as well as digital and social media strategies aimed at raising awareness and encouraging healthier consumption behaviors (Scapin et al., 2025; Graziano et al., 2025; Cameron et al., 2016). Such actions play a significant role in influencing decision-making processes and purchasing behaviors (Willett et al., 2006; Hecht et al., 2020).

Despite the extensive literature on nutritional, health, and well-being strategies promoted by retailers and on in-store interventions. Less attention has been devoted to how these initiatives are communicated within digital environments and how consumers engage with and interpret such messages online (Samoggia et al., 2019; Ceccoli et al., 2025). Given the growing centrality of digital platforms in shaping food-related norms, meanings, and public discussions (Kumar et al., 2025), this gap limits our understanding of how retailers' health-oriented strategies are constructed, conveyed, and interpreted within contemporary food environments.

Digital Communication and promotion of healthy, well-being, and healthy eating

In the food sector, digital media do not merely disseminate information. They actively contribute to the social construction and legitimation of food-related norms and practices (Kumar et al., 2025).

Social media and online platforms make certain dietary choices more visible and desirable. In doing so, they foster their normalization and integration into everyday life (Dearlove et al., 2021; Zhang et al., 2023).

Through visual and narrative content, platforms such as Instagram, Facebook, and TikTok illustrate how healthy eating practices can be embedded into daily routines. This enhances their perceived accessibility and appeal (Mohammad, 2020; Zhang et al., 2023). In this context, influencer marketing represents a particularly relevant lever. It relies on the perceived credibility and relational proximity of influential figures to promote dietary behaviors. As a result, it can contribute to trust-

building and, in some cases, behavioral change (De Jans et al., 2021). At the same time, the interactive nature of digital media fosters dialogue and participation between brands and consumers, giving rise to symbolic communities centered on health and nutrition (Dearlove et al., 2021). Moreover, through algorithmic systems, social media platforms enable the delivery of highly personalized content aligned with individual preferences, health goals, and specific dietary and lifestyle needs (Mo et al., 2023).

Alongside these interactive tools, the production of informative and educational content - such as blogs and news articles – plays a significant role in improving consumers' understanding of nutritional information and enhancing awareness of the importance of balanced diets (Januraga et al., 2021). Well-structured educational content can positively influence consumer perceptions and increase their willingness to modify dietary habits (Januraga et al., 2021). Furthermore, effective textual communication enhances online visibility through search engines. This expands the reach and circulation of health- and nutrition-related messages (Dearlove et al., 2021; Januraga et al., 2021).

Finally, the participatory nature of digital environments generates a continuous flow of UGC, reflecting consumers' perceptions, interpretations, and evaluations of brands' communication strategies. These digital traces represent a valuable and dynamic source of data. They provide granular insights into how health-related messages are perceived and discussed. Through systematic analysis, UGC enables a deeper understanding of consumers' meaning-making processes and behavioral responses. This, in turn, allows brands to adjust their communication strategies with greater precision and flexibility (Todor, 2016; Rajamma et al., 2020). However, from a scholarly perspective, the potential of user-generated data to inform the promotion of health, well-being, and healthy eating remains only partially explored.

Grocery Retailers' Digital Communication for healthy, well-being, and healthy eating

Prior research shows that digital marketing can support more informed food-related decisions, with positive implications for individual health and well-being (Kumar et al., 2025; Dearlove et al., 2021; Zhang et al., 2023). At the same time, retailers are recognized as key actors in shaping consumer choices through both traditional and digital communication strategies (Graziano et al., 2025; Scapin et al., 2025). Despite the growing presence of grocery retailers on digital and social media platforms, and the growing incorporation of health- and nutrition-related themes into their online communication, scholarly attention to these practices remains limited. This gap is particularly noteworthy given evidence that owned social media can elicit heterogeneous consumer responses along the purchase funnel, leading to heterogeneous effects on engagement and sales outcomes (Akpinar & Berger, 2017; Van Doorn et al., 2010; Liadeli et al., 2022).

Only a limited number of studies have examined retailers' digital communication in relation to health, well-being, and healthy eating (Samoggia et al., 2019; Ceccoli et al., 2025). Specifically, Samoggia et al. (2019) analyzed grocery retailers' messages on Twitter, showing that communication about healthy food tends to remain broad in scope, addressing broad themes such as health and sustainability. While valuable, this study focuses on a single platform and does not account for potential differences across retailer formats. Building on this stream of research, the present study extends prior work in three ways. First, rather than focusing on a single platform, it maps retailers' communication across major online and social media channels. Second, it distinguishes between discount and non-discount grocery retailers, in line with the evidence that consumer perceptions differ across these formats. Third, and most importantly, it integrates the analysis of firm-generated ("owned") messages with user-generated ("earned") discourse. This allows to incorporate consumers' interpretations and discussions into the assessment of retailers' health-oriented communication, leveraging the wealth of data generated by UGC to gain deeper insights into consumer perceptions and behaviors.

Finally, by adopting a two-year longitudinal perspective, the study captures how retailers' communicative evolve and how these are received and discussed by consumers. This dual and longitudinal approach provides a more comprehensive understanding of the dynamics between brand

communication and audience response. It also offers both theoretical insights and actionable implications for enhancing the effectiveness of nutritional communication in the grocery retail sector.

3. Methodology

The research design employed a mixed-methods approach, combining quantitative and qualitative textual analysis (Andreotta et al., 2019). The analysis was conducted using the Blogmeter Suite, a web and social intelligence platform that collects and analyzes user conversations from social media and other web sources (Facebook, Twitter/X, Instagram, YouTube, TikTok, Twitch, forums, blogs, news, and app review sites). The platform extracts textual data from a database of over 2 billion documents, collected from both the official application programming interfaces (APIs) of social networks and Blogmeter's proprietary web crawlers. This social listening research approach follows the proposal of Caliandro and Gandini (2016) and accounts for the peculiarities of qualitatively analyzing digital content relative to traditional data.

The study adopts a longitudinal design based on two consecutive and methodologically aligned waves of data collection, covering January 1st – December 31st, 2024, and January 1st – December 31st, 2025. The same data collection protocol, retailer selection criteria, keywords configuration, and analytical procedures were replicated in both waves to ensure full comparability across time. Two preliminary phases preceded the main analysis. First, the grocery retail brands most discussed online in Italy were identified, with particular attention to non-discount and discount retailers. Retailers' selection was based on the total number of messages collected during the observation period across all Italian grocery retailers. A cut-off threshold of 10,000 messages was applied, as retailers exceeding this level showed a markedly higher volume of total messages compared to the remaining retailers. This procedure initially resulted in the selection of seven brands (four non-discount and three discount). One of the discount retailers included in 2024 did not meet the cut-off threshold in 2025 and was therefore not retained for the second wave. To maintain a consistent longitudinal comparison, this retailer was also excluded from the 2024 dataset. The final sample thus comprised six retailers (four non-discount and two discount) that were analyzed across both years.

Second, the dataset was classified using the Blogmeter Suite software through a keyword-based approach. Keywords were selected by experienced social listening analysts at Blogmeter, following a structured expert-driven procedure aimed at isolating content relevant to health, well-being, and healthy eating from the broader database. The selection process accounted for different natural language formulations, including variations in grammatical gender and number in Italian, which were systematically included when instructing the software to retrace documents. This approach ensured consistency and coverage across linguistically equivalent expressions related to the topics of interest. The sets of keywords selected for the health topic, terms like "health", "healthy", "healthcare", "medical", and "prevention" were included. For the well-being topic, terms such as "well-being", "wellness", and "feel good" were considered. Finally, for healthy eating, keywords like "healthy eating", "nutrition", "nutritionist", "dietitian", and "food pyramid" were selected. Once these preliminary phases were completed, the online content was collected and subjected to the main analysis.

Upon data extraction, the datasets underwent a cleaning and refinement phase aimed at ensuring thematic relevance and coherence. This process followed a combined automatic and manual approach. The Blogmeter Suite software automatically grouped the extracted content into classes based on predefined keyword-based topics. These classes were then manually reviewed by the researchers to assess their relevance to the research objective and to exclude off-topic or ambiguous content. This iterative screening process allowed the identification of coherent subsets of data for subsequent qualitative analysis.

Following this screening, the corpus was expanded to include additional terms that emerged as related to the topics of interest. Specifically, terms semantically linked to "high-protein lines", "vegan

and vegetarian lines", "gluten-free", "organic", and "natural" were included, as these product lines frequently appeared in connection with health, well-being, and healthy eating.

For the quantitative analysis, four metrics were employed: mentions, total messages, engagement, and positive/negative sentiment. Mentions represent the total number of posts or comments that contain at least one of the keywords considered (brands and topics). Total Messages refers to the sum of all posts mentioning the keywords during the observation period, together with their associated comments. Engagement captures the aggregate level of user interactions associated with posts, including comments, likes, shares, and views (for TikTok and YouTube), and is computed in line with the native definitions provided by each social media platform through their official APIs. It should be noted that a change occurred in 2025 regarding Instagram metrics. Specifically, Meta began providing Instagram Reel view counts as part of the engagement metric to third-party platforms, such as the Blogmeter Suite, without the possibility of retroactive retrieval. To address the issue of comparability across waves, the analysis reports engagement delta values excluding the view metric. For clarity, a distinction is made between "passive" engagement, referring to views, passive because they occur automatically when content is displayed, and "active" engagement, referring to likes, comments, shares, and reactions, active because they require explicit user action. Finally, sentiment analysis was conducted using a proprietary opinion mining system implemented within the Blogmeter Suite, based on a grammar-based domain specifically developed for the Italian language and tailored to the thematic focus of the study. The system assigns positive or negative polarity and identifies interrogative forms based on the co-occurrence of predefined lexical units in proximity to the analyzed keywords.

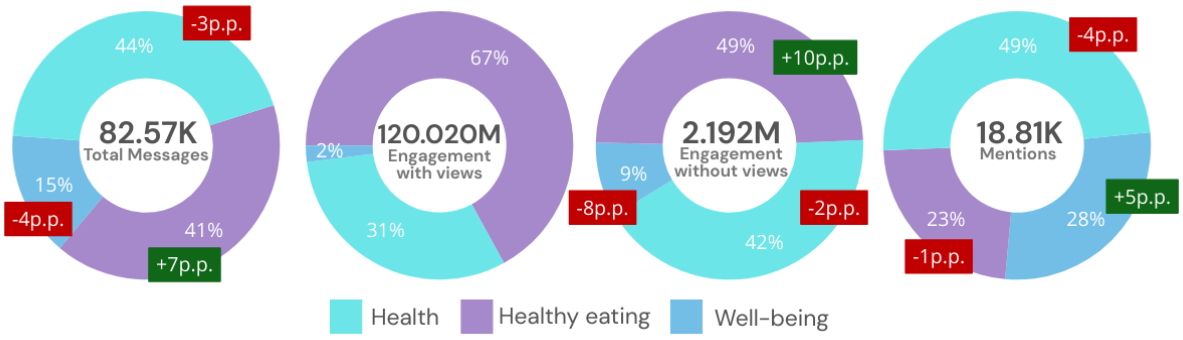
This analytical framework provided valuable insights into the digital visibility and user engagement generated by different retail brands, allowing for a comparative evaluation of their online impact. Following the quantitative analysis, selected subsets of data were examined qualitatively to gain deeper insights into thematic emphasis and discourse patterns.

4. Results

4.1. Evolution and Structuring of Health-, Well-Being-, and Healthy Eating–Related Conversations

Between 2024 and 2025, online conversations linking grocery retailers to themes of health, well-being, and healthy eating accelerated markedly. A comparison between the overall conversation surrounding grocery retailers and discussions specifically focused on these topics reveals a 50,63% increase in the so-called thematic conversation, compared with a general increase of 5,71% in retailer-related discussion (Figure 1). The disparity between these growth rates suggests that the expansion of thematic conversation cannot be attributed merely to the overall increase in online discussion about grocery retailers; rather, it reflects a distinct and noteworthy trend. This pattern points to a rising interest in content related to healthy lifestyles, highlighting a shift in online conversation that warrants further investigation.

Figure 1 – Grocery retailer conversation growth in 2025: General Vs. Topics

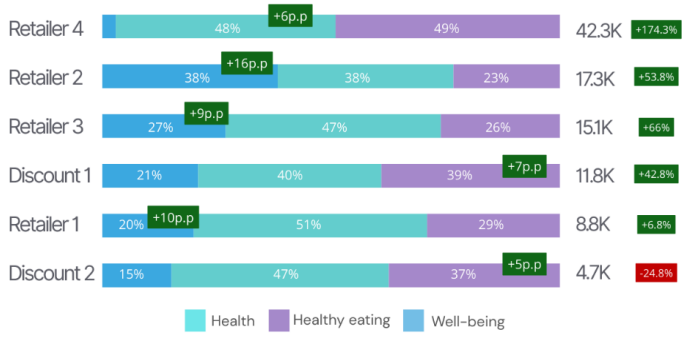


Source: our elaboration

Analyzing the individual topics, it can be observed that in 2025 they are treated more distinctly compared to the previous year. In 2024, discussions of one topic tended to encompass the others, whereas in 2025, the topics are addressed in a more specific and differentiated manner. Moreover,

considering the topics in relation to the KPIs (Figure 2), it emerges that, in terms of both Total messages and Engagement without views, healthy eating shows a significant increase between the two years. This indicates a growing public interest in content related to conscious dietary choice and nutritional practices, likely in response to informational campaigns or heightened media attention on healthy diets. Regarding mentions, the topics of health remain predominant, while well-being records an increase of 5 percentage points, suggesting a greater integration of content linking grocery retailers to the concept of well-being.

Figure 2 – Topics in relation to KPIs: 2024 vs 2025



Source: our elaboration

By breaking down the topics by retailer and considering the KPI Total messages related to grocery retailer conversations that also mention the topic (Figure 3), several changes emerge compared to 2024. Notably, there is a shift in the ranking: while Discount 1 held the top position in 2024, in 2025 Retailer 4 records the most significant growth (+174.3%), largely attributable to a project on health through nutrition, responsible for the 72% of the total messages associating Retailer 4 with the topics.

Overall, if health was the predominant topic for all retailers in 2024 (except Retailer 4), in 2025, healthy eating has gained greater relevance for nearly all retailers.

Compared to the previous year, both discount retailers have increased conversations around healthy eating. In 2024, an issue had emerged regarding the perception of their offerings, which were not actively communicated, whereas in 2025 this trend appears to have reversed. Discount 1 shows growth primarily in healthy eating, driven by conversation regarding the decision to allocate more shelf space to vegan products. Discount 2 also demonstrates a proportional increase in healthy eating, despite being the only grocery retailer to show an overall decrease in association with the topics. Retailer 4, which held the largest share of healthy eating conversations in 2024, maintains its leadership on this topic but loses relevance in well-being, thereby emphasizing the centrality of health. Conversely, Retailer 1, Retailer 2, and Retailer 3 show an increase in conversation related to well-being.

Figure 3 – Total Messages on grocery retailers' conversations with topics

Source: our elaboration

4.2. Owned vs. Earned Content: Communication Strategies and Consumer Perceptions

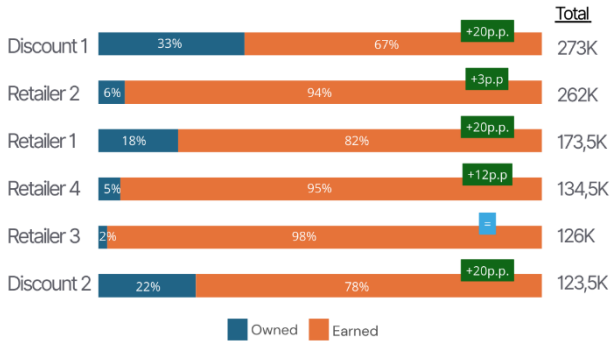
To further investigate the origins of the conversations and better understand the dynamics underlying the construction of online discourse, a distinction was made between message sources: owned content (originating from retailers' proprietary channels) and earned content (generated by third parties). The analysis was conducted at the retailer level to assess the relative contribution of each source type to the association with the themes under investigation.

Figures 4 and 5 present the distribution of owned and earned content. Figure 4 refers to conversations related to general discussion, whereas Figure 6 focuses specifically on the selected topics (health, well-being, and healthy eating). The comparison enables an assessment of both the overall intensity of thematic communication and the degree of specificity with which individual topics are addressed.

The results reveal several noteworthy trends. With respect to earned content, general conversations generated by third parties increased for all retailers except Retailer 3, indicating a broader expansion of online discourse related to grocery retailers (Figure 4). Discount 1 remains the leader in general conversations; however, its share decreases when the focus shifts to health-related topics (Figures 4 and 5). Nevertheless, in 2025, it emerges as one of the most active players in communicating specific topics through its owned channels. A comparison with 2024 clarifies the extent of this change: although Discount 1 was already among the most active brands in terms of overall social media presence, it devoted limited attention to explicit communication on the topics under analysis. Associations between Discount 1 and health were therefore largely spontaneous and, in several cases, negative. In 2025, this dynamic changes: Discount 1 adopts a more proactive approach, significantly increasing its owned communication on health, well-being, and healthy eating (+4 pp), thereby regaining greater control over narrative construction (Figure 5). Similarly, Retailer 2 increases the share of thematic content delivered through its owned channels (+2 pp), aligning with the more proactive strategy observed for Discount 1 in 2025 (Figure 5).

Retailer 4, in turn, expands its share of earned content on the topics. However, as previously highlighted, a substantial portion of this growth is attributable to structured collaborative initiatives (Figure 5). Consequently, the increase in earned content does not necessarily reflect spontaneous consumer associations but rather the amplification of strategically planned communication. For the remaining players, owned communication on the topics remains largely consistent with the patterns observed in 2024 (Figure 5).

Figure 4 – Owned vs Earned in general



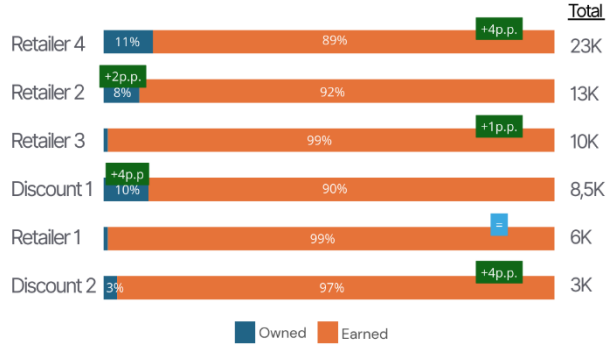


Figure 5– Owned vs Earned on topics

Source: our elaboration

Focusing on the three main players driving owned content on topics (Retailer 4, Retailer 2, and Discount 1 as shown Figure 5), Table 1 provides a qualitative summary of the key content themes, comparing both owned and earned content across 2024 and 2025.

The analysis highlights that, while the communication strategies of Retailer 4 and Discount 1 remain largely consistent over the two years, their scope and intensity expanded in 2025. Notably, the primary focus of each retailer's messaging remains unchanged. The main shift is observed in

consumer perceptions: Retailer 4 shows improved associations with product quality but experiences reputational challenges in other, non-health-related areas. Discount 1 exhibits the most pronounced change, moving from a perception of low quality to being recognized as a leading brand for vegan and vegetarian offerings in terms of price, variety, and quality.

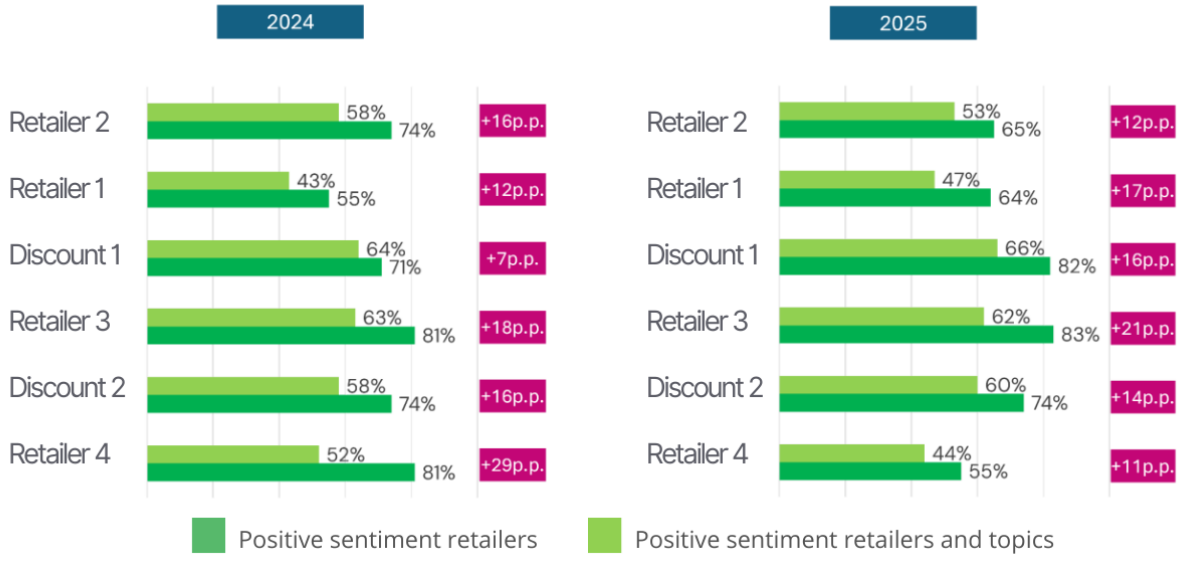
Conversely, Retailer 2 slightly refocuses its communication, shifting from animal welfare and quality associations toward more product-centered messages and guidance on healthy consumption; however, consumers tend to take the nutritional quality of the brand's products for granted and focus their discussions primarily on recipes and taste.

Table 1 – Qualitative analysis: Owned vs Earned (2024-2025)

Retailers	Owned content 2024	Earned content 2024	Owned content 2025	Earned content 2025
Retailer 4	Promotes high-quality, sustainable products from controlled supply chains, offered at accessible prices	Consumers are skeptical about product quality	Explains how to choose higher-quality products; debunks myths about safety and quality; suggests healthy recipes presented by a nutrition expert	Consumers are generally engaged and curious about the content; rarely explicitly associate the brand with product quality or health; perceived partnerships slightly reduce trust in the content; topic-related posts trigger discussion of other negative brand aspects unrelated to health.
Retailer 2	Campaigns focused on animal sustainability and ingredient quality	Generally positive perception of product quality; minor negative mentions regarding product recalls	Slightly more "traditional" health communication: static posts with ingredients and general product images; presents ingredients linked to "well-being" or "healthy" without technical nutritional explanations; explains how to consume and store ingredients; highlights origin/provenance as a quality factor	Consumers are generally positive but not always focused on health and healthy eating; more often comment on taste and recipes
Discount 1	Sports and vegan/plant-based diet promotion	Strong negative perception due to the low price associated with low quality	Communicates "lifestyle" messages linking healthy eating and health to being athletic, interested in "fit recipes," or following a vegetarian/vegan diet	Consumers are generally positive; not always explicitly receptive to health/food content, but occasionally express positive sentiment toward the retailer; vegan/vegetarian offerings are recognized for variety and quality

Source: our elaboration

4.3. The Reputational Impact of Health-Related Conversations



With regard to sentiment analysis, Figure 6 presents two distinct graphs, referring respectively to 2024 and 2025, comparing overall positive sentiment toward retailers with positive sentiment in conversations that simultaneously mention retailers and the selected topics. The findings show that

in both 2024 and 2025, conversations related to health, well-being, and healthy eating were associated with higher levels of positive sentiment toward retailers. In 2024, these topics corresponded to an average increase of +16.8 percentage points, while in 2025 the differential amounted to +15.1 percentage points. Although slightly lower than the previous year, the 2025 figure remains strongly indicative of a positive association, confirming that commitment to health-, well-being-, and healthy eating–related themes contributes to enhancing retailers' online reputation.

A more detailed comparison between the two years nevertheless reveals different dynamics at the individual retailer level. Retailer 4, although the most strongly associated with the topics in terms of volume, is also among those benefiting least from this association in terms of sentiment improvement in 2025 and shows a less favorable trend compared to 2024. This suggests that stronger exposure to the topics does not automatically guarantee a proportional increase in positive sentiment. Conversations around these topics may, in fact, function as discursive spaces in which users express broader evaluations of the retailer. Even when not directly related to the topics under analysis. Consequently, communication initiatives focused on health, well-being, and healthy eating, while effective, are not in themselves sufficient to structurally reshape the overall sentiment toward the retailer.

Retailer 3 records the greatest improvement across the entire pane in both 2024 and 2025, despite not being the retailer most strongly associated with the topics, nor one of the most active on these through its owned channels (Figure 5). This suggests that association with health, well-being, and healthy eating themes may stem not only from explicit communication on products or diets, but also from a broader and more coherent positioning grounded in services and initiatives linked to the concept of well-being. Finally, Discount 1 is among the retailers exhibiting the most pronounced increase in the positive differential between 2024 (+7p.p.) and 2025 (+16p.p.). While in 2024, a critical issue concerning perceived product quality, this negative association appears to have weakened in 2025. Further analysis is nevertheless required to better understand the drivers underlying this shift.

Figure 6 – Positive sentiment: general Vs topics

Source: our elaboration

In terms of negative sentiment, the qualitative analysis reveals several significant critical issues, highlighting a meaningful evolution compared to 2024.

In 2024, discount retailers were primarily affected by a negative association between low price and low quality, which had reputational implications in relation to health-related topics. This association translated into widespread skepticism regarding the quality of food products sold in

discount formats:

"Discount where convenience does NOT meet quality."

"Sorry, but you can't save on food."

"What you save at the discount store you use at the pharmacy later."

In 2025, the scenario appears to have partially shifted. Although negative comments toward discount retailers persist, particularly in relation to sensitive categories such as meat.

"I wonder how anyone can buy meat at a discount store."

The negativity is no longer confined to this format alone. Criticism has expanded across grocery retailers more broadly, indicating a perceived convergence between retail formats from the consumers' perspective.

The narrative increasingly revolves around two macro-themes: distrust toward animal welfare standards and the quality of meat derived from intensive farming, and the generalized increase in food prices. Regarding the grocery retailers, comments reflect a systemic critique directed at the entire retail sector:

"Why mention Retailer 2 when all the chickens sold in supermarkets come from intensive farming?"

Simultaneously, food inflation in 2025 (Statista, 2025) constitutes a central dimension of the discussion. Price increases are perceived as widespread and directly affect the accessibility of healthy products, which are increasingly described as unaffordable across all supermarket formats. Consumers frequently highlight a polarization between healthy products, perceived as expensive, and cheaper alternatives, which are implicitly associated with negative health consequences:

"This dynamic leads to a compression of consumption: if products become unaffordable, families will be forced to purchase smaller quantities or worse, buy lower-quality products at the expense of their health."

Within this framework, some comments question the overall quality of products sold in large-scale retail, reinforcing the perception that supermarket channels are intrinsically linked to inferior standards:

"You can buy it in 'Canicattì', but if you purchase it at the supermarket, it is still a low-quality product."

However, alongside rising prices, a partial reconsideration of discount product quality emerges. The increase in prices within non-discount retailers appears to have attenuated the sharp distinction previously perceived between formats, fostering a relative re-evaluation of discount retailers among some consumers:

"Many food products at Discount 2 are truly excellent and even better than more well-known brands."

"I shop at Discount 1 and fill my fridge with really good food."

This does not imply that discount retailers are exempt from criticism. They are likewise discussed in relation to price increases:

"Even shopping at discount stores and buying promotional items, what you could buy with €100 four years ago is now difficult to buy with €150."

Compared to 2024, the competitive landscape therefore appears more complex. Consumers actively compare inflation and total basket costs across both traditional large-scale retail and discount formats, demonstrating a more sophisticated evaluative approach. Within this context, a third competitive actor, previously marginal, gains prominence: proximity stores and small local

producers, perceived as offering higher quality, greater authenticity, and improved health standards:

"If you want chicken, go to a butcher or a trusted local farmer."

"I never buy olive oil at the supermarket; I buy it directly from the mill so I can be sure it is extra virgin olive oil."

Overall, the qualitative evidence suggested that in 2025 the discourse no longer revolved exclusively around the discount–quality dichotomy. Instead, it unfolded within a broader framework characterized by inflationary pressure, redefined hierarchies of trust, and the increasing legitimization of alternative channels to organized grocery retailers.

4.4. Which Products Mean "Health"? Exploring Consumers' Natural Associations

In comparing 2024 and 2025, the analysis of product lines associated with health and healthy eating shows substantial continuity in the categories perceived as "healthy" (Figure 7), alongside some notable shifts in their prominence and conversational volume (Figure 8). In both years, high-protein products represent the category with the highest percentage association to health topics, representing the strongest and most stable link between product attributes and perceived healthiness. Already in 2024, protein-rich products emerged as the category most strongly health-oriented, and in 2025 they maintain this apex position, registering only marginal growth while consolidating their dominant role in the health-related semantic landscape (+2p.p.; Figure 7). At the same time, organic/natural/BIO product lines further strengthened their association with health, though without surpassing the primacy of high-protein products.

The most notable discontinuity concerns sugar-free products, which in 2025 emerge as the category with the largest increase in association with health, well-being, and healthy eating, marking a particularly strong growth compared to the previous year (+35 p.p.; Figure 7). This change is even more significant when considered alongside overall conversational volumes (Figure 8): while most categories in 2025 (vegan/vegetarian, protein, gluten-free, organic) experienced a decline in total discussions, the sugar-free category represents the only exception, showing growth in absolute terms as well. Overall, the comparison suggests that, despite a general reduction in discourse attention toward many health-oriented categories, high-protein products maintain their role as a symbolic anchor of health, while sugar reduction is increasingly recognized across conversations, partially reshaping the semantic hierarchies observed in 2024.

5. Discussion

The present study aimed to jointly analyze retailer-generated digital communication (across both discount and non-discount formats) and the perceptions and conversations developed by consumers around health, well-being, and healthy eating. A longitudinal design was adopted to capture changes between 2024 and 2025. Over this period, thematic conversations increased, indicating a growing interest from both retailers and consumers.

In 2025, the topic of health, which led discussions in 2024, received slightly less attention, while healthy eating and well-being gained prominence, reflecting a more specific and targeted form of communication. This trend represents a departure from previous studies, which found that retailers tended to communicate on more generic topics to avoid reputational risks (Samoggia et al., 2019; Ceccoli et al., 2025).

Regarding editorial strategies, the study highlights the contrast between volumes of owned and earned content. Retailers generally invest relatively little in communication through their own channels on the topics analyzed, despite evidence that proprietary channel communication influences both engagement and purchasing behavior (Liadeli et al., 2022; Grewal et al., 2022). Nevertheless, Discount 1, after a particularly challenging year in 2024, increased its communication on health-related topics, emphasizing a healthy lifestyle approach. This increase in messaging was positively received by consumers, who strengthened their favorable perception of the brand regarding these topics. In particular, the vegetarian and vegan product lines were appreciated for taste, affordability, and quality. In 2025, Discount 1 achieved a reputational boost and partially mitigated the previous low-cost = low-quality perception. This case exemplifies how leveraging brand strengths can effectively improve consumer perceptions.

In contrast, despite significant efforts by Retailer 4 through projects and partnerships on healthy eating, communications were exposed to negative comments concerning other, non-topic-related decisions. This represents a critical issue, as it not only generates negative sentiment around the brand but also amplifies the visibility of such concerns. Social media algorithms tend to expose these posts to users interested in health, well-being, and healthy eating. However, these users also read the negative comments, potentially affecting overall brand opinion, reducing trust, and diverting consumers toward competitors. In such cases, monitoring comments under sponsored posts and responding with timely, targeted communication strategies is advisable (Shahbazi & Bunker, 2024).

Another relevant insight concerns the convergence of retail formats in consumer perception. In 2024, differences between discount and non-discount retailers were pronounced, with discount stores perceived as less health-oriented. In 2025, distrust extended across all formats, linked both to perceived lower quality of fresh products (e.g., meat) and supply chain issues, as well as to inflation (Statista, 2025), which rendered healthy products less accessible. Consumers, needing to balance budgets, often turned to products perceived as lower quality. Rising food prices also prompted comparisons between supermarkets and small-scale or local producers, such as butchers, highlighting a strategic insight that may reshape the competitive landscape of grocery retail (Gonzalez-Benito et al., 2005).

Finally, across both 2024 and 2025, consumers consistently perceived high-protein products as the healthiest. This trend persists despite scientific evidence cautioning against excessive consumption of processed protein (Ortega et al., 2024). Additionally, there is growing consumer interest in sugar-free products, aligning with recommendations to reduce daily sugar consumption below 10% of daily energy intake (Yan et al., 2022). Consumers value these lines because they allow for a balance between indulgence and health. However, further investigation is needed to assess whether sugar reductions are accompanied by substitutions with potentially less healthy ingredients (Sharma et al., 2025).

6. Theoretical Implications and Managerial Guidelines for Grocery Retailers

6.1.Theoretical Implications

This study contributes to the literature in several ways. First, it introduces a longitudinal perspective on retailer social listening by comparing two consecutive years. This approach provides a more comprehensive understanding of how retailer communication strategies and consumer perceptions evolve over time. The findings reveal that retailer's reputation in the health-related domains is not static but can shift significantly. In particular, the results show clear evidence of reputational reconfiguration across retail formats and brands from 2024 to 2025, suggesting that the effect of digital communication are dynamic and context-dependent. These dynamics are shaped by factors such as inflationary pressure, strategic communication adjustments, and the evolution of user-generated discourse.

Second, the research extends prior studies on the effects of online communication in the food sector (e.g., Kumar et al., 2025) by shifting the analytical focus from producers to retailers. By examining how retailer communication influences consumer discourse, this study enriches our understanding of the retailer as an active agent in the construction of health-related narratives.

Third, the study advances the literature on retailers' online communication listening by integrating both owned and earned content and by jointly analyzing brand communication and consumer reactions (Samoggia et al., 2019). In doing so, it bridges retailer-driven communication strategies with consumer-level perception and sentiment analysis, providing a more integrated framework for understanding digital interaction in grocery retailing.

Finally, the findings contribute to the literature on competitive convergence in grocery retailing by identifying the emergence of proximity stores and small local producers as perceived competitors in consumer discourse (Gonzalez-Benito et al., 2005), suggesting a shift in competitive boundaries driven not only by market structure but also by consumer perception.

6.2. Managerial Guidelines for Grocery Retailers

The following guidelines illustrate how grocery retailers can strategically align their communication with evolving consumer priorities while managing reputational and competitive risks.

Strengthening the Presence of Health-Related Themes in Owned Media

The analysis shows a clear increase in online conversations about health, well-being, and healthy eating over the two years observed. Moreover, discussions of these topics are more strongly associated with positive sentiment than conversations focused on other themes.

Despite this growing salience, the share of owned content dedicated to these topics remains limited. This indicates a gap between the evolution of consumer discourse and retailers' communication efforts. Adopting a more proactive and structured approach to health-related communication within owned media would allow retailers to better align with evolving consumer priorities and reinforce their positioning in a domain that already demonstrates comparatively advantageous sentiment dynamics.

Monitor Reactions to Partnerships and Sponsored Content

The analysis indicates that collaborations with experts and influencers can increase visibility. As these partnerships attract higher engagement, they also stimulate broader online conversations, which may extend beyond the focal topic of health, well-being, or healthy eating. Monitoring these interactions is therefore essential, as they can shape how the retailer is perceived. Notably, even critical comments on highly visible posts may contribute to keeping the topic salient in online discussions, as observed in the case of Retailer 4.

Leverage Strategic Differentiation Instead of Imitation

Emulating competitors can dilute brand positioning. Discount 1 provides a relevant example: rather than directly competing on traditional "healthy quality" narratives after criticism for low quality, it strategically expanded its vegan and vegetarian assortment. This approach allowed the

retailer to capitalize on a growing trend while preserving its competitive advantage in affordability. The vegan and vegetarian assortment is positively recognized for variety, quality, and price accessibility, dimensions not equally acknowledged for other retailers in the sector. These findings suggest that retailers can benefit more from leveraging their distinctive strengths than from replicating competitors' communication strategies.

Address the Emerging Affordability–Quality Tension

The broader context of inflation and rising prices affects consumer perceptions of grocery retailers. Healthy products are increasingly perceived as less accessible, and even discount retailers are criticized for rising basket prices. An emerging competitive threat appears to come from small proximity stores and local producers, which are perceived as offering higher quality, more genuine, and sustainable products. When price differences narrow, consumers may reconsider value perceptions and shift toward these alternatives.

Retailers should therefore actively manage the perceived trade-off between affordability and quality, particularly in the health, well-being, and healthy eating domains.

7. Limits and suggestions for future research

This study contributes to understanding online communication by grocery retailers and consumer perception on health, well-being, and healthy eating, yet it presents several limitations. First, the analysis focuses on six grocery retailers, selected based on online visibility thresholds. Although these were the most discussed online during the observation period, the limited sample constrains the generalizability of the findings. Future research could expand the scope to include a broader range of retailers to test the robustness of the observed patterns.

Second, the absence of demographic information on users limits the ability to examine variations in perception and engagement. For example, younger consumers may perceive discount retailers differently from adults due to differences in economic availability (Thangavel et al., 2022) and may be more sensitive to health, well-being, and healthy eating topics (Becerra et al., 2023; Halicka et al., 2025).

Finally, reliance on manual data cleaning may introduce subjectivity and constrain scalability. Future studies could integrate automated or machine-learning-based preprocessing to reduce potential bias and enable the analysis of larger datasets. Further research could also investigate the cultural, lifestyle, and marketing factors that drive the strong association between "high protein" messaging and perceptions of health and well-being.

Orchestrating Digital Passenger Experience: Digital Touchpoints and Organisational Choices in a Smart Airport

CARLO RICCARDO RAGGI[1], MARCO REMONDINO[2]

Abstract

Frame of the research. *Digitalisation is reshaping airports through digital touchpoints aimed at improving operational efficiency and passenger experience. Prior research has mainly examined individual airport technologies, user perceptions or service quality outcomes, devoting limited attention to how digital passenger experience emerges from the orchestration of digital touchpoints, data flows, organisational processes and managerial responsibilities across the passenger journey. Airports represent complex socio-technical service systems in which digital technologies operate within governance structures and operational processes.*

Purpose of the paper. *This paper investigates how digital touchpoints and organisational choices are orchestrated to shape digital passenger experience in a smart airport. The study conceptualises digital passenger experience as an organisationally orchestrated outcome rather than the result of isolated technological interactions.*

Methodology. *The research adopts a qualitative single-case study based on a theory-driven thematic analysis of ADR's Integrated Annual Report 2024, focusing on Rome Fiumicino Airport. The analysis follows the passenger journey and examines relationships between digital touchpoints, organisational arrangements, and passenger experience implications.*

Results. *Findings indicate that passenger experience depends less on the presence of digital technologies than on orchestration mechanisms governing integration, reliability, governance, and support. The study highlights trade-offs between efficiency, perceived control, trust, and inclusion in digitally mediated passenger journeys.*

Research limitations. *The study is based on documentary data and focuses on a single case.*

Managerial implications. *Results emphasise that airport managers should govern digital passenger experience as an end-to-end service system, aligning passenger-facing technologies with back-end data infrastructures, operational responsibilities, quality metrics and support mechanisms.*

Originality of the paper. *The paper advances smart airport research by framing digital passenger experience as an emergent socio-technical outcome.*

Keywords: *Digitalisation, Digital touchpoints, Passenger experience, Organisational orchestration, Smart airports.*

1. Introduction

Airports are increasingly evaluated not merely as transportation infrastructures, but as complex service systems in which passenger experience has become a central dimension of competitiveness, legitimacy and managerial performance. As air travel volumes have returned to, and in many hubs surpassed, pre-pandemic levels, airports are facing the challenge of accommodating growing demand while maintaining smooth, reliable and reassuring journeys. In this context, digital technologies such as mobile applications, biometric identification, real-time information systems, artificial intelligence and data-driven flow management have become central tools for reducing friction, increasing predictability and supporting operational resilience (Dini et al., 2023).

However, the relationship between digitalisation and passenger experience is neither linear nor unambiguously positive. Airports remain environments characterised by time pressure, uncertainty, security constraints and high emotional intensity, particularly for passengers facing disruptions, language barriers, unfamiliar procedures or reduced mobility. Digital interfaces may reduce these tensions by providing information, automation and personalised support, but they may also introduce new sources of anxiety when they fail, overload users with information, or replace human assistance

[1] University of Genoa, carloriccardo.raggi@edu.unige.it
[2] University of Genoa, marco.remondino@economia.unige.it

in moments of stress. This makes the governance of digital touchpoints a central managerial challenge in contemporary airport management.

The academic literature reflects this complexity. Airport management and transportation studies have traditionally emphasised service quality, operational efficiency, congestion management and the progressive transformation of airports into smart infrastructures. In parallel, information systems and service research have examined how digital interfaces reshape customer journeys, user expectations, technology acceptance and value co-creation. These streams provide valuable insights, but they have often evolved separately. As a result, existing research tends to examine either specific technologies and their adoption, or broader service quality outcomes, while paying less attention to the organisational mechanisms through which digital passenger experience is designed, coordinated and governed across the passenger journey.

This paper addresses this gap by focusing on the interplay between digital touchpoints and organisational choices. In airports, passengers do not experience digitalisation through isolated interfaces, but through a sequence of interdependent encounters before, during and after their presence in the terminal (Patrício et al., 2008; Lemon & Verhoef, 2016). The usefulness of a mobile application depends on the accuracy of back-end data; the perceived fairness of automated security depends on transparent procedures and support mechanisms; and the reassurance provided by real-time information depends on the airport's capacity to coordinate operational responses during disruptions. Digital passenger experience emerges not simply from the presence of advanced technologies, but from the way these technologies are aligned with data flows, operational processes, managerial responsibilities and service quality metrics.

The study investigates this issue through an in-depth case study of Rome Fiumicino Airport, one of the largest and most technologically advanced hubs in Europe. Managed by Aeroporti di Roma (ADR), Fiumicino has consistently positioned digitalisation as a strategic pillar of its development, integrating data-driven operations, customer-facing platforms and innovation programmes into its broader vision of a smart and sustainable airport, in line with broader transformations toward smart and digitally enabled airports (Newbold, 2020). The case is therefore particularly informative for examining how digital passenger experience is designed and governed at scale within a complex airport service ecosystem.

Accordingly, the study addresses the following research question:

How are digital touchpoints and organisational choices orchestrated to shape passenger experience in a smart airport?

The originality of the paper lies in conceptualising digital passenger experience not as the direct outcome of single technologies, but as an organisationally orchestrated phenomenon emerging from the alignment of digital touchpoints, data flows, operational processes, responsibilities and service quality metrics along the passenger journey. Rather than evaluating the technical performance of individual systems, the study examines how front-end interfaces such as information systems, navigation tools and automated processes are connected to back-end coordination structures, data infrastructures and quality management mechanisms, and how this interaction shapes perceived control, trust and overall experience.

The analysis is guided by an integrated theoretical framework combining the Technology Acceptance Model (TAM) and Service-Dominant Logic (SDL). TAM provides a lens to understand how passengers evaluate digital touchpoints in terms of perceived usefulness and ease of use, which are particularly relevant in high-pressure environments such as airports (Davis, 1989). SDL, in turn, conceptualises the passenger journey as a process of value co-creation in which technologies, organisations and users jointly shape service outcomes (Vargo & Lusch, 2008). Together, these perspectives make it possible to theorise digital passenger experience as the result of socio-technical orchestration, not of technological deployment alone.

By answering the research question, the paper makes three contributions. First, it advances research on smart airports and digital aviation services by providing a theory-driven account of how digitalisation is operationalised across the passenger journey. Second, it contributes to service and information systems research by showing how technology acceptance is conditioned by organisational orchestration and ecosystem-level coordination. Third, it offers actionable insights for airport managers on how to design and govern digital infrastructures in ways that enhance passenger experience while avoiding new sources of friction, exclusion and mistrust.

2. Theoretical framework: digital passenger experience in smart airports

The transformation of airports into digitally mediated service environments requires theoretical lenses that can capture both individual user responses and the systemic organisation of service encounters. To this end, this study integrates the Technology Acceptance Model (TAM) and Service-Dominant Logic (SDL) to conceptualise how digitalisation is orchestrated to shape passenger experience across the airport journey. While TAM explains why passengers accept or reject specific digital touchpoints, SDL situates these interactions within a broader ecosystem of actors, technologies and organisational processes through which value is co-created.

2.1 Digitalisation and the airport as a service system

Airports have progressively evolved from infrastructure providers into complex service organisations coordinating a wide range of passenger-facing and back-end activities. This evolution has been driven by several factors, including the growth of non-aeronautical revenues, increasing passenger expectations and the need to manage high volumes under stringent security and safety constraints. Digital technologies have become central to this transformation, enabling the integration of information, the automation of processes and the real-time coordination of resources (Halpern et al., 2021).

In smart airports, digitalisation is not limited to isolated applications but takes the form of an integrated service architecture. Passenger-facing interfaces such as mobile applications, biometric gates and self-service kiosks (Bogicevic et al., 2017) are connected to data platforms, sensors and operational control centres that continuously monitor and adapt the system. This architecture allows airports to shift from reactive to proactive service management, anticipating congestion, reallocating resources and communicating with passengers in real time.

From a theoretical standpoint, this shift challenges traditional views of service delivery based on linear processes and stable roles. Instead, the airport becomes a dynamic service system in which value is produced through the interaction of heterogeneous actors and technologies. Passengers, airport operators, security agencies, airlines and digital platforms jointly contribute to the experience, often in ways that are only partially visible to one another. Understanding digital passenger experience therefore requires a framework that can accommodate both user perceptions and organisational orchestration. In line with customer journey research, digital touchpoints are treated as interdependent episodes that unfold over time and across channels; consequently, passenger experience depends on the coherence of the end-to-end journey, not only on the performance of isolated interfaces (Verhoef et al., 2015; Kuehnl et al., 2019).

2.2 Technology Acceptance Model in the airport context

The Technology Acceptance Model has been widely used to explain the adoption of information systems across a variety of contexts. At its core, TAM suggests that perceived usefulness and perceived ease of use determine users' attitudes toward a technology and their intention to use it (Davis, 1989). TAM is not used here as a predictive behavioural model, but as an interpretive lens to understand how digital service configurations shape passengers' perceived control, ease, and trust

within a broader socio-technical system. In the airport environment, these constructs acquire specific meanings shaped by time pressure, risk and emotional involvement.

In high-stakes and security-sensitive services such as airports, acceptance is also shaped by perceived fairness and privacy concerns, especially when biometric and AI-enabled systems are involved; these factors can amplify or dampen perceived usefulness and perceived control.

Perceived usefulness in airports is closely linked to the ability of digital touchpoints to reduce uncertainty and enhance predictability. Passengers face multiple sources of ambiguity, including changes in gates, delays, security procedures and unfamiliar spatial layouts. Digital tools that provide accurate, timely and personalised information can therefore be experienced as highly useful, as they support situational awareness and enable passengers to make informed decisions. Yet, when information becomes outdated, inconsistent, or difficult to interpret, digitalisation may itself become a source of anxiety rather than a mechanism for its reduction. Perceived ease of use is equally critical in this context. Airports serve a highly heterogeneous population, including infrequent travellers, elderly passengers, families and individuals with disabilities. Digital interfaces that require complex interactions, repeated log-ins or high levels of digital literacy risk excluding or frustrating significant segments of users. In such cases, even technically advanced systems may be rejected or bypassed in favour of human assistance, reducing their experiential and operational value. Importantly, TAM also implies that acceptance is shaped by the broader service environment. Consistent with this broader perspective, prior research on airport technologies highlights the critical role of privacy concerns, trust formation, and perceived fairness as additional evaluative dimensions in shaping passengers' evaluations of biometric and automated systems (Kasim et al., 2021). Passengers' perceptions of usefulness and ease of use are influenced not only by interface design but also by organisational reliability, trustworthiness and support. For example, a biometric gate may be perceived as easy to use when staff are available to assist and procedures are clearly communicated, but as threatening or unfair when errors occur without explanation. This suggests that technology acceptance in airports cannot be fully understood without considering organisational and governance dimensions (Venkatesh et al., 2003).

2.3 Service-Dominant Logic and the passenger journey

Service-Dominant Logic provides a complementary perspective by framing the passenger journey as a process of value co-creation. In SDL, value emerges through the integration of resources by multiple actors rather than being embedded in a product or technology (Vargo & Lusch, 2004, 2008). In the airport context, passengers co-create their experience by combining their own skills, preferences and behaviours with the airport's physical, digital and human resources. Digital touchpoints play a crucial role in this process by enabling new forms of interaction and resource integration. This perspective aligns with research on customer journey design, which conceptualises service experiences as emerging from the configuration and orchestration of multiple touchpoints rather than from isolated interactions (Kuehnl et al., 2019). A mobile application allows passengers to access information and adjust their plans; sensors and analytics allow the airport to adapt operations; automated systems redistribute tasks between humans and machines. These interactions create opportunities for enhanced efficiency and personalisation, but they also create dependencies and vulnerabilities. When digital systems fail or are perceived as misaligned with passenger needs, co-creation can turn into co-destruction, resulting in frustration and loss of trust.

SDL also highlights that value is context-dependent and phenomenologically determined (Vargo & Lusch, 2016). Two passengers may experience the same digital service in radically different ways depending on their goals, stress levels and prior experiences. This underscores the importance of designing digitalisation not only for average users but for diverse and sometimes vulnerable populations.

2.4 Orchestration, governance and digital experience

Integrating TAM and SDL leads to the concept of orchestration as a central mechanism in digital passenger experience. In this paper, orchestration is understood as the managerial capability to align digital touchpoints, data flows, operational processes, responsibilities and performance metrics along the passenger journey. It refers not only to the technical integration of systems, but also to the organisational work through which digital initiatives are selected, governed, coordinated and translated into passenger-facing service outcomes (Tilson et al., 2010; Lusch & Nambisan, 2015).

This distinction is important because orchestration is related to, but not identical with, integration, coordination or governance. Integration concerns the connection of systems, channels and data infrastructures; coordination concerns the alignment of actors and activities in operational processes; governance concerns decision rights, accountability mechanisms and rules for managing digital initiatives. Orchestration encompasses these dimensions, but emphasises their purposeful alignment around passenger experience across the end-to-end journey (Lemon & Verhoef, 2016). In this sense, orchestration provides the managerial link between technology acceptance and value co-creation, since digital touchpoints are more likely to be perceived as useful, easy to use and trustworthy when they are supported by coherent organisational processes and embedded in a broader service ecosystem.

In smart airports, orchestration is increasingly enabled by digital infrastructures such as Airport Operation Centers and integrated data platforms that connect security, operations, retail and mobility services. These infrastructures allow the airport to sense conditions in real time, coordinate responses and communicate with passengers, thereby shaping the experiential qualities of the journey. However, orchestration also introduces new challenges related to power, accountability and transparency, as digital platforms concentrate control over information and decision-making (Tilson et al., 2010; Constantinides et al., 2018).

From this perspective, digital passenger experience is best understood as a socio-technical outcome of how airports orchestrate their digital ecosystems. In smart airports, perceived usefulness and ease of use are not properties of individual digital interfaces alone, but emergent outcomes of the alignment between touchpoints, data flows, organisational responsibilities and operational processes. Technology acceptance and value co-creation are shaped not only by the characteristics of single technologies, but by how these technologies are embedded in the passenger journey and supported by organisational choices (Davis, 1989; Vargo & Lusch, 2008). This integrative lens allows the analysis to move beyond technology-centric explanations and to examine how managerial orchestration structures passenger experience across interconnected touchpoints.

3. Methodology

3.1 Research design

This study adopts a qualitative single-case study design to investigate how digitalisation shapes passenger experience in a smart airport. Case studies are particularly suitable for examining complex socio-technical phenomena in real-life contexts, especially when the boundaries between technology, organisation and user experience are inherently intertwined (Yin, 2018). The digital transformation of airports involves multiple interacting actors, infrastructures and governance mechanisms, making a case-based approach appropriate for capturing these dynamics in depth. Accordingly, the study adopts a theory-informed interpretive case approach aimed at understanding how digital touchpoints, organisational choices and passenger experience implications are connected, instead of testing causal effects. Rome Fiumicino Airport was selected because it represents a large European hub with a strong strategic orientation towards digital innovation and customer centricity. Consistent with case study research, the aim is not statistical generalisation, but analytical generalisation through the refinement of theoretical mechanisms (Eisenhardt, 1989). Managed by Aeroporti di Roma (ADR), Fiumicino Airport has received multiple international recognitions for service quality, security

processing and digital transformation, positioning it as a theoretically informative case for exploring how digital passenger experience is designed and governed in practice. Fiumicino can thus be interpreted as a revelatory case in which orchestration mechanisms become particularly visible.

3.2 Data sources

The empirical analysis is based on ADR's Integrated Annual Report 2024 (Aeroporti di Roma, 2024), which provides detailed accounts of digital initiatives, governance mechanisms and service quality systems. The report is treated as an institutional document, not as a neutral account of organisational performance. Following documentary analysis approaches, such sources are useful for examining how organisations frame strategic priorities, legitimise managerial choices and represent socio-technical transformation processes (Bowen, 2009). Accordingly, the report is used to analyse how digitalisation, passenger experience and service quality are framed, governed and communicated by the airport organisation.

The annual report was complemented by a limited review of publicly available ADR and Fiumicino airport web materials, used exclusively to clarify the scope and intended functions of specific digital initiatives referenced in the report. These materials were not treated as independent empirical sources, but as contextual documents supporting the interpretation of the primary data.

3.3 Analytical strategy

A theory-driven thematic analysis was conducted, guided by the conceptual framework developed in Section 2. The analysis was structured along four analytical phases of the passenger journey: (i) pre-journey and access to information, (ii) in-terminal processes and flow management, (iii) disruption management and organisational orchestration, and (iv) post-journey feedback, quality management and learning.

For each journey phase, the documentary material was organised around three analytical dimensions:

1. *Digital touchpoints*, referring to front-end technologies and interfaces through which passengers interact with the airport (e.g. apps, sensors, biometric systems, information platforms);
2. *Organisational choices*, referring to governance mechanisms, investments, coordination structures and operational processes that enable and regulate these technologies;
3. *Passenger experience implications*, referring to how these technologies and organisational arrangements are expected to influence perceived control, ease, trust and overall satisfaction, as described in the documents or proxied by recognised quality and customer experience indicators.

The analytical process involved iterative reading of the documentary material, identification of relevant passages and their organisation according to the journey phases and analytical dimensions.

Particular attention was paid to linkages between technological initiatives and organisational arrangements, in order to capture digitalisation as an orchestrated service-system process, not as a set of isolated tools.

To clarify the analytical structure, Table 1 summarises how the passenger journey phases were connected to digital touchpoints, organisational choices and expected experience implications.

Table 1. Analytical framework linking passenger journey phases, digital touchpoints, organisational choices and experience implications

Journey phase	Digital touchpoints	Organisational choices	Experience implications
Pre-journey and information access	Digital information totems; web-based indoor navigation; WhatsApp chatbot; real-time flight information	Extension of passenger communication beyond physical counters; investment in scalable and mobile information channels; integration of spatial and flight information	Increased perceived control; reduced uncertainty; lower cognitive load before and during airport access
In-terminal processes and flow management	LiDAR-based sensors; queue monitoring systems; AI-supported security screening; digital retail solutions	Data-driven flow management; dynamic resource allocation; automation of selected security and commercial processes	Shorter and more predictable waiting times; smoother transitions; potential concerns over transparency and perceived fairness
Disruption management and organisational orchestration	APOC-enabled monitoring systems; integrated operational dashboards; passenger-facing information systems	Centralised coordination of operational units; real-time decision-making; business continuity and cyber-resilience arrangements	Greater reliability during disruptions; improved reassurance; dependence on the consistency and timeliness of digital communication
Post-journey feedback and quality management	ASQ surveys; complaint management systems; customer satisfaction monitoring; quality dashboards	Formal quality management systems; use of service metrics and benchmarking; continuous improvement routines	Organisational learning; improved service responsiveness; reinforcement of trust and perceived service quality

This analytical structure supports the case analysis presented in Section 4, where each journey phase is examined by linking visible passenger-facing technologies with the organisational arrangements that enable and govern them.

3.4 Validity and limitations

The use of official corporate and institutional documents provides high consistency in terms of strategic intent and organisational positioning, while inevitably reflecting the organisation's perspective. To address this limitation, the analysis adopts an interpretive stance, treating reported outcomes not as objective performance measures, but as indicators of how passenger experience, digitalisation and service quality are framed, monitored and governed.

References to internationally recognised benchmarking systems (e.g. ASQ, Skytrax) are analysed as governance devices shaping organisational sensemaking rather than as independent validation metrics. The validity of the analysis therefore rests on the coherence between the theoretical framework, the documentary evidence and the interpretation of the case, rather than on representativeness across multiple airports. Rome Fiumicino Airport, as a highly digitalised and award-winning hub, represents an extreme and revelatory case that renders orchestration dynamics especially observable.

4. Case study: Digital passenger experience at Rome Fiumicino

Rome Fiumicino Airport, managed by Aeroporti di Roma (ADR), represents a highly developed example of digital transformation in the European airport landscape. Its trajectory is consistent with broader developments observed in digitally advanced hubs, where digital and biometric solutions are increasingly used to support more seamless passenger journeys (Miyamoto, 2022). Over the last decade, ADR has progressively repositioned the airport from a traditional transport infrastructure into

a data-driven service platform, in which passenger experience, operational excellence and sustainability are treated as interdependent strategic objectives. Digitalisation is not framed as a set of isolated projects but as a core element of how the airport manages flows, interacts with passengers and coordinates its ecosystem of actors.

ADR's strategic roadmap explicitly links technological innovation to customer centricity, operational resilience and quality of service. Within this framework, the airport has invested in a portfolio of digital initiatives that span the entire passenger journey, from pre-arrival information and navigation to security, retail and post-journey feedback. These initiatives are embedded in a broader organisational architecture that includes integrated control centres, data analytics and formal quality management systems. The case can be analysed along four main phases of the passenger journey: pre-journey and access to information, in-terminal processes, disruption management, and post-journey feedback and learning.

4.1 Pre-journey and access to information

The first layer of digital passenger experience at Fiumicino concerns how passengers access information and orient themselves before and during their arrival at the airport. ADR has invested in digital interfaces that extend beyond traditional flight information displays and static signage. In 2024, the airport introduced digital information totems that allow passengers to access terminal maps and indoor navigation services through a web-based application (Aeroporti di Roma, 2024). These tools provide spatial guidance across arrival areas, terminal buildings and transport connections, including the railway station, enabling passengers to visualise routes and plan their movements in advance. This type of digital wayfinding reflects an organisational choice to treat spatial orientation as a key component of passenger experience. Rather than relying exclusively on physical signage and staff, ADR integrates digital mapping into its service architecture, allowing information to be updated dynamically and aligned with real-time conditions. For passengers, this reduces cognitive load and uncertainty, particularly in a large and complex hub such as Fiumicino, where distances, multiple terminals and changing gate assignments can easily generate stress.

In parallel, ADR has developed a WhatsApp-based chatbot that provides push notifications on flight status and answers to frequently asked questions (Aeroporti di Roma, 2024). This tool shifts part of the communication function from physical counters and call centres to an always-on digital channel that accompanies passengers throughout their journey. From an organisational perspective, this represents a move toward scalable, automated communication that can handle high volumes of enquiries while maintaining a personalised interface. For passengers, the availability of real-time, mobile-based information enhances perceived control and reduces dependence on physical points of contact, which are often crowded or difficult to locate. Together, these tools illustrate how ADR uses digitalisation to create an informational layer that envelops the passenger journey, transforming how travellers interact with the airport even before reaching the terminal.

4.2 In-terminal processes and flow management

Once passengers enter the terminal, digitalisation becomes more deeply intertwined with operational processes. Fiumicino has invested in technologies that generate continuous data on passenger movements, congestion and waiting times. A notable example is the testing of LiDAR (Light Detection and Ranging)-based sensor systems to monitor airport traffic and flows, producing real-time and historical data on occupancy, congestion and queue lengths in different areas of the terminal (Aeroporti di Roma, 2024).

These data streams enable a shift from static planning to dynamic, data-driven flow management, reflecting the generative properties of digital data streams highlighted in prior research (Pigni et al., 2016). Rather than relying solely on scheduled capacities or manual observations, the airport can detect emerging bottlenecks and adjust resources, opening additional security lanes or reallocating staff where needed. Although these systems operate largely in the background, their effects are

experienced by passengers through shorter and more predictable waiting times, smoother transitions between checkpoints and reduced crowding in high-pressure areas such as security screening.

Digitalisation also extends to security and screening processes. ADR has tested artificial intelligence-based solutions, such as APIDS (Automated Prohibited Items Detection System) algorithms for the automatic detection of prohibited items in carry-on baggage (Aeroporti di Roma, 2024). These systems aim to increase both efficiency and consistency in security checks, reducing the need for manual inspections and the associated delays and frustrations. From the passenger's perspective, the value of such technologies lies not only in speed but also in the perceived fairness and transparency of the process, as automated systems are expected to apply rules more uniformly. At the same time, the increasing reliance on automated and data-driven systems shifts part of the passenger experience from visible service encounters to largely opaque processes, potentially affecting perceptions of reassurance and control. Beyond security, digital technologies are used to enrich the commercial and experiential dimension of the terminal. ADR has experimented with immersive and digital retail solutions, including virtual stores that allow passengers to explore products through 3D representations and predictive models that optimise commercial offerings. These initiatives reflect a broader strategy of integrating retail into the digital ecosystem of the airport, blurring the boundary between physical and online shopping and enabling more personalised and data-driven engagement with passengers.

4.3 Disruption management and organisational orchestration

A distinctive feature of Fiumicino's digital strategy is the emphasis on organisational orchestration through integrated control and coordination mechanisms. At the core of this architecture lies the Airport Operation Center (APOC), which functions as a central hub for monitoring and managing airport operations. Through the APOC, ADR supervises key processes, coordinates different operational units and manages interruption and disruption events, such as delays, weather-related issues or security incidents (Aeroporti di Roma, 2024). The APOC is not merely a technical facility but a governance structure that connects digital data to managerial decision-making. By integrating information from sensors, airline systems, security agencies and passenger-facing platforms, the APOC enables the airport to respond more quickly and coherently to changing conditions. This is particularly important during irregular operations, when the quality of communication and coordination has a disproportionate impact on passenger experience. In this sense, orchestration at Fiumicino operates not as a purely technical capability, but as a managerial practice that connects digital infrastructures, organisational routines and passenger-facing communication.

Digitalisation also underpins business continuity and cyber resilience. ADR reports that its core operational and information systems are supported by certified business continuity management processes and cybersecurity governance designed to ensure the availability and rapid recovery of critical applications (Aeroporti di Roma, 2024). In an environment where digital touchpoints are deeply embedded in the passenger journey, system failures can quickly translate into confusion, delays and loss of trust. The investment in continuity and security therefore constitutes an essential, if often invisible, component of digital passenger experience.

4.4 Feedback, quality management and learning

The final layer of Fiumicino's digital passenger experience concerns how the airport measures, evaluates and learns from customer feedback. ADR operates a formal quality management system certified to international standards (e.g., ISO 9001 and ISO 10004), which covers complaint management, customer satisfaction measurement and continuous improvement processes. Passenger experience is monitored through established instruments such as the Airport Service Quality (ASQ) survey, which collects systematic feedback on multiple aspects of the journey (Aeroporti di Roma, 2024). These data are used not only for reporting but also for guiding managerial action and investment priorities. In this sense, digitalisation supports a feedback loop in which passenger perceptions are translated into organisational learning. The airport's repeated recognition in

international programmes, such as Skytrax and ACI awards for ease of journey, security processing and digital transformation, reflects how these measurement systems are integrated into the strategic narrative and governance of the organisation.

Importantly, these awards function as external validation of the airport's digital and service strategies. While they do not provide direct causal evidence of performance, they signal that Fiumicino's approach to integrating digital technologies, operations and service design is recognised by industry bodies and benchmarking institutions. This reinforces the legitimacy of digitalisation as a core component of passenger experience management.

5. Discussion

This study examined how digital touchpoints and organisational choices interact to shape passenger experience in a smart airport, using Rome Fiumicino as an in-depth case. The findings provide empirical grounding for the patterns identified in recent integrative reviews of smart airports and digital aviation services, which emphasise that digital passenger experience emerges from the interplay between technology, organisation and user acceptance rather than from isolated digital tools.

While the case of Rome Fiumicino reflects a highly mature and award-winning approach to airport digitalisation, the findings also reveal a set of structural trade-offs inherent in the orchestration of digital passenger experience. First, increasing automation and self-service efficiency may reduce opportunities for human reassurance, particularly for passengers facing uncertainty, disruption, or low digital literacy. Second, the integration of real-time data flows and predictive systems enhances operational control and passenger flow management, but simultaneously raises issues related to perceived fairness, privacy, and transparency in how information is generated and communicated (Constantinides et al., 2018). Third, the expansion of omnichannel digital touchpoints improves informational continuity across the journey, yet it also risks cognitive overload and fragmented attention if not carefully coordinated. These structural trade-offs indicate that digital passenger experience in smart airports is not a direct outcome of technological intensity, but a contingent result of how orchestration actively balances efficiency, trust, inclusion and sense-making across interconnected service encounters.

5.1 From fragmented technologies to orchestrated digital journeys

A recurring theme in the literature on smart airports is the shift from discrete technological applications to integrated digital service systems. While many studies focus on individual solutions such as biometric boarding, self-service kiosks or mobile apps, they often underestimate the organisational work required to make these technologies meaningful from the passenger's perspective. The Fiumicino case illustrates this point clearly: digital touchpoints such as real-time information, wayfinding and automated security only contribute to a smoother experience when they are connected to data-driven coordination and decision-making structures.

This finding is consistent with research on airport digital transformation, which suggests that airports are evolving into data-centric service ecosystems in which value is generated through the orchestration of multiple technological and organisational components (Halpern et al., 2021; Dini et al., 2023). At Fiumicino, the integration of sensors, analytics and control rooms enables the airport to sense conditions and adapt operations in real time, aligning front-end passenger interactions with back-end resource allocation. This alignment is critical for transforming digitalisation from a collection of tools into a coherent passenger journey.

5.2 Reinterpreting technology acceptance in high-stakes service environments

The case also refines how the Technology Acceptance Model applies to airports. In much of the IS literature, perceived usefulness and ease of use are treated as attributes of specific interfaces. However, in the airport context these perceptions are shaped by the reliability and coordination of the

entire service system. For example, a mobile app is only perceived as useful if the underlying data are accurate and if organisational processes ensure that information is acted upon. Similarly, automated security systems are only experienced as easy to use when they are supported by clear procedures and staff intervention when needed. This suggests that in smart airports, technology acceptance is systemic rather than local. Passengers do not evaluate a single device in isolation but form expectations about the digital environment as a whole. Trust in one digital touchpoint depends on experiences with others, as well as on the airport's ability to handle disruptions and explain automated decisions. This extends TAM by embedding acceptance in organisational and governance contexts. In this sense, perceived usefulness and ease of use emerge not as properties of individual interfaces, but as systemic outcomes of socio-technical orchestration across the airport service system.

5.3 Digitalisation as a driver of co-creation and co-destruction

From a Service-Dominant Logic perspective, Fiumicino's digital infrastructure enables new forms of value co-creation by allowing passengers to access information, self-manage parts of the journey and interact with the airport through multiple channels. At the same time, the case reveals the potential for co-destruction when digital systems are perceived as opaque, unreliable or exclusionary.

Consistent with value co-destruction research, the same digital resources that enable value co-creation can also generate negative value when actors' practices, expectations, and institutional constraints are misaligned, for instance through perceived unfairness, exclusion, or heightened anxiety during disruptions (Plé & Cáceres, 2010; Echeverri & Skålén, 2011).

The airport's investment in feedback systems, quality management and international benchmarking can be interpreted as mechanisms to stabilise this co-creation process. By continuously monitoring passenger perceptions and aligning digital initiatives with recognised standards of service quality, ADR seeks to maintain a balance between automation and human-centred service. This highlights that digitalisation does not replace service management but makes it more complex, requiring ongoing calibration between technological possibilities and user expectations.

5.4 Digital governance and the politics of passenger experience

An important, and often underexplored, dimension of digital passenger experience concerns governance. The Fiumicino case shows that platforms such as the Airport Operation Center and integrated data systems concentrate significant power over how flows are managed, how information is prioritised and how disruptions are handled. These governance choices have direct experiential consequences for passengers, influencing who receives information, how quickly problems are resolved and how transparently decisions are communicated. This insight connects airport digitalisation to broader debates on platform governance and data-driven infrastructures. Even when technologies are deployed in the name of efficiency and customer centricity, they embed particular logics of control and prioritisation. Understanding digital passenger experience therefore requires attention not only to interfaces and outcomes but also to the organisational and institutional arrangements that shape how digital systems operate.

5.5 Implications for research on smart airports and digital services

By examining airport digital transformation through the case of Rome Fiumicino, this study connects conceptual discussions on smart airports with the organisational practices through which digital passenger experience is designed and governed. It shows that the transformation toward smart airports is best understood as a process of socio-technical orchestration, in which digital touchpoints, data infrastructures and governance mechanisms jointly shape passenger experience. Future research could build on these findings by comparing different airport governance models, regulatory regimes or levels of digital maturity, as well as by integrating passenger-level data with organisational analysis. Such work would further illuminate how digitalisation reshapes not only operational efficiency but also the lived, emotionally charged experience of air travel.

Building on the case evidence, this study formulates three propositions:

P1. Digital passenger experience improves when touchpoints are designed and governed as a coherent journey supported by integrated data infrastructures.

P2. Orchestration capabilities (cross-functional coordination, real-time control rooms, and shared metrics) mitigate journey fragmentation during disruptions.

P3. Perceived transparency and fairness of automated decisions moderate technology acceptance and the balance between value co-creation and co-destruction.

6. Managerial implications

The findings of this study provide several managerial implications for airport managers and policymakers engaged in digital transformation initiatives.

First, digitalisation should be approached as a service system design challenge, not merely as a technological one. The Fiumicino case shows that passengers value digital tools when they increase perceived control, reduce uncertainty and simplify decision-making. Investments in apps, sensors or AI therefore need to be evaluated not only in terms of technical performance, but also in terms of how they contribute to a coherent and intelligible passenger journey.

Second, the orchestration of digital touchpoints requires strong organisational capabilities. Real-time data on passenger flows, security and congestion are only useful if they are embedded in governance structures that enable rapid coordination and intervention. Platforms such as Airport Operation Centers play a critical role in connecting front-end experiences with back-end operations. Airport managers should accordingly invest in cross-functional coordination, data integration and decision rights that allow digital insights to be translated into concrete service improvements. From this perspective, orchestration emerges not merely as a technological coordination function, but as a core organisational capability encompassing governance, decision-making, and cross-functional integration.

Third, digital passenger experience raises critical issues related to the governance of trust, fairness and inclusion. While automation and AI can improve efficiency, they may also generate governance challenges related to privacy, transparency and the treatment of vulnerable passengers. The case suggests that formal quality management systems, business continuity planning and cybersecurity governance are not merely technical safeguards but essential components of a trustworthy digital service environment. Airports that fail to address these governance dimensions risk undermining passenger acceptance even when deploying advanced technologies.

Finally, digitalisation has implications beyond operations, affecting commercial and retail activities, mobility services and stakeholder relationships. By integrating retail, mobility and information services into a shared digital ecosystem, airports can create new opportunities for value co-creation but also concentrate control over data and access to passengers. Managers should pay particular attention to how digital platforms reconfigure power, control, and visibility across the airport ecosystem.

7. Conclusions

This paper examined how digital touchpoints and organisational choices are orchestrated to shape passenger experience in a smart airport, using Rome Fiumicino as an in-depth revelatory case. The analysis shows that digital passenger experience is not determined by technology alone, but by the way digital tools are configured within organisational structures, data infrastructures and quality management systems that govern the passenger journey.

By integrating the Technology Acceptance Model and Service-Dominant Logic, the study suggests that digitalisation enhances passenger experience when it increases perceived usefulness, ease of use

and trust, and when it supports effective value co-creation between passengers and the airport organisation. At the same time, the case highlights the trade-offs introduced by automation and platformisation, which require active governance to avoid new sources of friction, exclusion and mistrust.

The paper contributes to the literature on smart airports and digital services in three main ways. First, it advances smart airport research by framing digital passenger experience as an emergent outcome of organisational orchestration beyond the effect of isolated digital technologies. This shift redirects analytical attention from discrete touchpoints to the socio-technical coordination mechanisms through which digital journeys are stabilised and rendered meaningful. Second, by integrating the Technology Acceptance Model and Service-Dominant Logic, the paper extends technology acceptance research by demonstrating that perceived usefulness and perceived ease of use operate as systemic properties shaped by governance arrangements, data integration and operational reliability, rather than as attributes of individual technological interfaces. Third, through an in-depth revelatory case study of Rome Fiumicino Airport, the study provides an empirically grounded explanation of how digitalisation is strategically enacted within a complex service ecosystem, highlighting the structural trade-offs between efficiency, perceived control, trust and inclusion inherent in digitally mediated passenger journeys.

As with all qualitative single-case studies, the findings should be interpreted in light of the study's analytical scope. The research does not aim at statistical generalisation, but at developing analytically generalisable insights into the socio-technical mechanisms through which digitalisation reshapes airport passenger experience. The empirical material relies primarily on institutional and documentary sources, which are particularly suitable for examining managerial representations and governance logics, but do not capture passengers' or employees' direct perceptions. Future research could extend this work through comparative airport studies, interviews with airport managers and frontline employees, passenger surveys, or focus groups with different passenger segments.

Transforming consulting services in the era of agentic AI: Evidence from leading management consultants in Italy

RAFFAELLA MONTERA[1]

Abstract

Frame of the research. *The management consulting sector faces growing challenges from the rise of agentic AI, yet there is still limited scholarly understanding of how these firms strategically adapt to such technologies.*

Purpose of the paper. *This paper explores how consulting firms adjust their value propositions in the era of the agentic economy by examining the approaches underling agentic AI-based consulting services.*

Methodology. *This study employs a qualitative multiple case design based on 15 leading consulting firms operating in Italy, drawing on corporate websites and white papers through an inductive analysis.*

Results. *Three dominant approaches through which consulting firms frame agentic AI in their service offerings are identified: a techno-centric approach centred on infrastructural integration and automation; an institutional/legitimacy approach focused on accountability and governance; and a socio-technical approach emphasizing the co-evolution of technology and human capabilities.*

Research limitations. *The number of case studies analysed within a specific set of consulting firms operating in Italy constrain the generalizability of the findings. The reliance on secondary data may introduce interpretive biases.*

Managerial implications. *The identified approaches provide consulting firms with a lens to examine their service portfolios and strategic positioning, while offering client managers clearer criteria for selecting consultants for agentic AI initiatives.*

Originality of the paper. *The paper advances a multi-level theorization of technological adaptation in management consulting, advancing three propositions that elucidate how agentic AI reshapes industry structures, organizational value propositions, and actor-level roles.*

Keywords: *management consulting firms; agentic AI; digital transformation; service portfolio; case studies*

1. Introduction

The consulting sector has traditionally been viewed as a knowledge-intensive industry in which legitimacy and economic value stem from specialized expertise, analytical problem-solving capabilities, and close engagement with client organizations (Sturdy et al., 2009; Tavoletti et al., 2019). Over the past decade, consulting firms have assumed an increasingly prominent role in the context of digital transformation, as they increasingly support organizations in evaluating and aligning their information technology strategies with overarching business objectives (FEACO, 2023). Anyway, the rapid diffusion of digital transformation across industries has significantly reshaped the environment in which consulting firms operate (Ramos et al., 2025). Clients now expect more timely insights, data-driven and evidence-based recommendations, and solutions that integrate technological capabilities, rather than relying solely on conceptual frameworks or experience-based expertise. Simultaneously, the emergence of digital-native competitors, specialized niche consultancies, and platform-based advisory models intensifies competitive pressure on established firms by offering more scalable, efficient, and analytics-enabled alternatives. Together, these developments raise critical questions regarding how consulting firms can maintain competitive advantage, cope with growing strategic complexity, and realign their value creation approaches with rapidly changing market conditions (Andersson, 2025).

The widespread adoption of artificial intelligence (AI), and the emergence of agentic AI in particular, have introduced additional challenges for the consulting industry. Consulting firms are increasingly required to address the ethical, legal, and regulatory implications associated with the use of AI, investing in compliance mechanisms to mitigate legal risks and potential reputational damage

[1] Associate Professor in Business Management, Sapienza University of Roma, e-mail: raffaella.montera@uniroma1.it

(Samokhvalov, 2024). At the same time, they must develop the skills and expertise necessary to effectively design, implement, and integrate AI-based solutions, not only to avoid the displacement of human consultants but also to enhance the value delivered to clients (Pattanayak, 2022). These developments entail a transformation that extends beyond the content of consulting services to encompass the organizational structures, operating models, and strategic orientations of consulting firms themselves (Tiwari, 2025). AI is not only augmenting consultants' analytical capabilities but is also reshaping how consulting services are produced and delivered, thereby opening new avenues for innovation and growth. Management consulting firms are widely acknowledged as influential actors in the spread of managerial innovations across industries (Assoconsult, 2025). The function of management consulting firms as innovation intermediaries and knowledge brokers has been extensively examined in prior research (e.g., Anand et al., 2007).

However, scholarly understanding remains limited with respect to how consulting firms adapt and innovate their own approaches in response to ongoing waves of digital transformation, leaving significant gaps in explaining how these firms navigate such changes (Tavoletti et al., 2022). Much of the existing research has concentrated on manufacturing, platform-based industries, or large technology firms, while the management consulting has received relatively limited scholarly attention and empirical investigation (Mosonyi et al., 2020; Andersson, 2025), despite its substantial growth. Since 2015, consulting services associated with digital transformation - often described as technology-driven consulting - have represented the fastest-growing segment of the management consulting market in Europe (Tavoletti et al., 2022). In response, several authors have called for further research in the area of management consulting and digital transformation, urging increased empirical inquiry by management scholars (Cerruti et al., 2019). In particular, prior studies highlight the need for qualitative research approaches (Crișan and Marincean, 2023) and for deeper examination of management consulting companies' strategies and sources of competitive advantage (Canato and Giangreco, 2011).

The paper aims to explore the adjustment of value proposition of consulting firms in the era of the agentic economy. The following research question guided the study:
RQ: How do management consulting firms design consulting services based on agentic AI?

To address the research question, this study adopts a qualitative multiple case study design (Yin, 2003) based on 15 leading management consulting firms operating in Italy and selected from the "Consulenti dell'anno 2025" list published by Il Sole 24 Ore. Data, collected from corporate communication materials and white papers published on the firms' official websites, were analysed using an inductive methodology (Gioia et al., 2013).

This study identifies three predominant approaches through which consulting firms frame agentic AI in their service offerings. A techno-centric approach emphasizes the reinforcement of organizational capacity through the deployment and deep integration of autonomous agentic systems into core operational and technological infrastructures. An institutional/legitimacy approach focuses on accountability structures and formal monitoring mechanisms to ensure that agentic AI operates within ethical, legal, and organizational boundaries. Finally, a socio-technical approach highlights the co-evolution of advanced technologies and human capabilities, stressing the integration of agentic AI with organizational processes and workforce development.

This study offers three main theoretical contributions. First, it enriches the management consulting literature that has highlighted the limited empirical understanding of consulting firms' adaptation to technology-driven change. This study focuses on consulting firms, examining how they structure and legitimize agentic AI within their service portfolios. In doing so, it responds directly to calls for more empirical and qualitative research on consulting firms' strategies and sources of competitive advantage. Second, the study advances existing research by inductively identifying three distinct approaches to agentic AI offering in management consulting. Third, the study formulates three propositions that offer a multi-level explanation of how agentic AI reconfigures the consulting field. These propositions illuminate how the diffusion of agentic AI shapes competitive differentiation at the industry level, reinforces established value propositions at the organizational level, and transforms

consultants' roles at the actor level.

From a practical perspective, the identified approaches offer consulting firms a diagnostic lens to critically assess their service portfolios, enabling them to evaluate the orientation toward which their offerings gravitate, and to examine the coherence between strategic intent and service articulation. In addition, the findings support client managers in developing clearer selection criteria when engaging consulting firms for agentic AI initiatives, by making explicit the underlying approaches embedded in consulting offerings.

The paper is structured as follows. Section 2 outlines the theoretical framework, followed by a description of the research methodology in Section 3. Section 4 presents the findings of the empirical analysis, which are subsequently interpreted and discussed in Section 5. Finally, Section 6 highlights the main theoretical and managerial contributions of the study, acknowledges its limitations, and outlines avenues for future research.

2. Theoretical background

2.1 Management consulting firms

Management consultancy refers to the provision of independent, expert advice aimed at improving organizational performance and supporting change through the application of specialized knowledge, capabilities, and innovative solutions (Christensen et al., 2013; Bronnenmayer et al., 2016). Thus, consultants play a central role in shaping strategic choices and managing change by transferring knowledge across contexts, acting as credible external advisors, and supporting decision-making under conditions of uncertainty (O'Mahoney and Markham, 2013). The value generated by management consulting companies lies in their ability to influence and reshape client organizations while developing novel ideas to address complex business challenges (Canato and Giangreco, 2011). Beyond their advisory function, consultants contribute to the diffusion, legitimation, and institutionalization of management practices, often influencing the emergence of management fashions and providing external justification for organizational choices (Sturdy, 2011).

Management consulting includes encompasses multiple specialized domains (strategy, operations, IT, HR, and financial services), each addressing distinct organizational needs (Bode et al., 2022). Across these domains, firms increasingly combine advisory and implementation support, particularly in digital and operational transformation, creating hybrid models that combine analysis and execution (Kipping and Clark, 2012).

Consulting is inherently relational and collaborative. Effective consulting depends on the interaction between consultant expertise and client engagement and is shaped by contextual factors such as organizational culture, power relations, and uncertainty. As a result, consulting is often characterized as an 'insecure' practice that requires consultants to balance credibility, trust, and ethical collaboration to enable meaningful organizational change (Block, 2000). Moreover, the reliance on intangible and cognitive inputs makes consulting outcomes difficult to measure and evaluate in the short term. As a result, the immediate benefits of consulting engagements are often hard to trace, and consultants' contributions tend to be perceived as challenging to quantify and formally account for (Mattila and Tukiainen, 2019).

2.2 The evolution of AI: toward agentic AI

Influential definitions conceptualize AI as the study and design of intelligent agents and systems that perceive their environment and act to achieve specific goals (Norvig, 2016) by replicating aspects of human cognition (McCarthy, 2007). From a management perspective, AI is often understood in functional terms as systems that interpret data, learn from it, and adapt their behavior to accomplish objectives, thereby augmenting or substituting human cognitive capabilities and influencing work, decision-making, and value creation processes (Kaplan and Haenlein, 2019).

AI is currently undergoing a significant shift, moving from passive, task-specific applications

toward more autonomous systems capable of exhibiting forms of agency, making independent decisions, adapting to changing contexts, and proactively shaping outcomes (Abou Ali et al., 2026). Contemporary agentic AI systems are characterized by their ability to plan proactively, retain contextual information, use digital tools effectively, and adapt their behavior in response to feedback from the environment (Viswanathan et al., 2025). Rather than operating solely as problem-solving tools, these systems increasingly function as collaborative partners, able to perceive complex situations, reason about goals, and coordinate sequences of actions either independently or within multi-agent settings (Du et al., 2025).

This development can be understood as the outcome of a broader evolution of AI that has unfolded across several overlapping phases. The symbolic AI era (1950s–1980s) relied on logic-based rules and explicitly encoded knowledge (Liang, 2025). The machine learning era (1980s–2010s) shifted toward data-driven models that learned from data but still required significant human input (Nithya et al., 2023). The deep learning era (2010s–present) enabled automatic learning of complex representations, advancing fields such as image recognition and language processing (Dong et al., 2021). The generative AI era (2014–present) introduced models capable of producing original content using architectures like transformers and large language models (Surbakti, 2025). Most recently, the agentic AI era (2022–present) has focused on autonomous, goal-oriented systems, increasingly organized as collaborative multi-agent arrangements (Piccialli et al., 2025).

2.3 Management consulting firms and IA within the context of digital transformation

AI is fundamentally reshaping the ways in which industries operate, and the consulting sector is no exception (Lari and Manu, 2024). Despite the body of research on this topic is far from uniform, digital transformation is consistently described as an expanding and increasingly influential phenomenon within the consulting industry (Cerruti et al., 2019; Larsson et al., 2020). Moreover, the literature converges on the view that the emergence of digital business models has become unavoidable for consultants (Jerónimo et al., 2019; Mosonyi et al., 2020).

As a result, although consulting firms have historically relied on project-based, high-touch advisory models, recent studies document a shift toward hybrid configurations that combine traditional advisory services with digital, data-driven, and scalable solutions (Nissen, 2019). Tavoletti et al. (2022) show that leading consulting firms increasingly reconfigure their value propositions by integrating end-to-end digital transformation services, spanning strategy, technology implementation, and ongoing operational support. This evolution is often supported by investments in digital assets, analytics capabilities, and ecosystems of partners, reflecting a move toward platform-oriented and multi-actor configurations. Similarly, Andersson (2025) highlights how consulting firms adopt multi-layered business models to balance relational consulting with standardized, technology-enabled offerings, allowing them to cope with rising strategic complexity and competitive pressure.

Despite these developments, the literature consistently points to heterogeneity in the adoption and depth of digital transformation across consulting firms. Crișan and Marincean (2023) identify multiple mechanisms through which digital transformation manifests in management consulting. These include the platformization of traditional consulting services, the emergence of crowdsourcing-based advisory models in which consultants act as orchestrators of distributed expertise, and the digital reconfiguration of consultant–client matching processes. Importantly, these mechanisms differ in their transformative scope, suggesting that digital transformation in consulting unfolds incrementally and unevenly rather than through uniform, industry-wide shifts. In this regard, the paradoxical role of consulting firms as both agents and objects of digital transformation becomes evident. On the one hand, consulting firms are widely recognized as key actors in promoting and diffusing digital transformation practices across industries, often through the production of reports, frameworks, and best-practice narratives (Sturdy, 2011). On the other hand, empirical evidence suggests that consulting firms themselves have historically lagged behind their clients in adopting digital tools and practices internally, creating a tension between advisory discourse and organizational reality (Bode et al., 2021). Crișan and Stanca (2021) further show that the adoption of digital

transformation within consulting firms depends on specific combinations of internal and external triggers, including client acceptance of digital consulting practices, efficiency pressures, and prior digital experience. These findings underscore that digital transformation in consulting is contingent on contextual conditions and strategic choices.

Recent work has also examined how digital transformation reshapes the nature of consulting work and the consultant's role (Sayyadi et al., 2023; Goldman, 2024). While some authors warn that AI's analytical efficiency may lead to job displacement (Kaczorowska-Spychalska et al., 2024), others frame AI as an opportunity to redefine consulting roles and value propositions rather than replace human consultants (Oppioli et al., 2023). Consistent with this view, AI and automation are largely understood as augmenting, rather than substituting, human capabilities by taking over repetitive analytical tasks and allowing consultants to focus on strategic, creative, and judgment-intensive activities (Cemaloglu et al., 2019). Empirical evidence illustrates how this augmentation unfolds in practice. Dell'Acqua et al. (2023) identify emerging AI-enabled work modes - "Centaurs" and "Cyborgs" - both of which demonstrate significant productivity and quality gains when tasks fall within AI's capability frontier. However, their findings also highlight the risks of over-reliance on AI, as performance declines when consultants uncritically adopt AI outputs for tasks beyond its effective scope. Complementing these insights, prior research conceptualizes AI as an enabling 'exoskeleton' that enhances service professionals' performance, while emphasizing the continued importance of human oversight, critical judgment, and uniquely human skills such as empathy and creativity (Wirtz et al., 2018; Sack et al., 2024).

Thus, the literature on AI in consulting highlights both efficiency gains and new sources of complexity. Generative and analytical AI systems enable faster data processing, scenario analysis, and decision support, potentially enhancing the speed and scalability of consulting services (Pattanayak, 2020). However, scholars also emphasize ethical, legal, and reputational risks associated with AI adoption, including issues of bias, transparency, data privacy, and accountability (Gînguță et al., 2023). These concerns are especially pronounced in consulting, given its reliance on trust-based relationships and its role in legitimizing managerial decisions.

Importantly, existing studies on AI in consulting largely focus on AI as a set of tools that automate or augment specific tasks, such as analysis, reporting, or knowledge management. Much less attention has been paid to how AI reshapes consulting services at a systemic level, including how it is embedded within service portfolios, organizational structures, and value propositions. Crișan and Marincean (2023) note that while digital technologies increasingly permeate consulting practices, the literature remains fragmented and predominantly descriptive, with limited insight into how consulting firms strategically frame and institutionalize advanced AI-based services. In addition, while the broader management and information systems literature has begun to examine agentic forms of AI, particularly in relation to autonomous decision-making, human-AI interaction, and organizational design (e.g., Abou Ali et al., 2025; Gonzales et al., 2026), its implications for management consulting remain underexamined. Existing research has yet to provide a deep understanding of how consulting firms articulate agentic AI within their value creation logics, a gap that motivates the present study.

3. Method

3.1 Research design and case selection

A qualitative multiple case study analysis was conducted, as this approach is particularly suitable for investigating contemporary and complex real-life phenomena (Yin, 2003). Focusing on leading Italian consulting firms, this design enabled a comparative analysis of similarities and differences in how agentic AI-related services are framed and structured, thereby contributing to theory development through pattern recognition and cross-case comparison (Eisenhardt, 1989; Corbin and Strauss, 1990; Maxwell and Chmiel, 2014).

The case selection was based on the *Consulenti dell'anno 2025* list, published by *Il Sole 24 Ore* in

collaboration with Statista. This list constitutes an authoritative and fully citable secondary source, as it is derived from a large-scale survey based on recommendations from both consultants and clients, and is designed to identify the most relevant consulting firms operating in the Italian context. Focusing on Italy provides a suitable empirical setting, as it represents a mature European consulting market characterized by the presence of both global multinational firms and established domestic players (FEACO, 2023). Using this source allowed the study to start from a structured and widely recognized population of firms, thereby reducing the risk of arbitrary selection and enhancing the overall robustness of the research design. The list comprises 69 consulting firms, characterized by heterogeneous sizes and areas of specialization.

From this initial pool, a purposive sampling strategy was employed to narrow the sample to firms that were most closely aligned with the objectives of the study. Specifically, two inclusion criteria were applied. First, firms were required to operate in sectors of have a specialization in Data Analytics, Big Data, & Artificial Intelligence, and Information Technology, as identified through the corresponding filter available in the database hosting the list (https://lab24.ilsole24ore.com/consulenti/). This criterion was adopted to ensure the selection of firms more likely to be actively engaged in advanced AI-related services, including agentic AI. Second, firms had to offer either services explicitly described as agentic or services exhibiting the agentic characteristics identified in Section 2.2 (e.g., independent decision-making, autonomous coordination of actions, participation in multi-agent systems). This criterion was manually verified through an in-depth review of the firms' official websites. Applying these criteria resulted in 15 consulting firms (Tab. 1), which are sufficiently to ensure variation and cross-case comparability, while remaining manageable for in-depth qualitative analysis.

Tab. 1: The case studies

Consulting firms	Legal headquarters in Italy
Accenture	Milan

3.2 Data collection and analysis

In December 2025, secondary data collection was undertaken. The use of secondary sources offers key advantages, including time efficiency and access to a substantial volume of data that would otherwise be difficult to gather independently (Johnston, 2017). Data were collected from official corporate communication materials published on the firms' websites, including service descriptions, practice overviews, and AI-related sections. The analysis was further strengthened through triangulation with publicly available white papers, which are increasingly recognized as valuable empirical sources in management research (Zhang et al., 2021; Fernández et al., 2023). In the

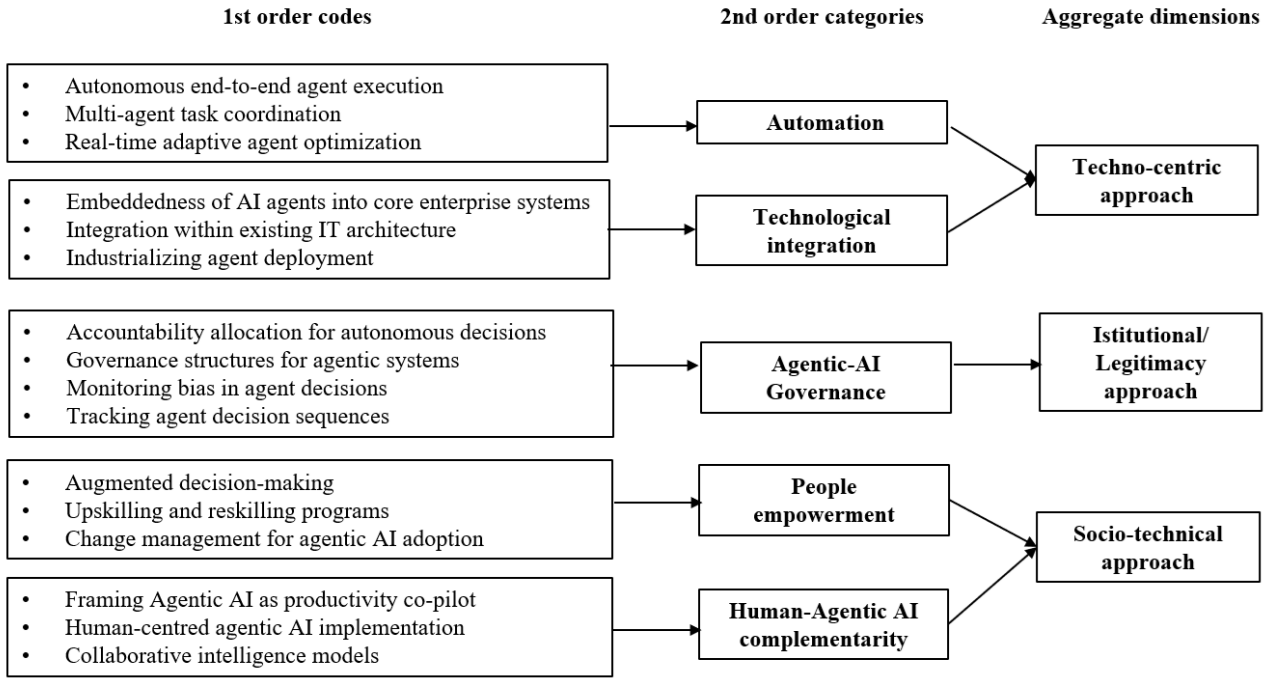
consulting industry, white papers serve as strategic documents through which firms address issues of interest to potential clients and position themselves as experts capable of understanding and solving emerging business challenges (Monod et al., 2024). In this study, white papers focused on digital transformation and/or AI were analyzed to complement the examination of corporate websites and to provide deeper insight into the approach to agentic AI.

A qualitative content analysis grounded in the Gioia methodology (Gioia et al., 2013) was adopted to analyse data. The analytical process unfolded through three main phases. First, we systematically performed an inductive, open coding of documents into first-order codes (Strauss and Corbin, 1990, p. 61). We coded a service as prominent when it was displayed in website headlines, primary landing pages, or opening paragraphs of service descriptions, indicating a higher level of strategic emphasis in the firm's official communication. This operationalization is consistent with research on corporate narrative disclosure and impression management, which highlights how the prominence and salience of themes in organizational communication reflect strategic positioning and attempts at legitimation (Vaara and Tienari, 2008; Merkl-Davies and Brennan, 2011). Second, we performed an abductive, axial coding of the identified first-order codes to group them into second-order categories (Strauss and Corbin, 1990, p. 96). Finally, first-order codes and second-order categories were integrated to derive aggregate dimensions, representing the highest level of abstraction in the analysis. These aggregate dimensions captured the core patterns emerging from the data and provided a basis for interpreting the approaches to agentic AI. To mitigate the influence of individual researcher bias and strengthened the reliability of the analytical process, a PhD student was involved in the data analysis activity (Gioia et al., 2013).

4. Results

Across the fifteen firms, agentic AI is embedded within broader service portfolios rather than presented as a standalone offering. For instance, Accenture describes agentic AI as "*accelerating our digital transformation programs*," positioning it within established transformation services. Similarly, Capgemini emphasizes "*embedding agentic AI into end-to-end intelligent industry solutions*" signaling integration into pre-existing sectoral offerings, while Deloitte refers to agentic AI as "*an extension of our advisory services into autonomous environments*".

The cross-case analysis of service portfolios revealed that firms strategically position agentic AI within their offerings through distinct emphases, leading to the identification of three overarching aggregate dimensions: Techno-centrism approach, Institutional/Legitimacy approach, and Socio-technical approach. Each aggregate dimension encompasses a conceptually coherent second-order themes, which synthesize a set of first-order codes grounded in firms' communicative framings and narratives (Fig. 1). These dimensions capture the predominant approaches to the agentic AI within consulting offerings, as described below.



4.1 Techno-centric approach

The aggregate dimension, predominantly evident across Accenture, NTT DATA, Capgemini, Reply, Cognizant, BIP and BearingPoint, denotes a techno-centric approach to the agentic AI based on the reinforcement of organizational capacity of the client organizations through the deployment and embedding of autonomous agentic systems within their core operational and technological structures. This dimension unfolds through the second-order themes: Automation and Technological integration.

The Automation logic reflects how firms articulate agentic AI as a logic of autonomous execution and coordination across interconnected processes. Across cases, leading consulting firms position agentic systems not as isolated decision-support tools, but as autonomous infrastructures capable of managing and recalibrating multi-step operational sequences. For instance, Accenture emphasizes end-to-end automation across business processes, highlighting "*the ability of agentic systems to*

connect data ingestion, decision-making, and execution within a unified operational chain". Similarly, Capgemini stresses the orchestration of complete workflows, positioning agentic AI as capable of "*handling extended operational cycles rather than discrete tasks*". In these cases, the focus shifts from single-task automation to process-level autonomy. A recurring element in firms' narratives concerns the coordination of multiple agents within distributed environments. Reply highlights "*architectures in which agents operate across different domains while continuously exchanging information*". Likewise, Cognizant underscores the orchestration of "*distributed autonomous components to reduce operational fragmentation and enhance cross-functional synchronization*". Thus, agency is not centralized but embedded within networks of interacting agents, enabling systemic coordination across complex workflows. Another prominent feature concerns real-time adaptability. NTT DATA emphasizes the capacity of agentic systems "*to dynamically adjust decisions based on real-time data inputs, reinforcing operational responsiveness*". Similarly, BearingPoint highlights adaptive optimization mechanisms that allow agents "*to recalibrate actions as contextual conditions evolve*". Across these firms, optimization is framed as continuous and context-sensitive, suggesting that agentic AI enhances the organization's ability to respond to environmental variability. Human involvement is acknowledged, but primarily in terms of supervision, configuration, and monitoring of technical deployment. As one description notes, agentic systems are implemented to "*augment delivery capacity through automated execution under defined human supervision*" (BIP), reinforcing the view of humans as overseers of a technologically driven process. This reinforces the interpretation that infrastructural empowerment is technologically grounded, with human involvement positioned as a stabilizing mechanism within a predominantly technology-driven process.

Fig. 1: Consulting approaches to agentic AI

Source: our elaboration

While Automation emphasizes what agents do, Technological integration focuses on how agentic systems are structurally embedded within enterprise environments. Across cases, firms frame agentic AI not as an external layer of functionality, but as a component incorporated into the digital backbone of client organizations, becoming part of the underlying architecture that sustains their operations. For instance, Accenture highlights "*the integration of agentic AI directly within ERP, CRM, and*

supply-chain management platforms"; similarly, NTT DATA emphasizes "*the deployment of agentic layers within enterprise platforms, underscoring their integration into data infrastructures and core transactional systems*". Firms also stress compatibility with existing IT architectures. Capgemini underscores "*the interoperability of agentic systems with legacy infrastructures and hybrid cloud environments*", emphasizing seamless integration rather than disruptive replacement. Likewise, BearingPoint highlights integration strategies that "*align agentic deployments with existing enterprise data layers, APIs, and cloud-native environments*". Thus, technological integration enables firms to preserve architectural continuity while simultaneously extending system capabilities. By ensuring interoperability with existing infrastructures, it reduces implementation friction and strengthens overall infrastructural coherence. A further recurring element relates to the industrialization of agent deployment, that implies repeatability, modularity, and architectural standardization. Such features transform agentic AI from experimental innovation into institutionalized operational practice within the organization. In this regard, Cognizant stresses "*scalable AI engineering frameworks designed to standardize and replicate agent capabilities across business units*"; Reply describes "*modular deployment models capable of being rolled out enterprise-wide across geographies and functional domains*"; and BIP highlight "*structured deployment pipelines that embed agents within defined architectural environments, ensuring alignment with IT standards*".

4.2 Institutional/legitimacy approach

The aggregate dimension, emerging prominently across Deloitte, KPMG, EY, and PwC, reflects an Institutional/legitimacy approach to agentic AI, grounded in the structuring of accountability and the establishment of formal monitoring procedures designed to ensure that autonomous agentic systems operate within client organizations in accordance with defined ethical, legal, and organizational boundaries. Ensuring legitimacy therefore requires explicit responsibility allocation, supervisory mechanisms, and continuous control structures capable of aligning agentic autonomy with regulatory expectations and organizational norms. This dimension unfolds through the second-order theme of Agentic-AI governance.

Accountability allocation for autonomous decisions emerges as a central concern across firms which emphasize the necessity of clearly defining responsibility chains. For instance, Deloitte underscores that "*organizations must establish explicit accountability frameworks clarifying who retains responsibility for AI-driven outcomes, even when decisions are autonomously executed*". Similarly, PwC highlights that "*AI governance must specify decision ownership, escalation pathways, and board-level oversight to ensure traceability and responsibility for autonomous actions*". These narratives indicate that autonomy does not displace human accountability but instead requires its formal reconfiguration within corporate governance structures. Closely related is the code Governance structures for agentic systems, which reflects the emphasis on institutionalizing oversight mechanisms. KPMG, for example, stresses the importance of "*embedding AI governance within existing risk and compliance architectures, ensuring alignment with regulatory expectations and internal control systems*". EY likewise notes that "*agentic AI deployment should be supported by dedicated oversight committees, standardized policies, and continuous compliance monitoring across the system lifecycle*". In this perspective, governance is not an add-on, but an organizational infrastructure that legitimizes the use of autonomous agents. The monitoring-oriented codes further reinforce this legitimacy logic. Under 'Monitoring bias in agent decisions' code, firms emphasize the need for systematic evaluation of algorithmic outputs to prevent discriminatory or unintended effects. Deloitte notes that "*continuous bias testing and fairness assessments are essential to maintain stakeholder trust in autonomous systems*". Likewise, EY highlights the necessity of "*ongoing validation mechanisms capable of detecting deviations from ethical and regulatory standards in real time*". Finally, 'Tracking agent decision sequences' code reflects the importance of traceability and auditability. PwC refers to "*end-to-end traceability frameworks that document decision pathways, enabling retrospective analysis and regulatory audit*". KPMG similarly emphasizes "*maintaining*

detailed logs of agent interactions and decision sequences to support explainability and post-hoc accountability".

4.3 Socio-technical approach

The aggregate dimension, largely characterizing BCG, McKinsey, Bain & Company, and Kearney, articulates a socio-technical approach to agentic AI that places the co-evolution of advanced technologies and human capabilities at its core. Within this approach, the effectiveness of agentic systems depends on their coherent integration with decision-making processes, workforce skills, organizational culture, and broader operating models. This dimension is structured around two second-order themes, named People empowerment and Human-Agentic AI complementarity.

People empowerment reflects a shared narrative in which agentic AI is framed as a lever for enhancing human capability. Through the code 'Augmented decision-making', agentic AI is presented as expanding managerial judgment and supporting complex, multi-step decision processes. McKinsey, for instance, emphasizes that "*the real power of advanced AI lies in augmenting human judgment, enabling faster and better-informed decisions across the enterprise*". Similarly, BCG highlights that "*agentic systems expand the cognitive capacity of teams, allowing leaders to focus on strategic priorities rather than operational complexity*". Bain underscores that such systems "*act as intelligent copilots, enhancing productivity while preserving human accountability*," while Kearney stresses the importance of "*keeping human oversight central when deploying autonomous AI capabilities*". The codes Upskilling and reskilling programs further reinforce this orientation. The four firms argue that the successful deployment of agentic AI depends on large-scale capability building and organizational adaptation. BCG notes that "*building agentic AI fluency at scale is essential to unlocking sustainable value from advanced technologies*". McKinsey stresses that "*capability building and role redesign are critical to scaling agentic AI successfully*" while Bain maintains that "*organizations must invest in structured reskilling programs to ensure their workforce can fully leverage agentic AI-enabled productivity gains*". Kearney similarly frames "*capability development as fundamental to preparing employees to collaborate effectively with agentic systems and to contribute to value creation*". The 'Change management for Agentic AI adoption' code captures the emphasis these firms place on treating agentic AI deployment as an organizational transformation challenge, encompassing leadership involvement, cultural adaptation, incentive realignment, and workflow redesign, ensuring that agentic AI becomes embedded in organizational routines and mindsets. For instance, BCG highlights that "*companies must go beyond tool deployment and govern, train, and redesign workflows in ways that foster adoption and employee trust*" pointing to the importance of coherent change planning. Kearney highlights that organizations must "*build their change muscle*" to continuously adapt organizational structures and cultures in response to AI-driven shifts, suggesting that agentic AI adoption is an ongoing transformation rather than a one-off project. The 'Human–Agentic AI complementarity' category reflects the collaborative interaction between autonomous agents and human actors within organizational processes. The code 'Framing agentic AI as a productivity co-pilot' captures the widespread metaphor of AI as an embedded assistant. McKinsey describes agentic AI as "a *digital copilot integrated into daily workflows, accelerating analysis and execution*". BCG refers to "*intelligent agents operating alongside professionals to enhance speed and precision*," while Bain emphasizes that "*agentic AI should free employees from repetitive tasks so they can focus on higher-value activities*". Kearney similarly argues that "*agentic AI works best when paired with human expertise in complex and judgment-intensive environments*". The code 'Human-centred agentic AI implementation' highlights the emphasis on user-oriented design and workflow integration. For instance, BCG states that "*successful agentic AI transformations begin with redesigning workflows around how people actually work*", while Bain connects effective implementation to "*embedding agentic AI into core processes in ways that are intuitive and practical for employees*". Finally, Collaborative intelligence models reflect the broader vision of hybrid intelligence systems. McKinsey observes that "*organizations combining advanced analytics with human insight consistently outperform their peers*"; BCG highlights "*hybrid*

intelligence models where human creativity and AI precision reinforce one another", and Bain emphasizes "*orchestrating collaboration between people and machines to capture the full value of agentic AI*".

4. Discussion

Our findings give rise to three theoretical propositions, contributing to theory building (Eisenhardt and Graebner, 2007; Hollebeek et al., 2024). They explain how the consulting industry is transforming across the industry, organizational, and actor levels in response to the rise of agentic AI.

The empirical results, showing a distribution of 7 firms aligning with techno-centric approach, 4 with institutional/legitimacy approach, and 4 with socio-technical approach, strongly support this non-convergent pattern. This near-balanced distribution across distinct approaches suggests that agentic AI has not yet solidified into a singular 'best practice' or a universally adopted institutional norm within the sector. Drawing on insights from organizational theory, technological innovations can either lead to isomorphic pressures, forcing organizations to adopt similar structures and practices for legitimacy (e.g., DiMaggio and Powell, 1983), or they can be assimilated in ways that reinforce existing strategic heterogeneity (Mosonyi et al., 2020). In the context of agentic AI, consulting firms are adapting the technology to fortify their unique competitive advantages, rather than conforming to a standardized model (Yang et al., 2024). Therefore, the following proposition is conceptualized:

P1: At industry level, the diffusion of agentic AI does not trigger institutional convergence across consulting firms. Instead, it preserves and strengthens differentiated service orientations - technological, governance-based, and human-centred - as firms strategically position themselves to address heterogeneous client expectations regarding innovation, risk, and organizational change.

The study demonstrates that the integration of agentic AI within management consulting is not leading to a wholesale redefinition of firms' competitive logics but rather serves to reinforce and deepen their established value propositions. In this logic, agentic AI allows consultants to strengthen their existing competitive advantages rather than embarking on a complete strategic overhaul (Costa Climent et al., 2024). This aligns with Rigby and First (2026), who argue that AI is among the forces pushing organizations into cycles of chronic transformation that promise revitalization but may ultimately erode organizational strength. More durable progress, they suggest, derives from sustained adaptation, such as the incremental evolution of consultants' service portfolios - rather than from continuous disruption. Drawing upon the results, the different roles of agentic AI within consulting firms' service portfolios reflect a strategic effort to differentiate services in a competitive market while building upon established strengths (Yang et al., 2024). Within the techno-centric approach, agentic AI acts as a technological tool to be implemented and embedded within digital infrastructure to orchestrate workflows, automate decisions, and scale enterprise-level integration. Academic research supports this view, highlighting how agentic AI can be packaged and integrated into general workflows to create sophisticated agentic networks, handling diverse tasks from email processing to human resource recruitment and customer support (Shen, 2025). These systems are shown to automate complex, repetitive tasks, freeing human resources for more strategic activities, increasing throughput, and improving decision quality through real-time, data-driven insights (Tallam, 2025). In the institutional/legitimacy approach, agentic AI is framed as an asset requiring structured governance and responsible deployment. The increasing autonomy of AI systems, particularly agentic AI, necessitates robust responsible AI frameworks (Ackerman, 2025). The introduction of agentic AI intensifies existing challenges to traditional oversight mechanisms, requiring new governance dimensions such as cross-departmental implementation, comprehensive evaluation, enhanced security protocols, operational visibility, and systematic auditing (Schmitz et al., 2025). Ethical concerns associated with AI in business consulting include potential job losses, lack of human interaction, discrimination, privacy invasion, denial of individual autonomy, and unjustifiable results (Gînguță et al., 2023). Therefore, human oversight remains a critical component, addressing the risk of over-reliance on AI and promoting decision-making autonomy (Fischer, 2024). Within the socio-

technical approach, agentic AI plays the role of 'decision partner' that augments the human capabilities in terms of data-informed managerial judgment, execution and strategic alignment. Literature acknowledges that AI can function as an organizational strategist, improving decision quality and coordination, especially in data-rich environments (Ruokonen and Ritala, 2024). Moreover, studies suggest that human-AI collaboration within agentic systems can lead to sustainable competitive advantages (Csaszar et al., 2024). Drawing on these considerations, the following proposition is proposed:

P2: At the organizational level, consulting firms incorporate agentic AI into their existing value propositions rather than redefining them. Agentic AI is variably framed as a technological tool, governed organizational asset, or a decision partner, depending on the firm's established strategic positioning.

According to the empirical evidence, the agentic AI fundamentally reconfigures the identity and responsibilities of consultants, moving them beyond their conventional advisory capacity into more specialized and integrated roles. This illuminates the evolving nature of professional expertise and the reconfiguration of consultant roles in an AI-driven context (Bereznoy, 2024). Instead of merely augmenting existing tasks, agentic AI integration leads to a qualitative shift in the consultant's function, creating distinct roles tailored to the approaches characterize consulting services built around agentic AI. Consultants aligned with the techno-centric approach evolve into orchestrators of complex technical systems. Their expertise lies in understanding AI architectures and coordinating implementation across client infrastructures (Besker et al., 2025; Adimulam et al., 2026). This requires merging deep technical knowledge with a detailed understanding of the specific environment in which the new technologies would be applied (Iansiti and Levien, 2004) since user-centric design principles and usability are critical for AI adoption (Kaplan et al., 2024). In the institutional/legitimacy approach, consultants assume the role of stewards of accountability and compliance. They design and formalize governance frameworks that define accountability structures and decision rights, while establishing oversight mechanisms - such as auditing protocols, performance monitoring systems, and risk assessment procedures - to address the challenges posed by algorithmic autonomy. In doing so, they translate legal standards and ethical principles into operational guidelines and enforceable internal controls. This specialized function is critical for navigating the ethical, legal, and operational complexities introduced by autonomous AI (Schmitz et al., 2025), as it enables the institutionalization of responsible AI practices and ensures compliant, transparent, and accountable deployment (Gînguță et al., 2023). Within the socio-technical approach, the consultant operates as a hybrid integrator, combining relational, interpretive, and sensemaking capabilities with the ability to effectively articulate and implement the possibilities of value co-creation between the client organization and agentic AI (Herrmann and Pfeiffer, 2023; Simón et al., 2024). Consultants work within AI-enabled decision architectures to facilitate innovative solutions and augment organizational performance (Jain, 2024). This involves guiding clients in unlocking new strategic options and fostering environments where human and AI capabilities synergize (Kiron and Schrage, 2019). Follows a further proposition:

P3: At the actor level, the integration of agentic AI expands consultants' roles beyond traditional advisory functions, shifting it toward technological orchestration, accountability and compliance stewardship, and hybrid integration.

5. Conclusion and implications

This study explores the adjustment of value proposition of consulting firms in the era of the agentic economy, focusing on how consulting services centred on agentic AI are designed for client organizations. In doing so, this paper offers interesting implications for both theory and practice.

Theoretically, three significant contributions advance the management consulting literature and the broader understanding of technological innovation within professional services. First, it addresses

a notable gap in scholarly understanding regarding how consulting firms, as influential actors in spreading managerial innovations, themselves adapt and innovate their own approaches in response to advanced technologies like agentic AI (Bezuidenhout et al., 2025; Pemer et al., 2024). By shifting the focus from consulting firms as mere facilitators of client transformations to examining their internal strategic responses, this research provides novel insights into how these firms structure and legitimize agentic AI within their own service portfolios. This directly responds to calls for more empirical and qualitative research on consulting firms' strategies and sources of competitive advantage in the digital era, particularly given the historical underexploration of the consulting sector's unique characteristics regarding technology adoption (Cerruti et al., 2019; Crișan and Marincean, 2023; Yang et al., 2024). Second, the study contributes by inductively identifying three distinct approaches – techno-centric, institutional/legitimacy, and socio-technical – through which agentic AI is articulated in consulting services. By conceptualizing these approaches, the paper moves beyond generic accounts of AI adoption and offers a structured understanding of how firms frame agentic AI. Third, this study advances a multi-level theorization of technological adaptation in management consulting firms. By articulating three interconnected propositions, the paper moves beyond descriptive accounts of a value proposition based on agentic AI and demonstrates how technological change simultaneously reconfigures industry structures, organizational value propositions, and actor-level roles. Focusing on the industry level (P1) enables a deeper understanding of how the broader competitive landscape is being reshaped, with significant implications for industry evolution and firms' strategic positioning (Tavoletti et al., 2022; Costa Climent et al., 2024). Indeed, the diffusion of agentic AI carries far-reaching consequences for economic systems and competitive dynamics (Rothschild et al., 2025). Analyzing the organizational level (P2) explains the diversity in offerings and competitive strategies seen among firms. Understanding organizational adaptation to technological discontinuities involves considering how firms make choices in a dynamic environment (Carter, 2020; Srikanth and Ungureanu, 2024). The actor level (P3) is vital for understanding the cultural impact of technological change (Bozkuş, 2023) in terms of concrete changes in skills, responsibilities, and day-to-day practices for the individuals within business (Bezuidenhout et al., 2025).

From a practical perspective, the findings offer immediate and actionable insights for both management consulting firms and their client organizations. For consulting firms, the identified approaches provide a valuable diagnostic lens to critically assess their current service portfolios. Firms can evaluate whether their offerings predominantly align with one of the identified approaches and critically examine the coherence between their strategic intent and how their services are articulated in the market. Understanding these approaches can guide strategic planning, enabling firms to consciously refine their positioning, invest in specific capabilities, and develop offerings that more precisely align with their chosen competitive logic in the agentic AI landscape (Mohan, 2024; Tronnier et al., 2025). Furthermore, the study's findings support client managers in making more informed decisions when choosing a consulting partner for agentic AI initiatives. This helps clients select firms whose strategic framing of agentic AI best matches their specific organizational needs, risk appetites, and desired outcomes for AI implementation. Effective collaboration between AI experts and clients is crucial for successful AI application planning and implementation (Kim et al., 2024).

Although this study provides novel insights into how management consulting firms are bringing agentic AI into organizations, some limitations should be acknowledged. First, the qualitative design of the study constrains the generalizability of the findings. First, the number of case studies analysed (15 firms) and the focus on a specific set of consulting firms operating in Italy limit the extent to which the results can be extended to the broader consulting industry or to different national contexts. Case studies, while providing rich and meaningful data, are often criticized for their findings not being generalizable to a larger population (Tsang, 2014). Given that the adoption and regulation of agentic AI may vary significantly across countries and markets, future research should examine a more diverse and internationally comparative set of cases to enhance external validity. Second, the

reliance on secondary data analysis, while offering efficiency benefits, can lead to researcher biases that distort the evidence base, especially concerning issues like data fitness, data quality, and the clarity of the original data collection procedures (Cheong et al., 2023). The absence of a direct relationship with the participants can place the secondary analyst at risk of making incorrect interpretations, as they are not privy to the primary researcher's insider experience (Clarke and Cossette, 2000). Future studies could benefit from incorporating additional primary data sources, such as interviews or surveys involving both consulting firms and client organizations, quantitative analyses of service portfolios, or longitudinal research designs, in order to further validate and extend the findings presented here and mitigate potential biases.

How Strategic Supply Chains Shape SMEs' Strategic Responses in the Post-Globalisation Era: An Exploratory Study

MARIAEMILIA GARBELLI

Abstract

Frame of the research. *Italy's manufacturing fabric, historically organised around industrial districts, is increasingly shifting toward more structured inter-firm arrangements here labelled Strategic Supply Chains (SSCs): governance-intensive evolutions of district-based coordination, where socio-territorial embeddedness is reconfigured through explicit governance mechanisms.*

Purpose of the paper. *The paper explores whether SMEs' participation in SSCs is associated with differentiated economic performance, strategic behaviour and adaptive capacity under heightened uncertainty.*

Methodology. *Exploratory comparative design on survey data from 52 manufacturing SMEs in Brescia (Italy), classified as SSC-embedded (N=38) or non-embedded (N=14) on three governance-based criteria. The analysis combines descriptive comparisons with Fisher's exact test and a Mann–Whitney U test on a Strategic Proactiveness Index (SPI); group dimensional comparability was verified.*

Results. *SSC-embedded SMEs report more favourable performance dynamics, more articulated market expectations and significantly higher strategic proactiveness (SPI: 2.34 vs. 0.93; p = 0.013). Sustainability practices appear largely aligned with SSC-imposed requirements (34% vs. 0% of non-embedded), while half of non-embedded firms report no planned adaptive action.*

Research limitations. *Small sample, single-territory focus and cross-sectional design limit generalisability. A residual confounder — higher internationalisation rates among embedded SMEs (82% vs. 36%) — cannot be statistically separated at the present sample size.*

Managerial and policy implications. *The critical lever appears to be the governance quality of SSC arrangements, not mere membership. Intermediate institutions can facilitate access to well-governed SSCs, thereby supporting SME capability-building.*

Originality. *The paper frames SSCs as a structured evolution of the Italian industrial district tradition; four meso-level mechanisms are proposed (governance signalling, capability upgrading, expectation coordination, territory-to-global bridging) connecting SSC participation to SME adaptive capacity.*

Keywords: *Strategic Supply Chains; Industrial Districts; SMEs; territorial embeddedness; manufacturing resilience; post-globalisation.*

1. Introduction

The contemporary economic environment is marked by persistent instability driven by geopolitical tensions, fragmented markets, and a significant reconfiguration of international economic relations (Gereffi, 2020; Kano et al., 2022). The globalisation paradigm is steadily fading, while regionalisation, nearshoring and friend-shoring are reshaping competitive dynamics for firms operating in open economies (Ivanov & Dolgui, 2020). Within this context, European and particularly Italian manufacturing systems face the urgent challenge of redefining sustainable pathways for industrial development, in ways that build upon their distinctive organisational heritage rather than simply replicate cost-driven global sourcing logics.

Italy holds a particularly relevant position in this debate. Its productive system has been historically organised around industrial districts: geographically localised clusters of SMEs combining productive specialisation, inter-firm cooperation and a dense embeddedness in the social and institutional fabric of territories (Becattini, 1990; Becattini et al., 2009; Dei Ottati, 2018). Recent data from ISTAT (2024) shows that structured inter-firm arrangements in Italian manufacturing are associated with measurable differences in value added, labour productivity and internationalisation intensity. Yet the district paradigm has undergone significant transformation over the past two decades (Bellandi & Caloffi, 2014; De Marchi & Grandinetti, 2014). Technological change, the internationalisation of lead firms and the post-pandemic reshoring wave have pushed traditional district configurations toward more structured, governance-based inter-firm arrangements that in this

paper we label as Strategic Supply Chains (SSCs).

Despite a growing scholarly attention to SSC resilience (Christopher & Peck, 2004; Wieland & Wallenburg, 2013) and inter-firm embeddedness (Granovetter, 1985; Uzzi, 1997), empirical evidence on how SME participation in SSCs operates under post-globalisation conditions is still limited. Most studies focus on large lead firms or orchestrators, treating SME benefits as spillover effects (Hortovanyi & Szepesi, 2026; Bak et al., 2020). The specific conditions under which SMEs effectively leverage SSC participation, especially within territorial systems with a strong district heritage, remain underexplored. The gap is particularly relevant for industrial systems where collaborative arrangements simultaneously represent opportunities and constraints: participation is typically associated with reduced uncertainty and greater access to markets, knowledge and standards, but it can co-exist with power asymmetries, dependency risks and reduced strategic autonomy (Poppo et al., 2008; Uzzi, 1997).

Against this background, this study focuses on the role of SSCs in shaping SME economic performance, strategic orientation and adaptive responses under conditions of market instability, through an exploratory empirical analysis. Focusing on a highly specialised Italian industrial region, the province of Brescia, the analysis compares two groups of SMEs operating within the same territorial and sectoral context: firms actively participating in one or more structured SSCs (SSC-embedded) and firms operating outside such arrangements (non-embedded). Through this comparative lens, the study examines whether and how SSC embeddedness is associated with different performance dynamics, investment behaviours, innovation and sustainability attitudes, market expectations, and strategic adaptation orientations.

Three research questions guide the analysis:

RQ1: *Are SSC-embedded SMEs associated with different economic performance dynamics and market expectations compared to non-embedded SMEs operating in the same territorial and sectoral context under conditions of high uncertainty?*

RQ2: *Is SSC embeddedness associated with different innovation-related and sustainability-related practices among manufacturing SMEs?*

RQ3: *Is SSC participation associated with different strategic orientations – proactive versus defensive – among SMEs in a specialised manufacturing territory?*

Given the exploratory nature of this study, the research questions are formulated in associative rather than causal terms. The analysis aims to identify systematic patterns of co-variation between SSC participation and the dimensions of interest, rather than to test directed causal relationships.

The paper contributes to the literature in several ways. First, it proposes and operationalises a definition of SSC as an evolution of the Italian industrial district tradition, providing conceptual clarity on a construct that has often been used ambiguously in the management literature. Second, it sets out a four-channel meso-level architecture – governance signalling, compliance-driven capability upgrading, expectation coordination through lead-firm focal points, and territory-to-global institutional bridging – through which SSC participation and SME adaptive capacity appear to evolve alongside in a territory with a strong district heritage. Also, it offers SME-focused empirical evidence on SSC embeddedness in such a territory, addressing the persistent imbalance in favour of lead-firm perspectives. Finally, it draws policy-relevant implications regarding the role of intermediate institutions (industry associations, chambers of commerce, regional development agencies) in shaping well-governed SSCs that support SME adaptation.

The remainder of the paper is organised in different sections. Section 2 develops the theoretical background, defining SSCs and locating them at the intersection of district tradition, SSC resilience and embeddedness theory. Section 3 describes the empirical context, sample, measures and analytical strategy. Section 4 presents the findings. Section 5 discusses the results in light of the theoretical background, before the paper closes with implications, limitations and avenues for future research.

2. Theoretical Background

2.1 Post-globalisation, environmental turbulence and supply chain reconfiguration

The contemporary economy is increasingly described as a post-globalisation regime, in which globally integrated markets have weakened and international economic relations are being re-organised along regional, political and strategic lines (Gereffi, 2020; Kano et al., 2022). Trade fragmentation, geopolitical tensions, reshoring and friend-shoring strategies, and recurrent systemic shocks have produced a structural transformation of the competitive environment, replacing the assumptions of stability and efficiency that characterised the previous paradigm with a condition of persistent uncertainty and discontinuity.

Environmental turbulence (the degree of instability, unpredictability and interconnectedness of a firm's external environment, in the classical formulation of Emery & Trist, 1965) has therefore become a structural feature rather than a cyclical condition. The consequences are particularly significant for SMEs, which typically operate with limited resource buffers, constrained financial slack and less formalised strategic planning processes (Lengnick-Hall & Beck, 2003; Battisti & Deakins, 2017). Under such conditions, traditional sources of competitive advantage lose effectiveness, and firms increasingly need to mobilise dynamic capabilities – sensing, seizing, reconfiguring – to absorb shocks and adapt their business models (Teece, 2007; Hortovanyi & Szepesi, 2026).

Environmental turbulence also reshapes SSC themselves, increasing the need for flexibility, modular configurations, diversified sourcing and rapid reconfiguration of inter-firm relationships (Datta, 2017; Ivanov & Dolgui, 2020). SSC resilience, understood as the capacity to anticipate, absorb, adapt to and recover from disruptive events while maintaining continuity of operations (Christopher & Peck, 2004; Ponomarov & Holcomb, 2009), increasingly depends not only on firm-level capabilities but also on network-level coordination mechanisms such as joint risk assessment, shared information systems, flexible contractual arrangements and collaborative governance structures (Scholten et al., 2014; Wieland & Wallenburg, 2013). Scholarship has progressively moved from viewing resilience as redundancy and robustness toward a more dynamic perspective that emphasises learning, collaboration and reconfiguration of inter-organisational ties (Pettit et al., 2010). As recent reviews note, however, empirical evidence on how these dynamics operate at the SME level – particularly for firms embedded in regional manufacturing systems – remains relatively limited (Bak et al., 2020).

2.2 The Italian industrial district tradition and its post-globalisation evolution

Any analysis of inter-firm arrangements in Italian manufacturing cannot leave aside the industrial district tradition. Building on Alfred Marshall's insights, Becattini (1990) redefined the industrial district as "a socio-territorial entity characterised by the active presence of both a community of people and a population of firms in one naturally and historically bounded area". Unlike a mere geographical concentration of firms, the Italian industrial district is a socio-economic construct in which productive specialisation, division of labour among SMEs, inter-firm cooperation and community-level institutions reinforce one another (Becattini et al., 2009; Dei Ottati, 2018; Sforzi, 2015). Industrial districts have historically characterised – and in many sectors continue to characterise – the competitive advantage of Italian manufacturing, particularly in the so-called "Made in Italy" industries (fashion, furniture, food, machinery, mechanical components).

The district paradigm has nevertheless undergone substantial transformation over the past two decades. Global competition, technological change, the internationalisation of leading district firms and successive crises have eroded some of the traditional foundations of the district, notably the density of local linkages and the symmetry of inter-firm relationships (Bellandi & Caloffi, 2014; De Marchi & Grandinetti, 2014). At the same time, new forms of inter-firm coordination have emerged: medium-sized district leaders increasingly structure relationships with their supplier base through explicit governance mechanisms (quality standards, certifications, information-sharing protocols),

and the boundaries of the district have become more porous, with relevant suppliers located outside the traditional territorial perimeter. As a consequence, the organisational geometry of Italian manufacturing has shifted from the classical district model – based on proximity, community and reciprocity – toward hybrid configurations in which stable, governance-rich supply relationships play an increasingly central role (Rullani, 2009).

These hybrid configurations are what we refer to as SSC in this work. In our reading, SSCs are not simply a foreign import from international supply chain management: they can also be read as an adapted and evolved version of the Italian district tradition, in which the socio-territorial embeddedness that historically characterised districts is progressively reconfigured through explicit inter-firm governance mechanisms. This framing – Italian-rooted but theoretically compatible with the international scholarship on supply chain resilience – offers a useful analytical lens for studying SME adaptation in specialised manufacturing regions.

2.3 Defining Strategic Supply Chains

The notion of "Strategic Supply Chain" (SSC) is used in the management and operations literature with considerable terminological heterogeneity, which this section aims to clarify. Three points deserve explicit attention.

First, the present paper uses the acronym SSC to refer to Strategic Supply Chains, not to Sustainable Supply Chains, for which SSC is also a common acronym. The choice reflects the theoretical focus of the study on governance and strategic orientation, rather than on environmental or social sustainability per se (although sustainability practices are among the empirical dimensions examined).

Second, SSCs as used here must be distinguished from three adjacent constructs: generic supply chains, defined by operational coordination without stable strategic alignment; Global Value Chains (GVCs), defined by cross-border governance of dispersed value-adding activities typically orchestrated by lead firms (Gereffi et al., 2005); and industrial districts in the strict Becattini sense, defined by territorial proximity and community-level embeddedness without necessarily implying explicit inter-firm governance.

Third, building on Hult et al. (2007) and on the relational view tradition (Dyer & Singh, 1998; Dyer et al., 2018), in this paper SSCs are defined as:

> *structured, multi-firm production arrangements characterised by recurrent and stabilised exchange relationships between a lead firm and one or more tiers of suppliers; by shared strategic objectives that go beyond a purely transactional logic; and by explicit governance mechanisms – quality standards, certifications, information-sharing protocols, joint planning routines – that regulate inter-firm coordination and capability development.*

This operational definition serves three purposes. It allows a clear empirical classification of firms as SSC-embedded or non-embedded (see Section 3.3); it connects the construct to the dominant theoretical traditions (supply chain resilience, relational view, embeddedness); and it makes explicit the continuity-discontinuity relationship between SSCs and the Italian industrial district tradition discussed above.

2.4 The Relational View and embeddedness in inter-firm networks

The theoretical foundations for understanding how SSC participation may affect SME behaviour are found in two complementary perspectives: the relational view and embeddedness theory. The relational view (Dyer & Singh, 1998; Dyer et al., 2018) argues that competitive advantage may reside not only in firm-specific resources but also in the routines, processes and governance mechanisms that connect firms. Relation-specific assets, knowledge-sharing routines, complementary resources and effective inter-firm governance can generate relational rents that individual firms could not achieve independently. Subsequent work has highlighted the role of collaboration and joint problem-solving in fostering innovation, efficiency and adaptability (Lavie, 2006; Poppo et al., 2008).

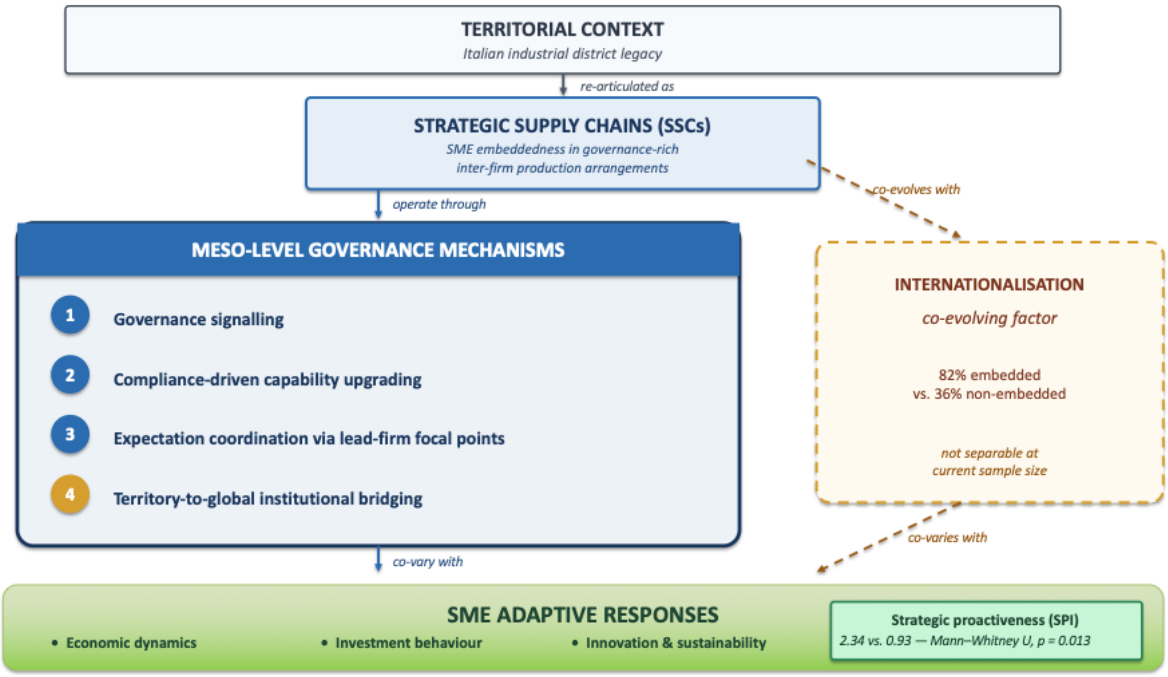
The application of the relational view to SMEs raises, however, a conditional question: under what circumstances do smaller firms actually appropriate relational rents? While SMEs may benefit from

access to shared resources, stable demand and technological spillovers through SSC participation, they can also face dependency risks and limited bargaining power vis-à-vis larger partners (Poppo et al., 2008). Empirical evidence on this question remains mixed, pointing to a contingency on industry structure, governance arrangements and strategic orientation.

Embeddedness theory (Granovetter, 1985; Uzzi, 1996, 1997; Gulati, 1998) provides the complementary perspective. In this view, economic action is shaped by social, relational and institutional contexts rather than being purely transactional. Management scholarship distinguishes between structural embeddedness (a firm's position within a network) and relational embeddedness (the quality and strength of inter-firm ties), both of which can enhance information access, reduce uncertainty and support learning and innovation (Gulati et al., 2009). For manufacturing SMEs, embeddedness can compensate for resource constraints by providing market access, knowledge and legitimacy (Häkansson & Snehota, 1995); excessive embeddedness, however, risks lock-in effects and over-reliance on dominant partners (Uzzi, 1997; Bak et al., 2020).

The three theoretical perspectives together – supply chain resilience, the relational view and embeddedness – offer complementary analytical lenses. SSC resilience illuminates the network-level adaptive mechanisms; the relational view explains how inter-firm arrangements generate firm-level value; embeddedness theory extends the analysis to the socio-territorial and institutional dimensions that shape SME behaviour. When considered in conjunction with the Italian district tradition, these perspectives converge on a proposition: in specialised manufacturing regions, SSC participation may operate as a territorial mechanism through which the adaptive advantages historically associated with district-based embeddedness are reconfigured under post-globalisation conditions. Table 1 summarises the constructs and their role in the empirical analysis.

Table 1. Conceptual architecture: from Italian industrial districts to SSCs



Construct	**Core idea**	**Mechanism of action on SMEs**	**Empirical dimension (RQ)**
Italian Industrial District (Becattini, 1990; Dei Ottati, 2018)	Socio-territorial entity combining community and firm population in a bounded area	Diffuse reciprocity, tacit knowledge circulation, shared identity	Context framing (not tested directly)
Strategic Supply Chain (this paper; Hult et al., 2007)	Structured multi-firm production arrangement with explicit governance	Standards, information-sharing routines, capability-building pressures	All RQs – core classification variable
Supply Chain Resilience (Christopher & Peck, 2004; Pettit et al., 2010)	Network-level capacity to absorb, adapt to and recover from shocks	Coordination, joint risk management, flexible governance	Economic performance, expectations (RQ1)
Relational View (Dyer & Singh, 1998; Dyer et al., 2018)	Competitive advantage from relation-specific routines and assets	Relational rents; knowledge-sharing routines; governance mechanisms	Strategic adaptation, investment, innovation (RQ2, RQ3)
Embeddedness (Granovetter, 1985; Uzzi, 1997)	Economic action shaped by social and relational context	Trust, reputation, institutional diffusion of norms and standards	Sustainability, innovation, expectations (RQ2)

Source: Authors' elaboration.

Figure 1 synthesises the conceptual architecture of the study, framing Strategic Supply Chains as a meso-level configuration through which territorial embeddedness is reshaped into governance-based mechanisms that occur along with SME adaptive responses. The figure shows SSC participation linked to adaptive responses: a central pathway operating through the four governance

mechanisms (articulated in Section 5.2), and a dynamic interaction lateral pathway through internationalisation, the material residual confounder discussed in Section 3.5, here re-located within the theoretical architecture rather than outside it.

Figure 1. SSC as a meso-level configuration for SME adaptive capacity

Source: Authors' elaboration. Arrows denote association / co-variation, not directed causal effects.

3. Research design and methodology

3.1 Research design

Given the limited empirical observation on SSC participation for SMEs in turbulent contexts, the study adopts an exploratory, comparative and context-based research design. The approach does not test directed causal relationships; it examines whether and how SSC embeddedness is systematically associated with differentiated patterns in economic performance, innovation and sustainability practices, and strategic orientation, holding territorial and sectoral context as constant as possible. The comparative logic, namely the comparison of embedded and non-embedded firms operating in the same territory and, predominantly, the same macro-sector, is consistent with prior research that treats inter-firm configurations as enabling or constraining conditions for firm behaviour (Uzzi, 1997; Scholten et al., 2014; Bak et al., 2020). The research questions are formulated in associative rather than causal terms, and inferential statistics are used to support descriptive patterns rather than to establish directional effects.

3.2 Empirical context: the Brescia manufacturing system

The empirical setting is the province of Brescia (Lombardy, Italy), one of the most industrially dense and export-oriented manufacturing regions in Italy. According to the Brescia Chamber of Commerce (2023), local manufacturing firms account for 3.6% of total Italian exports – ranking fourth among Italian provinces – and for 7.7% of Lombardy's total imports. In 2022, the aggregate export value of Brescian manufacturing reached €22.3 billion, with 97.3% attributable to the manufacturing sector. The local productive structure is dominated by SMEs operating in specialised industrial niches (metalworking, mechanical engineering, automotive components) and historically organised around dense inter-firm relationships that exhibit, in varying degrees, the features of the

industrial district model described in Section 2.2.

Brescia also displays a strong presence of structured supply arrangements centred on medium-sized lead firms that coordinate tiers of smaller suppliers through explicit governance mechanisms. Recent data from the local Chamber of Commerce survey (2023) documents that geopolitical tensions and post-pandemic disruptions have prompted a significant share of Brescian firms to reassess and partially reconfigure their supply relationships through nearshoring and reshoring strategies, increasing the strategic relevance of structured SSC arrangements at the local level. At the regional level, the Italian Permanent Business Census (ISTAT, 2024) confirms that Lombardy exhibits among the highest rates of declared filière participation in the Italian manufacturing sector, associated with measurable differences in value added, labour productivity and internationalisation intensity. These aggregate patterns provide a macroeconomic backdrop, aligned with the firm-level dynamics examined in this study.

It should be noted, however, that no publicly available micro-level database allows the systematic identification and classification of individual firms by their participation in structured SSC arrangements. Existing statistical sources capture filière participation through aggregate firm-level self-declaration at the territorial or macro-sectoral scale, without providing the firm-specific relational data needed to operationalise the embedded/non-embedded distinction (ISTAT, 2024). This data gap provides the rationale for the primary survey-based data collection adopted in this study.

3.3 Sample and classification criteria

Data were collected through a structured survey administered to SMEs affiliated with a local industrial association. The final sample comprises 52 manufacturing SMEs. Firms were classified as SSC-embedded or non-embedded on the basis of three explicit criteria derived from the operational definition in Section 2.3.

Firms were classified as SSC-embedded (N=38) when they simultaneously reported:

(i) recurrent and stabilised participation in one or more supply chains over at least the previous three years, with identifiable lead firms or buyers;

(ii) the presence of explicit governance elements in the relationship, operationalised as the requirement of formal standards, certifications, or quality/information-sharing protocols imposed by SSC partners;

(iii) strategic rather than merely transactional relevance of the relationship, self-reported by the respondent and cross-checked with the share of turnover generated by the main SSC(s).

Firms were classified as non-embedded (N=14) when none of the above three conditions held simultaneously: that is, when their supplier or customer relationships were predominantly market-based, lacked structured governance elements, and did not exhibit strategic continuity with identifiable partners. Borderline cases were evaluated through follow-up clarifications with respondents and conservatively assigned to the non-embedded group.

The sample distribution by dimensional characteristics is reported in Table 2. The group sizes are deliberately unbalanced, reflecting the structure of the affiliated population: in an industrially dense territory such as Brescia, the majority of SMEs operate within some form of structured SSC. This is itself a substantive finding about the territory, rather than a defect of the sampling frame. To mitigate the risk that observed differences between groups reflect pre-existing dimensional heterogeneity rather than SSC participation as such, non-parametric comparability checks were performed on employee size and annual turnover (see Section 3.5).

Table 2. Sample distribution by turnover and size

Category	**Sub-category**	**Embedded SMEs (N=38)**	**Non-embedded SMEs (N=14)**
Annual turnover	≤ 0.5 M€	5.3%	7.1%
	0.5–1 M€	2.6%	28.6%
	1–2 M€	10.5%	28.6%
	2–5 M€	34.2%	14.3%
	5–10 M€	34.2%	21.4%
	> 10 M€	2.6%	0.0%
Employees	1–5	7%	5%
	6–9	36%	3%
	10–15	36%	32%
	16–19	7%	22%
	20–49	14%	24%
	50–99	—	11%
	100 +	—	3%
Internationalisation	Share of firms exporting	82%	36%

Source: Authors' elaboration. Note: percentages for the non-embedded group are computed on firms providing complete responses for each item.

3.4 Measures and analytical approach

The survey was designed to combine objective economic indicators and subjective managerial assessments, as in prior research that emphasises the value of combining hard and soft data when analysing firm behaviour under uncertainty (Eisenhardt & Graebner, 2007; Gibbert et al. 2008).

Hard indicators captured firms' economic dynamics: trends in domestic and foreign orders, production levels, turnover, production costs, and investment dynamics during the reference period.

Soft indicators captured managerial perceptions, attitudes and intentions: innovation and R&D orientation, engagement with sustainability practices and documentation, short-term market expectations, and strategic adaptation intentions. Strategic intentions were operationalised through a multiple-response framework (non-mutually exclusive options), aligned with the compound nature of strategic decision-making under uncertainty.

To synthesise adaptive orientation, a Strategic Proactiveness Index (SPI) was constructed as a count of proactive, capability-enhancing actions reported by each firm out of nine predefined options (vertical integration; internal reorganisation or cost-efficiency measures; entry into new geographical markets; new product development or sector entry; introduction of new technologies or automation; partnerships, alliances or networks; sustainability and CSR investments; digitalisation and Industry 4.0; entry into new SSCs). Each action was coded 1 if selected and 0 otherwise; the index is the simple sum, with theoretical range 0–9. No weighting scheme was applied, as the index is intended to capture the breadth rather than the intensity of strategic responses.

Group differences were assessed using three complementary techniques. Descriptive comparisons (frequencies and cross-tabulations) highlight the distributional patterns by SSC participation. Fisher's exact test was applied to selected binary variables relevant to the research questions, given that small and unbalanced group sizes and low expected cell frequencies make this test more reliable than the chi-square test in this setting. The SPI, an ordinal/count variable, was compared between groups through the Mann–Whitney U test, appropriate for small samples and non-normal distributions. Statistical significance is interpreted, following the exploratory design, as indicative rather than

confirmatory: inferential results are used to support descriptive patterns, identify dimensions where group differences are most pronounced, and support – rather than substitute – theory-grounded interpretation.

3.5 Group comparability check and residual confounders

Because the two groups are unbalanced and may differ not only in SSC participation but also in structural characteristics, dimensional comparability was verified prior to interpreting the substantive comparisons. Non-parametric Mann–Whitney U tests were conducted on the two-dimensional variables available for both groups. Size (operationalised as the ordinal employee-count category) and annual turnover (operationalised as the ordinal revenue class) show no statistically significant differences between embedded and non-embedded firms (size: $U = 86$, $p = 0.799$; turnover: $U = 130$, $p = 0.421$), with identical median categories across groups. On these two key structural variables the two groups are broadly comparable along these dimensions, although perfect equivalence cannot be assumed.

The data also reveal one important residual non-comparability that must be acknowledged up-front. The two groups differ markedly on internationalisation: 82% of SSC-embedded firms export a non-negligible share of turnover, against only 36% of non-embedded firms (Table 2). The gap is substantive and cannot be controlled for at the current sample size, since the sub-sample of internationalised non-embedded firms (roughly five firms) is too small for stratified analysis. As a consequence, part of the differences observed in subsequent sections on performance dynamics, market expectations and strategic proactiveness could plausibly reflect the greater internationalisation of the embedded sub-sample rather than – or in addition to – SSC participation as such. Three considerations temper this caveat without eliminating it. First, internationalisation and SSC participation in the Brescia manufacturing system are not independent phenomena: they typically go together, and the theoretical framing of the study (SSC as a territorial bridge between district anchoring and extended markets, see Section 5) explicitly treats this co-occurrence as part of the mechanism, rather than as a nuisance to be netted out. Second, the most robust empirical finding of the study, namely the difference in the Strategic Proactiveness Index (SPI), concerns a composite behavioural index that is unlikely to be mechanically reducible to export intensity. Third, in Section 6 the disentanglement of the SSC and internationalisation contributions is treated as a priority avenue for future research on a larger and sectoral balanced sample. Throughout the paper, the language of the outcomes reflects this caveat: differences are systematically described as associations, not as effects.

Beyond internationalisation, the non-embedded sub-sample also exhibits higher rates of missing structural data and some residual sectoral heterogeneity, including a small number of IT and wood-processing firms alongside the metalworking core. These additionally sources of non-comparability warrant further caution and are discussed in Section 6. These additional sources of non-comparability are acknowledged as limitations of the exploratory design and are discussed in Section 6.

4. Results

4.1 Economic performance, investment behaviour and market expectations (RQ1)

The reference period was characterised by weak demand, cost pressures and persistent uncertainty across the full sample: more than half of the SMEs reported negative trends in turnover, production and domestic orders. Positive dynamics were present but limited in frequency. Within this common backdrop, however, SSC-embedded and non-embedded firms display systematically different patterns.

Table 3 reports the distribution of the main economic indicators. Embedded SMEs show a higher incidence of positive dynamics across all indicators: 43% report growing turnover (against 17% of non-embedded firms), 39% report growing domestic demand (against 8%), and 38% report growing

foreign demand (against 8%). Investment patterns show the most pronounced divergence: investment levels remain stable for the large majority of embedded firms (92%), while nearly half of non-embedded SMEs report investment contractions (48%), against only 8% of embedded firms.

Table 3. Main 2025 trends by SSC participation (survey items)

Indicator	**Level**	**Embedded (N=38)**	**Non-embedded (N=14)**
Annual turnover	Increase	43%	17%
	No variation	*9%*	*33%*
	Decrease	49%	50%
Production	Increase	32%	17%
	No variation	*18%*	*25%*
	Decrease	50%	58%
Domestic demand	Increase	39%	8%
	No variation	*15%*	*25%*
	Decrease	45%	67%
Foreign demand	Increase	38%	8%
	No variation	*28%*	*58%*
	Decrease	34%	33%
Investments (quarterly)	Increase	0%	3%
	Stable	*92%*	*48%*
	Decrease	8%	48%

Source: Authors' elaboration.

Market expectations show a recurrent pattern (Table 4). Embedded SMEs report substantially higher domestic market optimism (43% positive against 8%) and more articulated expectations on EU markets (31% positive against 0%). Non-embedded firms anticipate domestic contraction more frequently (50% against 29%). Forward-looking assessments thus appear to be shaped not only by the direct economic position of the firm but also by the relational anchoring provided by SSC participation.

Table 4. Short-term market expectations by SSC participation (survey items)

Market	**Expectation**	**Embedded (N=38)**	**Non-embedded (N=14)**
Domestic	Positive	43%	8%
	Steady	*29%*	*42%*
	Negative	29%	50%
EU markets	Positive	31%	0%
	Steady	*52%*	*100%*
	Negative	17%	0%
Extra-EU markets	Positive	9%	0%
	Steady	*68%*	*80%*
	Negative	23%	20%

Source: Authors' elaboration.

Overall, the descriptive data are consistent with RQ1: SSC-embedded SMEs display more favourable economic dynamics and more articulated forward-looking assessments than non-embedded firms operating in the same territory. These differences should be interpreted as descriptive patterns supporting the theoretical expectations, not as causal effects.

4.2 Innovation and sustainability practices (RQ2)

Innovation activity is limited across the full sample, with over 60% of firms reporting no formal R&D engagement. The result appears to be coherent with the structural characteristics of Italian manufacturing SMEs (Marchini et al., 2010; Carannante, 2021). Within this baseline, Table 5 shows that SSC participation is associated with different patterns of engagement with innovation-related activities. Non-embedded SMEs more frequently report autonomous innovation activities, such as patent filings (33% against 13%) and participation in patent-generating projects (33% against 6%). Embedded SMEs, by contrast, more frequently report use of third-party patented technologies (31% against 0%) and acquisition of licences (13% against 0%). Both groups report a substantial level of informal R&D activity without formal patenting (50% embedded, 67% non-embedded), although the strategic meaning of this category is interpretively ambiguous and is reported here for completeness.

Table 5. Innovation and patent-related activities (survey items)

Innovation activity	**Embedded (N=38)**	**Non-embedded (N=14)**
Participation in projects with potential patent outcomes	6%	33%
Filing of one or more patents in the last five years	13%	33%
Interest in collaborating in research/innovation projects with patent potential	13%	33%
Use of materials, components or technologies covered by third-party patents	31%	0%
Acquisition of licences for the use of third-party patents	13%	0%
Engagement in R&D activities generating know-how without formal patenting	50%	67%

Source: Authors' elaboration on multiple-choice item.

Turning to sustainability practices (Table 6), SSC participation is associated with substantially higher engagement in structured sustainability documentation. In particular, 34% of embedded SMEs indicate that sustainability certifications or reporting are explicitly required by SSC partners, against 0% of non-embedded firms. Non-embedded SMEs also report higher rates of non-engagement (43% against 21%). Interestingly, however, non-embedded firms show a slightly higher propensity toward voluntary sustainability adoption (21% against 13%), which suggests that where non-embedded firms do engage, the motivation is more strategically intrinsic rather than compliance-driven.

Table 6. Sustainability reporting and practices (survey items)

Sustainability-related activity	**Embedded (N=38)**	**Non-embedded (N=14)**
Subject to sustainability reporting obligations (CSRD)	5%	0%
Adoption of sustainability reporting model for micro/small enterprises (VSME)	5%	0%

Sustainability-related activity	Embedded (N=38)	Non-embedded (N=14)
Consideration of voluntary adoption of sustainability reporting tools/standards	13%	21%
Sustainability documents/certifications required by SSC partners	34%	0%
Not subject to mandatory obligations; internal monitoring of selected indicators	42%	43%
No engagement in structured sustainability reporting activities	21%	43%

Source: Authors' elaboration on multiple-choice item.

The patterns support RQ2: SSC embeddedness is associated with different – not necessarily higher – engagement in innovation and sustainability practices. In both domains, SSC participation appears to channel firm behaviour toward network-mediated and compliance-oriented modes, while non-embedded firms display a more autonomous and intrinsically motivated profile. These patterns are descriptive and should be interpreted with caution given the sample size.

4.3 Strategic adaptation and proactiveness (RQ3)

Strategic intentions differ substantially between groups (Table 7). Embedded SMEs report higher engagement across nearly all proactive actions: internal reorganisation (45% against 14%), market expansion (42% against 7%), new product development (37% against 14%), technology introduction (32% against 14%). Approximately half of non-embedded SMEs (50%) report no substantial strategic changes planned, pointing to a predominantly defensive or inertial orientation. A non-negligible share of firms in both groups report postponing strategic decisions – coherently with the pervasive uncertainty qualifying the context.

Table 7. Strategic adaptation actions (survey items)

Strategic action	Embedded	Non-embedded
Internal reorganisation / cost-efficiency measures	45%	14%
Search for or entry into new geographical markets	42%	7%
New product/service development or entry into new sectors	37%	14%
Introduction of new technologies or automation	32%	14%
Search for partnerships, alliances, or networks	21%	14%
Investments in sustainability, CSR, or certifications	21%	7%
Digitalisation projects or Industry 4.0 initiatives	18%	7%
Entry into new strategic supply chains	16%	7%
Business refocusing (reduction or redefinition of activities)	11%	7%
Decision postponed / strategic uncertainty	11%	14%
Vertical integration upstream and/or downstream	—	7%
Disinvestment / closure of low-performing business lines	3%	—
No substantial strategic changes planned	13%	50%

Source: Authors' elaboration on multiple-choice item.

The Strategic Proactiveness Index (Table 8) synthesises these patterns into a single measure. Embedded SMEs score substantially higher than non-embedded firms on both the mean (2.34 against 0.93) and the median (2.5 against 0). The Mann–Whitney U test confirms that the difference is statistically significant ($p = 0.013$). Interestingly, this difference emerges despite the relatively small sample, which makes its relevance noteworthy. This is the single statistically robust finding of the study, and arguably also the most theoretically central: it suggests that SSC participation is associated with a broader repertoire of proactive strategic responses to environmental uncertainty, not merely with better economic outcomes in absolute terms.

Table 8. Strategic Proactiveness Index (SPI)

Group	**SPI mean**	**SPI median**
Embedded SMEs (N=38)	2.34	2.5
Non-embedded SMEs (N=14)	0.93	0

Source: Authors' elaboration. Mann–Whitney U test: p = 0.013.

Together, the outcomes point to a coherent, though exploratory, picture: under conditions of heightened uncertainty, SSC-embedded SMEs report stronger current performance, more articulated forward-looking assessments, more frequent engagement with network-mediated innovation and sustainability practices, and a substantially broader repertoire of proactive strategic responses than firms operating outside such arrangements in the same territorial and sectoral context. As discussed in Section 3.5, the interpretation of these patterns must be moderated by the residual internationalisation gap between the two groups, which cannot be statistically separated at the current sample size.

5. Discussion

The findings of this exploratory study point to a consistent, though not unambiguous, picture of SSC embeddedness, associated with differentiated performance dynamics, innovation and sustainability engagement and – most robustly – strategic proactiveness among manufacturing SMEs in a specialised Italian territory. The discussion develops three implications that emerge from reading the empirical patterns through the theoretical framework outlined in Section 2: first, the reinterpretation of SSCs as an evolution of the Italian industrial district; second, the articulation of four channels through which territorial embeddedness and SME adaptation appear to evolve in this setting (governance signalling, compliance-driven capability upgrading, expectation coordination and territory-to-global institutional bridging); third, the role of intermediate institutions in supporting SME adaptation.

5.1 SSCs as a structured evolution of the Italian industrial district

The comparative evidence suggests that SSC participation in the investigated context, does not simply replicate a generic supply-chain logic imported from the international scholarship. Rather, it reconfigures – through explicit governance mechanisms such as standards, certifications, information-sharing protocols and sustainability requirements – the same socio-territorial embeddedness that historically characterised Italian districts. Embedded SMEs do not merely transact with larger partners: they participate in stabilised relationships that diffuse quality norms, sustainability certifications and strategic reference points. In this sense, SSCs appear to act as a governance-rich continuation of the district logic under post-globalisation pressures (Bellandi & Caloffi, 2014; De Marchi & Grandinetti, 2014), rather than as a substitute for it.

This suggests that the traditional district configuration is being reshaped – not dissolved – by the emergence of structured supply arrangements: the embeddedness described by Becattini (1990) and

Dei Ottati (2018) is increasingly being reshaped through explicit inter-firm governance mechanisms, rather than disappearing. Also, it suggests that the resilience and adaptation mechanisms associated with SSC participation may have deeper territorial roots than is typically acknowledged in studies focused on international supply chains and lead firms.

5.2 Territorial embeddedness as a meso-level mechanism of SME adaptation: four channels

The single statistically robust finding of the study, namely the difference in strategic proactiveness (SPI: 2.34 against 0.93; $p = 0.013$), deserves particular attention. Both groups of firms faced the same external shocks, operated in the same territory, and were dimensionally comparable on size and turnover (Section 3.5). Yet SSC-embedded SMEs reported a substantially broader repertoire of proactive responses. The pattern is coherent with the hypothesis that resilience in this context co-varies primarily with relational coordination and normative reference points, rather than with resource buffering or operational redundancy; it is also coherent with the dynamic perspective on supply chain resilience (Pettit et al., 2010; Wieland & Wallenburg, 2013) and with embeddedness theory (Uzzi, 1997; Gulati et al., 2009).

Moving beyond the aggregate pattern, the results can be interpreted through the four mechanisms through which both SSC participation and SME adaptive capacity appear to evolve in a territory with a strong district heritage. These mechanisms should be considered as an interpretive framework rather than as directly inferred from the data.

Mechanism 1 – Governance signalling. In traditional districts, coordination rested largely on tacit knowledge, diffuse reciprocity and community-level norms (Becattini, 1990; Dei Ottati, 2018). As globalisation, technological change and successive crises have eroded these informal foundations (Bellandi & Caloffi, 2014; De Marchi & Grandinetti, 2014), SSC arrangements make explicit – through certifications, quality standards, information-sharing protocols and joint planning routines – what districts used to transmit implicitly. In our data, the high share of embedded firms reporting SSC-mandated sustainability certifications (34% against 0%) and the co-existing pattern of systematically more articulated market expectations are in line with this channel: explicit governance signals appear to substitute, and at the same time re-structure, the diffuse reciprocity that has historically anchored SME behaviour in Italian industrial districts.

Mechanism 2 – Compliance-driven capability upgrading. Participation in SSCs typically requires meeting capability requirements imposed by lead firms, whether technological (process certifications, interoperability protocols) or institutional (sustainability documentation, traceability). While these requirements are compliance-driven in their origin, they appear to coincide with a broader repertoire of capability-building actions on the part of embedded SMEs: the observed differences in internal reorganisation (45% against 14%), technology introduction (32% against 14%) and digitalisation (18% against 7%) are all coherent with the interpretation that SSC-imposed standards operate as an external driver of capability upgrading. This echoes, in a more structured form, the district mechanism of "learning by osmosis" (Becattini et al. 2009) that Italian district scholarship has long documented, here reinterpreted as learning under explicit governance pressure.

Mechanism 3 – Expectation coordination through lead-firm focal points. Manufacturing SMEs operating in post-globalisation uncertainty face non-trivial interpretive ambiguity: what scenario should one plan for, what markets should one prioritise, what investments are worth making? The presence of lead firms within a structured SSC provides explicit focal points for expectations: their strategic direction, communicated through ordinary supply chain interactions, becomes a usable reference point for the smaller participants. In our data, the most striking pattern – embedded firms reporting 43% positive domestic expectations against 8% for non-embedded firms – supports this coordination-through-focal-points channel. Non-embedded firms, lacking such focal points, appear to default to the defensive-inertial pattern reported by recent scholarship on SME behaviour under uncertainty (Hortovanyi & Szepesi, 2026; Bak et al., 2020).

Mechanism 4 – Territory-to-global institutional bridging. This is the most distinctive mechanism from the perspective of Italian management scholarship, and it directly addresses the

internationalisation gap highlighted in Section 3.5. In the classical district, access to extended markets was mediated by the territorial system as a whole, through shared distribution infrastructures, trading firms and sectoral associations. As districts have weakened, SSCs appear to partially substitute this bridging role: they offer SMEs a structured relational channel through which to access international markets without having to internalise internationalisation capabilities firm-by-firm. The marked internationalisation gap observed in our data (82% against 36%) is therefore not a pure confounder to be controlled away: it is partly constitutive of the mechanism itself, since SSC participation and access to international demand evolve within the same process. Teasing apart the two contributions at the firm level would require longitudinal designs and larger samples and is flagged as a priority for future research.

The four mechanisms are not mutually exclusive and may in fact operate as a bundle: governance signalling appears to underpin compliance-driven capability upgrading; focal points work alongside expectation alignment; institutional bridging plays a connecting role between the territorial system and global markets. Interpreted through this lens, SSC participation appears as a composite inter-firm configuration that partly reconstitutes – in a more formal and governance-driven form – the adaptive advantages historically associated with the Italian industrial district tradition. The non-embedded sub-sample, by contrast, displays the defensive-inertial pattern that recent scholarship has associated with limited network embeddedness and reduced access to coordination routines (Bak et al., 2020; Hortovanyi & Szepesi, 2026).

5.3 The role of intermediate institutions and policy implications

The outcomes have implications for the role of intermediate institutions, namely industry associations, chambers of commerce, and regional or local development agencies, in supporting SME adaptation. Three points are particularly relevant for the Sinergie-SIMA conversation on post-globalisation management.

First, the evidence suggests that SSC membership in itself is not a guarantee of adaptive benefit for SMEs: the quality of inter-firm governance matters, which is precisely the object of Mechanisms 1 and 2 articulated in Section 5.2. The patterns observed in innovation and sustainability engagement, with compliance-driven adoption prevailing among embedded SMEs and voluntary engagement slightly more frequent among non-embedded firms, suggest that SSCs can diffuse minimum standards effectively but may not automatically support the deeper strategic internalisation of innovation or sustainability goals. Intermediate institutions therefore have a role not only in facilitating access to SSCs, but also in monitoring their governance quality and in supporting asymmetry-reducing mechanisms (capability-building programmes, training, shared infrastructures).

Second, the relatively high share of non-embedded firms reporting no planned strategic change (50%) points to a structural marginalisation risk for SMEs operating outside structured supply arrangements, reflecting the absence of the focal-points coordination channel described as Mechanism 3. In a specialised manufacturing region, policy attention should therefore include explicit attention to non-embedded firms, for whom district-based informal reciprocity is eroding while formalised SSC participation remains out of reach. Instruments such as territorial innovation platforms, regional development agencies and collective service centres (historically associated with district policy in Italy) could be redirected toward facilitating the transition of these firms toward well-governed SSC arrangements.

Third, the results highlight the continuing strategic relevance of territorial and institutional context in the post-globalisation era, an observation that the territory-to-global bridging channel (Mechanism 4) places at the centre of the theoretical framework. Rather than being neutralised by global reconfigurations, territorial and institutional embeddedness appears to be re-emerging – in restructured form – as a meaningful factor for SME resilience and adaptation. This is arguably a distinctive contribution that Italian management research can offer to the broader conversation on post-globalisation manufacturing, given the country's rich empirical and theoretical tradition on the inter-organisational governance of productive systems.

6. Conclusions, limitations and future research

This exploratory study has investigated whether and how SME participation in Strategic Supply Chains, understood as a structured evolution of the Italian industrial district tradition, is associated with differentiated economic performance, innovation and sustainability engagement and strategic adaptation under post-globalisation uncertainty. By comparing 38 SSC-embedded and 14 non-embedded manufacturing SMEs operating in the specialised industrial region of Brescia, the analysis shows that embedded firms exhibit more favourable economic dynamics, more articulated market expectations and – most robustly – a significantly broader repertoire of proactive strategic responses (SPI: 2.34 against 0.93; $p = 0.013$).

This paper offers four contributions to the existing literature. Conceptually, it provides an operational definition of SSCs that distinguishes them from generic supply chains, Global Value Chains and industrial districts in the strict Becattini sense, thereby addressing an ambiguity that has weakened previous empirical work. Theoretically, it frames SSCs as a post-globalisation evolution of the Italian industrial district tradition, mobilising a distinctively Italian scholarly perspective within the international conversation on supply chain resilience, the relational view and embeddedness. Analytically, it proposes a four-channel architecture – governance signalling, compliance-driven capability upgrading, expectation coordination, territory-to-global institutional bridging – as a candidate framework for interpreting SSC–SME co-evolution in specialised manufacturing regions. Empirically, it provides SME-focused observations from a specialised manufacturing region where the tension between district legacy and structured supply arrangements is particularly visible.

The study has important limitations, which should explicitly guide the interpretation of the outcomes. First, the sample is small (N=52) and deliberately unbalanced, reflecting the structure of the local SME population but limiting statistical power. Only one inferential test reaches conventional significance (SPI), and the remaining findings should be interpreted as descriptive patterns aligned with – but not proof of – the theoretical expectations. Second, as discussed in Section 3.5, a material residual confounder, namely the systematically higher internationalisation rate among embedded SMEs (82% against 36%), cannot be statistically controlled at the present sample size; the language has been calibrated accordingly, and the internationalisation channel is reinterpreted theoretically as part of Mechanism 4 rather than as a pure confounder. Also, the single-territory focus enhances internal coherence but limits external generalisability: findings may not transfer to sectors or territories with different organisational histories. Additionally, the cross-sectional design does not capture the dynamic trajectories along which SSC participation and SME adaptive behaviour evolve over time. Last, some residual sectoral heterogeneity in the non-embedded sub-sample, together with missing data on some structural indicators, constitute additional sources of caution.

Future research can extend the present study along several directions. First, larger and sectorally balanced samples would enable propensity-score matching and allow separating the SSC and internationalisation contributions, a priority given the confounder highlighted in this paper. Second, longitudinal designs could trace how SSC participation and SME adaptive trajectories develop jointly over time, and whether the observed patterns of strategic proactiveness are associated with durable performance effects. Additionally, multi-territorial comparisons across Italian regions and across European manufacturing systems with different organisational traditions (e.g., German “Mittelstand” networks, French “pôles de compétitivité”) would illuminate the extent to which the “SSC-as-district-evolution” framing generalises beyond the Italian case. Also, qualitative case studies of SSC governance mechanisms could test the four channels articulated in Section 5.2 (governance signalling, compliance-driven capability upgrading, expectation coordination, territory-to-global bridging), unpacking the specific relational and institutional processes they involve.

Last, the results support a cautiously optimistic policy implication: in post-globalisation manufacturing systems, the strengthening and governance of SSC, as structured continuations rather than replacements of the territorial and institutional embeddedness that has historically characterised European manufacturing, may represent a meaningful lever for SME resilience and adaptive capacity.

Abstract

Frame of the research. *Despite the development of internal communication in Italy, historically studies focused primarily on organizational structures and managerial processes, and no psychometrically validated instrument currently exists to measure internal communication satisfaction among Italian-speaking employees.*

Purpose of the paper. *This paper aims to validate the Italian version of the internal communication satisfaction questionnaire (ICSQ).*

Methodology. *The validation has been conducted leveraging the data collected in a broad three-wave, cross-national survey study, using only the data from the Italian sub-sample (348 employees). Internal consistency reliability, structural validity and model fit were assessed.*

Results. *All eight dimensions of the ICSQ showed satisfactory internal consistency. The original eight-factor structure of the ICSQ demonstrated slightly better fit than the higher-order model.*

Research limitations. *Results highlight the tension inherent in cross-cultural measurement between structural invariance and contextual adaptation.*

Managerial implications. *The Italian ICSQ offers organizations a diagnostic and developmental tool to systematically assess communication effectiveness from the employee perspective.*

Originality of the paper. *Methodologically, the paper confirms the transferability of a multidimensional measure while illustrating the importance of contextual interpretation in cross-cultural scale adaptation. Practically, it equips Italian organizations with a structured tool for diagnosing and improving their communicative environments.*

Keywords: *internal communication; internal communication satisfaction; scale validation; internal communication satisfaction questionnaire; measurement instrument*

1. Introduction

Internal communication has a growing relevance as part of the communication discipline both at the academic and professional level (Mazzei, 2010; Men and Bowen, 2017; Tkalac Verčič *et al.*, 2012; Welch, 2012) globally and in Italy.

The development of the internal communication field requires understanding its relationships with other related constructs, such as employee engagement, employee commitment, job satisfaction, employee retention, and should be based on a reliable and valid measure of communication satisfaction (Tkalac Verčič, 2021; Tkalac Verčič *et al.*, 2021). To this end Tkalac Verčič and colleagues (2009) developed and validated the Internal Communication Satisfaction Questionnaire (ICSQ), a measurement instrument originally developed in Croatian. To expand the use of the ICSQ for studies involving employees who use English as their second language, Tkalac Verčič and colleagues (2021) translated and validated the scale in English.

One of the major implications of the validation in English is the possibility to replicate the study in other countries to generalize its results (Tkalac Verčič *et al.*, 2021). The aim of the present study is to translate and validate the ICSQ in Italian. Despite the institutional development of internal communication in Italy, no psychometrically validated instrument currently exists to measure internal communication satisfaction among Italian-speaking employees.

In Italian companies, the institutionalization of internal communication in the form of a dedicated

[4] Università IULM e-mail: alfonsa.butera@iulm.it

function is continuously growing, as it has been documented by studies since the end of the '90s (Invernizzi 1996, 2000) and up to the current scenario (Mazzei and Quaratino, 2019, 2020; Mazzei *et al.*, 2026 in press). Institutionalization brings the growth of staff, dedicated financial resources and above all a rising strategic attention.

The field of internal communication has developed over the last 20 years with the publications of scientific studies in Italian and in English by Italian authors (e.g., Biraghi, 2015; Mazzei, 2009; Mazzei *et al.*, 2022), the presence of Italian scholars in the academic international community and the institutionalization of university courses and stable university research groups in Italy including the CERC (entre for Employee Relations and Communication), and the existence of a professional association of internal communication professionals and managers (ASCAI – Associazione per lo sviluppo della comunicazione aziendale in Italia). The increasing interest in internal communication calls for rigorous studies looking at new aspects of the internal communication phenomenon. Therefore, the availability of a measurement instrument such as the ICSQ in Italian would be essential.

This paper recalls first the development of internal communication in Italy, to give a framework useful for understanding the need for the validation of a new measurement instrument. Then it presents the methodology, the results and the discussion of a study conducted using an Italian-speaking sample of employees to validate the ICSQ. It concludes by discussing limitations, avenues for future studies, and managerial implications.

2. Literature review

2.1 Measurement instruments in Italian internal communication studies

Italy has experienced an intense process of development of the debate on internal communication since the late '80s to the mid '90s. A review of the most important research studies (Mazzei, 1994) highlighted four topics: the activities managed by the internal communication professionals, the organizational architecture dedicated to the function, the managerial methods adopted, and the level of involvement of the top management in the definition of the communication strategy. Overall these studies confirmed the "hypotheses of the organizational communication" formulated by Invernizzi, being organizational communication considered as a synonym for internal communication (Invernizzi, 1993). However, these studies focused primarily on organizational structures and managerial processes, rather than on employees' subjective evaluations of internal communication.

The field developed thanks to a series of academic publications in the '90s (e.g., Amigoni, 1991; Baccarani and Golinelli, 1992; Butera, 1990; Del Mare *et al.*, 1990; Ferri, 1993; Gabrielli and Invernizzi, 1994; Iacci and Coletti, 1991; Nelli, 1994; Quaglino, 1992; Romano and Felicioli, 1991).

The most influential framework that impacted the development of internal communication in Italian academia was framed under the *lens of organizational communication, linking the development of the communication of organizations to the evolution of the organizational theories and models*, meant as a single phenomenon intertwining internal and external environment (Invernizzi, 1996, 2000; Invernizzi and Mazzei, 1993, 1997).

Beside this conceptual development, a group of Italian scholars based at Università IULM devoted high attention to the measurement of the evolution of organizational/internal communication in Italian companies. The prevalent conceptual framework was based on the hypotheses of the "generalized diffusion of internal communication" and of the "emergence of the paradigm of organizational communication" (Invernizzi, 1996, 2000).

With the new Millennium, a new wave of studies emerged (e.g., Ancarani and Baietti, 2000; Artuso and Mason, 2008; Baglieri, 2000; Barone and Fontana, 2005; Biraghi, 2015; Fiocca, 2002; Galardi, 2024; Invernizzi *et al.*, 2020; Invernizzi and Mazzei, 2006; Marchiori, 2001; Mazzei and Butera, 2024; Minghetti and Cutrano, 2004). Among these studies, a conceptual framework has been proposed based on a multidisciplinary approach: management and its resource-based theory of the

company, public relations and its theory of publics, and organizational communication with its communicative constitution of organizations principle (Mazzei, 2004, 2009, 2010, 2025). This perspective puts at the center of internal communication the role of all organizational members as communicators, strategic or adversarial, and the role of the internal communication function as the creator of an enabling work context (Mazzei, 2014). The role of employees as procompany or anticompany communicators has been investigated as an output of the level of engagement and related to the work context conditions in terms of employee relationship management, organizational justice and human resources practices (Mazzei *et al.*, 2019; Mazzei *et al.*, 2025).

In this flourishing of studies, some topics attracted particular attention in the Italian internal communication community, leading to studies again involving managers and practitioners in the field: internal crisis communication (e.g. Mazzei and Butera, 2021; Mazzei and Ravazzani, 2011) and diversity management (Mazzei and Ravazzani, 2012; Ravazzani, 2016). Again, on these topics the qualitative and quantitative instruments were focused on the managerial perspective, mapping and analyzing practices of communication related to specific issues at the organizational level.

From the operational point of view researchers developed measurement instruments to map the evolution of internal communication in Italy. In 2011 and 2017 ASCAI investigated the presence and the staffing of a dedicated function, channels and tools, budget, team, planning, aims and strategies, measurement (Nelli, 2017). While these instruments provide valuable benchmarking data, they do not constitute psychometrically validated measures of internal communication satisfaction at the employee level.

In 2019 and 2025-2026, two studies conducted at the research center CERC (Centre for Employee Relations and Communication) of Università IULM depicted the state of the art of internal communication in Italian companies (Mazzei and Quaratino, 2019, 2020; Mazzei *et al.*, 2026 in press). Some of the themes covered by this questionnaire are the *existence of a formal function* dedicated to internal communication, the *involvement of top management* into the definition of aims, *staffing*, *aims* of internal communication, the *role of employees as communicators* across the organizational borders, and the *managerial methods* to plan and evaluate internal communication. In the hypotheses of these studies internal communication impacts the level of employee engagement and it has the role to enable employees to perform procompany communication behavior.

All in all, considering the studies about internal communication in Italy according to the classification by Downs (1994 in Tkalac Verčič *et al.* 2021), the Italian tradition confirms the use of comprehensive instruments that "analyze communication practice on a macro level" (Tkalac Verčič *et al.* 2021: 592). These instruments are useful to map the state of the art of a profession or of an organizational area to diagnose the phase of development and maturity as for example the CCI Study (Goodman and Hirsh, 2010) or the European Communication Monitor (Tench *et al.*, 2025).

To evaluate the effects of internal communication on employees, there are some psychometric scales validated in Italian that can be used to assess a series of constructs that can be influenced by internal communication. For instance, there are scales available that have been validated in Italian in order to measure employee engagement in specific industries (Pisanti *et al.*, 2008), or to measure perceived organizational support (Battistelli and Mariani, 2011). Similarly, scales are available in Italian to assess job satisfaction, which also include some items specifically referred to the satisfaction of employees with communication issues (Platania *et al.*, 2021).

The need to study internal communication thoroughly is strictly related to the fast pace of its development in Italian companies. In 2019, the study conducted by CERC of Università IULM to assess the state of the art of internal communication in Italy showed that 56% of the companies surveyed had a formal function dedicated to internal communication, 30% had had this function in place for 11 to 20 years and 5% for more than 20 years (Mazzei and Quaratino, 2019, 2020). In the second edition of this study, 79% of the companies surveyed have a formal function dedicated to internal communication, 30% have had this function in place for 11 to 20 years and 10% for more than 20 years (Mazzei *et al.*, 2026 in press).

As emerged from the above, Italian studies on internal communication focused on applied

research, the development of validated managerial practices, and guidelines. This is coherent with a normative approach typical of corporate communication (Christensen and Cornelissen, 2011), the background of most Italian communication scholars. This kind of research led to the development of benchmarking tools such as the "Enabling Model of Internal Communication" (Mazzei and Quaratino, 2019). Therefore in Italy there is no tradition of academic studies conducted with Italian psychometric instruments and in particular related to internal communication satisfaction.

The need to expand the number and the quality of psychometrically validated employee-level measurement instruments is strictly related to the institutionalization of the professional field and the academic discipline of employee communication.

Measuring employee communication contributes to identify and validate methods, tactics, tools and messages that are effective or not (Men and Bowen, 2017). Efforts in employee communication are tied to important employee outcomes such as job attitudes, behavioral changes, productivity, organizational performance and these should be measured (Mazzei, 2025; Men and Bowen, 2017) to sustain the relevance of these efforts, the investments, and the legitimization of the function. There are a lot of obstacles and resistance in measuring employee communication (Men and Bowen, 2017) and companies signal that they have no formal assessment tool to evaluate the success of employee communication campaigns (Men and Berger, 2012). Therefore, having measures for constructs such as employee engagement, employee communication satisfaction, and the like, is crucial to overcome these difficulties and ease the process.

The quest arriving from the professional field is clear and strong, considering the organizational need to measure the results of internal communication activities (Mazzei and Quaratino, 2019; Mazzei *et al.*, 2026 in press; Men and Bowen, 2017). Therefore, academia and universities have an opportunity and the duty to develop scales that can measure psychometric constructs, as it is common in other fields such as psychology of organizations. The translation into local languages is essential to develop instruments that are easy to adopt for professionals.

Also, from the academic point of view, having psychometrically validated employee-level measurement instruments is an opportunity to carry out studies that can explore quantitative hypotheses with a culturally-based approach.

The aim of this study is therefore to start to fill this gap by examining the psychometric properties of the Italian version of the internal communication satisfaction questionnaire (ICSQ), as already done for the Croatian and English versions of the same instrument (Tkalac Verčič *et al.*, 2009; Tkalac Verčič *et al.*, 2021).

2.2 Internal communication and internal communication satisfaction

Internal communication is widely recognized as a strategic management function that shapes organizational cohesion, alignment, and performance. Contemporary scholarship in public relations and organizational communication moves beyond the traditional "sender–receiver" model and conceptualizes internal communication as a relational and participatory process through which meaning is co-created among employees and management.

Within this broader framework, Internal Communication Satisfaction (ICS) represents the evaluative outcome of internal communication processes. ICS refers to employees' subjective evaluation of the quality, clarity, adequacy, and usefulness of communication within their organization (Tkalac Verčič *et al.*, 2025). Unlike structural indicators such as channel frequency, communication flows, or message design, ICS captures how employees psychologically experience and interpret the communicative environment in which they work. It is therefore an attitudinal construct that reflects employees' perceptions rather than managerial intent or technical communication quality.

Conceptually, ICS is grounded in broader theories of satisfaction as an evaluative response to environmental conditions (Hecht, 1978; Spector, 1997). In organizational settings, it represents an affective–cognitive judgment about whether communication is timely, transparent, responsive, and meaningful. Employees form such judgments through daily interactions with supervisors and

colleagues, exposure to leadership messages, participation in meetings, feedback processes, informal exchanges, and increasingly through digital communication tools. ICS thus reflects employees' holistic appraisal of the communicative climate.

Historically, research on communication satisfaction emerged from studies of communication climate and message directionality (Downs and Hazen, 1977). Contemporary approaches conceptualize ICS as a multidimensional construct encompassing satisfaction with feedback, communication climate, supervisory communication, horizontal communication, corporate information, communication media, informal communication, and communication during meetings. This multidimensionality acknowledges that communication operates across hierarchical levels and functional contexts.

Theoretically, ICS is frequently explained through Social Exchange Theory (SET). From this perspective, internal communication functions as a relational signal. Clear, respectful, and informative communication communicates organizational investment in employees and strengthens perceptions of reciprocity and fairness. Empirical research demonstrates that Perceived Organizational Support (POS) and Psychological Contract Fulfillment (PCF) predict ICS, suggesting that employees who feel valued and believe organizational promises are honored evaluate internal communication more positively. ICS therefore reflects the perceived quality of the employee–organization relationship as enacted through communication.

In digitally mediated workplaces, ICS is also shaped by employees' perceptions of communication technologies. Drawing on the Media Affordances Perspective, research shows that employees' adaptability to and acceptance of digital communication tools significantly contribute to ICS. When communication platforms are perceived as usable, flexible, and aligned with task requirements, employees report higher communication satisfaction. Importantly, ICS does not merely reflect exposure to digital tools, but rather employees' evaluations of how well those tools support meaningful and relational interaction. Previous research has linked internal communication satisfaction to employee engagement and broader well-being outcomes (Tkalac Verčič *et al.*, 2025). In sum, internal communication satisfaction represents employees' integrated evaluation of their communicative work environment. It bridges relational, structural, and technological dimensions of communication and serves as a key explanatory construct in understanding how internal communication influences engagement, well-being, and broader organizational outcomes. The ICSQ operationalizes this multidimensional conceptualization and provides a structured measure of employees' evaluations of internal communication (Tkalac Verčič and Verčič, 2026).

2.3 Theoretical framework and construct positioning of internal communication satisfaction

The present validation effort is grounded in a multilevel theoretical framework integrating organizational communication theory, relational perspectives in public relations, and attitudinal theories of satisfaction**.** This framework clarifies both the nature of internal communication satisfaction (ICS) as a construct and the rationale for its psychometric validation.

First, from the perspective of organizational communication theory, internal communication is conceptualized as a constitutive process through which organizations are enacted and maintained (Mazzei, 2010). Communication is not merely a transmission mechanism but a system of interactions that shapes meaning, coordination, and organizational reality. Within this paradigm, employees are not passive recipients but active participants in communicative processes. Consequently, any assessment of internal communication must account for how communication is *experienced* by organizational members. ICS emerges as a key construct capturing this experiential dimension.

Second, the study draws on relational and public relations perspectives, particularly the view that communication reflects and sustains the quality of relationships between organizations and their members. In this sense, ICS functions as an indicator of the employee–organization relationship, as it reflects employees' evaluations of transparency, reciprocity, responsiveness, and inclusion in communication processes. This positioning aligns ICS with constructs such as trust, perceived organizational support, and relationship quality, while maintaining its distinct focus on

communication-specific evaluations.

Third, ICS is theoretically grounded in attitudinal theories of satisfaction, which conceptualize satisfaction as an evaluative judgment resulting from the comparison between expectations and perceived experiences (Hecht, 1978; Spector, 1997). Within organizational settings, ICS represents a domain-specific satisfaction construct, analogous to job satisfaction but focused exclusively on communication processes. It integrates both cognitive evaluations (e.g., clarity, adequacy of information) and affective responses (e.g., feeling informed, included, respected).

Building on these perspectives, ICS can be defined as a multidimensional latent construct representing employees' overall evaluative appraisal of the organizational communicative environment**.** Its multidimensionality reflects the complexity of communication processes, which operate across hierarchical levels (e.g., top management, supervisors), functional domains (e.g., feedback, coordination), and communication channels (e.g., formal, informal, digital).

Importantly, this theoretical positioning provides the foundation for the validation of the ICSQ. From a measurement perspective, ICS is treated as a reflective latent construct, where observed variables (items) represent manifestations of an underlying evaluative perception. The validation process therefore tests whether the empirical structure of the instrument corresponds to the theoretically defined dimensions of communication satisfaction. In this sense, confirmatory factor analysis is not merely a statistical procedure but a theory-testing approach, assessing the extent to which the proposed multidimensional model aligns with observed employee perceptions.

Finally, ICS occupies a central position within organizational communication research as a mediating and explanatory construct. It links communication processes to key organizational outcomes such as employee engagement, well-being, and behavioral alignment. By capturing how communication is interpreted and evaluated by employees, ICS provides a critical mechanism through which internal communication influences organizational effectiveness. The validation of the ICSQ in Italian therefore contributes not only to measurement development but also to the theoretical advancement of internal communication research by enabling systematic empirical testing of these relationships.

3. Methodology

The Italian subsample formed part of a broader three-wave, cross-national survey study designed to test a theoretically grounded process model of ICS and its organizational, technological, and psychological antecedents and outcomes (Tkalac Verčič *et al.*, 2025). For the purposes of this study, only the Italian data were used to assess the psychometric properties of the Italian version of the ICSQ. Data were collected between July and September 2025 using a structured online questionnaire administered through a professional polling agency. The validation focuses primarily on the wave in which internal communication satisfaction was measured, while additional variables from the broader project were used to examine theoretically expected associations.

3.1 Sampling and participants

Participants were recruited using stratified quota sampling to ensure representation across key demographic and organizational characteristics, including age, gender, industry sector, and organizational size. Eligibility required respondents to be employed (full-time or part-time) at the time of data collection. The Italian validation sample consisted of 348 employees. Of these, 181 (52.0%) were male and 167 (48.0%) were female. Participants ranged in age from 20 to 65 years, with a mean age of 45.62 years (SD = 10.39), indicating a professionally experienced workforce. In terms of education, the majority of respondents reported higher education qualifications. Specifically, 188 participants (54.0%) held a university degree, 83 (23.9%) reported post-secondary education below the university level, 52 (14.9%) held postgraduate qualifications, and 25 (7.2%) reported other forms of education. Participants were employed across a range of organizational contexts, positions, and industries, contributing to the heterogeneity of the sample and enhancing the relevance of the

findings for diverse organizational settings within Italy. The sample size exceeds commonly recommended thresholds for confirmatory factor analysis and psychometric validation, supporting the adequacy of the dataset for testing the structural and reliability properties of the Italian ICSQ.

3.2 Measure

ICS was measured using the ICSQ, a 32-item multidimensional instrument originally developed and validated in Croatian and subsequently validated in English. The ICSQ operationalizes ICS as employees' evaluative perception of internal communication within their organization and comprises eight dimensions: communication climate, relationship to supervisor, organizational integration, media quality, horizontal communication, organizational perspective, personal feedback, and communication with top management. Items are assessed on a 7-point Likert-type scale ranging from 1 (very dissatisfied) to 7 (very satisfied). A sample item is: "Information about changes in the organization." Higher scores indicate higher levels of ICS. The full 32-item structure was retained for validation in the Italian sample in order to examine the stability of the original dimensional configuration.

Perceived organizational support, psychological contract fulfillment, digital communication adaptability, employee engagement, and life satisfaction were measured using established multi-item scales. All instruments were translated into Italian using a back-translation procedure to ensure linguistic and conceptual equivalence between the original and Italian versions.

3.3 Data analysis

Data analysis proceeded in several stages to evaluate the psychometric properties of the Italian version of the ICSQ. Descriptive statistics, including means and standard deviations, were calculated for each of the eight dimensions and for the overall ICS score. Internal consistency reliability was assessed using Cronbach's alpha coefficients for each dimension and for the overall index, with values above .70 considered acceptable. Structural validity was examined through confirmatory factor analysis testing the original eight-factor model and a higher-order model specifying ICS as a second-order construct. Model fit was evaluated using chi-square, comparative fit index, Tucker–Lewis index, root mean square error of approximation, and standardized root mean square residual. In addition, associations between ICS and theoretically related constructs, including perceived organizational support, psychological contract fulfillment, digital communication adaptability, employee engagement, and life satisfaction, were examined using regression analyses in order to evaluate whether ICS behaved in accordance with theoretical expectations. All analyses were conducted on the Italian sample (N = 348).

4. Results

4.1 Descriptive statistics and reliability

Descriptive statistics and internal consistency coefficients for the eight dimensions of the ICSQ and for the overall ICS index are presented in Table 1. Mean scores across dimensions ranged from 4.34 (organizational integration) to 4.80 (communication climate), indicating moderate to relatively high levels of internal communication satisfaction in the Italian sample. The overall ICS mean was 4.58 (SD = 1.14), suggesting that respondents evaluated internal communication in their organizations positively, though not at the highest end of the scale. Cronbach's alpha coefficients ranged from .74 (organizational integration) to .89 (media quality). All eight dimensions exceeded the recommended threshold of .70, indicating satisfactory internal consistency. The overall ICS index demonstrated excellent reliability ($\alpha = .97$), reflecting a high degree of internal coherence among the 32 items.

Tab. 1: Descriptive statistics and reliability of the Italian ICSQ dimensions and overall internal communication satisfaction

Dimension	Mean	Standard deviation	Cronbach's alpha
Communication climate	4.80	1.11	0.76
Relationship to supervisor	4.49	1.33	0.85
Organizational integration	4.34	1.18	0.74
Media quality	4.49	1.41	0.89
Horizontal communication	4.74	1.30	0.83
Organizational perspective	4.52	1.15	0.80
Personal feedback	4.66	1.31	0.83
Communication with top management	4.62	1.18	0.79
Overall ICS	4.58	1.14	0.97

Source: our elaboration

All reliability coefficients exceeded the recommended threshold of .70, confirming satisfactory internal consistency for each dimension and excellent reliability for the overall ICS index.

4.2 Confirmatory factor analysis

Confirmatory factor analysis was conducted to test the original eight-factor structure of the ICSQ in the Italian sample. In addition, a higher-order model specifying ICS as a second-order construct was examined. Fit indices for both models are presented in Table 2. For the eight-factor model, results were as follows: $\chi^2(436) = 1353.13$, CFI = .893, TLI = .878, RMSEA = .078, and SRMR = .160. The higher-order model yielded $\chi^2(456) = 1436.21$, CFI = .885, TLI = .875, RMSEA = .079, and SRMR = .161. The RMSEA values for both models fall within the acceptable range, though close to conventional upper thresholds. The CFI and TLI values are slightly below the commonly recommended cutoff of .90, indicating that model fit is marginal rather than optimal. The SRMR values exceed typical acceptable levels, suggesting suboptimal absolute fit. Overall, the eight-factor model demonstrates slightly better fit than the higher-order model, though both models show only moderate adequacy.

Tab. 2: Confirmatory factor analysis fit indices

Model	chi-square (chi2)	df	CFI	TLI	RMSEA	SRMR
Eight-factor model	1353.13	436	0.893	0.878	0.078	0.160
Higher-order model	1436.21	456	0.885	0.875	0.079	0.161

Source: our elaboration

Interpretation: RMSEA is in the acceptable range (borderline). CFI and TLI are slightly below common cutoffs (.90). SRMR is not acceptable. The eight-factor model fits slightly better than the higher-order model.

4.3 Standardized factor loadings

Standardized factor loadings for the eight-factor model are presented in Table 3. Most items loaded satisfactorily on their intended dimensions, with standardized loadings ranging from .579 to .867. Two items fell below the conventional .50 threshold: QICS.11 (organizational integration; $\lambda = .407$) and QICS.21 (organizational perspective; $\lambda = .489$). All remaining items exceeded .58, indicating acceptable to strong relationships with their respective latent factors. The strongest loadings were observed within the media quality, horizontal communication, and personal feedback dimensions. Taken together, the pattern of loadings suggests that the original dimensional structure of the ICSQ is largely replicated in the Italian sample, although certain items demonstrate weaker contributions and may warrant further examination in future research.

Tab. 3: Standardized loadings for the eight-factor ICSQ model

Item	Factor	Std. loading
QICS.1	CC	0.764
QICS.2	CC	0.614
QICS.3	CC	0.679
QICS.4	CC	0.648
QICS.5	RS	0.778
QICS.6	RS	0.849
QICS.7	RS	0.751
QICS.8	RS	0.609
QICS.9	OI	0.694
QICS.10	OI	0.688
QICS.11	OI	0.407
QICS.12	OI	0.808
QICS.13	MQ	0.752
QICS.14	MQ	0.800
QICS.15	MQ	0.844
QICS.16	MQ	0.796
QICS.17	HC	0.658
QICS.18	HC	0.867
QICS.19	HC	0.796
QICS.20	HC	0.621
QICS.21	OP	0.489
QICS.22	OP	0.639
QICS.23	OP	0.736
QICS.24	OP	0.700
QICS.25	PF	0.804
QICS.26	PF	0.819
QICS.27	PF	0.860
QICS.28	PF	0.707
QICS.29	TM	0.738
QICS.30	TM	0.801
QICS.31	TM	0.716
QICS.32	TM	0.579

Source: our elaboration

Key point: the claim “all loadings exceed .50” is not supported in the Italian data. Two items fall below .50 (QICS.11 = 0.407; QICS.21 = 0.489). Everything else is ≥ 0.58.

Overall, the Italian data provide general support for the original eight-factor structure of the ICSQ. Internal consistency was satisfactory across all dimensions, and the majority of items demonstrated adequate factor loadings. However, global model fit indices indicate marginal fit, and two items exhibited loadings below .50. The Italian version therefore broadly replicates the original structure, though not without minor psychometric limitations that should be acknowledged.

5. Discussion

The present study examined the psychometric properties of the Italian version of the Internal Communication Satisfaction Questionnaire (ICSQ) and aimed to assess whether the original multidimensional structure could be replicated in an Italian-speaking organizational context. Overall, the findings provide substantial support for the structural integrity and reliability of the instrument while simultaneously revealing several nuances that are typical of cross-cultural scale adaptation.

Rather than indicating structural failure, the results suggest partial adaptation effects that merit closer interpretation.

5.1 Interpretation of the CFA results and meaning of "marginal fit"

Confirmatory factor analysis largely supported the original eight-dimensional configuration of the ICSQ, with most items loading satisfactorily on their intended constructs and internal consistency indices exceeding recommended thresholds. However, global fit indices indicate what can be described as marginal model fit, a result that requires careful interpretation.

In psychometric validation studies, marginal fit does not imply that the theoretical structure is incorrect; rather, it indicates that the empirical covariance structure reproduces the data adequately but not optimally according to conventional statistical benchmarks. In the Italian sample, RMSEA values fall within the acceptable range, suggesting that model approximation error remains within tolerable limits. In contrast, CFI and TLI values fall slightly below the commonly referenced .90 cutoff, while SRMR values exceed preferred thresholds. Taken together, these indices suggest that the factorial structure is broadly supported but that certain item relationships or residual correlations differ from those expected under the original specification.

Importantly, marginal fit should be interpreted comparatively rather than absolutely. The original Croatian validation demonstrated strong structural coherence, while the English validation also reported acceptable but not perfect fit indices, reflecting the complexity inherent in measuring communication satisfaction across organizational and linguistic contexts. The Italian results therefore align with an emerging pattern in which the ICSQ structure remains stable across adaptations, yet minor deviations appear as the instrument enters new cultural environments. Such outcomes are common in multidimensional organizational scales, where contextual interpretations of communication practices inevitably influence response patterns.

From a substantive perspective, the marginal fit may also reflect the inherently contextual nature of internal communication satisfaction. Unlike personality traits or cognitive abilities, communication satisfaction is shaped by organizational norms, managerial styles, and culturally embedded expectations regarding hierarchy, feedback, and information sharing. Consequently, slight departures from ideal model fit can be interpreted as evidence of contextual sensitivity rather than psychometric weakness.

5.2 Interpretation of weaker items in the Italian context

Two items exhibited standardized loadings below the conventional .50 threshold (QICS.11 and QICS.21), indicating weaker associations with their respective latent constructs. While statistically notable, these results should not be interpreted as simple measurement deficiencies; instead, they invite reflection on linguistic and contextual explanations specific to the Italian organizational environment.

The weaker loading of QICS.11 within the organizational integration dimension may reflect differences in how Italian employees interpret organizational information and role clarity. Italian organizational culture has historically emphasized relational coordination and informal communication networks alongside formal structures. Employees may therefore evaluate integration less through explicit informational clarity and more through interpersonal interaction or managerial mediation. If the translated wording emphasizes formal organizational alignment, respondents may interpret the item differently from its intended conceptual meaning.

Similarly, the lower loading of QICS.21 within organizational perspective may indicate cultural variation in perceptions of strategic communication from the organization. Italian employees may experience organizational vision and long-term perspective as mediated through leadership credibility or local managerial interpretation rather than through centralized communication messages. As a result, satisfaction with organizational perspective may overlap conceptually with other relational dimensions, slightly weakening its statistical distinctiveness.

Linguistic factors may also contribute. Even with rigorous back-translation procedures, subtle

semantic shifts can occur when translating evaluative constructs such as satisfaction, clarity, or organizational outlook. Italian language usage often allows broader interpretive nuance, which may increase variability in responses and reduce item–factor alignment without altering the underlying construct itself.

Importantly, the presence of only two weaker items within a 32-item instrument suggests localized rather than systemic measurement issues. The overall loading pattern remains strong, supporting retention of the full scale while encouraging future research to monitor these items across additional Italian samples.

5.3 Comparison with Croatian and English validations

When positioned within the broader validation trajectory of the ICSQ, the Italian findings reinforce the cross-cultural robustness of the instrument. The Croatian validation established the original factorial structure and demonstrated strong psychometric performance within the cultural context in which the scale was developed. The English validation extended the instrument's applicability to an international research environment and confirmed structural stability despite linguistic adaptation.

The Italian validation represents a further step in this trajectory. Consistent with earlier studies, reliability coefficients remain high and the multidimensional structure is preserved. At the same time, the slightly weaker global fit and isolated item deviations illustrate a predictable pattern of incremental variation as the instrument moves across linguistic and institutional contexts. Rather than weakening the scale, this progression strengthens its empirical credibility by demonstrating that the ICSQ retains conceptual coherence while remaining sensitive to contextual differences.

In this sense, the Italian results contribute to cumulative validation evidence: the instrument appears structurally stable across Southern European and Anglo-language contexts while allowing culturally specific response dynamics. Such findings support the use of the ICSQ as a comparative research tool capable of capturing both universal and context-dependent aspects of internal communication satisfaction.

5.4 Analytical reflection on limitations

The limitations of the present study should be interpreted analytically rather than as isolated methodological constraints. First, marginal model fit highlights the tension inherent in cross-cultural measurement between structural invariance and contextual adaptation. While the original structure is retained, the Italian data suggest that communication satisfaction may manifest through slightly different relational emphases, pointing to the need for continued validation rather than structural revision.

Second, the presence of two weaker items underscores the importance of examining semantic equivalence beyond literal translation. Measurement instruments assessing organizational perceptions are particularly sensitive to culturally embedded communication expectations. Future studies should therefore explore whether the observed item behavior reflects linguistic nuance, organizational norms, or sample-specific variance.

Third, reliance on self-reported survey data introduces common-method considerations, yet this limitation is intrinsic to research on satisfaction constructs, which are inherently subjective evaluations. Rather than a methodological flaw, self-reporting represents the appropriate epistemological approach for measuring perceived communication quality.

Finally, although embedded within a broader cross-national research project, the present analysis focuses exclusively on the Italian subsample. Consequently, conclusions concern validation within Italy rather than cross-cultural equivalence testing. Future comparative analyses may further clarify measurement invariance across national contexts.

5.5 Managerial implications and diagnostic use in Italian organizations

Beyond its methodological contribution, the Italian ICSQ offers concrete practical value for organizations. The instrument enables Italian companies to move from descriptive assessments of

communication activities toward systematic diagnosis of employees' communicative experiences.

Specifically, organizations can use the ICSQ diagnostically in several ways. First, the multidimensional structure allows managers to identify strengths and weaknesses across distinct communication domains, such as supervisory communication, feedback processes, media quality, or communication with top management. Rather than relying on general employee climate surveys, organizations can pinpoint which communication processes require intervention.

Second, repeated administration of the instrument enables longitudinal monitoring of communication initiatives. Italian organizations undergoing digital transformation, hybrid work implementation, or organizational change can track whether communication improvements translate into increased satisfaction across specific dimensions.

Third, the ICSQ provides a structured basis for dialogue between communication professionals, HR departments, and leadership. Results can inform targeted managerial training, redesign of feedback mechanisms, or refinement of leadership communication practices. In this sense, the instrument functions not merely as a measurement tool but as a decision-support mechanism.

Finally, the availability of a validated Italian version facilitates benchmarking across organizations and industries. As internal communication continues to institutionalize within Italian companies, standardized measurement can contribute to professionalization of the field by linking communication practices to measurable employee outcomes.

6. Limitations and future research

Future avenues based on the validation of the ICS in Italian include the possibility to explore in the Italian context connections and interrelations among a series of constructs.

Just to mention some that are urgent in the Italian context: the link between the perceived quality of internal communication (ICS) and organizational citizenship / prosocial and proactive safety (communication) behavior; or the link between ICS and the level of employee engagement or DEI communication behavior.

Furthermore, the study on the state of the art of employee communication conducted by CERC at Università IULM in 2025 indicates the priorities of employee communication for Italian companies that deserve more investigation: the digitalization of internal communication, the integration of artificial intelligence, the adoption of the digital workplace in the framework of hybrid work contexts, leadership and informal communication in the context of hybrid workplaces, the change processes. All these topics affect, and their successful implementation is affected, by internal communication satisfaction. Therefore there are avenues for studies considering these correlations that will be relevant both for theory advancement and from a managerial point of view.

From the methodological point of view, in Italy it is desirable to extend the study on internal communication with the typical explorative approach of the organizational communication discipline, mainly by qualitative methods. And at the same time, to improve the number and the value of quantitative studies, expected (although not exclusively) by the disciplines of corporate and strategic communication. The development of validated scales represents the first step and an incentive to proceed in this direction.

7. Conclusions and managerial implications

This study set out to translate and validate the Internal Communication Satisfaction Questionnaire (ICSQ) in the Italian context, addressing a long-standing gap in Italian internal communication research: the absence of a psychometrically validated instrument capable of measuring employees' evaluations of internal communication. The results indicate that the Italian version of the ICSQ largely preserves the original multidimensional structure and demonstrates satisfactory reliability across all eight dimensions. Despite marginal global model fit and minor item-level deviations, the

overall findings support the conceptual coherence and empirical applicability of the instrument within Italian organizations.

From a scholarly perspective, the validation contributes to the cumulative international development of internal communication research by extending the ICSQ validation trajectory beyond its Croatian origin and English adaptation. The Italian findings reinforce the proposition that internal communication satisfaction constitutes a stable multidimensional construct that can be meaningfully assessed across linguistic and institutional environments. At the same time, the observed variations highlight the contextual sensitivity of communication perceptions, confirming that measurement instruments in organizational communication must balance structural stability with cultural adaptability.

The study also contributes to the evolution of Italian internal communication scholarship. Historically, Italian research has focused primarily on organizational structures, managerial practices, and professional benchmarking. While these approaches have significantly advanced the institutionalization of internal communication, they have provided limited insight into employees' subjective experiences of communication processes. The availability of a validated Italian ICSQ enables a shift toward employee-centered empirical research, allowing scholars to examine internal communication not only as a managerial function but also as a perceived organizational environment.

Beyond its academic contribution, the Italian ICSQ offers practical value as a diagnostic and developmental tool for organizations. Internal communication in Italy has increasingly acquired strategic relevance, yet evaluation practices often remain limited to descriptive indicators such as channel usage, communication outputs, or managerial perceptions. The validated instrument allows organizations to systematically assess communication effectiveness from the employee perspective, thereby strengthening evidence-based communication management.

First, the multidimensional structure enables diagnostic analysis of internal communication systems. Organizations can identify which specific communication domains function effectively and which require improvement. For example, relatively lower scores in organizational integration or feedback dimensions may signal insufficient clarity regarding roles, expectations, or performance communication. Such differentiated insights allow targeted interventions rather than generalized communication initiatives.

Second, the ICSQ can support organizational change management**.** Italian organizations increasingly face transformations linked to digitalization, hybrid work arrangements, and evolving leadership practices. Communication satisfaction serves as an early indicator of how employees interpret and accept organizational change. Periodic measurement can therefore help managers detect emerging communication gaps before they translate into disengagement or resistance.

Third, the instrument facilitates managerial learning and leadership development**.** Several dimensions of the ICSQ directly relate to supervisory and top-management communication. Results can inform leadership training programs by highlighting areas where communication behaviors influence employees' perceptions of transparency, accessibility, and support. In this way, communication measurement becomes integrated into broader organizational development processes.

Fourth, the ICSQ provides a foundation for strategic benchmarking**.** As more Italian organizations adopt standardized measurement approaches, comparisons across departments, organizational units, or industries become possible. Benchmarking enables communication professionals to demonstrate the organizational value of internal communication using comparable data rather than anecdotal evidence.

Finally, the instrument encourages a shift from reactive to evidence-informed communication governance**.** By linking communication satisfaction to broader organizational outcomes such as engagement, trust, or well-being, managers can position internal communication as a measurable organizational capability rather than a purely operational activity.

In sum, the Italian validation of the ICSQ represents both a methodological and practical advancement. Methodologically, it confirms the transferability of a multidimensional measure of internal communication satisfaction while illustrating the importance of contextual interpretation in

cross-cultural scale adaptation. Practically, it equips Italian organizations with a structured tool for diagnosing and improving their communicative environments.

As internal communication continues to evolve in response to technological change and organizational complexity, the ability to measure employees' communicative experiences becomes increasingly central. The Italian ICSQ provides a foundation for this development, enabling future research and practice to move toward more systematic, comparative, and evidence-based approaches to internal communication.

Beyond Disclosure: Evidence from the Italian Banking System on the Role of Digital in the Bank–Stakeholder Relationship

MARIA FEDELE[1], IHOR RUDKO[2], AYSAN BASHIRPOUR BONAB[3], VINCENZO FORMISANO[4]

Abstract

Frame of the research. *In this article, we assess how Italian banks disclose digital-related topics in their non-financial reports.*

Purpose of the paper. *In particular, we explore how disclosures of digitalization and digital transformation within the field of Italian banks are related to the three roles that the "digital" plays within the relationship between bank and its stakeholders: enabler, enhancer, and structurer.*

Methodology. *We do it primarily by means of geometric data analysis, a methodology that combines in-depth exploration of geometric space constructed and a subsequent interpretation of resulting relationships and structural homologies.*

Results. *By means of GDA we have constructed and analyzed the structural homologies within the field of Italian banks with respect to how digital types and digital roles are disclosed in banks' non-financial reports.*

Research limitations. *The limitations of our results are related primarily to the interpretative nature of the methodology.*

Managerial implications. *To achieve genuine digital transformation, Italian retail banks should strive to integrate complex market-engaged activities, like private banking and proprietary trading, to evolve into "structurers" of their stakeholder environment while balancing digital growth with the reputational risks of branch closures.*

Originality of the paper. *This research bridges a significant gap in banking management studies by analysing how digital disclosure functions as a holistic positioning strategy within the complex landscape of Italian banking enterprises.*

Keywords: *digital; non-financial reporting; structurer; banks; Italy; geometric data analysis*

1. Introduction

The rapid evolution of the financial services landscape, precipitated by the proliferation of information and communication technologies (ICTs) and accelerated by the post-pandemic digital imperative, has fundamentally altered the relationship between banking institutions and their stakeholders (Bofondi & Gobbi, 2017; Calderon-Monge & Ribeiro-Soriano, 2024; Niemand et al., 2021). While the literature has extensively documented the technical adoption of digital tools, there remains a critical lack of understanding in how these advancements are communicated and strategically positioned within banks' non-financial reporting. This study addresses a significant research gap by investigating the narrative construction of digital strategies within the complex ecosystem of Italian banking. In particular, we analyze how the disclosure of digitalization and digital transformation in banks' non-financial reports can be mapped onto the complex filed/ecosystem of Italian banking institutions as defined by a heterogenous combination of structural, managerial, and institutional factors.

Italy provides a uniquely pertinent context for our research goal due to its heterogeneous banking structure comprising large international groups, regional commercial entities, and deeply rooted cooperative banks. All of the above are currently navigating the transition from the Non-Financial Reporting Directive (NFRD) to the more stringent Corporate Sustainability Reporting Directive (CSRD). Despite the systemic importance of this sector, the disclosure of digital transformation as a non-financial performance indicator remains under researched. Therefore, a proper understanding of

[1] University of Cassino and Southern Lazio, m.fedele@unicas.it
[2] University of Cassino and Southern Lazio, ihor.rudko@unicas.it
[3] University of Cassino and Southern Lazio, aysan.bashirpourbonab@unicas.it
[4] University of Cassino and Southern Lazio, v.formisano@unicas.it

how banks signal their digital maturity to mitigate information asymmetry and secure social legitimacy constitutes an important research gap worthy of further investigation.

To begin with, we posit that there exists a substantial conceptual and empirically grounded distinction between the two categories that are often conflated in the management discourse: *digital transformation* and *digitalization*. We posit that digitalization entails tactical enhancements to operational efficiency (Pagani & Pardo, 2017), whereas digital transformation signifies a holistic, strategic shift that redefines a bank's value proposition (Naimi-Sadigh et al., 2022). We also explore how these two distinct categories are related to the three roles that the "digital" plays within the relationship between banks and their stakeholders: enabler, enhancer, and structurer. In brief, a bank that is engaged in the enabler's role focuses on providing access by means of digital tools, including removing physical barriers and creating new touchpoints between the institution and customers (Plekhanov et al., 2023; Zachariadis & Ozcan, 2022). The role of enhancer focuses on quality of said relationship, including increasing frequency of interactions, the build-up of trust, and personalization of services (Chandna & Ubba, 2026; Lóska & Uotila, 2024). Finally, the most important role with respect to the digital transformation aspects is that of structurer which focuses on redefining the very ecosystem of bank by means of digital tools (Baptista & Nunes, 2026). Our research synthesizes these fragmented perspectives into a cohesive typology to analyze the strategic "roles" of digital disclosure in bank's non-financial reports.

As our study is largely an in-depth exploration of a complex ecosystem of Italian banks with respect to both the role and the type of "digital" that these disclose in their non-financial reports, we do not rely on an a priori hypothesizing. Instead, the primary goal of our article can be better expressed in the form of a research question that we try answering by means of advanced exploratory techniques.

RQ. How do digital transformation and digitalization relate to the three roles of "digital" within the relationship between Italian banks and their stakeholders, and how do these categories jointly interact within the complex field of Italian banking institutions?

The originality of the work is threefold: it introduces a Bourdieusian perspective into the management studies of banking companies. In this respect, it allows digital transformation to be interpreted not as a merely technical choice or isolated organizational variable, but as a positioning strategy within a structured space of relationships, capital and institutional actors. In addition to enriching the literature on digital dissemination and banking management studies, the paper adopts a structural perspective on the banking field, highlighting the gap between transformation narratives and actual practices and identifying the conditions in which digital transformation becomes a positioning strategy in the Italian banking system. Second, only a small number of studies have so far analyzed the disclosure of "digital" in banks' non-financial reports (Bernini et al., 2022; Diener & Špaček, 2020; Shehadeh, 2025). Our study, therefore, is one of the few existing tapping into this important research gap. Finally, the methodology of geometric data analysis (GDA), although particularly suitable for the study of complex system-level interactions, is not yet widespread within business and management research. Indeed, it has been, so far, applied mostly within sociology for the construction and understanding of homologies within complex social fields (Boelaert & Ollion, 2025). We posit that a proper systemic view of a complex phenomenon **(**Barile & Saviano, 2011), like that of "digital" disclosure within a diverse field of banking institutions call for a methodology that intentionally disregard "the most parsimonious model" approaches of standard inferential statistics but instead treat complexity holistically. Coincidentally, this is precisely what GDA strives to accomplish (Roux & Rouanet, 2004).

We start with a brief literature review that elaborates more in-depth on the above concepts. In particular, we emphasize the conceptual distinction between digital transformation and digitalization, outline the difference between the three digital roles and review how the "digital" is approached in non-financial reporting of Italian banks. Then, after a detailed description of how we constructed the sample, we proceed with exploring the geometric space of Italian banks with respect to the digital role and the digital type categories. We conclude the article with a detailed discussion and implications of our results for both practitioners and researchers.

2. Literature review

2.1 Digitalization and digital transformation: similarities and differences

In recent years, among the challenges that have led to in-depth changes in traditional business models, operational processes and stakeholder relations, a particularly important role has been played by the rapid proliferation of digital technologies (Bofondi & Gobbi, 2017; Calderon-Monge & Ribeiro-Soriano, 2024; Niemand et al., 2021). In this scenario, the banking sector represents a significant example when rapid digital development has taken place that has led to a profound change in the ways in which banks offer cutting-edge products and services (Akatkin et al., 2017). Concerning the digital, however, it is necessary to make a conceptual distinction between the term digitization and the term digital transformation.

Digitalization concerns the conversion of data into digital format and the use of information technologies to improve the efficiency of existing processes (Pagani & Pardo, 2017). Furthermore, according to Nguyen et al. (2023), the bank digitalization is the incorporation of digital technology into all banking areas that alters the way banks operate and communicate with customers.

Digital transformation, instead, represents a broader and more strategic change: a process through which digital technologies generate discontinuities that push organizations to review their value creation methods, while addressing structural changes and organizational resistance that influence their outcomes (Vial, 2019). In addition to all this, digital transformation facilitates the disclosure of corporate social responsibility activities, increasing a relationship with stakeholders based on greater trust, transparency, and credibility.

The difference, therefore, is substantial and is isomorphic to a broader distinction between any kind of organizational change and the disruptive innovation (Schilling, 2013). In other words, digitalization implies any advancement in the usage of digital tools in the banking sphere, be it creation of an online platform, an introduction of a chatbot at the level of customer service, etc. Conversely, digital transformation, definitionally, implies an out-of-scale change brought about by the introduction and proper strategic leveraging of digital tools, for instance, a shift toward agenetic AI (Elgendy et al., 2025), embedded finance (Hensen & Kötting, 2022), and digital assets (Loukil et al., 2025).

This distinction is also relevant at the level of banks' non-financial reporting. In contemporary banking literature, a critical distinction is maintained between digitalization and digital transformation, though the terms are frequently conflated in casual discourse. Digitalization refers to the tactical integration of digital technologies into existing business processes to enhance operational efficiency and data accessibility (Diener & Špaček, 2020). In a non-financial banking report, this typically manifests as the automation of manual back-office tasks or the transition from paper-based records to digital databases. Conversely, digital transformation represents a holistic, strategic shift that redefines the bank's entire value proposition and organizational culture (Naimi-Sadigh et al., 2022). It is not merely an upgrade of legacy systems, but a fundamental reimagining of how the banking institution engages with customers and generates revenue in a platform-driven economy (Alqararah et al., 2025; Verhoef et al., 2021). While digitalization optimizes the current business model, digital transformation creates a new one, often leveraging artificial intelligence and ecosystem partnerships to move beyond traditional transactional banking toward integrated financial experiences. As such, the banks able to advance a proper digital transformation act as *structurers* able to redefine and guide their entire ecosystem by means of innovative and strategic use of digital tools (Baptista & Nunes, 2026). As a result, while digitalization affects short-term technical and operational processes, a profound cultural change (also based on learning) is needed for a digital transformation that can support a long-term evolutionary dynamic (Nadkarni & Prügl, 2021).

2.2 The three roles of "digital" within the relationship between bank and its stakeholders

In order to empirically interpret how "digital" affects the relationship between the bank and its stakeholders, in this article we primarily rely on the affordance perspective (Faraj & Azad, 2012;

Leonardi, 2011), which highlights how technology can produce different effects depending on how it is integrated into organizational practices. Following this theory, we conceptualize that the "digital" can be considered an infrastructure that can act as an *enabler, enhancer,* or *structurer* with respect to the relationship between the bank and its stakeholders.

It acts as a relationship *enabler* because it fosters the activation of previously nonexistent relationships through new touchpoints (home banking, apps, chatbots, etc.), or that were before objectively infeasible due to the lack of physical proximity (Lemon & Verhoef, 2016; Magatef et al., 2023). It also fosters customer loyalty, which demands increasingly advanced and high-quality products and services (Schmidt et al., 2017), reduces coordination/control costs, and fosters collaborative relationships based on trust (de Reuver et al., 2018; Papathomas & Konteos, 2023; Plekhanov et al., 2023; Zachariadis & Ozcan, 2022).

When it comes to the role of *enhancer*, in addition to creating relationships, digitalization strengthens existing ones through personalized and more frequent interactions, leveraging the benefits of the integration between physical and digital channels (Chandna & Ubba, 2026; Lóska & Uotila, 2024). All of this is reinforced by the needs of customers who increasingly demand sustainable products and services (Taneja et al., 2024).

To all the above we must add that digital technologies act as a *structurer* of the relationship because they broaden the operating environment, organize it in a systemic and stable perspective, transforming the network of stakeholders, the roles and stimulating the creation of digital platforms and ecosystems (Baptista & Nunes, 2026).

In this respect, we posit that assuming the role of *structurer* is crucial so that a proper digital transformation can take place as the two are definitionally linked (i.e., digital transformation entails the restructuring of an entire organizational field, including the very relationships with stakeholders by means of ICTs). However, we do not exclude that some banking institutions could be tempted to bring about *digital transformation* topic in their non-financial reports in an elaborated attempt at the institutional entrepreneurship in order to convince the stakeholders that actual transformative activities are taking place when what is actually happens is mere digitalization processes (Beloglavec & Zdolšek, 2026; Mihaylova & Blumer, 2025).

2.3 Digitalization and digital transformation in the non-financial reporting of Italian banks: A Signaling and Legitimacy Perspective

Given the multiple pressures, including the obligation of compliance, the demands of the market and the unremitted pace of technological development, including that of ICTs and AI (Todupunuri, 2025), the complex ecosystems of EU banking institutions has, for year, been undergoing in-depth structural transformation (Stefanelli & Manta, 2023). This is primarily true with respect to the European regulatory framework for reporting that, over the last two decades, has undergone a substantial evolution, also with respect to banking institutions which, due to their importance, has been increasingly subject to ever stricter non-financial reporting constraints (Biancone et al., 2025). In the Italian context, non-financial reporting has been reshaped by the transition from the Non-Financial Reporting Directive (NFRD) to the Corporate Sustainability Reporting Directive (CSRD). This shift significantly expands the population of entities subject to reporting requirements and mandates the use of European Sustainability Reporting Standards (ESRS) to harmonize and enhance the quality of sustainability-related data (Biancone et al., 2025; Veltri, 2023). Moreover, it has expanded the typology of banking entities that are required to report under the guise of the European Sustainability Reporting Standards advanced by the European Financial Reporting Advisory Group (Fedele et al., 2025).

Among heterogenous themes and topics that banks chose to disclose in their non-financial reports, the disclosure of digitalization and digital transformation processes and strategies is among the most prominent and important (Mohsen et al., 2024). Such disclosure, indeed, often reflects the level of digital maturity of a banking entity and the related ability of the upper management to navigate complex processes of organizational change (Mohsen et al., 2024; Niehoff, 2022).

This perspective is perfectly aligned with signaling theory (Connelly, et al., 2011; Spence, 2002). According to Spence (2002), for companies (including those in the banking sector) non-financial disclosure takes on the role of information with a multidimensional value: as a strategic tool, to communicate to the market (including all relevant stakeholders) their long-term strategic vision, their skills and their financial stability. A primary intent, therefore, is to stand out from the competition, improving the perception of primary stakeholders, mitigating the existing conditions of information asymmetry and therefore the uncertainty perceived by the market (Diebecker & Sommer, 2017; López-Santamaría et al., 2021).

To strengthen the interpretative key, signaling theory must be associated with legitimacy theory. According to the latter, the non-financial report, in addition to reducing information asymmetries, actively contributes to the creation and strengthening of the social legitimacy of the banking enterprise. Conversely, it is well known that organizations prepare the content of their reports in accordance with the values, regulations, regulatory and social expectations of the reference context to ensure business continuity and to build consensus around their strategic choices. From this perspective, disclosures on digitalization and digital transformation in banks' non-financial reports may function not only as accounts of technological change but also as instruments of symbolic transparency and legitimacy seeking, potentially widening a digital disclosure-practice gap (Tariq, 2025).

3. Sample and methods

The data collection proceeded in several steps.

To construct the initial pool of observations, we downloaded the list of banking enterprises operating on the Italian territory from the Banca d'Italia site. Subsequently, the 339 banking enterprises were divided into those that belonged to a banking group and those that were independent (i.e., not a part of a banking group). The decision to discriminate between the two categories comes from the fact that banks that are the part of banking groups share consolidated financial statements, including the respective non-financial statements. Subsequently, we have excluded banking enterprises that, at the time of the issuing the report, did not yet follow Corporate Sustainability Reporting Directive (CSRD) that reinforced the reporting standards also for the banks already under the Non-Financial Reporting Directive (NFRD). This selection criterion reduced the initial sample size to 257 banking enterprises. From these, given the high cost of manually going through the entirety of non-financial, we have selected a random sample of 50 banks. The respective non-financial reports were then downloaded directly from the official repositories (i.e., banks' own websites).

The selection of this sample was motivated by the need to analyze the leaders of the Italian banking sector who are currently fully transitioned toward new reporting standards. By focusing on banks already adhering to the Corporate Sustainability Reporting Directive (CSRD), we aimed at capturing the most up-to-date practices of digital disclosure which, we posit, provides a more adequate benchmark for the industry's strategic direction compared to a hypothetically diluted overview of smaller entities with minimal reporting requirements. The year 2024 was selected as the primary observation period because it represents a pivotal "year zero" for mandatory sustainability reporting under the CSRD framework. This allows for the analysis of digitalization and digital transformation discourse at its most mature and regulated stage, ensuring that the qualitative data extracted reflects current strategic priorities of Italian banking sector.

To acquire basic structuring information about Italian banking field for the successive exploratory and confirmatory data analyses, we relied on the secondary data consisting of both quantitative and qualitative variables denoting heterogenous structural, managerial, and institutional characteristics of banks. In particular, the acquisition of qualitative and quantitative data (location of registered office, legal form, specialization, number of branches and rank with respect to assets) for the construction of

the dataset was carried out using the Moody's-Orbis database (Bureau van Dijk), which provides structuring information acquired from official and verified sources.

We then proceeded to complement the obtained dataset with additional structuring information. In particular, we have coded the specialization for each bank (*specialization* variable) in line with taxonomy as proposed by Qi et al. (2025) who divided banks into three macro categories: commercial banks, cooperative banks, and non-depository institutions (each of these are further divided into sub-categories some of which were pertinent to our sample, see Table 1). Likewise, the information about banks' business models has been obtained following Savona's (2024) taxonomy distinguishing focused retail business model, diversified business model, market engaged business model, and wholesale-retail business model (for their further explanations see Table 1).

Finally, the information on whether banks emphasize digitalization or digital transformation in their non-financial reports and what kind of role the "digital" play in the relationship between banks and their stakeholders was collected by means of a qualitative content analysis (QCA) (Krippendorff, 2018). QCA is a systematic research method used to interpret the meaning of text data. Unlike quantitative analysis, which focuses on counting words or frequencies, QCA dives into the context, nuances, and themes within (written) communication. It is widely used in social sciences, marketing, and healthcare to analyze interviews, focus groups, open-ended surveys, or media content (Vourvachis & Woodward, 2015), as means to classify information in determinate categories (Guthrie et al., 2004). Moreover, lately, it has been increasingly popular and validated within business and management studies (Gaur & Kumar, 2018; Lock & Seele, 2015; Ruel, 2017), including in analyzing non-financial reports of banks in the context of Italy (Pesci & Costa, 2014).

In particular, the fifty non-financial reports were then imported into qualitative data analysis software (MAXQDA, version 24.11.1) where we have subsequently carried out the QCA. Particularly, to simplify the procedure, we have searched the term "digital" in all texts simultaneously. The total number of occurrences extracted was 4948. Upon eliminating duplications and non-pertinent text segments, 2801 text snippets were manually assessed and analyzed. In particular, we have applied deductive coding (Fife & Gossner, 2024). As such, the coding categories were defined in advance and then reported in the respective coding manual to which all the coders subsequently adhered.

Particularly, at the upper level, the coding categories distinguish between the type of the "digital" processes and strategies as reported in non-financial reports (*digitalization* vs *digital transformation*) and the role that these are playing within the relationship between banks and their stakeholders (*enabler*, *enhancer*, and *structurer*). While the more detailed description of five lower-level categories is provided in the *Literature Review* section, Table 1 recapitulates the essential information about all the variables used for the subsequent analyses as well as in which analyses these were used.

Table 1: Variables used in subsequent analyses. Source: own elaboration

Where used	**Variable**	**Modalities/values**	**Explanation**
Active variables in MCA, structuring variables in ascending hierarchical clustering	*business_model*	*diversified SI* *focused-Retail* *market-Engaged* *wholesale-Retail Hybrid*	Diversified: these institutions function within global markets, primarily focusing on issuing loans that are funded through a combination of retail deposits and various debt securities. Focused retail: these banks concentrate on their home market, centering their business model on conventional banking activities such as gathering deposits and providing credit to local customers. Market-engaged: these entities prioritize investment activities in stocks and bonds alongside interbank lending, frequently engaging in cross-border financial operations. Wholesale-retail hybrid: these organizations bridge the gap between sectors by facilitating large-scale financial deals conducted among professional market participants and institutional entities.

	specialization	*Bank holding company* *Commercial bank* *Cooperative bank* *Investment bank* *Savings bank*	Bank holding company: a central corporate entity that maintains a majority stake in one or more banking institutions without directly offering financial services to the public. Commercial bank: a mainstream financial provider dedicated to managing business and consumer accounts, issuing loans, and offering various banking products to the general population. Cooperative bank: a financial organization owned by its members, who act as both clients and shareholders to democratically manage the institution for improved rates and mutual benefit. Investment bank: a specialized firm that assists governments and large corporations in securing capital through security underwriting, issuance, and strategic guidance on mergers and acquisitions. Savings bank: an institution centered on individual consumer banking, primarily focusing on the collection of personal deposits and the provision of residential mortgages and small-scale financing.
	location	*south* *center* *north*	The geographic location of the headquarters in Italy.
	legal_form	*S.C.p.A* *S.P.A* *Soc. Coop*	Società Consortile per Azioni. Analogue to Joint Venture (JV) Corporation or a Consortium Company. Società per Azioni. Analogue to PLC and Inc. Società Cooperativa. Analogue to Co-operative Society and Co-op.
	rank_quart	*very low* *low* *high* *very high*	Country rank by assets. This qualitative variable was transformed into categorical according to bank's position with respect to four quartiles of related quantitative variable.
	branches_quart	*very low* *low* *high* *very high*	The overall number of branches. This qualitative variable was transformed into categorical according to bank's position with respect to four quartiles of related quantitative variable.
Supplementary variables in MCA, Variables used in chi-square independence testing of respective contingency table	*digital_type*	*digitalization* *digital transformation*	Digitalization refers to the tactical integration of digital technologies to automate existing processes and improve efficiency, such as transitioning from paper records to digital databases or launching a mobile app. Digital transformation is a holistic, strategic shift that redefines the bank's entire business model and culture, leveraging technology to create entirely new value propositions and customer-centric ecosystems.
	digital_role	*enabler* *enhancer* *structurer*	Enabler: focuses on access (removing physical barriers and creating new touchpoints like apps). Enhancer: focuses on quality (increasing frequency, trust, and personalization). Structurer: focuses on framework (redefining roles and building entire digital ecosystems).
Quantitative variables used in multinomial logistic regression	*rank_assets*	discrete variable	Overall rank of the bank by assets in Italy. Should be read in reverse: higher values indicate lower rank.
	world rank assets	discrete variable	Overall rank of the bank by assets globally. Should be read in reverse: higher values indicate lower rank.
	branches	discrete variable	Number of branches that bank has.
	focused-retail	binary variable	A dummy variable coding whether bank's business model is retail focused (= 1) or no (= 0)

Source: own elaboration

From the initial 2801 coded snippets, we then only selected those jointly reporting information both on the type of the "digital" disclosure (digitalization and digital transformation) and the role that digital play in the relationship between banks and its stakeholders (enabler, enhancer, structurer). In total, 224 segments were extracted. It is also worth noting that while 224 coded segments and the related information about 50 banks entered the dataset, because of the methodological constraints of multiple correspondence analysis (see the following section), we had to eliminate rows with missing values in order to proceed. Accordingly, 20 rows (each denoting an information about particular extract from the non-financial report and the respective structuring information about the bank) were eliminated. In the final instance, 204 coded segments and the complementing structural, managerial, and institutional information about banks entered the analysis.

4. Results

In order to explore what types of homologies exist between digitalization/digital transformation themes in banks' non-financial reports and the structural, managerial, and institutional factors of those banks, we performed a multiple correspondence analysis (MCA) as it is applied within the framework of geometric data analysis (GDA) (Hjellbrekke, 2018; Roux & Rouanet, 2004). In particular, MCA is a dimensionality reduction technique similar to principal component analysis (PCA) but applied exclusively to the categorical data (both nominal and ordinal, as in our case). What makes its application unique within the framework of GDA is a specific kind of reasoning that prioritizes in-depth exploration of the resulting clouds of individuals and modalities and how these can be interpreted given the additional structuring information projected onto them. In brief, one reason in terms of complex homologies between heterogenous clusters of variables (Hjellbrekke, 2018).

In our case, six variables (Q = 6) entered the analysis as active variables, meaning that their modalities (K = 26) contributed to the creation of the geometric space of Italian banks. The active variables included *business_model, location, rank_quart, legal_form, specialization,* and *branches_quart.* Two variables (*digital_type* and *digital_role*) with two modalities each were chosen as supplementary, hence, these did not contribute to the definition of space but were subsequently used to reveal the presence of homologies between the type of "digital" initiatives as discussed in the non-financial reports / the three identified roles that "digital" play in a bank's relationships with stakeholders and the underlying plethora of structural, managerial, and institutional factors that, conversely, actively contributed to the creation of the geometric space of Italian banks.

After running the PCA, a representation over the first two axes was considered optimal. Indeed, according to the common criterion, the number of dimensions sufficient for the interpretation in MCA should cumulatively explain at least 80% of (adjusted) variance (Hjellbrekke, 2018). The latter is expressed in terms of Benzécri's modified rates which are a correction to eigenvalues necessary to account for the mathematics of MCA (essentially, MCA creates a high-dimensional space that tend to inflate the total unadjusted inertia). In our case, the first two dimensions cumulatively accounted for 85.7% of modified inertia rates (see Table 2).

Table 2: Eigenvalues and explained inertia. First two dimensions. Q = 6, K = 26

Dim	Eigenvalue	Var	Benzécri's modified rates	Cum%
1	0.721	20.6	73.7	73.7
2	0.390	11.2	12	85.7
3	0.328	9.4	6.2	91.9
4	0.298	8.5	4.1	96
5	0.272	7.8	2.6	98.6
6	0.238	6.8	1.2	99.8
7	0.190	5.4	0.1	99.9
8	0.167	4.8	0.0	99.9

Source: own elaboration

To interpret the two dimensions, it is useful to look at which categories has contributed the most to the creation of the two axes. In particular, these are modalities of active variables with more than an average contribution to the definition of axes (i.e., >1/K; hence > 3.8% in our case). Table 3 reports these categories and their contributions as well as respective coordinates on the graph of modalities/categories.

Table 3: Modalities with more than average contribution to the construction of axes.

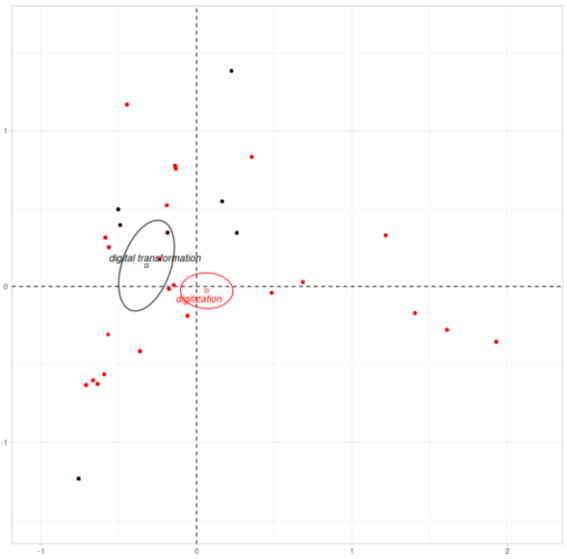
Dim. 1 (+)	**Ctr**	**Coord**	**Dim. 1 (-)**	**Ctr**	**Coord**
specialization: Cooperative bank	15.6	1.9	business_model: Diversified SI	4.5	-0.79
legal_form: S.C.p.A	15.4	2.06			
rank_quart: very low	12.6	1.42			
branches_quart: very low	9.5	1.24			
location: south	9.4	2.27			
business_model: focused-retail	7.8	0.93			
Dim. 2 (+)	**Ctr**	**Coord**	**Dim. 2 (-)**	**Ctr**	**Coord**
rank_quart: low	13.7	1.09	branches_quart: very high	15.1	-1.15
branches_quart: very low	13.3	1.2	rank_quart: very high	11.4	-1.17
business_model: Market-Engaged	11.7	1.35	specialization: Commercial Bank	10.1	-1.164
			business_model: Diversified SI	8.4	-0.79

Source: own elaboration

In brief, the most contributing (first dimension) opposes local cooperative banks on it positive side (Dim1+) and those with diversified business model (and hence with marked international presence) on the negative side (Dim1-). The second dimension, in turn, opposes small banks with low number of branches that are leaning toward market-engaged business model (Dim 2+) and large commercial banks with high rank and high number of branches (Dim2 -).

We have then proceeded with the exploration of likely homologies between types of "digial" disclosed in non-financial reports and the structural characteristics of the banks. We have therefore projected two supplementary variables (*digital_type* and *digital_role*) onto space reporting the cloud of individual observations (i.e., single coded segments). The results are shown in Figure 1 and Figure 2.

Figure 1: Structural homology and confidence ellipses. "Digital" type.



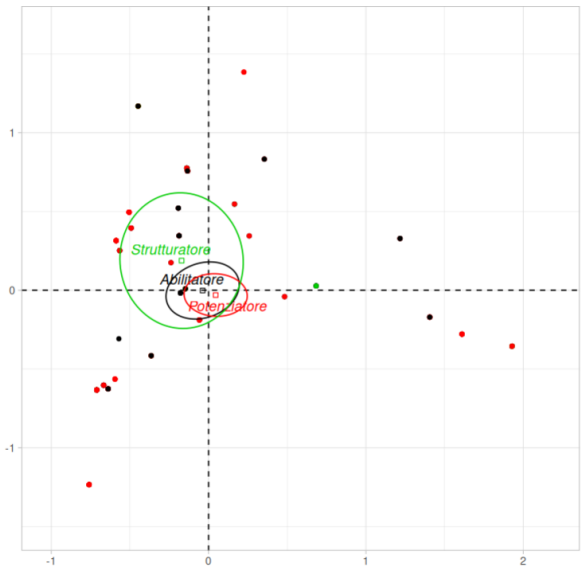


Figure 2: Structural homology and confidence ellipses. "Digital" role.

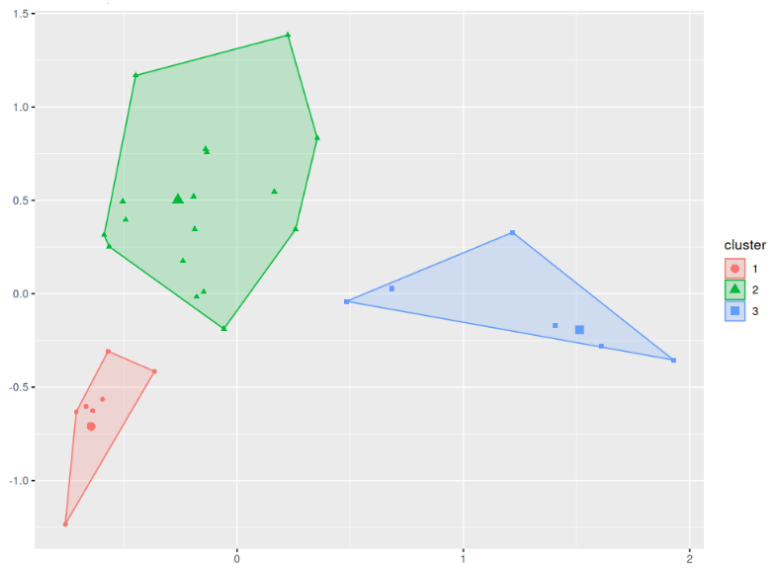
Source: own elaboration

Figures 1 and 2 depict the local barycenters pertinent to the respective categories of supplementary variables as well as confidence ellipses around them. The barycenters as such denote local centers of "gravity" around which observations with that specific profile tend to be located. Accordingly, even if supplementary variables did not partake in the definitions of the axes, what we might observe is a certain homological tendency between specific profiles of banks within the space (as identified by the combination of structural, managerial, and institutional factors that defined the very space) and the characteristics captured by the supplementary variables. Conversely, confidence ellipses denote areas of uncertainty around the position of a category's true mean point. Substantially, these are the extensions of confidence intervals to the two dimensions. As in the case of confidence intervals, overlapping ellipses suggest that there is no statistically significant distinction between banks' profiles with respect to the projected categories of a supplementary variable.

This, indeed, was the case for the *digital_role* variable whose modalities had overlapping confidence ellipses (Figure 2). On the contrary, *digital_type* variable turned out to be of homological-structuring importance. As can be seen in Figure 1, the local barycenter for "digitalization" almost coincided with the global barycenter (denoting a hypothetical bank with the "average" profile of factors). Hence, the most typical bank Italian bank in terms of its profile (as structured by the six factors as described above) is not that different from a bank that mentions "digitalization" in its non-financial reporting.



Yet, the case is opposite for banks that emphasize "digital transformation" in their non-financial reports. The two modalities are indeed significantly different (at 5% level), as suggested by non-overlapping confidence ellipses. Moreover, the confidence ellipse for the "digital transformation" category does not intersect the origin of axes, suggesting that respective bank profiles are more idiosyncratic and, therefore, are different from a factor profile of an "average" Italian bank. Given the position of the local barycenter for the "digital transformation" category (upper left quadrant), the types of banks that tend to emphasize digital transformation in their reports are therefore defined in terms of following combination of variables (see Table 3):

Dim 1(-): *business_model: Diversified SI*

Dim 2(+): *rank_quart: low, branches_quart: very, low business_model: Market-Engaged*

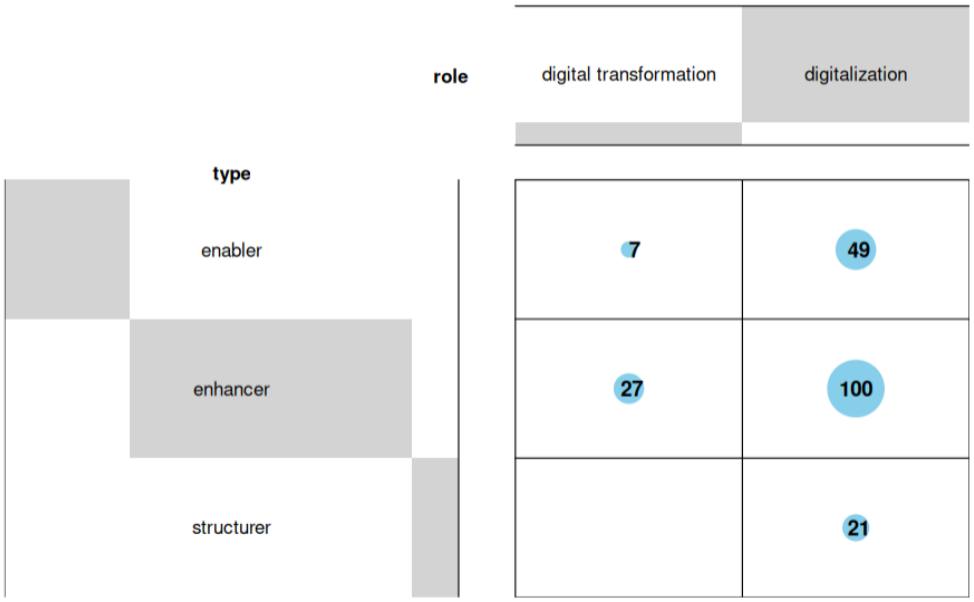
To better understand the unique profile of "digital transformation"-leaning banks, we performed an ascending (agglomerative) hierarchical clustering (AHC) on the results of MCA. This, indeed, is a common supplementary procedure in GDA to enhance the interpretation of its results (Roux & Rouanet, 2004). In particular, we have combined Ward's Method with Squared Euclidean distance measure, as is standard in AHC (Hjellbrekke, 2018). Ward's method minimized the total within-cluster variance by joining the clusters in a way that the result in the smallest possible increase in the sum of squared errors. The number of clusters to retain for further interpretation was calculated automatically by the software (*Factoshiny* package in R) (Vaissie et al., 2025) by setting the cut-off point at the level immediately before the disproportionate "jump" in variance resulting from the ascending merging of clusters. Three clusters of banks were identified in this manner (Figure 3).

Figure 3: Three clusters projected onto MCA plane.

Source: own elaboration

By observing the disposition of resulting clusters on the factor map in Figure 3, and by confronting it with the results in Figure 1, we might conclude that banks in cluster 2 (the green one in Figure 3) match most closely the profile of banks that engage in "digital transformation" according to their respective reports. To understand what kind of banks are these, it is useful to see what categories have contributed the most to the definition of the second cluster. Table 4 shows the most contributing categories to the composition of three clusters.

Table 4: Top 5 most contributing categories in each cluster (p.value < 0.05).



cluster 1 (+)	**cla/mod**	**mod/cla**	**global**	**cluster 1 (-)**	**cla/mod**	**mod/cla**	**global**
branches_quart: very high	100	90	26.47	business_model: Focused-Retail	0	0	39.21

branches_quart_low	70.91	90.7	26.9	business_model: Diversified SI	0	0	31.37
business_model: Focused-Retail	53.75	100	39.26	rank_quart: rank_quart_low	0	0	26.96

Source: own elaboration

As can be seen in the table, cluster 2 is composed by middle-to-low ranked banks (by assets) with either high or low number of branches whose headquarters are typically located in North of Italy, and whose business model is focused on equity and bond investments and interbank transactions, including international transactions (i.e., Market-Engaged business model). These, according to the homology revealed by MCA, are also more prone to mentioning "digital transformation" in their non-financial reports.

While GDA did not reveal homologies between the three roles of the "digital" in the relationship between bank and its stakeholders, and bank's combination of structural, managerial, and institutional factors, a secondary relationship between the two can still be deduced by looking at the distribution of *digital_role* supplementary variable with respect to the *digital_type* variable (that is itself constitutive of a homology as described above). The two categorical variables, indeed, resulted significantly associated as revealed by the Pearson's Chi-square test (X-squared = 6.8291, df = 2, p-value = 0.03289). Figure 4 displays the respective balloon plot. It is worth noting that the numbers inside each cell do not stand for individual banks but rather for the number of coded segments displaying that particular combination of two categories.

Figure 4: Digital role and digital type. Balloon plot.

Source: own elaboration

Across all three roles digitalization is significantly more common than digital transformation. Among the three roles, enhancers are most frequently associated with this category (100 coded instances). These are followed by enablers (49) and structurers (21). Notably, all three roles are covered when it comes to more digitalization. This is not the case when it comes to digital transformation. In fact, while enhancer is still the most frequent associated role (27 coded segments) followed by enabler (7 segments), the role of structurer is entirely absent in the analyzed sample. Hence, structurer appears to be the role strictly confined to digitalization and, as such, it represents a domain of theoretical possibility concerning digital transformation activities.

To reiterate, digital technology acts as a structurer when it moves beyond simple interaction and begins to redefine the very organizational landscape, for instance, by means of expanding operating environment, systematic organization, network transformation and creation of ecosystems. Yet, surprisingly, given the definitionally transformative nature of such activities, no coded segment in the dataset was jointly defined by "digital transformation" type and the "structurer" role.

Given this practical gap and the respective space of theoretical possibility that it opens, it is also interesting to understand what kind of structural change would be needed for "digital transformers" to be able to switch the roles from enables to structurers and from enhancers to structurers. To explore this, we run a multinomial logistic regression with digital role as a dependent variable (three modalities: *enabler*, *enhancer*, and *structurer*) and considering structurer as a reference level. The covariates were quantitative variables denoting the number of branches, bank's global rank by assets, Italian rank by assets, and the dummy variable denoting whether the bank is focused on retail or not (1 = retail-focused). Choosing structurer as the reference level substantially means that the statistical model is "standing" on the structurer category to look at the other two. Hence, every coefficient in the output is telling how a specific characteristic moves a bank away from being a structurer and toward being an enabler or enhancer. The results, however, can be interpreted in the opposite direction.

To begin with, a low R-squared does not mean the model is necessarily unfit. If predictors have significant p-values ($p<.05$), the model is still successfully identifying statistically significant relationships, even if it doesn't predict every outcome perfectly. This is rather expected in our case, as there is a degree of underlying structural complexity behind the data, as reified in a banking ecosystem whose determinations cannot, in any case, be determined by only few key variables. Indeed, since the value of R-squared is 0.0295, it merely indicates that while the model has identified real trends, there are many other factors not included in the model that influence a bank's digital role.

Among the factors (i.e., covariates) analyzed, however, only one respective coefficient turned out to be statistically significant: that of the *focused-retail* variable denoting whether the bank's overall business model is retail oriented (= 1) or not retail oriented (= 0). This is valid however, only for the passage from structurer to enabler and viceversa. Hence, nothing can be concluded given the data when it comes to the structurer-enhancer path.

Source: own elaboration

To recapitulate, banks that tend to emphasize digitalization in their non-financial reports have significantly different distribution of three roles (enabler, structurer, enhancer) than those banks that emphasize digital transformation. In particular, while in the role of enhancer is most predominant for two digital types (digitalization and digital transformation) followed by enabler, the role of structurer is absent with respect to "digital transformation" types. This gap, therefore, represents a theoretical possibility for banking enterprises engaged in digital transformation activities. In particular, a multinomial linear regression suggests one possible path from the enabler to the structurer role: the

incorporation of additional non-retail elements in their business models. This result can also be interpreted in reverse: enterprises that already perform the role of structurer (both with respect to digital transformation and digitalization categories) can reinforce their "enabler" roles by incorporating more retail-focused elements in their business models.

5. Discussion

Since we have relied on a complex set of methodological tools to explore the field of Italian banks with respect to how these approach the "digital" in their non-financial reporting, a brief summary of the results is useful when it comes to the proper discussion. To begin with, the results of multiple correspondence analysis within the framework of geometric data analysis (Roux & Rouanet, 2004), revealed a significant structuring factor according to which the complex geometric space of Italian banks can be described and understood: the distinction between digitalization and digital transformation in non-financial reports. Particularly, banks that emphasize mere digitalization processes and strategies in their reports are similar in their profiles to an "average" bank profile as revealed by MCA. Hence, digitalization emphasis is common and more or less equally distributed within the complex filed of Italian banking institutions. Conversely, banks that emphasize a more in-depth and consequential digital transformation (in terms of the very re-structuring of the field of banking institutions around digital technologies), tend to follow a more idiosyncratic factors profile. A joint reading of the results of MCA and that of ascending hierarchical clustering (in particular, the composition of the cluster two) show precisely what characteristics of their profile apropos the average profile of an Italian banking institution are distinct and, hence, stand out. In particular, banks that engage in digital transformation narratives in their non-financial reports are precisely banks with low number of branches, located mostly in Northern Italy that typically follow a market engaged business model. Accordingly, these are the banks that move away from the traditional banking models and position themselves as a bridge between corporations and capital markets. The particularities of their business model also explain (and correlates) with the low number of branches: rather than focusing on a vast network of local branches, these types of banks prioritize investment banking, private banking, and sophisticated proprietary trading.

One possible explanation worthy of further academic exploration is that these banks use digital transformation as a legitimacy tool. Because they lack the physical presence that individuals traditionally associate with banking security (Mammah & Ohazurike, 2025), they might use the non-financial reports to emphasize that their digital infrastructure makes them more modern, efficient, and globally connected than the traditional regional banks. Moreover, the results hint at the (unsurprising) "digital divide" (Bergantino et al., 2025; Gioacchino et al., 2015; Lera-Lopez et al., 2021) within the country, as, according to the literature, banks in Northern Italy tend to (1) invest more in R&D, which is necessary for a proper digital transformation activities (Garavaglia, 2014), (2) face higher labor costs pushing them toward "digital transformation" narratives to ensure profitability by successfully adopting a low-branch model. The latter dynamic, indeed, has been recently confirmed by the report of Banca D'Italia on the reduction in bank branches and rising digital reliance (Marini et al., 2025).

When it comes to the three roles that the "digital" plays within the relationship between banks and their stakeholders, no direct structural homology was found with respect to the field of Italian banks as constructed thorough MCA. However, we have detected one such structural homology indirectly, by relating the two digital types as discussed above (*digital transformation* and *digitalization*) and the three roles as distributed across the non-financial reports of banks (*structurer*, *enhancer*, *enabler*) via a contingency table. According to the Chi-square test of independence, the two variables, denoting respectively, digital type and role, were deemed dependent across their modalities. In particular, the distribution of roles remains similar across the modalities of *digitalization* and *digital transformation;* however, in absolute terms, across all three roles, *digitalization* is significantly more common than *digital transformation.* More interestingly, all three roles are fully represented with respect to

digitalization narratives in non-financial reporting. Yet, when it comes to *digital transformation,* the role of structurer is entirely absent and, hence, it remains a theoretical possibility not yet fully practiced by banks pursuing digital transformation.

To recapitulate, the role of structurer in the relationship between the "digital" and bank's stakeholders consists in broadening, by means of advanced ICT tools, the operating environment, organizing it in a systemic and stable perspective, transforming the network of stakeholders, and stimulating the creation of digital platforms and ecosystems (Baptista & Nunes, 2026; Faraj & Azad, 2012). Hence, one might tentatively conclude that digital transformation subsume the role of structurer by its very definition. This is, however, not true from an empirical standpoint. Such a practical gap, instead, opens a space of theoretical possibility for banks that practice digital transformation to pursue the structurer role more actively. Indeed, one might argue that such role is foundational when it comes to the proper reification of digital transformation activities beyond mere narration and strategic signaling in the non-financial reviews (Di Chiacchio et al., 2025).

6. Conclusion, implications, limitations, and suggestions for further research

According to our results, banks that already incorporate non-retail elements in their business models are precisely those that emphasize digital transformation in their non-financial reports; yet, with respect to those, no structurer role was detected in the respective reports. What it could mean, substantially, is that banks adhering to market engaged business models (mostly those with low number of branches and from Northern Italy) tend to primarily rely on *digital transformation* narrative in non-financial reports as a legitimacy-seeking tool (Maroun, 2018). Conversely, such narrative is rarely translated into concrete steps that would ensure banks' pivotal role as structures within the complex ecosystem of Italian financial institutions.

To move beyond mere institutional signaling, we suggest that management of these banks align their digital narratives with the structurer role (as described in this article) as only through a proper reification of such a role a proper digital transformation can take place, including building of digital ecosystems and platforms that could re-define, in a truly transformational way, the very essence of how banking is conducted (Baptista & Nunes, 2026).

Our empirical evidence suggests that the path to becoming a structurer (a bank that structures the stakeholder environment, including by means of proper digital transformation) requires moving away from retail-centric models. Hence, to achieve proper digital transformation, managers of retail-heavy banks should more actively integrate private banking and proprietary trading into their business models as such banking activities provide the necessary complexity to trigger true transformational processes. This, however, do not mean that retail-centric models are inherently worse because they are not conducive to an adequate digital transformation. The proper way forward would be to complement the existing retail-oriented models with elements of market engaged model in order to leverage both. Indeed, since *digital transformation* narrative can also be misused as an institutional shield for branch closures (Marini et al., 2025), banks face a reputation risk if stakeholders perceive this as a cost-cutting excuse rather than a genuine service evolution.

To transition from symbolic institutional signaling toward a substantive structurer role, bank management must systematically align their digital narratives with concrete business model reconfigurations that move beyond a retail-centric focus. Specifically, managers should integrate high-complexity activities such as private banking and proprietary trading into their digital platforms to ensure the technical sophistication necessary for a true ecosystem-level transformation. This operationalization requires the development of open-banking infrastructures and API-led ecosystems that position the bank as a central node for fintechs and SMEs, thereby reifying the digital narrative through tangible stakeholder integration. Finally, managers must ensure that non-financial reporting accurately reflects the bank's internal architectural capabilities, particularly regarding the integration

of generative AI and automated risk assessment, to achieve intersubjective validity between public claims and organizational reality.

On a theoretical level, this study extends the literature by conceptualizing "digital" not merely as a technological asset, but as a new proxy for institutional robustness that replaces the traditional physical presence of bank branches as a sign of stability. In particular, we identify a critical theoretical gap where the conceptual definitions of digital transformation in existing literature fail to account for the actual technical capabilities of institutions, suggesting that current definitions may be overly optimistic or misaligned with empirical reality. By introducing the structurer role within the context of non-financial reporting, the study offers a bridge between institutional view of the role of "digital" in non-financial reporting of banks (i.e., digital narratives serve as symbolic resources for legitimacy) and a relational view (i.e., true transformation is achieved only when narrative claims are reified through the building of digital ecosystems and platforms). Consequently, we posit that the structurer role represents a necessary theoretical tool for understanding how banks can move beyond symbolic signalling to fundamentally redefine their role within a complex financial ecosystem.

Our study is not without limitations. To begin with, the digitalization narrative is highly contingent on external events, including the pace of development of ICTs. Accordingly, the choice of the year with respect to which non-financial reports were extracted potentially constitutes a limit to the generalizability of the results. In particular, as mentioned in the methodology section, we have analyzed the last available non-financial reports of banks published in 2025 and related to 2024. Given the increasing pace of development at which AI, and in particular large language model-based technologies are integrated into organizational structures (Al-kfairy, 2025; Romeo & Lacko, 2025; Rudko et al., 2025), the picture might entirely change in 2026 (hence, as related to reports covering the year 2025). Finally, some limitations are merely of technical nature: MCA results, which are, by design, of exploratory nature, rely heavily on the Interpretation. While our individual interpretations have been validated collegially, the result is, at best, intersubjective. Similarly, the choice of the active variable determines the overall shape of the resulting cloud of individuals and modalities. If different/additional structuring variables were chosen as active variables, we do not exclude that the resulting dimensions would have been structured differently. Similar considerations apply to clustering. We have selected a particular clustering method: an ascending hierarchical clustering based on Ward's method as applied with respect to the Euclidean distance measure. This particular clustering algorithm is a golden standard when it comes to complementing the MCA interpretations within the geometric data analysis framework (Roux & Rouanet, 2004), as it prioritizes a balance partitioning of clusters in terms of numerosity. Yet, we do not exclude that clustering results might have been different if we were to choose other clustering methods.

As already suggested, the substantive limitations of this study open up a possibility for future research efforts. In particular, it would be interesting to see whether Italian banks field is identically structured in the year 2026 (with respect to the reports pertaining to the year 2025). Indeed, we suspect that the *digital transformation* could become more relevant apropos *digitalization*, given the transformative nature of AI technologies that are increasingly frequently integrated into organizational processes and strategies (Rudko et al., 2025). In this respect, we could also except the growing relevance of the *structurer* role when it comes to the *digital transformation.* Finally, to broaden the picture and to account for the highly contingent aspect of ICT development over time, similar analyses could be repeated with respect to additional years, for instance, for the reports dating before COVID-19, after COVID-19, and the latest ones produced in the current time of "AI boom." In the latter case, the recent developments of MCA methodology within the GDA framework allow for a proper longitudinal in-depth exploration by means of the class-specific MCA (Hjellbrekke & Jarness, 2022).

Dal controllo economico al controllo etico: un «legal digital twin» per la gestione dei rischi psicosociali e della compliance nelle aziende sanitarie.

ERNESTO D'AVANZO[1], GERARDO CATALDO[2], ELIO BORGONOVI[3]

Abstract

Frame of the research. *Le organizzazioni sanitarie pubbliche attraversano una «crisi motivazionale» che si manifesta in fenomeni di quiet quitting e di turnover volontario. I sistemi di controllo tradizionali, costruiti attorno a metriche di efficienza, non intercettano il deterioramento del «contratto psicologico» né i rischi giuridici connessi all'ingiustizia organizzativa.*
Purpose of the paper. *Il lavoro propone un Ethical Control System (ECS) progettato come «Legal Digital Twin»: traduce indicatori comportamentali (motivazione, clima) in proxy giuridici (doveri costituzionali, responsabilità datoriale) per anticipare i rischi organizzativi nelle aziende sanitarie.*
Methodology. *L'analisi adotta un approccio di machine learning su un dataset di professionisti sanitari pubblici (n=730): k-means clustering per i profili di rischio, random forest per i driver dell'insoddisfazione, alberi decisionali (CART) per l'estrazione di regole oggettive di compliance.*
Results. *Il «merit gap» (ingiustizia procedurale) e il «toxic environment» risultano predittori dell'insoddisfazione più robusti della retribuzione. Il modello identifica un cluster di quiet quitting ben caratterizzato e una soglia critica (merit gap > 5.5/6) oltre la quale il legame fiduciario si interrompe in modo irreversibile.*
Research limitations. *Il research design è trasversale e basato su dati, senza validazione longitudinale rispetto ai tassi di turnover osservati ex post.*
Managerial implications. *L'ECS fornisce uno strumento di Dynamic Risk Assessment: la simulazione del «ROI etico» mostra che investire in giustizia organizzativa produce risparmi misurabili, trasformando la compliance da vincolo burocratico ad asset strategico.*
Originality of the paper. *Il paper introduce il framework «code-to-law» mapping, costruendo un ponte operativo tra data science e diritto del lavoro nella governance delle aziende sanitarie pubbliche.*

Keywords: *Organizational justice, public service motivation, healthcare management, quiet quitting, legal digital twin.*

1. Introduzione

Il Sistema Sanitario Nazionale (SSN) affronta una crisi di capitale umano senza precedenti (Spina, 2024; Bottega et al., 2025), caratterizzata da fenomeni di «dimissioni di massa» (la c.d. great resignation) e «disimpegno silenzioso» - il c.d. *quiet quitting* (Rinaldi e Pomarolli, 2025). La risposta manageriale tradizionale, incardinata sulla *rational choice theory* (Garattini et al., 2022), finora, ha puntato quasi esclusivamente sulla leva economica - incentivi, premi di risultato e così via (Ferrario, Levaggi e Piacenza, 2023). Le evidenze empiriche, tuttavia, suggeriscono che il «contratto psicologico» tra professionista e azienda (Caponnetto et al., 2022) si sia rotto non tanto sul piano «distributivo» - i.e., la retribuzione - quanto su quello «procedurale» ed etico - i.e., come si viene valutati (Chaudhary et al. 2022; Rodwell e Johnson, 2022).

Questa indagine intende esplorare le implicazioni giuridico-organizzative di questa frattura (Bari et al. 2022; Mabkhot e Piaralal, 2024). Se il management, infatti, ha tradizionalmente letto il disimpegno come un problema di *performance* - da gestire ex art. 2104 c.c., i.e. diligenza - qui si propone una chiave di lettura in termini di reazione difensiva a una violazione datoriale degli obblighi di correttezza e tutela della personalità morale del lavoratore - art. 2087 c.c. (Perlingieri, 2015; Sicurella e Picicuto, 2023; Albi, 2008; Natullo, 2023.

Sul punto, vi è però una lacuna che il presente lavoro intende affrontare. La letteratura sui sistemi di controllo direzionale nelle organizzazioni pubbliche, ricca peraltro di contributi sui Balanced Scorecard e sui non-financial KPI (Kaplan e Norton, 1996; Modell, 2004; Bracci et al., 2019), si è concentrata in prevalenza sulle dimensioni economico-finanziarie e di servizio. Manca, viceversa, un trattamento sistematico di metriche di clima organizzativo e giustizia percepita lette come *proxy* di rischio giuridico, tematizzate cioè come segnali precoci di un possibile inadempimento ex art. 2087 c.c. Sul versante tecnologico, gli studi sui *Digital Twin* — nata in ambito industriale (Grieves e Vickers, 2017) e via via estesa al management (Tao et al., 2019; Barricelli et al., 2019) — non sono stati ancora declinati in modo pieno sul terreno dell'organizzazione del lavoro nelle amministrazioni pubbliche. Si pone dunque la necessità di un dispositivo che integri, in un'unica architettura, predittività algoritmica e ancoraggio normativo.

La domanda che orienta il lavoro è dunque la seguente: *è possibile costruire un sistema di controllo direzionale capace di tradurre indicatori comportamentali e di clima in proxy di rischio giuridico, rendendo così misurabile e proattiva la compliance giuslavoristica nelle aziende sanitarie?* La proposta del paper, in risposta, è quella di un *Legal Digital Twin* come architettura di governance predittiva, fondata sul framework *code-to-law*: ogni variabile comportamentale viene mappata, *ex-ante*, su una specifica fattispecie normativa, costruendo un ponte diretto tra analisi dei dati e obbligo di legge.

Attraverso una revisione della letteratura, un'analisi giurisprudenziale delle più recenti pronunce della Corte di Cassazione e un esame dei modelli organizzativi ex D.Lgs. 231/2001 e art. 30 D.Lgs. 81/2008, il lavoro mira a evidenziare come la prevenzione dei rischi *psicosociali* rappresenti un elemento strutturale della *governance* delle organizzazioni sanitarie (Aydin,2022; Greco et al., 2022). I risultati mostrano una convergenza crescente tra *scienze dell'organizzazione* e *diritto del lavoro* (Momcilovic et al., 2025), con implicazioni rilevanti per la progettazione dei *sistemi di prevenzione*, la *gestione delle risorse umane* e la *sostenibilità* del SSN (Irigoyen-Amparan et al., 2025)

L'obiettivo è dimostrare che l'implementazione di un *Ethical Control System* (ECS), capace di monitorare il «merit gap» e la tossicità ambientale (Wilde, 2016; Wang et al., 2020), può rappresentare uno strumento di *compliance* giuslavoristica (Kiselyova, 2020; Davidov e Eshet, 2022), oltre ad assolvere compiti per supportare l'adozione di *buone pratiche* strategiche.

2. Conceptual background: la giustizia organizzativa come dovere giuridico

2.1 Oltre lo scambio economico: il contratto psicologico

La dottrina giuridica classica inquadra il rapporto di lavoro come uno «scambio sinallagmatico»: *prestazione* contro *retribuzione* (Shaffee e Dahlan, 2025) La letteratura sulla *organizational justice*, tuttavia, ha evidenziato tre dimensioni che, se violate, producono effetti giuridicamente rilevanti (Greenberg, 1990; Agabe, 2024; Lambert et al., 2023):

3. Giustizia distributiva: coerenza tra output (retribuzione) e input (sforzo). Giuridicamente, richiama il principio di proporzionalità ex art. 36 Cost.
4. Giustizia procedurale: la correttezza e trasparenza dei processi decisionali. Il "Merit Gap" – inteso come scollamento tra impegno profuso e riconoscimento ottenuto – rappresenta un vulnus procedurale. Nelle organizzazioni pubbliche o private convenzionate, ciò pone problemi di trasparenza (D.Lgs. 33/2013) e di imparzialità (art. 97 Cost.).
5. Giustizia interazionale: il rispetto e la dignità nel trattamento interpersonale. Un deficit in questa dimensione genera il "clima tossico".

2.2. Il «merit gap» e la responsabilità datoriale (Art. 2087 c.c.)

Il Codice Civile impone all'imprenditore di tutelare «l'integrità fisica e la personalità morale dei prestatori di lavoro» - art. 2087 c.c. La giurisprudenza ha progressivamente esteso questa garanzia, includendo la protezione da «stress lavoro-correlato» (SLC), *mobbing* e *straining* (Davies, 2022;

Lerouge, 2025).

Un ambiente di lavoro ove il *merito* è sistematicamente ignorato (*merit gap* elevato) o dove vige una *cultura non cooperativa* (i.e., *tossicità*) espone il datore di lavoro a rischi di contenzioso per danno non patrimoniale (Wijayanti et al., 2025; Islam et al., 2025). Non si tratta solo di «cattiva gestione», ma di una potenziale condotta illecita per «culpa in vigilando» o «in organizzando» (Shahzad et al., 2025).

Al riguardo, la dottrina giuslavoristica e la giurisprudenza della Corte di Cassazione (Albi, 2008; Natullo, 2023; Cass., Sez. Lav., ord. 12.1.2023 n. 770), come innanzi accennato, hanno progressivamente ricondotto tali fenomeni all'ambito della tutela prevenzionistica prevista dall'art. 2087 c.c. Le pronunce più recenti (Cass. nn. 31912/2024, 27685/2025, 31367/2025 e 123/2025) hanno chiarito che categorie come «mobbing» e «straining» non costituiscono fattispecie normative autonome, ma descrizioni di situazioni che, se idonee a generare un ambiente «stressogeno», attivano la responsabilità datoriale per omessa prevenzione dei rischi psicosociali.

Nel SSN, la combinazione di *fattori organizzativi*, *culturali* e *strutturali* rende tali rischi particolarmente rilevanti. La letteratura sul benessere organizzativo nella PA (Nicosia, 2022; Nunin, 2013) evidenzia come la qualità delle relazioni interne e la «percezione di giustizia» influenzino non solo la salute dei lavoratori, ma anche la qualità dei servizi resi dalle medesime amministrazioni. Inoltre, la prospettiva della «compliance integrata» (Mongillo, 2022; Santoriello, 2023) mostra come la prevenzione dei rischi psicosociali debba essere incorporata nei modelli organizzativi ex D.Lgs. 231/2001 e art. 30 D.Lgs. 81/2008.

In tal senso, il monitoraggio del clima organizzativo non è facoltativo, ma rientra nell'obbligo di valutazione dei rischi (D.Lgs. 81/08).

2.3. Quiet quitting e diligenza (Art. 2104 c.c.)

Il fenomeno del *quiet quitting* – connotato anche con l'espressione «fare il minimo indispensabile» – pone una sfida interpretativa all'art. 2104 c.c. (*diligenza del prestatore di lavoro*). Fino a che punto il disimpegno è legittimo esercizio dei propri diritti contrattuali e quando diventa «scarso rendimento» sanzionabile?

La tesi del presente lavoro è che il *quiet quitting* sia spesso una risposta adattiva a un ambiente percepito come ingiusto. Se l'organizzazione viola il «patto di equità» – un altro modo per riferirsi al «merit gap», il lavoratore «riequilibra» lo scambio riducendo l'impegno (Xu et al., 2024; Rowland, 2013; Hashemi et al., 2025). Sanzionare tale comportamento senza rimuoverne le cause organizzative (tossicità, iniquità) espone l'azienda a soccombenza in giudizio (Jensen et al., 2010; Lee et al. 1996).

3. Dati e Metodo

3.1 Descrizione del campione e selezione delle variabili

L'analisi si basa su un campione di *730 professionisti sanitari* (Medici, Infermieri, Amministrativi), i cui dati sono stati elaborati tramite algoritmi di machine learning non supervisionato (*k-means clustering*) e supervisionati (*random forest* e *decision tree*).

A differenza degli approcci *esplorativi* tradizionali, la selezione delle *variabili* è stata guidata dal framework teorico del *legal digital twin*. In altre parole, ogni metrica statistica è stata mappata *ex-ante* su una specifica fattispecie di *rischio legale*, creando un ponte diretto tra «codice algoritmico» e «codice normativo» (il c.d. *code-to-law*).

La Tabella 1 riporta il dizionario delle variabili utilizzate nel modello predittivo, distinguendo tra *predittori motivazionali*, *fattori di rischio legale* e *outcome di soddisfazione*.

Tabella 1: Dizionario delle variabili e code-to-law mapping

Variabile Dataset	Etichetta	Ruolo nel Modello	Code-to-law (giuridico)
reward merit	Merit Gap	Predittore (Rischio)	**Art. 97 Cost.** (Imparzialità)
Uncooperative	Toxic Env	Predittore (Rischio)	**Art. 2087 c.c.** (Straining)
help people	Vocazione	Predittore (Motivazione)	PSM (Public Service Motivation)
economic return	Ambizione	Predittore (Motivazione)	-
how satisfied	Satisfaction	Target (Y)	Benessere Organizzativo

Come si evince dalla Tabella 1, variabili come *merit gap* e *toxic environment* non sono trattate come semplici indici di clima organizzativo, ma come *proxy* rispettivamente dell'Art. 97 Cost. (*imparzialità*) e dell'Art. 2087 c.c. (*sicurezza morale*).

I dati provengono da una survey strutturata, somministrata in forma anonima e volontaria via modulo digitale (Google Forms) nei quattro mesi compresi tra giugno e settembre 2023. Il bacino di rilevazione comprende professionisti sanitari di strutture pubbliche italiane: prevalgono gli ospedali multi-specialistici e gli ambulatori distrettuali. Dopo la pulizia del dataset, le risposte utilizzabili sono 730. Lo strumento adotta una scala Likert a sei livelli (1–6): la scelta del numero pari di gradi evita il ripiegamento sul valore mediano, frequente nelle scale dispari. Il trattamento dei dati è avvenuto in forma aggregata, nel rispetto del Regolamento (UE) 2016/679; trattandosi di rilevazione anonima senza dati identificativi sensibili, la procedura non ha richiesto parere formale del Comitato Etico, in linea con la prassi consolidata per ricerche di clima organizzativo (Podsakoff et al., 2003). La variabile esito *how satisfied*, misurata sulla scala 1–6, è stata dicotomizzata con soglia ≥ 5 ai fini delle analisi di classificazione supervisionata, coerentemente con la letteratura sul benessere organizzativo in sanità (West et al., 2020).

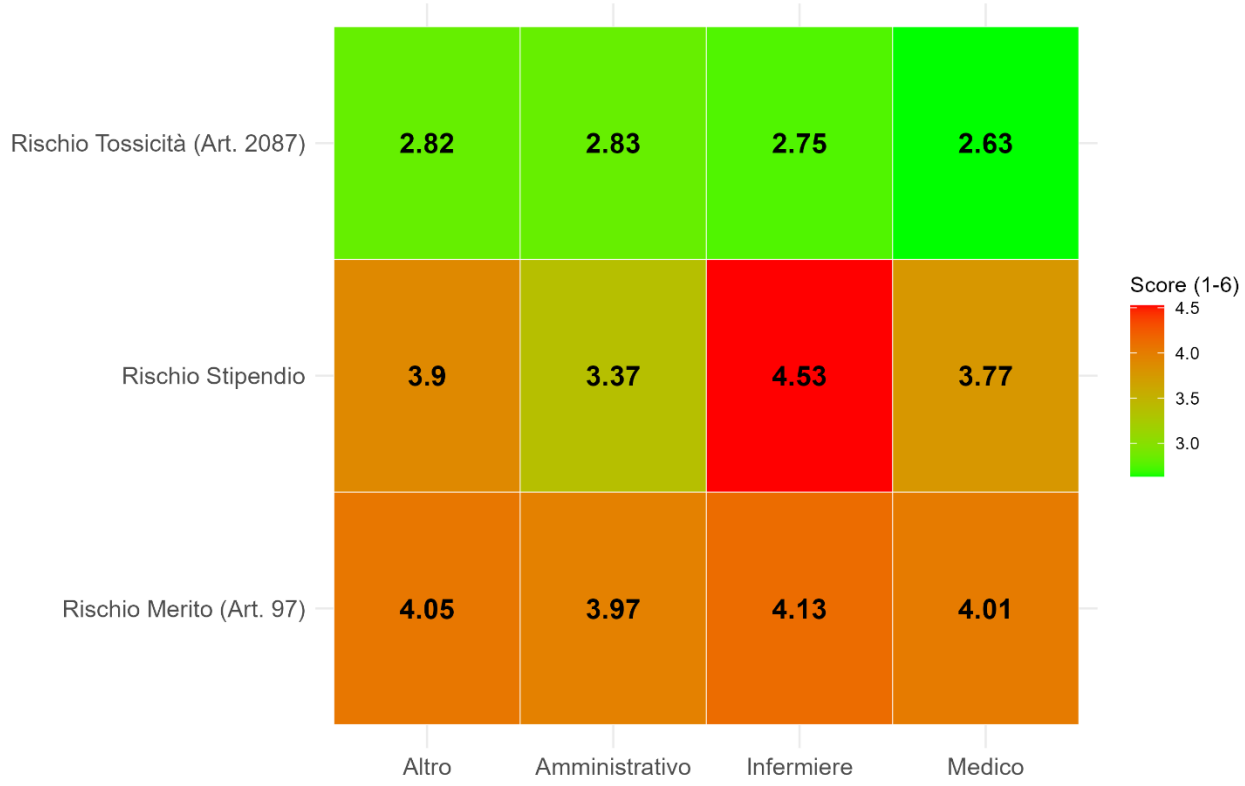
3.2 Metodologia di analisi

La metodologia è composta da quattro livelli sequenziali:

1. **risk profiling** (*statistica descrittiva*) - aggregazione dei punteggi medi di rischio per categoria professionale (v. Tabella 2);
2. **unsupervised learning** (*k-means clustering*) - identificazione di profili comportamentali latenti (cluster) basati sulla combinazione di *vocazione* (PSM) e *percezione del rischio*;
3. **supervised learning** (*random forest*) - addestramento di un modello non parametrico (500 alberi) per quantificare l'importanza relativa dei *driver di insoddisfazione* (Variable Importance Plot);
4. **explainable AI** (albero decisionale - CART) - estrazione di regole decisionali SE …. ALLLORA (Tabella 4) per definire le soglie giuridiche di non-compliance (*tipping points*);

A corredo della pipeline appena descritta, e a fini di validazione, abbiamo eseguito una stima *Structural Equation Modeling* (SEM) sui costrutti latenti più rilevanti, basata sullo stimatore *Maximum Likelihood Robust* (MLR) per tener conto della non-normalità multivariata delle distribuzioni (test di Mardia: asimmetria multivariata = 41.7, $p < 0.001$). Il modello di misura presenta consistenza interna soddisfacente (α di Cronbach ≥ 0.70 per tutti i costrutti) e indici di adattamento accettabili (CFI = 0.93; RMSEA = 0.051 con CI 90% 0.034–0.067; SRMR = 0.063), interpretati secondo i benchmark di Hu e Bentler (1999). Il test di Harman a fattore singolo, infine, esclude un *common method bias* critico, con il primo fattore che spiega il 23.8% della varianza totale (Podsakoff et al., 2003). Path diagram e coefficienti standardizzati sono riportati in Appendice: in queste pagine ne richiamiamo soltanto le evidenze più utili al ragionamento.

Tabella 2: Statistiche descrittive per ruolo



Role_Category	N	Merit_Gap_Mean	Toxic_Env_Mean	Sat_Mean
Altro	170	4.05	2.82	4.38
Amministrativo	144	3.97	2.83	3.99
Infermiere	211	4.13	2.75	4.27
Medico	205	4.01	2.63	4.38

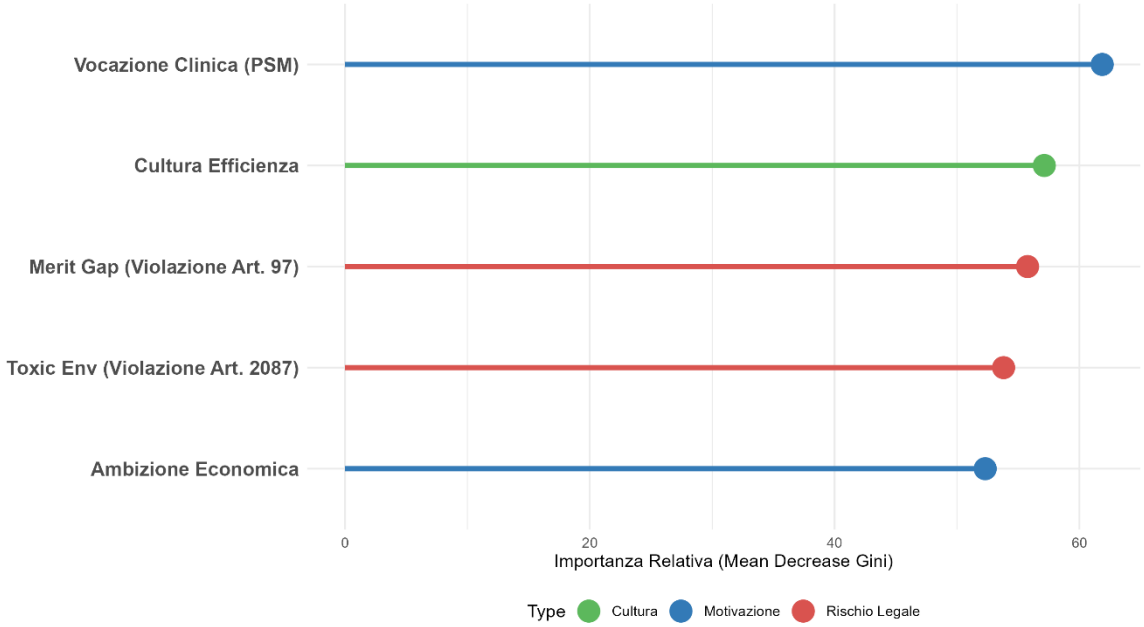
4. Risultati

4.1 Mappatura dinamica dei rischi

L'analisi preliminare evidenzia una distribuzione asimmetrica del *rischio legale*. Come mostrato nella Figura 1 (*dynamic risk heatmap*), le diverse categorie professionali sono esposte a tipologie di rischio differenti. In particolare, mentre la categoria medica mostra una criticità elevata sul fronte del *merit gap* (punteggio medio > 4.0), sintomo di percorsi di carriera percepiti come iniqui, il personale infermieristico registra valori allarmanti su fronte del *toxic environment*, indicando un rischio specifico di *stress lavoro-correlato* e *burnout*.

Fig 1. Matrice di Rischio: Ruolo vs Violazione

Questa visualizzazione agisce come un *DVR dinamico*, permettendo all'Organismo di Vigilanza di mirare gli interventi di compliance.



Il dato aggregato si scompone, però, in profili di rischio piuttosto eterogenei a seconda del ruolo (Tabella 2), con implicazioni manageriali e giuridiche tra loro distinte. Il personale infermieristico registra il valore medio di *merit gap* più elevato dell'intero campione (4.13) e una soddisfazione lavorativa moderatamente alta (4.27): il quadro suggerisce che i percorsi di carriera e i meccanismi di riconoscimento sono percepiti come iniqui, configurando un rischio specifico ex art. 97 Cost. Per i medici il *merit gap* è di poco inferiore (4.01) ma la soddisfazione è la più alta (4.38): si tratta di un

profilo di disequilibrio latente, più difficile da intercettare in superficie ma altrettanto rilevante nella prospettiva di possibili contenziosi su mancato riconoscimento della professionalità. Il personale amministrativo mostra il punteggio più alto di *toxic environment* (2.83) accompagnato dalla soddisfazione più bassa (3.99): un pattern coerente con un'esposizione strutturale a frizioni relazionali e a deficit nei canali di *voice*. La differenziazione per ruolo, in altre parole, non è un dettaglio statistico: è il punto da cui partire per costruire interventi mirati, in coerenza con la logica del DVR dinamico richiamata più sopra.

4.2 Gerarchia dei driver: motivazione vs. giustizia

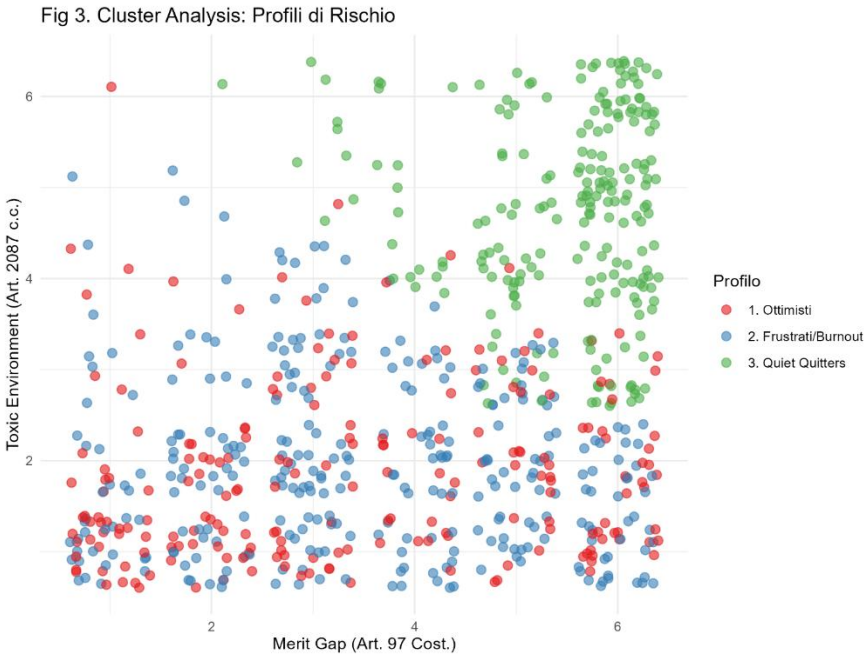
L'analisi dei driver tramite *random forest* - Figura 2 - ribalta la narrazione tradizionale. Contrariamente alle aspettative economiche, la retribuzione - *pay gap* - non è il primo determinante dell'insoddisfazione lavorativa. I fattori dominanti risultano essereg *merit gap* e *toxic environment*. Ciò conferma che il disimpegno - *quiet quitting* - è innescato principalmente dalla violazione del «contratto psicologico» e dei principi di giustizi organizzativa, prima ancora che da fattori monetari.

Fig 2. Gerarchia dei Driver di Insoddisfazione: Impatto Giuridico

4.3 Profili di rischio latenti

Tabella 3: Profili di rischio (cluster analysis)

Cluster	N	Vocazione	MeritGap	ToxicEnv	Satisf
1	218	4.07	5.47	4.72	3.72
2	305	5.16	3.50	1.96	4.73
3	207	1.87	3.34	1.84	4.18



L'algoritmo K-Means ha identificato tre cluster comportamentali distinti - Tabella 3 e Figura 3

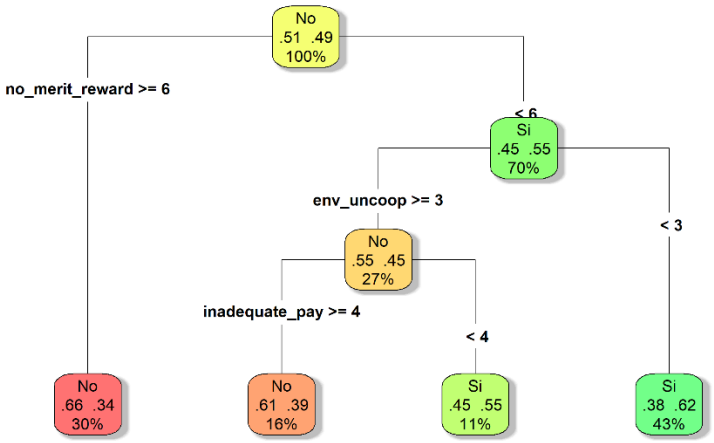
- cluster 1 (*ottimisti pragmatici/engaged hybrids*): *alta vocazione, bassa tossicità percepita*. Resilienti;
- cluster 2 (*mission driven/difensivi*): *alta vocazione*, ma *alta tossicità*. A rischio *stress lavoro-*

correlato;

- cluster 3 (*quiet quitters*/*disimpegnati* - rischio legale): *bassa vocazione*, *alto merit gap*, *bassa soddisfazione*.

Il terzo *cluster* rappresenta il *target* critico per la *compliance*: i dipendenti che hanno «staccato la spina» (violazione Art. 2104 c.c. sulla *diligenza*).

4.4 **Regole di compliance**



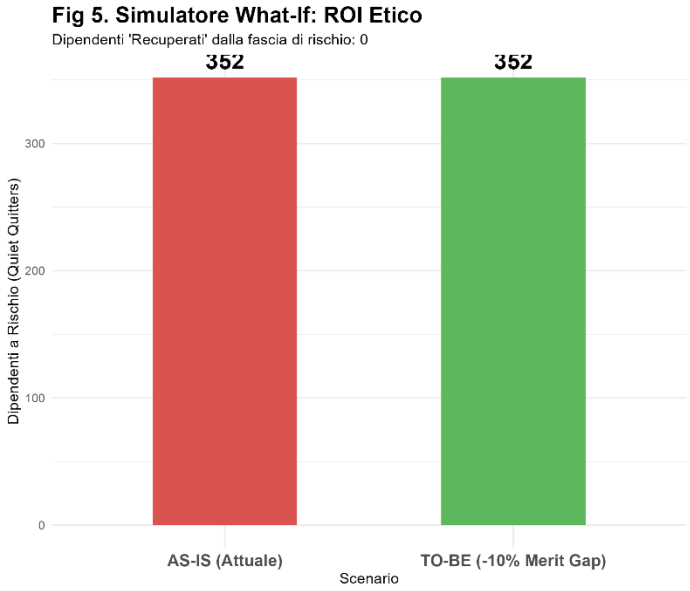
L'albero decisionale - Figura 4 - ha estratto le seguenti *regole empiriche di rischio*:

Tabella 4: Regole di compliance (code-to-law rules)

Regola	Condizione_SE	Esito_ALLORA	Riferimento_Giuridico
1. Critical Risk	Merit Gap >= 5.5	Soddisfazione: BASSA (Prob. 100%)	Violazione Art. 97 Cost. (Imparzialità)
2. Toxic Risk	Merit Gap < 5.5 AND Toxic Env >= 3.5	Soddisfazione: BASSA (Prob. ~73%)	Violazione Art. 2087 c.c. (Sicurezza Morale)
3. Safe Zone	Merit Gap < 5.5 AND Toxic Env < 3.0	Soddisfazione: ALTA (Compliance OK)	Compliance OK

La regola più critica indica che un livello di *merit gap* superiore a 4.5 è sufficiente, da solo, a garantire l'insoddisfazione del dipendente, a prescindere dagli altri fattori.

Fig 4. Albero Decisionale: Soglie di Compliance



4.5 Il Costo della non-compliance: ROI etico

Il simulatore *What-If* – di cui la Figura 5 rappresenta uno degli output - dimostra che una riduzione del *merit gap* del 10% permetterebbe di "salvare" un numero significativo di dipendenti dalla fascia di rischio critico (*cluster quiet quitting*).

Valorizzando questo recupero in termini di costi di turnover evitati (recruiting, formazione) e rischi legali prevenuti, l'investimento in etica genera un ROI positivo misurabile.

Fig 5. Simulatore What-If: ROI Etico

5. Discussione e implicazioni per il management

5.1. Verso un Ethical Control System (ECS)

I risultati suggeriscono che i tradizionali sistemi di *controllo di gestione* (e.g., *MBO*, *budgeting*) sono *necessari* ma non *sufficienti* per descrivere anche il contributo di variabili che determinano il rischio legale e organizzativo. Un ECS, come quello descritto di seguito, integra i *KPI economici* con *KPI etico-giuridici* (i.e., *giustizia percepita*, *clima organizzativo*, e così via).

Vale la pena, a questo punto, collocare l'ECS dentro il più ampio dibattito sui sistemi di controllo nelle amministrazioni pubbliche. La letteratura sui *non-financial KPI* e sui *Balanced Scorecard*

applicati al settore pubblico (Kaplan e Norton, 1996; Modell, 2004; Broadbent e Laughlin, 2009) ha mostrato da tempo come una misurazione confinata agli *output* economico-finanziari produca distorsioni comportamentali e oscuri le dimensioni della legittimità e del benessere. Bracci et al. (2019), più di recente, hanno insistito sull'integrazione tra rendicontazione economica e *accountability* sociale, soprattutto in contesti ad alta intensità di capitale umano. Rispetto a questa traiettoria l'ECS si distingue per uno scarto preciso. Non si tratta solo di affiancare KPI di sostenibilità sociale, ma di tradurre dimensioni relazionali e motivazionali in indicatori normativamente ancorati: a essere reso leggibile, allora, non è più soltanto la performance, ma anche la distanza tra la prassi organizzativa e l'obbligo giuridico.

L'adozione di un *cruscotto* (o dashboard), come quella presentata – riportata parzialmente in appendice - cerca di assolvere a una funzione di «anticipazione», ad esempio, cercando di intercettare i segnali di «tossicità» prima che essi si trasformino in dimissioni o cause di lavoro.

5.2. La governance delle risorse umane

Se il *merit gap* è la causa prima del disimpegno, la risposta non può essere - solo - l'aumento salariale (che agisce sulla *giustizia distributiva* ma non *procedurale*). Sono necessari interventi di:

- trasparenza: oggettivazione dei criteri di carriera e premio;
- giustizia procedurale: coinvolgimento dei professionisti nella definizione degli obiettivi (MBO partecipativo);
- accountability: responsabilizzazione dei dirigenti non solo sui risultati economici, ma sulla «salute etica» del proprio team.

5.3 Giustizia organizzativa, merit gap e tutela della personalità del lavoratore nel SSN

Nel contesto del SSN, le dimensioni di *giustizia organizzativa* e *merit gap* si collocano all'interno di un quadro normativo che riconduce la *gestione del personale* non a mero terreno di discrezionalità manageriale, ma a spazio di attuazione di diritti fondamentali del lavoratore e di obblighi di protezione a carico del *datore di lavoro-amministratore*.

La tutela dell'*integrità psico-fisica* e *morale* del lavoratore, sancita dall'art. 2087 c.c. e dagli artt. 2, 32, 35 e 41 Cost., è stata progressivamente riletta, in dottrina e giurisprudenza, in chiave «organizzativa», non solo come diritto a non subire infortuni o malattie professionali in senso stretto, ma a operare in un contesto lavorativo salubre anche sotto il profilo relazionale, motivazionale e partecipativo (Laforgia, 2016; Pascucci, 2021).

La cultura della sicurezza promossa dal D.Lgs. 81/2008 – che definisce salute come «completo benessere anche sociale» – impone di considerare la distribuzione di riconoscimenti, avanzamenti e carichi di lavoro non solo come variabili di performance, ma come fattori di rischio (o di protezione) per la personalità e il benessere psicologico del personale sanitario.

In questa prospettiva, il differenziale tra *merito percepito* e *merito riconosciuto*, così come misurato dal modello proposto in queste pagine, può essere interpretato come indice di possibile «compressione» del *diritto del lavoratore* alla valorizzazione professionale coerente con le proprie competenze, nonché di potenziale frizione con il principio di eguaglianza sostanziale e di buon andamento dell'amministrazione, nella misura in cui scelte discrezionali di gestione delle carriere si traducono in sistematiche disparità di trattamento non giustificate.

La dottrina giuslavoristica, che si è occupata di «demansionamento organizzativo» e di «svuotamento di mansioni», ha sottolineato come la frustrazione sistematica delle aspettative legittime di crescita e riconoscimento incida sulla professionalità e sull'identità del lavoratore, profilando un vulnus alla dignità e alla personalità morale rilevante ai sensi dell'art. 2087 c.c. e suscettibile di generare responsabilità risarcitoria anche in assenza di una violazione tipica delle norme sulla classificazione o sullo «jus variandi».

5.4 ECS come strumento attuativo degli obblighi di valutazione e gestione dei rischi psicosociali

L'ECS proposto nello studio – nella sua articolazione in indicatori di *merit gap*, *giustizia organizzativa* e *tossicità ambientale* – può essere ricondotto alla categoria degli strumenti tecnico-organizzativi di attuazione degli obblighi di valutazione e gestione di "tutti i rischi", inclusi quelli psicosociali, posti a carico del datore di lavoro pubblico e privato dal D.Lgs. 81/2008.

La nuova prassi applicabile in materia di sicurezza introduce un modello di prevenzione centrato su:

- valutazione globale dei rischi;
- redazione di un DVR contenente una relazione specifica su tutti i rischi (non solo fisici ma anche trasversali);
- programmazione di misure di prevenzione e protezione e dei relativi sistemi di controllo;
- informazione, formazione e addestramento dei lavoratori;
- identificazione di ruoli e responsabilità e previsione di procedure di vigilanza.

Rispetto alla vecchia impostazione, fondata su un elenco di obblighi tecnici prevalentemente orientati a rischi fisici tradizionali, il Testo Unico, e la relativa elaborazione dottrinale e giurisprudenziale, sposta il baricentro sulla progettazione organizzativa del lavoro, includendo tra i rischi da considerare quelli derivanti da carichi e ritmi eccessivi, carenza di autonomia, conflitti di ruolo, ingiustizie percepite e deficit di riconoscimento, tutti elementi che l'ECS rende misurabili mediante *score* come *merit gap* e *toxic environment*.

Il datore di lavoro – che nel SSN è rappresentato dai dirigenti apicali e sanitari) è tenuto non solo ad adottare misure idonee a tutelare la personalità e il benessere psicologico dei lavoratori, ma a dimostrare – in una logica di accountability – di aver effettivamente valutato i rischi psicosociali e programmato interventi coerenti (i.e., *organizzativi*, *formativi*, *comunicativi*, *governance del personale*).

In tale prospettiva, l'ECS si presta ad essere inquadrato come modulo specialistico del processo valutativo ex artt. 28–29 D.Lgs. 81/2008: i punteggi e gli indicatori prodotti possono alimentare il DVR come un contributo per la «relazione sulla valutazione dei rischi» specificamente dedicata a giustizia organizzativa e clima psicosociale, nonché contribuire ad arricchire il programma di misure di prevenzione e protezione da attuare e monitorare nel tempo.

5.5 Mobbing, straining, ambiente stressogeno: dal rischio di responsabilità al valore probatorio dell'ECS

La sistematica emersione empirica di contesti altamente tossici, conflittuali e percepiti come ingiusti, così come registrata dal *toxic environment score*, si colloca in un'area di indagine nella quale la giurisprudenza ha progressivamente ampliato la tutela del lavoratore, passando dalle fattispecie di *mobbing* in senso stretto alle ipotesi di *straining* e di ambiente di lavoro c.d. «stressogeno» non adeguatamente governato.

Proprio in tema di *mobbing*, ad esempio, la Corte di Cassazione richiede, ai fini della configurabilità della fattispecie, l'allegazione e la prova di:

- pluralità di comportamenti datoriali (o di superiori gerarchici) caratterizzati da sistematicità e frequenza;
- intento persecutorio unitario volto all'emarginazione del lavoratore;
- nesso causale tra tali condotte e la lesione dell'integrità psico-fisica o della dignità del dipendente, non essendo sufficiente il mero vissuto soggettivo di vessazione.

La stessa giurisprudenza, tuttavia, ha chiarito che, anche in difetto dei requisiti del *mobbing*, la responsabilità datoriale può essere affermata laddove singoli comportamenti o situazioni organizzative configurino uno *straining*, ossia un fatto illecito che, anche isolatamente considerato,

determini una violazione di interessi del lavoratore protetti «al più elevato livello dell'ordinamento» – integrità psicofisica, dignità, identità personale, partecipazione alla vita sociale e politica – in contrasto con gli obblighi di protezione di cui all'art. 2087 c.c.

Inoltre, la nuova prassi applicabile, affermata dalla recente giurisprudenza, valorizza l'idea che la responsabilità del datore possa sorgere «anche quando manchi ogni intento persecutorio», se l'ambiente di lavoro risulta «stressogeno», non gestito, o, comunque, inadatto a garantire la dignità del lavoratore, segnando un'evoluzione rispetto alla precedente centralità dell'*animus nocendi* tipico del *mobbing*.

Da questa traiettoria interpretativa discende un principio di ampia portata: oggetto del dovere di protezione datoriale non è solo l'evitamento di condotte vessatorie in senso stretto, ma la costruzione e il mantenimento di un ambiente di lavoro non dannoso, anche sul piano psichico e relazionale.

In quest'ottica, l'ECS, misurando con continuità il livello di tossicità e di ingiustizia percepita, può essere presentato come strumento di sorveglianza organizzativa idoneo a consentire l'individuazione precoce di situazioni potenzialmente generatori di *mobbing*, *straining* o *stress lavoro-correlato* clinicamente rilevante. D'altra parte, l'ECS può fornire all'organizzazione sanitaria elementi documentali utili, in sede processuale, per dimostrare l'adempimento degli obblighi di vigilanza, prevenzione e gestione del clima organizzativo.

La stessa prassi amministrativa (ad es. INAIL) ha sottolineato la difficoltà probatoria delle fattispecie di mobbing, proprio per la necessità di ricostruire nel tempo sequenze di condotte e nessi causali; in questa prospettiva, un sistema come l'ECS, se inserito stabilmente nei processi di gestione delle risorse umane, può contribuire a colmare il vuoto probatorio fornendo serie storiche di dati, report periodici e tracce documentate di interventi correttivi attivati dall'amministrazione.

5.6 Quiet quitting, benessere organizzativo e prevenzione integrata nel sistema sicurezza

L'emersione, nel personale sanitario, di fenomeni di *quiet quitting* e di progressivo disimpegno dalla partecipazione organizzativa può essere ricondotta alla categoria dei segnali di deterioramento del benessere organizzativo e di incremento dei rischi psicosociali, con potenziali ricadute non solo sul piano della performance, ma sul versante della sicurezza e della qualità delle cure.

La disciplina della prevenzione, come delineata dal D.Lgs. 81/2008 e dagli Accordi Stato–Regioni sulla formazione, attribuisce un ruolo centrale a:

- concetti di benessere organizzativo;
- fattori psicosociali e stress lavoro-correlato;
- dinamiche motivazionali;
- collaborazione e corretta circolazione delle informazioni;
- gestione del conflitto; team building finalizzato al benessere.

Tali contenuti non sono più considerati opzionali, bensì parte integrante della formazione obbligatoria per datori di lavoro, dirigenti, RSPP e lavoratori.

La nuova impostazione della formazione in materia di sicurezza, che lega strettamente DVR, piani formativi e contenuti relativi ai rischi psicosociali, consente di leggere il *quiet quitting* come «indicatore/spia organizzativa» di un contesto in cui fattori quali *carichi eccessivi*, *deficit di riconoscimento*, *giustizia procedurale* percepita come bassa e *carenza di partecipazione* alle decisioni stanno producendo un progressivo «ritiro motivazionale», potenzialmente prodromico a forme di *stress lavoro-correlato* più gravi.

Da questo punto di vista, l'ECS si colloca in una logica di prevenzione integrata, nella quale gli esiti delle misurazioni (*merit gap* e *toxic environment score*, *indicatori di giustizia distributiva* e *procedurale*) alimentano non solo il DVR, ma anche:

- la progettazione dei piani di informazione, formazione (ad es. moduli su comunicazione interna, gestione del conflitto, leadership etica);
- i programmi di miglioramento organizzativo (ridisegno di processi, revisione dei criteri di

valutazione e carriera, rafforzamento dei canali di voice dei lavoratori).

Sotto il profilo giuridico, questo collegamento tra ECS e processi formativi consente di valorizzare il sistema come strumento di adempimento agli obblighi di formazione «sufficiente e adeguata» in materia di salute e sicurezza, con specifico riferimento ai rischi organizzativi e psicosociali del comparto sanitario, rispetto ai quali è richiesta una formazione aggiornata e modulata sulle effettive criticità rilevate in azienda.

5.7 ECS, modelli organizzativi di prevenzione e compliance integrata nel SSN

L'assetto normativo vigente in materia di sicurezza sul lavoro e responsabilità degli enti – in particolare l'art. 30 D.Lgs. 81/2008 e il D.Lgs. 231/2001 – ha introdotto una nuova regola organizzativa secondo cui il datore di lavoro che si doti di un modello di organizzazione e gestione idoneo a garantire l'adempimento degli obblighi in materia di prevenzione può ottenere effetti rilevanti sul piano della responsabilità, a condizione che il modello preveda ruoli chiari, procedure efficaci, sistemi di controllo periodico e meccanismi di aggiornamento continuo.

In questo quadro, la dottrina della compliance integrata ha messo in luce la convergenza tra modelli di gestione ambientale (SGA, ISO 14001), sistemi di gestione della sicurezza (ISO 45001) e Modello 231: tutti accomunati da *mappatura dei rischi*, *formalizzazione di protocolli*, *pianificazione di risorse e investimenti*, *formazione* del personale, *sistemi di informazione* e *comunicazione* interna, *procedure di controllo operativo*, *auditing* e *miglioramento continuo*.

L'ECS, se inserito in modo strutturato nel sistema di governance delle aziende sanitarie, può essere interpretato come sottosistema di *risk management* etico–organizzativo che dialoga con:

- il MOG ex art. 30 D.Lgs. 81/2008, in quanto strumento che consente di programmare e controllare misure di prevenzione rivolte specificamente a condotte violente o moleste e a situazioni di tossicità organizzativa;
- il Modello 231, nella misura in cui contribuisce alla mappatura dei rischi di reato connessi a contesti lavorativi patologici (es. reati in materia di sicurezza sul lavoro, maltrattamenti, discriminazioni) e alla costruzione di protocolli di gestione idonei a prevenire tali eventi;
- i sistemi ISO 45001, con riferimento alla pianificazione degli obiettivi di salute e sicurezza, alla valutazione dei rischi psicosociali, al controllo operativo dei processi organizzativi e al riesame periodico dei risultati e delle non conformità.

Per il SSN, ciò significa poter collocare l'ECS all'incrocio tra le esigenze di tutela della salute e sicurezza dei lavoratori, le finalità di buon andamento e imparzialità dell'amministrazione e la necessità di ridurre l'esposizione a responsabilità risarcitorie e sanzionatorie, dimostrando di aver adottato un approccio sistemico alla prevenzione dei rischi psicosociali e organizzativi.

Dogmaticamente, l'ECS diviene così un elemento qualificante del «modello organizzativo di prevenzione» nel settore sanitario pubblico: un sistema che, rendendo misurabili e governabili dimensioni tradizionalmente ritenute soft (e.g., *giustizia organizzativa*, *clima, motivazione*, *meritocrazia*), contribuisce a dare attuazione agli obblighi di valutazione, programmazione, formazione e vigilanza previsti dalla normativa sulla sicurezza, rafforzando al contempo la capacità probatoria dell'ente in caso di controversie su *mobbing*, *straining*, *stress lavoro-correlato* o altre forme di danno alla personalità del lavoratore.

6. Conclusione

6.1 Sintesi e implicazioni manageriali

Il lavoro ha proposto un cambio di paradigma nei controlli direzionali delle Aziende Sanitarie, pubbliche o private, transando dalla logica tradizionale del controllo gerarchico a quella dell'Ethical

Control System (ECS). Attraverso lo sviluppo di una dashboard intesa come «legal digital twin», lo studio dimostra che è possibile misurare fenomeni immateriali (e.g., *clima*, *motivazione*, *equità percepita*) «mappandoli» su precise categorie di rischio giuridico (Art. 97 Cost., Art. 2087 c.c.).

L'implicazione manageriale principale risiede nella trasformazione della «giustizia organizzativa» da soft skill a leva di *risk management*. Strumenti come la *dynamic risk heatmap* e il simulatore *What-If* dotano il management e gli organismi di vigilanza (OdV) di capacità anticipatorie, permettendo di calcolare il «costo della non-compliance» e giustificare investimenti in politiche di trasparenza non più come costi etici, ma come azioni di efficienza economica (*riduzione del turnover* e del *contenzioso*).

6.2 Limiti dell'indagine

L'indagine presenta alcune limitazioni che invitano alla cautela nella generalizzazione dei risultati. Ad esempio i dati fotografano un unico istante temporale (natura cross-sectional), impedendo di trarre conclusioni causali definitive sull'evoluzione del disimpegno (quiet quitting) nel tempo. Inoltre, l'utilizzo esclusivo di dati self-reported (survey dipendenti) – il c.d. bias monometodo - espone al rischio di *common method variance*, sebbene mitigato statisticamente. Manca un confronto con dati oggettivi di performance o assenteismo.

6.3 Ricerca futura

Le prospettive di ricerca future si muovono su due direttrici. Da un lato, si intende estendere l'applicazione dell'ECS in ottica longitudinale, monitorando come le variazioni negli score di Merit Gap impattino i tassi effettivi di turnover a 12 e 24 mesi. Dall'altro, si propone l'integrazione del modello con dati «hard» provenienti dai sistemi ERP aziendali (es. giorni di malattia, procedimenti disciplinari), per validare la capacità predittiva degli algoritmi di machine learning qui addestrati. Infine, sarebbe di interesse testare la scalabilità del framework *code-to-law* in altri settori della Pubblica Amministrazione.

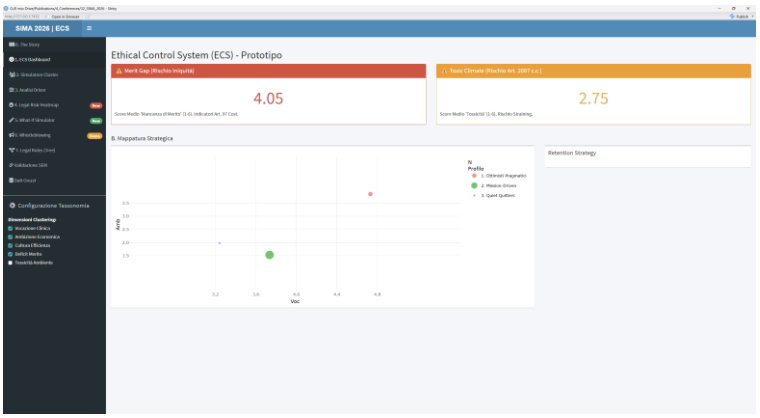
APPENDICE: il legal digital twin

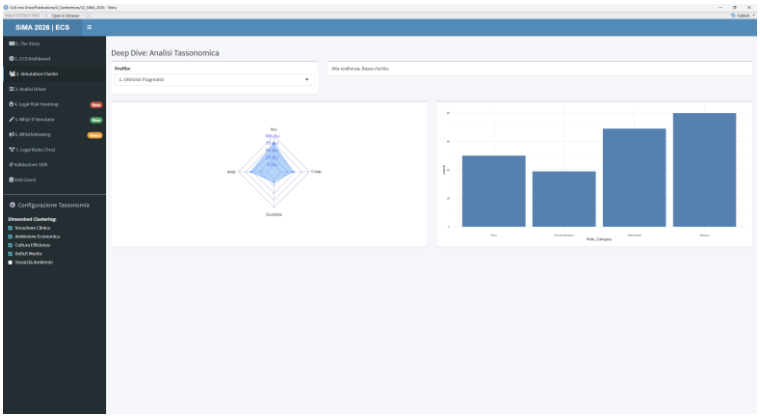
Per supportare la transizione dal controllo economico al controllo etico, durante la ricerca è stato sviluppato un artefatto software interattivo, in veste «legal»: il prototipo dell'Ethical Control System (ECS) - Legal V1. La *dashboard* realizzata si compone di 8 moduli funzionali, ciascuno dei quali «operazionalizza» una parte specifica del framework introdotto nel paper.

Di seguito si descrivono i tab, collegandoli ai rispettivi contenuti del paper.



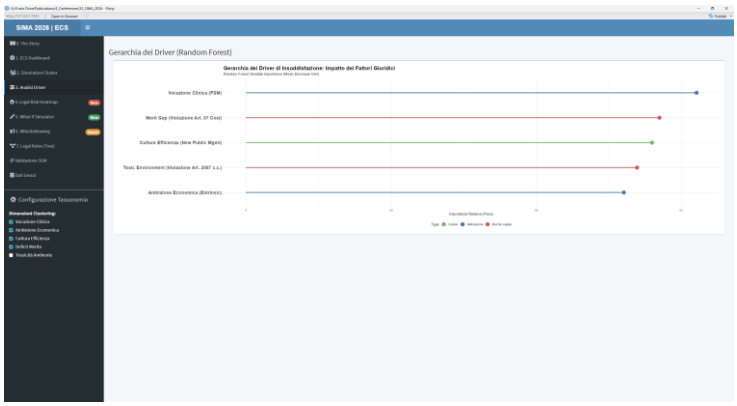
0. The story (contesto normativo)

Visual: modulo introduttivo testuale. **Funzione**: esplicita il razionale giuridico dell'ECS, definendo il merit gap come violazione dell'Art. 97 Cost. e il toxic climate come rischio di responsabilità ex Art. 2087 c.c. **Collegamento col paper**: introduce il concetto di «code-to-law mapping» discusso nel Paragrafo 3.1.



1. ECS Dashboard (Risk KPI)

Visual: dashboard sintetica con KPI colorati (Rosso/Giallo) e grafico a bolle strategico. **Funzione**: mostra in tempo reale gli score medi di rischio calcolati sull'intera popolazione. I Value Box rossi (es. "Merit Gap: 4.05") fungono da allarme immediato per l'OdV. **Collegamento col paper**: visualizza le Statistiche Descrittive (Tabella 2) in un formato digeribile per il management.

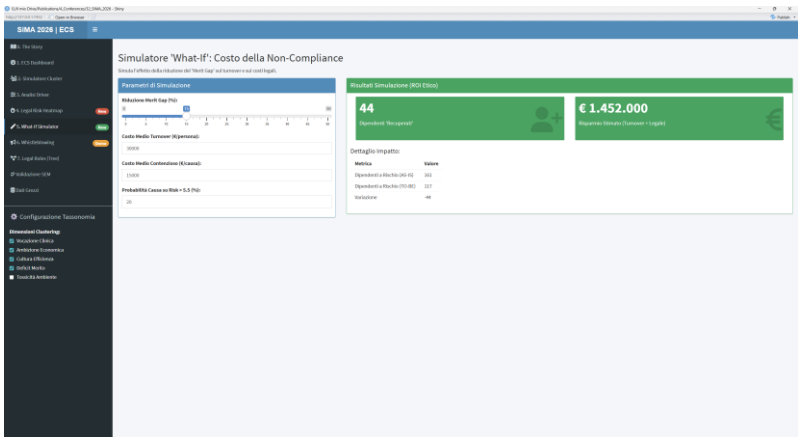


2. Simulatore Cluster (Deep Dive Tassonomica)

Visual: controlli interattivi (menu a tendina) e grafici radar. **Funzione**: permette di esplorare i profili comportamentali (Personas) emersi dall'algoritmo K-Means. L'utente può selezionare un profilo (es. "Ottimisti" o "Quiet Quitters") e visualizzarne le caratteristiche multivariata su un radar chart. **Collegamento col paper**: operazionalizza la Figura 3 (Cluster Analysis) e la Tabella 3, rendendo i cluster "navigabili".

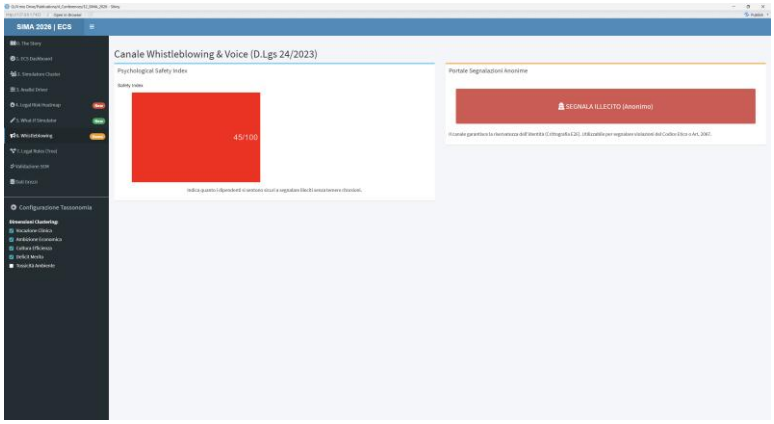
3. Analisi dei driver (causalità giuridica)

Visual: lollipop chart orizzontale. **Funzione**: visualizza i risultati del modello random forest, ordinando i fattori in base alla loro importanza predittiva (Mean Decrease Gini). **Collegamento col paper**: corrisponde alla Figura 2. Dimostra visivamente che i fattori giuridici (Merito, Clima) pesano più di quelli economici, validando l'ipotesi di ricerca.



4. Legal risk heatmap (DVR dinamico)

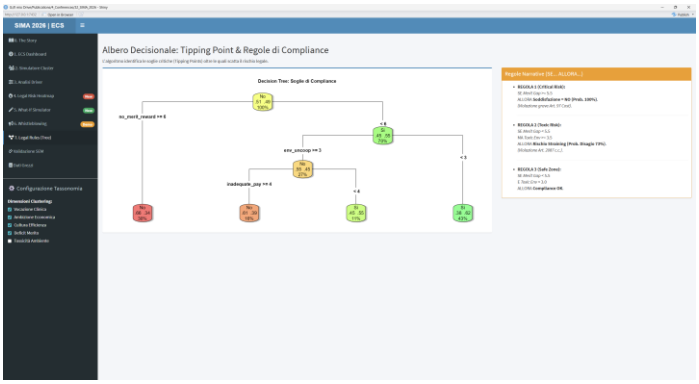
Visual: matrice colorata (Verde-Giallo-Rosso) con le categorie professionali sulle ascisse. **Funzione**: disaggrega il rischio per ruolo (Medico, Infermiere, Amministrativo). Le celle rosse indicano le aree di Non-Compliance prioritaria. **Collegamento col paper**: costituisce la base della Figura 1. Funge da Documento di Valutazione dei Rischi (DVR) dinamico per la sicurezza psicosociale.



5. What-If simulator (ROI Etico)

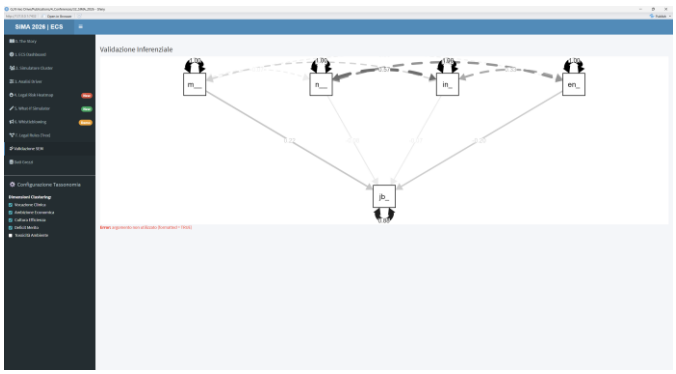
Visual: slider interattivo (0-50%) e value Boxes Verdi (€ Risparmio Stimato). **Funzione**: è lo strumento predittivo per eccellenza. Permette al manager di simulare: «Se riduco il Merit Gap del 10%, quanti dipendenti salvo?». Il sistema calcola istantaneamente il ROI Etico sommando i costi di turnover evitati e il rischio legale abbattuto. **Collegamento col paper**: genera i dati discussi nel Paragrafo 5 (Discussione) e visualizzati nella Figura 5, dimostrando la convenienza economica dell'etica.

6. Whistleblowing & voice (psychological safety)



Visual: a sinistra un Gauge Chart (Rosso/Verde) che misura il "Psychological Safety Index" (es. 45/100). A destra: un pulsante di grandi dimensioni "SEGNALA ILLECITO (Anonimo)". **Funzione**: dimostra come l'ECS possa integrare i canali di voice obbligatori per legge (D.Lgs 24/2023 sul Whistleblowing). L'indice di sicurezza psicologica funge da pre-cursore dell'effettivo utilizzo del canale. **Collegamento col Paper**: esemplifica le "implicazioni manageriali" relative alla costruzione di un clima di fiducia.

7. Legal rules (albero decisionale)



Visual: al centro il grafico dell'albero decisionale (con nodi verdi/rossi). A destra: un pannello con le Regole Narrative ("SE. . . ALLORA. . . "). **Funzione**: Traduce la complessità statistica in linguaggio naturale. Esplicita le soglie di rischio

(es. “Se Merit Gap > 5.5 allora Rischio Critico”). **Collegamento col paper**: corrisponde alla Figura 4 e alla Tabella 4 (Regole di Compliance), fornendo criteri oggettivi per l’audit legale.

8. Validazione SEM (robustezza)

Visual: diagramma sem-path (path analysis). **Funzione**: modulo tecnico che conferma la robustezza statistica delle relazioni ipotizzate tramite Modelli di Equazioni Strutturali. **Collegamento col Paper**: supporta l’Appendice metodologica, confermando che i nessi causali non sono spuri.

Detecting Strategic Decline: Anomaly Detection as an Early Warning System for Corporate Default in SMEs

IRENE ARIANTE[1], CARLO CAVICCHIA[2]

Abstract

Frame of the research. *Strategic management increasingly conceptualizes firm default as a cumulative and path-dependent process of organizational decline. Within this perspective, early warning depends on the ability to detect weak and evolving signals of vulnerability, yet this remains challenging in contexts characterized by uncertainty and rare adverse events.*

Purpose of the paper. *This study conceptualizes unsupervised anomaly detection as an analytical mechanism that supports strategic sensing. Rather than predicting default outcomes, it identifies persistent deviations from financial normality, making emerging vulnerability observable before formal failure occurs.*

Methodology. *The analysis is based on a longitudinal sample of 32,801 Italian SMEs (2016-2024). A rolling three-year window design is implemented to capture medium-term dynamics, and three complementary unsupervised anomaly detection techniques are applied to accounting data without relying on prior default labels.*

Results. *The results show that anomaly scores are temporally stable and identify firms whose financial deviations persist over time. These firms exhibit substantially higher ex post default rates, indicating that deviations from financial normality provide a meaningful signal of emerging risk.*

Research limitations. *The study focuses on Italian SMEs and accounting data. Future research may extend the analysis to different institutional contexts and incorporate non-financial indicators to capture additional dimensions of vulnerability.*

Managerial implications. *The findings suggest that anomaly detection can support early warning systems by identifying firms that warrant attention before deterioration becomes observable through formal outcomes.*

Originality of the paper. *The study shifts the focus from default prediction to anomaly-based sensing, offering a process-consistent empirical approach to financial vulnerability and providing a concrete operationalization of strategic sensing under conditions of limited labeled data.*

Keywords: *Strategic sensing; Anomaly detection; Organizational decline; Financial vulnerability*

1. Introduction

Firms increasingly operate in environments characterized by persistent uncertainty and structural disruption, conditions that place strain on small and medium-sized enterprises (SMEs). In many European economies, and especially in Italy, SMEs represent the backbone of the productive system in terms of employment and value creation, yet they remain structurally exposed to financial fragility due to limited resources, constrained access to capital, and reduced capacity to absorb prolonged shocks. Despite their economic relevance, adverse outcomes such as firm default remain relatively rare events, making their early identification both strategically important and empirically challenging.

Strategic management research has long emphasized that default should not be interpreted as a sudden or isolated event, but as the outcome of cumulative processes of organizational decline in which vulnerabilities progressively emerge and consolidate over time (Pasch, 2019). From this perspective, the antecedents of failure are embedded in subtle and often ambiguous deviations that precede formal default and remain difficult to identify ex ante. While this process-based view is well established at the theoretical level, translating it into empirical tools capable of supporting early detection remains problematic.

A central limitation of the existing literature lies in its predominantly retrospective orientation. Much of the empirical evidence on organizational decline reconstructs trajectories of deterioration

[1] University of Naples Federico II, Naples, Italy, irene.ariante@unina.it
[2] Erasmus University Rotterdam, Rotterdam, The Netherlands, cavicchia@ese.eur.nl

after adverse outcomes have already occurred (Mellahi, 2005). Although such approaches provide valuable insight into the mechanisms underlying failure, they offer limited guidance on how emerging vulnerabilities can be identified prospectively, particularly in contexts characterized by ambiguity and weak signals. Early manifestations of decline tend to be noisy, gradual, and embedded in routine organizational and financial fluctuations, making them difficult to distinguish from normal variation in performance (Korol, 2020).

Within this context, the challenge of early warning cannot be reduced to a purely technical problem of outcome prediction. Rather, it involves the ability to identify and interpret deviations from expected patterns before they become clearly associated with adverse events. This shifts the focus from prediction to sensing, understood as the capacity to make latent signals of vulnerability visible and to support managerial attention under conditions of uncertainty.

This study adopts this perspective by conceptualizing default as a progressive deviation from evolving patterns of financial normality. Instead of modelling failure as a binary outcome, it investigates how unsupervised anomaly detection can be used to identify firms that systematically diverge from prevailing financial configurations. In doing so, the study isolates the sensing dimensions of early warning, focusing on the detection of emerging anomalies independently from subsequent outcome realization.

Empirically, the analysis is based on a longitudinal sample of Italian SMEs observed over the period 2016-2024. The choice of this context reflects both its economic relevance and its structural vulnerability, which make it particularly suitable for examining early manifestations of financial fragility. A rolling three-year window design is implemented to capture medium-term dynamics, and multiple unsupervised anomaly detection models are applied to accounting data to generate firm-level anomaly scores over time.

Building on this framework, the study addresses the following research questions:

RQ1. How can unsupervised anomaly detection support the identification of emerging financial vulnerability in contexts characterized by rare events and high uncertainty?

RQ2. How do different anomaly detection logics contribute to the identification of persistent deviations from financial normality?

By addressing these questions, the study contributes to strategic management literature in two ways. First, it provides a process-consistent operationalization of organizational decline based on longitudinal deviations rather than discrete outcomes. Second, it conceptualizes anomaly detection as an analytical infrastructure that supports strategic sensing and attention allocation, offering a complementary perspective to outcome-based approaches.

The paper is structured as follows. Section 2 develops the theoretical background by integrating insights from the literature on organizational decline, early warning signals, and strategic sensing. The subsequent section outlines the research context, data, and methodological design. Section 4 presents the empirical results, followed by a discussion of their theoretical and managerial implications.

2. Theoretical Background

Firm default can be broadly defined as a condition in which a company experiences significant difficulties in meeting its financial obligations (Aliaj, Anagnostopoulos, and Piersanti, 2019). This definition encompasses not only formal insolvency, but also situations of severe financial distress in which firms remain solvent only through extraordinary measures, delayed payments, or debt renegotiation (Geoffrey, 2020). Such a broad conceptualization allows default to be interpreted not as a discrete event, but as the observable outcome of a progressive deterioration in financial sustainability unfolding over time.

This interpretation is consistent with a well-established tradition in strategic management that conceptualizes failure as a process of organizational decline. Early contributions describe decline as

the cumulative result of misaligned strategic decisions, increasing rigidity, and the gradual erosion of the firm's capacity to generate adequate cash flows (Billings, Milburn, and Schaalman, 1980). Financial deterioration rarely emerges abruptly. Rather, it develops through incremental and often ambiguous changes that precede the formal manifestation of default by several periods (Korol, 2020). Default therefore appears as a dynamic and cumulative phenomenon rather than as a sudden outcome.

Process models of decline further clarify the mechanisms through which vulnerability evolves over time. Weitzel and Jonsson (1989) describe decline as a sequence of stages that include blindness, delayed recognition, inadequate response, and progressive deterioration. A central implication of this model is that early phases of decline are characterized not by clearly negative indicators, but by difficulties in interpreting emerging signals. In these stages, changes in the relationships between resources, operations, and performance remain subtle and are often indistinguishable from background variation, becoming evident only in retrospect (Mellahi, 2005). Consistently, research on corporate failure has described decline as a downward spiral in which internal conditions and external pressures reinforce one another, progressively constraining adaptive capacity (Hambrick and D'Aveni, 1988).

Subsequent contributions emphasize the role of decision sequences and delayed responses, highlighting how unsuccessful turnaround attempts contribute to the consolidation of decline trajectories (Sheppard and Chowdhury, 2005). Integrative perspectives have further argued that failure should not be interpreted as an isolated event, but as the final outcome of accumulated vulnerabilities (Mellahi and Wilkinson, 2004). This view aligns with broader models of organizational development, which suggest that growth phases generate tensions that, if not addressed, may lead to rigidity and decline (Greiner, 1998). Taken together, these perspectives converge on a common insight. The antecedents of default are embedded in gradual and often ambiguous deviations that emerge over time and are difficult to identify in their early stages.

Within this framework, the problem of early detection becomes central. Early manifestations of vulnerability are typically weak, noisy, and embedded in routine organizational and financial fluctuations, making them difficult to distinguish from normal variation in performance (Korol, 2020). As a result, organizations frequently recognize deterioration only when it has already intensified and strategic options have narrowed. The identification of weak but persistent deviations is therefore not only an analytical issue, but also a problem of attention and interpretation.

Early warning systems have been proposed as mechanisms to address this challenge by transforming dispersed signals into potentially actionable information (Miles, 2010). Their function is not to eliminate uncertainty, but to support the identification and prioritization of emerging areas of concern. However, their effectiveness depends on the ability to balance sensitivity and robustness. Systems that are too sensitive may generate excessive false alarms, whereas systems that are too rigid may detect signals only when deterioration is already advanced (Divi et al., 2024). In addition, many existing approaches rely on predefined indicators or outcome-based calibration, which may limit their ability to capture heterogeneous and evolving forms of vulnerability, particularly in contexts characterized by rare adverse events.

The Attention-Based View provides a theoretical lens to understand how early warning signals are translated into strategic action. Given the limits of managerial attention, organizations rely on structures and processes that selectively direct attention toward issues perceived as relevant (Joseph et al., 2024; Love, 2024). Signals do not possess intrinsic meaning. Their relevance emerges through processes of selection, interpretation, and prioritization. In this sense, the challenge of early warning is closely related to the ability to make certain signals visible and salient within a broader field of information.

These considerations are closely related to the dynamic capabilities framework, which conceptualizes adaptation as the outcome of organizational capabilities associated with sensing, seizing, and reconfiguring (Teece et al., 1997). Among these, sensing refers to the ability to identify and interpret emerging threats and opportunities. Under conditions of uncertainty, effective sensing requires mechanisms that allow organizations to detect deviations from expected patterns and to

interpret their potential implications while preserving space for managerial judgment (Ben Selma et al., 2025). However, while the concept of sensing is well developed at a theoretical level, its empirical operationalization remains limited.

Despite the richness of these theoretical perspectives, a gap remains in understanding how early signals of decline can be identified prospectively in contexts characterized by ambiguity and rare adverse events. Much of the existing evidence relies on retrospective analyses that reconstruct warning signals after outcomes have occurred, thereby introducing interpretive bias. Approaches such as temporal bracketing have improved the analysis of process dynamics, but they presuppose that relevant phases can be identified in advance, an assumption that is difficult to sustain in the presence of heterogeneous and evolving trajectories (Monazzam and Crawford, 2024). As a result, there is limited longitudinal evidence on how signals of vulnerability emerge, persist, or dissipate over time (de Metz et al., 2024).

Within this theoretical space, anomaly detection offers a potential analytical approach for addressing these limitations. Anomaly detection systems are designed to identify observations that deviate from patterns of normality without requiring the prior specification of an outcome variable (Olateju et al., 2024). Unsupervised approaches are particularly suitable in contexts where adverse events are rare and observable only ex post, and where vulnerability emerges through heterogeneous configurations of signals rather than through a single dominant pattern (Shaukat et al., 2021).

From a strategic management perspective, anomaly detection can be interpreted as a mechanism that supports sensing by making latent deviations visible. Rather than providing deterministic predictions, it enables the identification of observations that diverge from prevailing patterns and may therefore warrant further attention. In this sense, anomaly detection contributes to structuring the field of attention by concentrating focus on a limited subset of potentially relevant cases. This function is consistent with the Attention-Based View, as it supports processes of selection and prioritization, and with the sensing dimension of dynamic capabilities, as it facilitates the identification of emerging vulnerabilities under uncertainty.

3. Research Design

3.1 Research context and data

This study focuses on small and medium-sized enterprises (SMEs), which constitute a central component of contemporary economic systems in terms of value creation and employment, while remaining structurally exposed to environments characterized by uncertainty, disruption, and systemic shocks (Otokiti et al., 2022). Compared to larger firms, SMEs typically operate with more limited financial resources, a reduced capacity to absorb prolonged adverse conditions, and less formalized risk management structures. These characteristics contribute to a higher sensitivity to fluctuations in financing conditions, access to credit, and broader macroeconomic instability (Akpe et al., 2022).

Periods of systemic uncertainty tend to further amplify these vulnerabilities, often inducing firms to prioritize short-term liquidity and operational continuity over longer-term investments. This reallocation of resources may affect the accumulation and maintenance of strategic assets, with implications for future competitiveness and resilience (Badykova and Dinmukhametova, 2025). Within this context, the identification of emerging financial fragility becomes particularly relevant, yet empirically challenging.

To examine these dynamics, the study relies on accounting items and financial ratios as the primary source of information. Financial statement data provide a standardized and systematically available representation of firm-level conditions, reflecting the cumulative outcome of strategic and operational decisions as well as their interaction with the external environment (Beaver et al., 2012). Prior research suggests that financial deterioration tends to emerge through gradual changes in profitability, liquidity, and capital structure rather than through abrupt shifts (Tran et al., 2023). Accounting-based

indicators are therefore suitable for capturing latent and progressive signals of vulnerability over time.

The empirical analysis is based on a longitudinal sample of 32,801 Italian SMEs observed over the period 2016-2024. The observation period from 2016 to 2024 provides a homogeneous and longitudinally consistent dataset, allowing for the analysis of financial dynamics across firms and over time under comparable reporting conditions.

Financial information is retrieved from the Orbis database and includes a set of accounting variables and derived financial ratios capturing complementary dimensions of firm performance. The dataset also contains basic firm characteristics, including industry classification according to NACE Rev. 2 and firm size. A binary default indicator is included and used exclusively for ex post validation purposes (Modina and Pietrovito, 2014; Cheraghali and Molnar, 2025).

The variables cover key dimensions of liquidity, capital structure, profitability, efficiency, and asset composition, allowing for a comprehensive representation of firms' financial configurations. This structure is consistent with an analytical approach focused on identifying deviations from patterns of normality rather than predicting discrete outcomes. Firms operating in the financial, insurance, and real estate sectors, as well as those in public administration and highly regulated industries, are excluded from the analysis in order to preserve comparability in accounting structures and risk dynamics (Arcuri and Levratto, 2020).

Micro-enterprises are not included due to differences in reporting standards that limit the comparability and informational richness of their financial statements. The classification of small and medium-sized enterprises follows the European regulatory framework (2003/361/EC) and related provisions that define size thresholds in terms of employment and turnover.

3.2 Methodology

Given the process-oriented and exploratory nature of the study, the research design adopts an unsupervised learning approach aimed at identifying deviations from patterns of financial normality rather than predicting discrete outcomes. This choice is consistent with the conceptualization of organizational decline as a gradual and heterogeneous process, in which early manifestations of vulnerability are not directly observable through predefined labels. Within this framework, anomaly detection is interpreted as an analytical mechanism that supports strategic sensing by enabling the identification of observations that diverge from prevailing financial configurations.

Unsupervised anomaly detection techniques do not rely on labeled outcomes and are therefore particularly suitable for contexts in which the event of interest, such as firm default, is rare and observable only ex post. These methods assume that anomalous observations occur less frequently than regular ones and that deviations from dominant patterns may signal emerging instability (Hilal, Gadsden, and Yawney, 2023). In the present study, the incidence of default is below one percent, a condition under which supervised classification models are often affected by class imbalance and instability in estimation (Shyalika, Wickramarachchi, and Sheth, 2024).

Prior to model implementation, financial data are preprocessed to ensure comparability and robustness. Given the heterogeneity of firms across industries and the presence of missing values, data imputation is conducted using a sector-based approach. Missing values are replaced with the median computed within each NACE Rev. 2 sector, preserving sector-specific financial structures while limiting the influence of extreme observations.

To account for the multidimensional nature of financial vulnerability, the analysis employs three complementary anomaly detection models, each reflecting a different representation of normality. Rather than relying on a single technique, the use of multiple models is motivated by the recognition that deviations can emerge through different configurations of financial indicators and may not be fully captured by a single analytical perspective. In addition, a multi-model approach allows the analysis to address the uncertainty associated with reliance on any single specification, strengthening the robustness of inference and supporting the interpretation of complex and heterogeneous patterns of financial abnormality (Giustolisi et al., 2007; Henley et al., 2020)

Isolation Forest identifies anomalies based on structural rarity, assigning higher anomaly scores to observations that can be isolated with fewer partitioning steps in the feature space (Liu, Ting, and Zhou, 2008). Autoencoders, implemented as neural network models, identify anomalies through reconstruction error, capturing observations whose financial configurations deviate from patterns learned from the data (Boukerche et al., 2020). One-Class Support Vector Machines define a boundary of normality in the feature space and classify observations falling outside this boundary as anomalous (Schölkopf et al., 2000).

From a strategic perspective, these models can be interpreted as alternative analytical lenses through which financial vulnerability becomes observable. Their joint application enables not only the assessment of convergence in anomaly signals, but also the identification of differences that reflect distinct representations of deviation. Convergence across models can be interpreted as an indication of robust and persistent anomalies, whereas differences may highlight specific dimensions of vulnerability that are emphasized under particular assumptions about normality.

All models are implemented within a longitudinal rolling-window framework with a fixed three-year window. For each evaluation year, models are trained exclusively on data from the preceding three years and then applied to the subsequent year. This approach allows the analysis to adapt to evolving economic conditions while maintaining temporal consistency. The three-year horizon reflects a balance between responsiveness to recent changes and the need to capture medium-term dynamics consistent with a process-based interpretation of financial deterioration (Howard and Otobo, 2025).

Consistent with the unsupervised and sensing-oriented nature of the study, model evaluation does not rely on traditional classification metrics such as accuracy or AUC, which are not well suited to contexts characterized by rare events and the absence of reliable labels (Sørbø and Ruocco, 2023). Instead, a multidimensional evaluation framework is adopted, focusing on temporal stability, persistence, cross-model convergence, and ex post economic relevance.

Temporal stability is assessed through rank-based correlation measures, specifically Spearman's rho and Kendall's tau, which allow the comparison of ordered anomaly scores across periods without imposing arbitrary thresholds (Bereta, 2024). The persistence of anomalous observations is evaluated using the Jaccard index, which measures the overlap of top-ranked firms across consecutive years and captures the extent to which a stable set of firms repeatedly exhibits anomalous characteristics (Alvarez et al., 2022). Cross-model convergence is examined by comparing the overlap of anomalous firms identified by different models, providing an indication of the robustness of detected signals.

At the same time, differences across models are interpreted as potentially informative rather than purely methodological noise. Variations in anomaly detection outcomes may reflect alternative representations of financial deviation and contribute to a richer understanding of emerging vulnerability. This interpretative approach is consistent with the conceptualization of anomaly detection as a mechanism that supports strategic sensing, where the objective is to make deviations visible and interpretable rather than to produce a single definitive classification.

Finally, the economic relevance of anomaly scores is assessed through an ex post enrichment analysis. The incidence of observed default within the top anomalous firms is compared with the baseline default rate, and a lift measure is computed. Although default outcomes are not used for model training, this analysis provides an indication that detected anomalies are associated with higher realized risk, supporting the validity of anomaly detection as an analytical approach for identifying emerging financial vulnerability under conditions of extreme class imbalance (Řezáč and Řezáč, 2011).

4. Results

This section reports the empirical results obtained from the rolling three-year window implementation of the anomaly detection models. In line with the methodological design, the analysis

focuses on the temporal behavior, persistence, convergence, and ex post economic relevance of anomaly scores.

To assess the temporal coherence of anomaly signals, the stability of firm-level rankings across consecutive years is evaluated using rank-based correlation measures. Specifically, Spearman's rho and Kendall's tau are computed between anomaly score rankings obtained in adjacent periods. Table 1 reports the average rank correlations for each anomaly detection model across the full observation window.

The results show that all three models generate rankings that exhibit a consistent degree of temporal stability, although differences emerge in terms of magnitude across techniques. This pattern indicates that anomaly signals are not driven solely by year-specific fluctuations, but instead display continuity over time. Such continuity is consistent with a process-based interpretation of organizational decline, according to which financial vulnerability develops through gradual and cumulative deviations rather than through isolated shocks. From a sensing perspective, the temporal stability of anomaly rankings suggests that detected signals reflect underlying structural conditions rather than transient noise.

Tab. 1: Temporal stability of anomaly rankings

Model	AVG. Spearman	AVG. Kendall
Isolation Forest	0.729	0.551
Autoencoder	0.625	0.451
OCSVM	0.542	0.542

Source: our elaboration

Beyond rank correlation, the analysis examines whether the most anomalous firms remain consistently identified across periods. For this purpose, the persistence of the top 1 percent of firms ranked by anomaly score is evaluated using the Jaccard similarity index between consecutive years. Table 2 reports the average persistence values for each model.

The results indicate that a subset of firms repeatedly appears among the most anomalous observations over time, although the degree of persistence varies across detection techniques. This finding suggests that extreme deviations are not isolated occurrences, but tend to recur across consecutive periods. This pattern aligns with process models of decline, which emphasize the cumulative and self-reinforcing nature of financial deterioration. Persistent anomaly signals can therefore be interpreted as indications of structural vulnerability that progressively consolidates, rather than as episodic deviations. From a strategic perspective, the recurrence of anomalous observations highlights the potential of anomaly detection to support sustained attention to firms that exhibit ongoing divergence from prevailing financial patterns.

Tab. 2: Average persistence of top 1% anomalous firms

Model	AVG. TOP-1% Persistence
Isolation Forest	0.229
Autoencoder	0.196
OCSVM	0.237

Source: our elaboration

To evaluate the robustness of anomaly detection outcomes across different methodological assumptions, the overlap between the sets of top anomalous firms identified by different models is examined. Pairwise Jaccard indices are computed for the top 1 percent of firms within each year and then averaged across the observation period. Table 3 reports the average cross-model overlap values.

Tab. 3: Average Jaccard overlap across models

Model Pair	AVG. Jaccard
Autoencoder – Isolation Forest	0.385
Autoencoder - OCSVM	0.506
Isolation Forest – OCSVM	0.524

Source: our elaboration

The results indicate partial convergence among models, with some pairs exhibiting higher levels of overlap than others. This convergence suggests that, despite relying on distinct detection logics, different approaches identify a shared subset of firms characterized by pronounced deviations. At the same time, the absence of full convergence indicates that each model captures specific dimensions of financial abnormality. From a theoretical perspective, this pattern supports the view that vulnerability does not manifest through a single dominant configuration, but rather through heterogeneous and context-dependent forms. The coexistence of convergence and divergence across models is therefore consistent with a sensing perspective in which multiple analytical lenses contribute to a richer interpretation of emerging signals rather than to their reduction to a single classification.

Although default outcomes are not used during model training or calibration, an ex post analysis is conducted to assess whether firms identified as highly anomalous exhibit higher observed default rates. For each year, the default incidence within the top 1 percent of anomalous firms is compared with the baseline default rate in the full sample, and a lift measure is computed.

Table 4 reports average baseline default rates, average default rates within the top anomalous group, and the corresponding lift values across the observation window. The results show that firms classified among the most anomalous display substantially higher default incidence relative to the population average. This enrichment indicates that anomaly scores capture deviations that are economically meaningful, even in the absence of outcome information during model estimation.

From a strategic perspective, this finding suggests that anomaly detection can identify firms that are not only statistically distinct, but also associated with materially higher ex post risk. This supports the interpretation of anomaly detection as a mechanism that contributes to early sensing by highlighting observations that warrant attention before adverse outcomes become observable. At the same time, the fact that anomaly detection does not rely on predefined labels implies that such signals remain open to interpretation and require integration with contextual and managerial knowledge.

Tab. 4: Default enrichment and lift

Model	AVG. Baseline Default Rate	AVG. TOP-1% Default Rate	AVG. Lift
Isolation Forest	0.00082	0.073	89.4
Autoencoder	0.00082	0.050	61.2
OCSVM	0.00082	0.064	78.0

Source: our elaboration

The results provide consistent evidence that anomaly detection models identify patterns of financial deviation that are temporally stable, persistent, and partially convergent across different detection logics. These properties support the interpretation of anomaly scores as indicators of evolving vulnerability rather than isolated statistical irregularities, in line with a process-based view of organizational decline and with the conceptualization of anomaly detection as a mechanism that supports strategic sensing under conditions of uncertainty.

5. Discussion and Conclusions

The empirical evidence presented in this study supports a process-based interpretation of financial vulnerability, in which firm default emerges as the observable outcome of a gradual and cumulative deviation from prevailing patterns of financial normality. Across the observation window, anomaly scores exhibit temporal stability, persistence among the most anomalous firms, and partial convergence across alternative detection logics, while also displaying a strong association with ex post default incidence. These properties indicate that the detected anomalies do not correspond to isolated statistical irregularities or transitory fluctuations. Rather, they capture recurring configurations that remain observable across time and are systematically associated with higher realized risk. In this sense, the findings provide empirical grounding for the view that financial deterioration unfolds through progressive and partially latent processes rather than through discrete events.

The temporal stability of anomaly rankings is particularly informative in relation to the literature on organizational decline. Prior research has emphasized that early stages of decline are characterized by weak and ambiguous signals embedded within routine organizational and financial dynamics. If such signals were predominantly driven by short-term shocks or measurement noise, one would expect limited continuity in firm-level anomaly rankings across adjacent periods. The observed stability suggests instead that a relevant portion of financial abnormality reflects underlying conditions that evolve gradually. This pattern is consistent with process models in which deterioration emerges through incremental misalignments between resource allocation, operational structures, and environmental conditions. By identifying deviations that persist across time, anomaly detection provides a way to observe these dynamics prospectively, without relying on retrospective reconstruction after failure has occurred.

The persistence of firms within the upper tail of anomaly rankings further reinforces this interpretation. The repeated presence of a subset of firms among the most anomalous observations indicates that extreme deviations tend to recur rather than dissipate. This finding aligns with theoretical accounts that describe decline as a cumulative and self-reinforcing process. Once firms enter a condition of sustained abnormality, their capacity to reconfigure and return to a state consistent with prevailing financial patterns may become progressively constrained. While persistence does not imply inevitability of failure, it signals the presence of trajectories in which vulnerability consolidates over time. Persistent anomaly status can therefore be interpreted as an observable manifestation of the dynamics described in the literature on downward spirals and delayed organizational response.

The analysis of cross-model convergence provides further insight into the nature of financial abnormality. The partial overlap among anomaly detection techniques indicates that different analytical representations identify a shared subset of firms characterized by pronounced deviations. At the same time, the absence of full convergence suggests that vulnerability does not manifest through a single, uniform configuration. Each model captures specific aspects of deviation, reflecting different assumptions about the structure of financial normality. This coexistence of convergence and divergence is consistent with the view that organizational decline is heterogeneous and may unfold through multiple pathways. From this perspective, the use of multiple detection logics reflects the multidimensional nature of financial abnormality and enables the identification of distinct yet partially overlapping patterns of deviation.

The ex post enrichment analysis provides an additional layer of validation. Firms identified within the top percentile of anomaly scores exhibit default rates that are substantially higher than the baseline observed in the full sample. This result indicates that deviations from financial normality are not only statistically identifiable, but also economically meaningful. Importantly, this association emerges without the use of default information during model estimation. This finding supports the interpretation that default represents the observable endpoint of a broader and earlier process of deterioration, and that anomaly detection can capture elements of this process before it becomes fully visible through formal outcomes. In this sense, the results reinforce a distinction between detecting

vulnerability and predicting failure, showing that the former can be empirically grounded even in the absence of explicit labels.

Taken together, these findings contribute to the literature on early warning systems by extending the analytical focus from outcome prediction to the identification of evolving deviations. Traditional approaches have often relied on predefined indicators or supervised models calibrated on historical failure events. While effective in settings where failure patterns are well specified, such approaches may be less suited to contexts characterized by rare events, heterogeneous trajectories, and limited availability of labeled data. The results of this study show that early warning can be grounded in the detection of persistent deviations from financial normality, allowing the identification of potentially vulnerable firms independently of predefined outcome categories. This perspective complements outcome-based approaches by enabling the prospective observation of vulnerability at earlier and less codified stages of its development. This shift also clarifies the theoretical role of anomaly detection within strategic management. The study conceptualizes anomaly detection as an analytical infrastructure that supports the sensing dimension of organizational adaptation. The findings provide empirical support for this interpretation by showing that anomaly detection enables the systematic identification of deviations that are stable, recurrent, and associated with higher realized risk. In doing so, it operationalizes sensing as the detection of departures from evolving patterns of normality, rather than as the identification of predefined warning signals. This reframes sensing as a data-driven process grounded in longitudinal observation and extends its empirical specification beyond its predominantly conceptual treatment in the literature.

Within the Attention-Based View, this mechanism can be interpreted as a means of structuring the allocation of managerial attention. Organizations operate under conditions in which relevant signals are dispersed and often difficult to distinguish from background variation. The results indicate that anomaly detection can reduce this complexity by identifying a limited subset of firms that exhibit persistent and pronounced deviations from prevailing financial patterns. This filtering function does not determine how signals are interpreted or acted upon, but it increases their visibility within the organizational field of attention. In this sense, anomaly detection contributes to the selective process through which issues become candidates for managerial consideration, while remaining distinct from subsequent processes of interpretation and action. A similar interpretation applies within the dynamic capabilities framework. The findings suggest that sensing can be operationalized as the identification of recurring deviations that signal potential misalignment between the firm and its environment. Anomaly detection contributes to this function by enabling the prospective observation of such deviations without presupposing their final outcomes. It therefore provides an analytical mechanism that supports the sensing component of broader organizational capabilities by expanding the informational basis on which subsequent processes of evaluation and response can be developed.

From an interpretive standpoint, the use of disaggregated financial indicators allows the detection of complex configurations of deviation that may not be reducible to predefined financial dimensions. At the same time, interpretation requires a distinct analytical step following detection. Once anomalous firms have been identified, their financial profiles can be examined ex post in relation to broader areas such as liquidity, capital structure, profitability, efficiency, and asset composition. This separation between detection and interpretation preserves the configurational nature of anomaly identification while enabling a more structured understanding of the underlying sources of deviation, without constraining the detection process through ex ante aggregation.

The practical implications of the study follow from this analytical logic. The proposed approach produces a ranking of firms based on the extent of their deviation from financial normality, rather than a binary classification of failure risk. This ranking can support monitoring activities by highlighting firms whose financial configurations warrant closer examination. Its applicability is facilitated by the use of accounting data that are widely available and standardized across firms. At the same time, the implementation of such models requires analytical capabilities that may not be uniformly distributed. In many cases, their use is more likely to be concentrated within intermediaries such as financial institutions, advisory organizations, or collective monitoring bodies, where anomaly

signals can be integrated with qualitative assessment and domain-specific knowledge. In this context, anomaly detection contributes to structuring the diagnostic process by identifying cases that merit attention, while remaining complementary to managerial judgment.

The study is subject to several limitations. The empirical analysis focuses on Italian SMEs, a context characterized by specific institutional and economic conditions. While this setting is appropriate for examining financial vulnerability, the extent to which the observed patterns generalize to other contexts remains an open question. In addition, the analysis relies exclusively on accounting data, which may not fully reflect early changes in governance, organizational structure, or market positioning. Finally, while the multi-model approach allows for a richer representation of financial abnormality, the study does not provide a formal decomposition of anomaly signals into interpretable components. These limitations suggest several avenues for future research. Integrating non-financial indicators with accounting-based anomaly detection may provide a more comprehensive representation of emerging vulnerability. Further work may also explore methods for systematically linking anomaly outputs to broader financial dimensions, thereby enhancing interpretability while preserving the configurational logic of detection. Comparative analyses across different institutional settings and firm populations may help assess the robustness of the observed relationships under varying conditions.

In conclusion, the study shows that unsupervised anomaly detection can support the identification of emerging financial vulnerability in contexts characterized by rare events and high uncertainty. By focusing on temporal stability, persistence, cross-model convergence, and economic relevance, the analysis demonstrates that deviations from financial normality can be observed prospectively and interpreted as indicators of evolving risk. Taken together, these findings address the two research questions by showing that unsupervised anomaly detection can support the prospective identification of emerging financial vulnerability and that alternative detection logics capture complementary forms of deviation from financial normality. In doing so, it shifts the unit of analysis from discrete failure events to persistent patterns of deviation, providing a process-consistent empirical lens on organizational decline and positioning anomaly detection as a rigorous analytical mechanism for supporting strategic sensing under conditions of uncertainty.

From Rhetoric to Reality: Configurational Pathways to Duty-Based Corporate Purpose in European Firms

FERNANDO CAMASTRA[1]

Abstract

Frame of the research. *Contemporary corporate governance faces a fundamental tension between the rhetorical embrace of stakeholder-oriented governance and the persistent structural dominance of shareholder primacy. This creates a persistent 'enactment gap' where firms adopt purpose-driven language without altering their decision-making architecture.*

Purpose of the paper. *This study investigates the governance configurations that enable large European firms to credibly enact a Duty-Based Corporate Purpose. We address the theoretical limitations of linear regression models by employing a configurational approach that captures the complex, interdependent nature of governance attributes.*

Methodology. *We employ fuzzy-set Qualitative Comparative Analysis (fsQCA) on a dataset of Euro Stoxx 50 firms. We measure purpose orientation via computer-aided text analysis and examine six governance conditions: ownership concentration, board size, gender diversity, board independence, CSR committees, and ESG-linked compensation.*

Results. *The analysis reveals three equifinal pathways to purpose: (1) Independent Monitoring, where board independence drives purpose in dispersed ownership firms; (2) Diverse Stewardship, where gender diversity counterbalances concentrated ownership; and (3) Pluralistic Consensus, where diversity overcomes inertia in large boards. Crucially, CSR committees and ESG-linked pay consistently appear as core 'hardware' across all high-purpose configurations, while board independence and gender diversity largely function as context-dependent substitutes.*

Research limitations. *The cross-sectional design captures governance at a single point in time, limiting insights into the dynamic evolution of purpose. Additionally, the focus on 50 big European firms constrains generalizability to smaller enterprises or non-European contexts.*

Managerial implications. *Findings challenge mimetic governance design: boards should calibrate their composition to the firm's ownership context, prioritizing gender diversity in concentrated-ownership firms and board independence in dispersed-ownership firms, rather than relying on uniform best-practices.*

Originality of the paper. *By demonstrating that governance mechanisms function as bundles, this study offers novel insights into the substitutability of monitoring mechanisms, effectively bridging agency and stewardship theories.*

Keywords: *corporate purpose; duty-based governance; fuzzy-set qualitative comparative analysis; board diversity; ownership concentration; ESG governance*

1. Introduction

The enactment of corporate purpose represents one of the defining governance challenges of the contemporary corporation (Davis, 2021; Tafuro and Piccaluga, 2025). We are witnessing a fundamental 'Purpose Turn' in the theory of the firm, a shift from the monistic primacy of shareholder value toward a pluralistic conception where the corporation is viewed as a social institution embedded in a complex ecological and societal system (Gartenberg et al., 2019). This paradigmatic transition was symbolically codified in 2019 when the Business Roundtable (BRT) formally abandoned its adherence to shareholder supremacy, committing instead to deliver value to all stakeholders (Business Roundtable, 2019). This declaration, echoed by the British Academy's "Future of the Corporation" program (Ebert and Hurth, 2022), suggests a move from an instrumental view, where social benefits are a by-product of profit, to a constitutive view, where solving societal problems is the firm's existential reason for being (Mayer, 2021).

However, a significant gap has opened between this normative rhetoric and empirical reality. A growing stream of critical literature documents a persistent enactment gap, a deep disconnect between high-level purpose statements and the operational mechanism of corporate decision-making. Bebchuk

[1] Sapienza University of Rome, email: fernando.camastra@uniroma1.it

and Tallarita (2020; 2022) argue that without binding legal or structural constraints, stakeholderism remains an "illusory promise" (Bebchuk and Tallarita, 2022, p. 1042), serving primarily to insulate management from accountability while delivering negligible benefits to third parties. Similarly, Westphal (2023) characterizes the current landscape as systemic symbolic management, where firms adopt the lexicon of purpose to garner legitimacy while retaining governance architectures designed for short-term financial extraction. In this landscape, even when firms adopt a "Duty-Based" purpose (George et al., 2023), these commitments risk being reduced to "cheap talk" (Smulowitz et al., 2025), because the underlying governance configurations remain aligned with shareholder primacy. This enactment crisis remains theoretically unsettled, and addressing it requires focusing on corporate governance as the critical institutional lever that determines whether purpose becomes a binding constraint or remains symbolic rhetoric. Governance structures encompassing ownership, board composition, monitoring mechanisms, and incentive systems constitute the organizational fabric through which managerial discretion is either disciplined toward stakeholder interests or left unconstrained (Levillain and Segrestin, 2019; Bebchuk and Tallarita, 2022). Understanding which governance configurations enable credible purpose enactment is therefore essential. However, as Misangyi et al. (2017) argue, organizations are not aggregations of independent variables but complex bundles of interconnected attributes. The failure of a single mechanism, such as a CSR committee, may often stem not from its inherent inefficacy but from the absence of complementary attributes, for example, specific ownership structures or board compositions, required to activate it. By treating these mechanisms in isolation, prior literature has obscured the configurations that enable the credible enactment of purpose.

Our paper addresses this theoretical gap by asking the following research question: *Under what governance conditions does corporate purpose shift from rhetoric to reality?*

We aim to answer by exploring the equifinal pathways through which different firms navigate the structural tensions of governance. Drawing on the "Governance Trilemma" framework, which posits inherent trade-offs between board independence, stakeholder responsiveness, and market efficiency (Claassen, 2025; Corrigan, 2025), we propose that credible enactment requires specific bundles that align the firm's legal, monitoring, and incentive structures.

To investigate this, we employ fuzzy-set Qualitative Comparative Analysis (fsQCA) on a dataset of Euro Stoxx 50 firms. This method is particularly well suited to identify the asymmetric and conjunctureal causes of purpose enactment. Our analysis identifies three distinct governance logics: *Independent Monitoring*, relying on dispersed ownership and board independence; *Diverse Stewardship*, leveraging blockholder power and gender diversity; and *Pluralistic Consensus*, utilizing diversity to overcome the inertia of large boards.

This study contributes to the institutional, stewardship and agency theories by reframing their classical problems in purpose-driven governance. We demonstrate, for example, that standard mechanisms like ESG pay are necessary but insufficient 'hardware' that must be activated by the 'software' of specific board compositions. By mapping these configurations, we move beyond the binary debate of shareholder vs. stakeholder to reveal the structural conditions under which purpose transitions from a symbolic gesture to a binding constraint. In doing so, the article makes three contributions. First, it specifies the governance structures that appear necessary for duty-based purpose to be credibly enacted in large European firms. Second, it shows how different combinations of ownership concentration and board composition enable distinct, equifinal pathways to the same outcome. Third, it connects these pathways to the governance trilemma, clarifying how firms relax different dimensions of efficiency, accountability, and representation. In fact, the article adopts the governance trilemma as an orienting lens rather than as a problem to be normatively solved. Claassen (2025) and Corrigan (2025) conceptualize this trilemma as a structural impossibility of simultaneously maximizing market efficiency, managerial accountability, and broad stakeholder representation within a single governance arrangement. Any concrete governance design must relax one of these dimensions in order to preserve the other two. The three configurational paths identified in this study can therefore be interpreted as distinct adaptive responses to the trilemma: independent

boards in widely held firms prioritize accountability and efficiency at the expense of direct stakeholder representation; diverse boards in blockholder-controlled firms enhance stakeholder voice while accepting some concentration of control; and large, pluralistic boards trade off decisional efficiency for representation, relying on diversity and formal purpose hardware to preserve accountability. Ultimately, the article positions its contribution as an empirical illustration of how large European firms navigate, rather than resolve, the governance trilemma.

2. Literature Review

2.1 Defining Corporate Purpose

The outcome of interest in this study is Corporate Purpose, specifically the degree to which a firm aligns with a "Duty-Based" orientation as opposed to a "Goal-Based" orientation. This distinction is derived from the influential theoretical framework proposed by George et al. (2023) and further elaborated in recent management literature (Tafuro and Piccaluga, 2025). Corporate purpose is often conflated with mission or vision, yet it represents a distinct construct answering the fundamental question: "Why do we exist?" (Tafuro and Piccaluga 2025, p. 3). George et al. (2023) categorize purpose into two dominant logics. The first is Goal-Based Purpose, which is instrumental, strategic, and typically centered on market leadership, competitive advantage, and shareholder value maximization. It views purpose as a target to be achieved. The language associated with this logic emphasizes dominance, profit, growth, strategy, and leadership. The second is Duty-Based Purpose, which is normative, ethical, and multi-stakeholder oriented. It views purpose as a moral obligation to society and the environment, distinct from pure profit generation. It emphasizes the firm's role in a broader ecosystem. The language associated with this logic emphasizes stakeholders, ethics, planet, society, and in general sustainability.

In the context of the Euro Stoxx 50 companies, investigating which governance configurations lead to a Duty-Based Purpose is critical for understanding how firms are responding to the growing regulatory and societal pressure to integrate stakeholder and societal concerns into corporate governance (Huang, 2022). It is important to distinguish this from simple CSR activity; purpose is foundational and existential, whereas CSR can be peripheral. A Duty-Based purpose implies that the firm’s core reason for being is tied to societal welfare, not merely that it performs charitable acts as a side activity. Throughout the paper, this tension between stated purpose and organizational practice is referred to as an enactment gap. The gap emerges when firms articulate duty-based commitments in their corporate discourse but fail to implement governance arrangements that embed those commitments as binding constraints on decision-making. In other words, purpose remains rhetorical when it does not shape actual managerial behavior, and becomes substantive only when supported by institutional structures that make it enforceable.

2.2 Governance configurations

The transition from a symbolic adoption of purpose to a duty-based enactment represents the central tension in contemporary governance scholarship. A substantial body of research indicates a persistent enactment gap where firms adopt the rhetoric of broad stakeholder commitment while retaining decision-making structures that prioritize shareholder primacy (Bebchuk and Tallarita, 2022). This phenomenon, described as "systemic symbolic management" by Westphal (2023), suggests that without specific safeguards, the pressure of the market for corporate control tends to produce mission drift (Levillain and Segrestin, 2019). Consequently, scholars argue that voluntary principles or "cheap talk" in annual reports are insufficient to constrain managerial discretion; instead, credible commitment requires the implementation of a "Constitutive Configuration" of governance mechanisms (Smulowitz et al., 2025; Levillain et al., 2024). This configuration necessitates a ‘hardware’ of specific structural devices, such as specialized Corporate Social Responsibility (CSR) committees and executive compensation linked to ESG targets, that translate abstract normative goals

into binding fiduciary constraints (Dell'Erba and Ferrarini, 2024).

However, the efficacy of this structural hardware is contingent upon the broader ownership environment and the monitoring capacity of the board. In firms characterized by dispersed ownership, the primary agency problem involves managerial shirking, in the classical sense of agency theory, and the risk that stated purpose becomes decoupled from actual strategy to appease short-term market sentiment (Westphal, 2023). In this context, independent directors serve as the critical 'trustees' of the corporate purpose, tasked with ensuring that the structural mechanisms of the CSR committee and ESG pay are not merely performative but effectively insulate the firm from the pressures of short-termism (Kershaw and Schuster, 2022; Mahoney, 2023). High board independence, when coupled with these structural safeguards, creates a zone of insulation that allows the 'hardware' of purpose to function, ensuring that the firm maintains coherence between its intentions and its actions (Morrison and Mota, 2023).

Conversely, the governance logic shifts significantly in the context of concentrated ownership, a prevalent feature in many large European enterprises. While blockholders and long-term owners often exhibit a longer temporal horizon consistent with stewardship theory, effectively mitigating the pressure for quarterly returns (Gartenberg, 2023), they introduce a distinct "Governance Trilemma" regarding stakeholder responsiveness (Claassen, 2025). The central risk in concentrated ownership is not short-termism, but rather a form of insularity or "tunnel vision" where the dominant owner's utility function overshadows the interests of broader societal stakeholders (Corrigan, 2025). In such scenarios, structural 'hardware' alone is insufficient; it requires a 'software', a mechanism to broaden the cognitive diversity of the board and challenge the dominant coalition. Board gender diversity functions as this critical counterbalance. Beyond the argument of fairness, the presence of a critical mass (Torchia et al., 2011) of female directors has been associated with a more comprehensive adjudication of stakeholder trade-offs and a higher sensitivity to ethical obligations. In constitutive governance configurations dominated by blockholders, gender diversity disrupts the homogeneity of the board, forcing a more rigorous debate on the firm's social function and ensuring that the "duty-based" orientation is not subsumed by the private benefits of control, in line with Segrestin and Levillain's (2023) argument that purpose needs legal and governance safeguards beyond shareholder primacy.

Finally, the enactment of purpose faces unique coordination challenges in firms with large board sizes, a structural characteristic often mandated by the complex two-tier board systems found in several European jurisdictions. The influence of board size on company performance has historically been a subject of debate (Yermack, 1996). While large boards theoretically offer greater representation, they are structurally prone to high coordination costs, which can impede the decisive action required to implement a transformative "duty-based" strategy (George et al., 2023). The "Governance Trilemma" suggests that maximizing representation often comes at the cost of efficiency and clear accountability (Claassen, 2025). To overcome the inertia inherent in large groups and prevent the regression toward a lowest common denominator consensus, which typically defaults to financial safety rather than ethical orientation, the composition of the board becomes crucial. In this specific configuration, board gender diversity acts not merely as a representation tool but as a catalyst for more inclusive and critical deliberation (Klettner et al., 2026), reducing the risk that large boards regress to lowest-common-denominator compromises. The inclusion of diverse perspectives within a large board prevents the calcification of decision-making processes, ensuring that the structural mechanisms of the CSR committee and ESG incentives are actively engaged rather than passively administered. Thus, within the constraints of a large board, diversity is the active ingredient that transforms structural potential into the substantive enactment of a social mission (Levillain and Segrestin, 2019).

The present paper treats these three governance logics as configurational expectations that will be assessed and refined through the fsQCA. Throughout the paper, in fact, we distinguish between governance hardware and governance software. By hardware, we mean the formal structural mechanisms (such as CSR committees or ESG-linked compensation schemes) that create binding

procedural constraints on decision-making. These are governance devices that, once institutionalized, impose monitoring obligations, information flows, and accountability triggers independent of who populates the board. By software, we mean the compositional attributes of the board (such as ownership concentration, independence levels and gender diversity) that determine the cognitive frames, interests, and power dynamics through which those procedural constraints are interpreted and enforced. This distinction builds on the concept of constitutive governance, where purpose becomes enforceable only when formal architecture (hardware) is animated by boards possessing both the incentives and cognitive diversity (software) to resist short-term financial pressures. Our configurational approach thus examines how different combinations of software activate or neutralize the same hardware, explaining why structurally identical governance mechanisms produce divergent outcomes across firms.

3. Methodology

To address the causal complexity of corporate purpose, this research employs fuzzy-set Qualitative Comparative Analysis (fsQCA). Unlike regression analysis, fsQCA assumes asymmetry and equifinality, allowing for the identification of multiple governance configurations leading to the same outcome (Ragin, 2009).

3.1 Sample selection and data collection

The empirical setting for this study is the Euro Stoxx 50, the leading blue-chip index for the Eurozone. This index represents the most capitalized and liquid stocks across the Eurozone, providing a crucial case design due to high institutional pressure for ESG compliance (Omenihu et al., 2025).If any substantive shift beyond shareholder primacy is occurring, it should be most visible in these elite firms, which face the highest exposure to the EU sustainable governance agenda (Coluccia et al. 2018).
The dataset was constructed by merging structured quantitative data from Refinitiv Workspace with unstructured textual data extracted automatically from corporate annual reports.
The final sample consists of 50 unique firm observations (N=50) with no missing data (Tab. 1).

3.2 Measure of the Outcome: Duty-Based Purpose

To measure the latent construct of "Duty-Based Purpose", we employed a Computer-Aided Text Analysis (CATA) approach. We analyzed the full text of the latest available Annual Reports and Sustainability Reports for all 50 companies using RStudio. This approach captures the projected identity of the firm beyond simple mission statements. We constructed two mutually exclusive Bag-of-Words dictionaries based on keywords found in purpose-related literature (George et al., 2023; Tafuro and Piccaluga, 2025):

1. Duty-Based Dictionary: stakeholder, society, sustainability, ethics, community, responsibility, planet, inclusive, diversity, environment, purpose, values, long-term, future, generations, impact, non-financial, esg, climate, social, human rights.
2. Goal-Based Dictionary: shareholder, profit, dividend, margin, revenue, growth, performance, return, equity, earnings, capital, market, dominant, competitive, sales, ebitda, net income, cash flow.

The algorithm calculated the raw frequency of terms for each firm. To control for varying document lengths, we computed a Duty-Orientation Ratio (DOR) using the following formula:

$$DOR_i = \frac{\text{Count(Duty Terms)}_i}{\text{Count(Duty Terms)}_i + \text{Count(Goal Terms)}_i}$$

This continuous variable serves as the raw input for the outcome calibration.

3.3 Measurement of causal conditions

We selected six conditions representing the core dimensions of corporate governance: Ownership Structure (Concentration), Board Composition (Size, Diversity, Independence), Monitoring Structures (CSR Committee), and Incentive Structures (Executive Pay). All raw data for these conditions was sourced from Refinitiv.

To ensure precision, we manually calculated ownership concentration as the ratio of "Closely Held Shares" (shares held by insiders and strategic investors) to "Total Shares Outstanding". This provided a precise continuous measure of blockholder control, ranging from dispersed ownership to highly concentrated structures.

Board size is measured as the total number of directors on the board at the fiscal year-end.

Board gender diversity is measured as the percentage of female directors on the board.

Board independence is measured as the percentage of independent board members.

CSR Sustainability Committee is a binary variable taking the value of 1 if the company has a dedicated CSR or Sustainability committee, and 0 otherwise. In the Euro Stoxx 50 sample, all firms possess such a committee (FS_COMM = 1), reflecting isomorphic adoption of sustainability governance structures among Europe's largest listed companies. This universal presence defines a scope condition: we examine firms that have already institutionalized this baseline mechanism. Consequently, FS_COMM does not discriminate between high and low purpose orientation within our sample, but its ubiquity suggests that a CSR committee may constitute a necessary threshold for purpose enactment, though clearly not sufficient on its own.

ESG Compensation is a binary variable taking the value of 1 if the company's executive compensation policy is explicitly linked to ESG performance targets (Refinitiv "Policy Executive Compensation ESG Performance"), and 0 otherwise.

The following table summarizes the operationalization of the six causal conditions and the outcome variable, linking them to their respective data sources and definitions (Tab. 2).

Tab. 2: Summary of causal conditions

Variable Label	Condition Name	Data Source	Definition
FS_OWN	Ownership Concentration	Refinitiv Worldscope	Calculated Ratio: Closely Held Shares / Total Shares Outstanding
FS_BSIZE	Board Size	Refinitiv ESG	Board Size: total number of directors on the board at fiscal year-end.
FS_BGD	Board Gender Diversity	Refinitiv ESG	Board Gender Diversity Percent: percentage of female directors on the board.
FS_INDEP	Board Independence	Refinitiv ESG	Independent Board Members %: percentage of independent directors.
FS_COMM	CSR Committee	Refinitiv ESG	CSR Sustainability Committee: existence of a board-level CSR team or committee.
FS_PAY	ESG Compensation	Refinitiv ESG	Policy Executive Compensation ESG Performance: executive pay linked to ESG targets.
PURPOSE	Duty-Based Purpose	Manual scraping and Text Mining	Duty-Orientation Ratio: calculated via text mining of annual reports.

Source: our elaboration

Taken together, these six conditions operationalize the governance architecture introduced in section 2.2. CSR committees (FS_COMM) and ESG-linked compensation (FS_PAY) constitute the enforcement ‘hardware’ that, in our conceptualization, translates duty-based commitments into binding decision rules, directly addressing the risk of cheap talk highlighted by Smulowitz et al. (2025). Ownership concentration, board size, board gender diversity and board independence

(FS_OWN, FS_BSIZE, FS_BGD, FS_INDEP) capture the contextual 'software' through which this hardware is either activated or neutralized. The configurational analysis therefore examines bundles of governance devices and contextual features.

3.4 Calibration procedures

We employed the Direct Method of calibration, that requires the specification of three qualitative anchors:

1. Full Membership (0.95): the threshold above which a case is considered fully in the set.
2. Crossover Point (0.50): the point of maximum ambiguity, where a case is neither clearly in nor out of the set.
3. Full Non-Membership (0.05): the threshold below which a case is considered fully out of the set.

Given the lack of universal thresholds for pan-European governance, we adopted sample-dependent anchors. Following the guidelines of Pappas and Woodside (2021) and standard practice in business research (Nikou et al. 2024), we utilized the 95th, 50th, and 5th percentiles of the sample distribution as the anchors for full membership, crossover, and full non-membership, respectively.

For the binary variables (FS_COMM and FS_PAY), calibration was crisp: True was coded as 1 and False as 0. For the continuous variables (FS_OWN, FS_BSIZE, FS_BGD, FS_INDEP, and the outcome PURPOSE), the percentile-based anchors in Tab. 3 were applied.

Tab. 3: Calibration Thresholds (Anchors)

Condition Set	**Raw Variable**	**95th %ile (Full Membership)**	**50th %ile (Crossover)**	**5th %ile (Full Non-Membership)**	**Calibration Rationale**
FS_OWN	Closely Held Shares (%)	79.8%	0.22%	0.0%	The median is extremely low (0.22%), reflecting the high liquidity of the index. High values capture the distinct blockholder model.
FS_BSIZE	Board Size (Count)	20	14	9	20 represents the large supervisory boards of German co-determination models; 9 represents smaller unitary boards typical of Dutch/French governance.
FS_BGD	Board Gender Diversity (%)	51%	40%	25%	The 40% crossover aligns with the French Copé-Zimmermann quota and proposed EU directives for gender balance.
FS_INDEP	Independent Members (%)	95%	70%	30%	70% acts as a robust crossover, distinguishing 'super-majority' independent boards from those with significant insider presence.
PURPOSE	Duty-Orientation Ratio (0-1)	0.85	0.55	0.25	Derived from the distribution of text mining scores; >0.55 indicates a discourse tipping towards duty-based logic.

Source: our elaboration

To address cases falling exactly on the 0.5 crossover point, we applied a random jitter procedure (adding a noise constant of 0.00001) to continuous variables prior to calibration. This prevents the artificial loss of cases during truth table minimization (Fiss, 2011). The analysis was performed using the QCA package in R. We utilized the Truth Table algorithm with a frequency threshold of n >= 1 and a raw consistency threshold of 0.80.

To assess the sensitivity of our findings to calibration choices, we replicated the analyses using a more conservative set of anchors at the 10th, 50th, and 90th percentiles of each distribution. The resulting fuzzy sets were then re-analyzed with the same truth table procedure, allowing us to compare solution consistency and coverage across calibration schemes.

4. Results

4.1 Descriptive analysis

Before proceeding to the configurational results in the subsequent section of the paper, it is essential to contextualize the dataset. The Euro Stoxx 50 sample represents a highly capitalized, heavily regulated, and scrutinized cohort, but it contains significant internal heterogeneity. The sample is divided between the two-tier board systems of Germany (e.g., BMW, Siemens, Adidas), characterized by large supervisory boards (N=16-20) with employee representation, and the one-tier systems of France and the Netherlands (e.g., LVMH, ASML), which tend to have smaller, more streamlined boards (N=10-15). This structural variability confirms the utility of board size (FS_BSIZE) as a differentiator within the model.

Regarding ownership, the dichotomy between firms with concentrated and dispersed ownership is evident. Entities such as Sanofi and TotalEnergies exhibit low closely held shares (<10%), operating under a dispersed shareholder model akin to US firms. Conversely, firms including Hermès International and BMW retain significant family control (>50% closely held), challenging the assumption that 'modern' corporations must be widely held. This variance provides the necessary empirical fuel for the fsQCA, allowing us for example to test if a configuration of "Family Ownership + ESG Pay" serves as a valid alternative path to Purpose compared to the traditional "Dispersed Ownership + Independent Board" model.

Finally, the fact that 100% of the sample possesses a CSR Sustainability Committee (FS_COMM) is a significant descriptive finding. It suggests that in the upper echelons of European business, the structure of sustainability governance has become isomorphic: a 'must-have' for legitimacy. Consequently, the fsQCA is not expected to find that a CSR committee alone is sufficient for a Duty-Based Purpose. Given that FS_COMM is present in all firms, any configurational difference in the outcome must be driven by how this committee interacts with other variables, such as whether it is empowered by ESG-linked pay or independent oversight. This confirms the appropriateness of the configural approach: the presence of the committee alone explains nothing (as it is constant), but its combination with other factors may explain the outcome.

4.2 Configurational analysis

The fsQCA began with an analysis of necessity to explore conditions that might be required for the outcome. In line with the descriptive statistics, CSR Sustainability Committees (FS_COMM) and ESG-linked Executive Compensation (FS_PAY) exhibit high consistency as potential necessary conditions, and in the sufficiency solution they appear as core components of all configurations. These elements therefore constitute the structural baseline for a Duty-Based Purpose in this sample.

The sufficiency analysis generates an intermediate solution with an overall solution consistency of 0.680 and an overall solution coverage of 0.804. This indicates that the identified configurations collectively cover about 80.4% of the empirical instances of a high Duty-Based Purpose, providing substantial explanatory power in a complex governance setting, albeit with moderate overall consistency. The analysis reveals three equifinal configurations, or 'recipes', which represent distinct

governance logics.

The first configuration (Path 1), which we can label as the *Independent Monitoring* logic, combines high board independence (FS_INDEP) with the structural baseline of committees and incentives (FS_COMM * FS_PAY). With a consistency of 0.698, a raw coverage of 0.634, and a unique coverage of 0.204, this path represents the most prevalent route in the sample. It is populated mainly by firms with low membership in the set of concentrated ownership, consistent with the widely held ownership model described in section 4.1, and it reflects a logic where high board independence acts as the primary driver ensuring that the structural 'hardware' of sustainability governance is effectively utilised.

The second configuration (Path 2), labelled as the *Diverse Stewardship* logic, combines high ownership concentration (FS_OWN) with high gender diversity (FS_BGD), supported by the requisite committees and pay structures (FS_COMM and FS_PAY). This path yields a consistency of 0.786, a raw coverage of 0.436, and a unique coverage of 0.049. It is populated by firms that, as described in the descriptive analysis, exhibit a classic blockholder or family-controlled pattern of ownership. In this context gender diversity acts as a critical counterbalance to concentrated ownership, suggesting that stewardship is achieved not through independence, but through the interplay of dominant owners and a diverse board composition.

The third configuration (Path 3), labelled as the *Pluralistic Consensus* logic, combines large board size (FS_BSIZE) with high gender diversity (FS_BGD), alongside the standard structural variables (FS_COMM and FS_PAY). This path demonstrates the highest individual consistency at 0.808, with a raw coverage of 0.483 and unique coverage of 0.059. This configuration implies that in larger, potentially more complex or two-tier board structures, gender diversity facilitates the consensus-building required to orient the firm towards a Duty-Based Purpose.

A comparative assessment of these paths highlights an important mechanism regarding board composition. While the *Independent Monitoring* logic relies on independent directors to drive the outcome, the *Diverse Stewardship* logic and the *Pluralistic Consensus* logic rely on gender diversity (FS_BGD). In Paths 2 and 3, gender diversity functions as a crucial mechanism that counterbalances either a dominant owner or the inertia of a large board. Consequently, FS_INDEP and FS_BGD function as context-dependent substitutes: in the absence of high gender diversity, board independence becomes the primary driver for purpose, and vice versa. Tab. 4 presents the sufficient configurations derived from the fsQCA. Following standard notation (Fiss, 2011), black circles (●) indicate the presence of a condition, while blank spaces indicate that the condition is causally irrelevant for that specific configuration.

Tab. 4: Sufficient configurations for Duty-Based Purpose

Causal Conditions	**1. Independent Monitoring**	**2. Diverse Stewardship**	**3. Pluralistic Consensus**
Ownership Concentration (FS_OWN)		●	
Board Size (FS_BSIZE)			●
Board Gender Diversity (FS_BGD)		●	●
Board Independence (FS_INDEP)	●		
CSR Committee (FS_COMM)	●	●	●
ESG Compensation (FS_PAY)	●	●	●
Raw Coverage	0.634	0.436	0.483
Unique Coverage	0.204	0.049	0.059
Consistency	0.698	0.786	0.808
Overall Solution Coverage	0.804		
Overall Solution Consistency	0.680		

Source: our elaboration
Note: ● indicates the presence of a condition. Blank spaces indicate 'don't care' conditions, meaning the outcome occurs regardless of the specific value of that condition.

4.3 Robustness checks

As anticipated in the previous section, to probe the robustness of these findings, we re-estimated the model using an alternative calibration scheme based on the 10th, 50th and 90th percentiles of each distribution. The intermediate solution under this more conservative calibration yields a set of recipes that closely mirrors the structure of the main model. CSR committees and ESG-linked pay remain present in all sufficient configurations, confirming their role as constitutive 'hardware' for duty-based purpose. Overall solution consistency increases to 0.800, while solution coverage remains substantial (0.635–0.638), albeit lower than in the baseline calibration (0.804). The stability of both the core conditions and the fit statistics indicates that the configurational results are not an artefact of a particular calibration choice. Compared to the main solution, the robust model introduces additional conjuncts that refine the three core governance logics. The first and third recipes in Table 5 are structurally consistent with the *Pluralistic Consensus* and *Diverse Stewardship* paths, but make explicit that these logics are more cleanly observed under, respectively, dispersed ownership combined with large, gender-diverse boards and concentrated ownership combined with smaller, gender-diverse boards. The second recipe mirrors the *Independent Monitoring* logic, but shows that its most robust instantiation under stricter calibration occurs in dispersed firms with relatively large boards. The fourth and fifth recipes represent hybrid designs in which diversity and independence are simultaneously high; these are relatively rare but substantively plausible configurations in which the enforcement hardware of CSR committees and ESG pay is embedded in boards that score strongly on both monitoring dimensions. In line with Schneider and Wagemann's (2006) distinction between proximate and remote conditions, these additional conjuncts are best interpreted as scope conditions that narrow the empirical domain within which each governance logic is most reliably associated with a duty-based purpose, rather than as fundamentally new causal mechanisms.

Tab. 5: Robust solution under 10–50–90 calibration

Robust configuration	**Outcome**	**Consistency**	**Coverage**
~FS_OWN_ROB * FS_BSIZE_ROB * FS_BGD_ROB * FS_COMM * FS_PAY	PURPOSE_ROB	0.821	0.390
~FS_OWN_ROB * FS_BSIZE_ROB * FS_INDEP_ROB * FS_COMM * FS_PAY	PURPOSE_ROB	0.860	0.323
FS_OWN_ROB * ~FS_BSIZE_ROB * FS_BGD_ROB * FS_COMM * FS_PAY	PURPOSE_ROB	0.843	0.360
FS_OWN_ROB * FS_BGD_ROB * FS_INDEP_ROB * FS_COMM * FS_PAY	PURPOSE_ROB	0.852	0.286
S_BSIZE_ROB * FS_BGD_ROB * FS_INDEP_ROB * FS_COMM * FS_PAY	PURPOSE_ROB	0.857	0.299
Overall solution		0.800	0.635–0.638

Source: our elaboration

4.4 Most representative cases for each configuration

To ground these abstract configurations, it is useful to briefly indicate some representative firms for each path.

In the Independent Monitoring configuration, companies such as Koninklijke Ahold Delhaize, Adyen, Airbus, Allianz, ASML, BASF, UniCredit, Danone and Deutsche Post combine dispersed ownership structures with highly independent boards, dedicated sustainability committees and ESG-linked pay policies.

The Diverse Stewardship path includes blockholder-controlled firms such as AXA, BNP Paribas, Deutsche Telekom, Enel, Eni, Siemens Energy, EssilorLuxottica, Hermès, Industria de Diseño Textil, LVMH, Safran, Vinci and Saint-Gobain, where concentrated ownership is balanced by a comparatively high share of women directors alongside the same purpose-related hardware.

The Pluralistic Consensus configuration is exemplified by large-board firms such as AXA, Bayer, Deutsche Telekom, Siemens Energy, Infineon, LVMH, Munich Re, Safran, Schneider Electric and Siemens, where gender-diverse supervisory boards work through sustainability committees and ESG

incentives to coordinate deliberation across a broad set of stakeholder claims.

It is also noteworthy that a small subset of firms are 'members' of more than one path. For example, Adyen, Enel, Eni and Vinci are classified both under Independent Monitoring and Diverse Stewardship, while AXA, Deutsche Telekom, LVMH and Safran meet the criteria for both Diverse Stewardship and Pluralistic Consensus. Siemens Energy and Schneider Electric satisfy the conditions for Independent Monitoring and Pluralistic Consensus, and Siemens Energy uniquely appears in all three configurations. These overlaps indicate that some big european firms implement hybrid governance designs that simultaneously approximate multiple logics, combining elements of dispersed and concentrated ownership or different board structures while always retaining the same enforcement hardware of CSR committees and ESG-linked pay. These boundary cases illustrate how the underlying governance logics can coexist within the same institutional setting.

5. Discussion

Our findings directly engage with a central paradox animating contemporary scholarship on corporate purpose: why does the rhetorical proliferation of stakeholder commitments so persistently fail to translate into substantive organizational change? Scholars such as Westphal (2023) have documented what he terms "systemic symbolic management" whereby corporations engage in ritualistic displays of purpose adoption (such as establishing sustainability committees, issuing public commitments, publishing codes of conduct) while leaving unchanged the fundamental incentive architectures that structurally privilege shareholder returns. Meanwhile, Bebchuk and Tallarita (2022) have demonstrated that even high-profile corporate pledges, such as the Business Roundtable's 2019 statement on corporate purpose, amount to what they dismiss as "illusory promises", devoid of any legal force or governance consequence. The implication of this critique can be read as follows: purpose-talk risks amounting to little more than managerial hypocrisy, a cynical public relations tactic that masks unchanged behavior.

Our configurational analysis, however, reframes this debate by rejecting the assumption that the enactment gap is primarily a question of managerial sincerity or moral failure. Rather, our results suggest that a key reason why the gap persists is a structural mismatch between governance design and organizational context. The central contribution of our study lies in revealing that the 'hardware' of governance structures must be precisely calibrated to the 'software' of board composition and ownership context. Where prior literature treats governance mechanisms as universally applicable best practices to be mimetically adopted, our fsQCA results reveal that successful purpose enactment requires contextually specific configurations, in accordance to the literature on configuration bundles (Misangyi et al., 2017). CSR Sustainability Committees and ESG-linked pay consistently appear as core components across all high-performing configurations and, in our sample, no high-purpose configuration occurs without them, but their sufficiency is contingent upon distinct combinations of independence, diversity, and ownership concentration. The enactment gap does not close through moral appeals or reputational pressure. It closes only when there is constitutive alignment between the formal apparatus of governance and the underlying distribution of power and voice within the firm. Viewed through the lens of the governance trilemma, the three configurations found can be interpreted as empirically grounded ways in which large European firms choose which dimension of the trilemma to relax. Independent Monitoring corresponds to designs that preserve market efficiency and strong managerial accountability, while accepting limited direct representation of stakeholder groups at board level. Diverse Stewardship shows how concentrated ownership can be reconciled with a duty-based purpose when representation is strengthened through gender-diverse boards that discipline the dominant owner. Pluralistic Consensus makes representation the priority in large, often two-tier boards, and relies on diversity and formal purpose hardware to compensate for lower decisional efficiency. In each case, the trilemma is not resolved but made tractable through a specific bundle of ownership, board and incentive mechanisms. The robustness analysis reinforces this

interpretation. When the calibration anchors are made more conservative, the three governance logics do not disappear but become more context specific. The *Independent Monitoring* configuration is most robustly observed in widely held firms with relatively large boards, *Diverse Stewardship* in blockholder-controlled firms with smaller but gender-diverse boards, and *Pluralistic Consensus* in dispersed or mixed-ownership firms combining large, gender-diverse supervisory boards with the same enforcement hardware. In other words, raising the calibration thresholds does not generate qualitatively new paths, but clarifies the ownership and board-structure contexts in which each logic most reliably supports a duty-based purpose. Finally, the case-level evidence confirms that these governance logics are not mutually exclusive types but can coexist within the same firm. A small number of large European corporations, including Adyen, Enel, Eni, Vinci, AXA, Deutsche Telekom, LVMH, Safran, Siemens Energy and Schneider Electric, satisfy the membership criteria of more than one sufficient configuration. Siemens Energy, for instance, meets the thresholds for all three paths. In set-theoretic terms this is fully consistent with the principle of equifinality: firms can activate multiple governance logics simultaneously, combining elements of independent monitoring, diverse stewardship and pluralistic consensus. Substantively, these hybrid cases are best understood as boundary designs that sit at the intersection of ideal-typical configurations, further underscoring that purpose governance in practice is assembled from overlapping bundles (Misangyi et al., 2017) of ownership structures, board compositions and enforcement mechanisms rather than from isolated best practices.

5.1 Theoretical implications

Our study offers three theoretical implications[2] grounded in the configurational pathways we identified for duty-based purpose enactment.

First, we contribute to institutional theory by demonstrating that CSR committees and ESG-linked pay function as necessary governance hardware for purpose enactment. Neo-institutional scholars have long debated whether sustainability governance structures constitute substantive innovations or merely symbolic gestures adopted to secure legitimacy (Westphal, 2023). Our fsQCA analysis resolves this tension empirically: all high-purpose configurations include both CSR committees and ESG-linked pay, and no configuration achieved high purpose adherence in their absence. This finding directly challenges the decoupling thesis that dominates institutional literature (Meyer & Rowan, 1977) and supports Levillain and Segrestin's (2019) argument that purpose constitutes a fiduciary problem requiring formal governance structures. We extend this reasoning by specifying that these mechanisms function as constitutive hardware: institutional safeguards that prevent purpose from degenerating into illusory promises (Bebchuk and Tallarita, 2022) or cheap talk (Smulowitz et al., 2025). Dell'Erba and Ferrarini (2024) similarly argue that ESG-linked compensation embeds duty-based objectives as enforceable fiduciary constraints. Our configurational evidence demonstrates that without this hardware, purpose statements remain vulnerable to mission drift under market pressure (Levillain and Segrestin, 2019; Mayer, 2021), regardless of board composition or ownership structure.

Second, we extend stewardship theory by revealing that ownership concentration enables purpose enactment only when coupled with board gender diversity. Traditional stewardship theory posits that

[2] It's important to underline that these implications rest on configurational patterns that proved robust to alternative calibration choices. As reported in Table 5, re-estimating the model with 10–50–90 anchors preserves both the governance hardware and the core substitution patterns between independence and diversity.
In addition, it's worthwhile to note that in our sample, 100% of firms possess CSR Sustainability Committees. This variable therefore function not as discriminating causal conditions but as scope condition (Schneider & Wagemann, 2006) that define our population: large European firms that have already adopted the minimal structural apparatus of purpose governance. This universal presence validates institutional critiques of mimetic isomorphism (Meyer & Rowan, 1977): CSR committees have become governance ornaments that secure legitimacy but guarantee nothing. The enactment gap persists precisely because these structures are everywhere yet differentially activated. Our configurational analysis reveals which additional governance attributes transform this baseline apparatus from symbolic into credible enforcement mechanisms. This finding reframes the governance-purpose debate: the question is not whether firms need CSR committees (as they all have them), but under what conditions these committees function as substantive oversight bodies rather than empty facades.

blockholders naturally foster long-term orientation and stakeholder consideration (Miller and Le Breton-Miller, 2006). Gartenberg and Serafeim (2023) exemplify this view, showing that firms with committed long-term owners more easily sustain purpose and profitability by resisting short-term market pressures. Our Diverse Stewardship pathway qualifies this assumption: ownership concentration appeared sufficient for duty-based purpose only when combined with high gender diversity. This result exposes a theoretical blind spot in classical stewardship literature, which overlook principal-principal conflicts inherent in concentrated ownership (Claessens et al., 2000). Blockholders may pursue private benefits or exhibit insularity that marginalizes broader stakeholder interests. Gender diversity functions as a counterbalancing mechanism that broadens board cognitive perspectives (Adams & Ferreira, 2009; Bear et al., 2010; Klettner et al., 2026), transforming ownership concentration from potential tunnel vision into genuine stakeholder stewardship. We therefore contribute by demonstrating that stewardship theory must be reformulated in conditional terms: concentrated ownership enables purpose enactment only when disciplined by diversity.

Third, we contribute to agency theory by demonstrating the context-dependent substitutability of monitoring mechanisms. Agency theory has traditionally emphasized board independence as the universal solution to managerial opportunism (Jensen & Meckling, 1976). Corporate governance codes, from the UK Corporate Governance Code to the OECD Principles, treat independence as a best practice to be maximized across all firms. Our configurational analysis reveals that independence and diversity function as context-specific substitutes. In the Independent Monitoring path, characterized by dispersed ownership, board independence emerged as critical. In the Diverse Stewardship path, where ownership is concentrated, independence disappeared while gender diversity became central. This asymmetry extends agency theory's understanding of governance fit by revealing that the source of potential agency costs, whether managerial shirking in dispersed firms or owner entrenchment in concentrated firms, determines which monitoring configuration enables purpose enactment. We contribute by demonstrating that effective governance architectures must calibrate monitoring mechanisms to ownership context rather than applying universal prescriptions.

5.2 Managerial implications

The practical implications of these findings are substantial, yet they fundamentally challenge the mimetic logic that dominates contemporary governance practice. The conventional approach to governance design treats best practices as universally portable: firms benchmark against peer organizations, adopt the governance structures most prevalent among high performers, and pursue compliance with prescriptive codes. This mimetic orientation is visible in the homogenization of board composition, the proliferation of identical committee structures, and the relentless focus on achieving independence quotas. The implicit assumption is that governance excellence is achieved through conformity to an idealized template.

Our configurational findings reject this isomorphic mentality and call instead for what we term diagnostic governance design. The message to nomination committees and board chairs is clear: effective governance for purpose enactment begins not with benchmarking but with diagnosis. Before designing board composition or committee mandates, directors must examine the firm's capitalization table. Is ownership dispersed among passive institutional investors, or is there a controlling family or founder? This single question determines which governance path is viable. For firms such as LVMH, Hermès, or other family-controlled enterprises, maximizing board independence is strategically misguided. Independence offers little value when the dominant owner controls both strategy and director selection. What these firms require is a critical mass of gender diversity, directors who can introduce stakeholder perspectives and challenge the closed-mindedness that comes with concentrated ownership. Nomination committees in such firms should prioritize diversity over independence, seeking board members with the cognitive distance and fiduciary courage to represent interests beyond the owner's immediate preferences.

Conversely, for firms such as Danone, Allianz, or other corporations with dispersed ownership, the traditional emphasis on independence remains appropriate. In these contexts, the board must

function as a body of independent trustees capable of disciplining professional management. Gender diversity may contribute value, but it is not sufficient to overcome the agency problem posed by managerial discretion. These firms require directors with no material ties to the executive team, individuals who can credibly threaten intervention when management drifts from the stated purpose in pursuit of short-term financial targets.

For chairmen and chief executives, the implications concern what might be termed the license to operate. Our findings demonstrate that CSR Sustainability Committees and ESG-linked pay are no longer distinguishing features or optional enhancements to purpose. They are instead the baseline. In our evidence, firms that lack these structures appear structurally poorly equipped to enact purpose. Without a dedicated committee tasked with monitoring mission alignment, and without material incentives that tie executive compensation to non-financial performance, purpose commitments remain cheap talk, vulnerable to erosion whenever financial pressures intensify. A possible policy implication is that regulators and standard-setters should cease treating these mechanisms as voluntary guidelines and begin conceptualizing them as minimum governance requirements for firms that publicly claim a duty-based orientation.

5.3 Limitations and future research

While this study makes significant contributions to our understanding of purpose governance, it is subject to significant limitations that also suggest avenues for future research. The first concerns sample size and composition. Our analysis focused on Euro Stoxx 50 firms, a deliberately selected sample of Europe's largest and most visible corporations. While this focus allows for detailed configurational analysis of elite firms operating under comparable institutional pressures, it necessarily constrains generalizability. The sample size of fifty cases, while appropriate for fsQCA methodology, limits the number of configurations that can be empirically detected. It is plausible that alternative governance paths to purpose enactment exist but remain unobservable in our data due to their rarity within the specific population we chose. These limitations also mean that our claims about the necessity of particular governance mechanisms should be interpreted as empirically grounded within this specific population, rather than as universal laws.

A second limitation concerns the cross-sectional nature of our research design. Our analysis captures governance configurations at a single point in time, providing a snapshot of how firms are currently organized rather than tracing the dynamic processes through which configurations emerge, stabilize, or dissolve. This temporal constraint is particularly significant given that purpose enactment is not a static achievement but an ongoing organizational accomplishment, subject to drift as leadership changes, ownership structures evolve, and market conditions shift. Future research should employ longitudinal fsQCA designs to examine how firms transition between governance paths. Do firms begin with one configuration and gradually shift toward another as they professionalize or as founding families relinquish control? Under what conditions do firms experience configuration 'collapse', whereby a previously coherent governance architecture fragments and purpose commitments erode? Addressing these questions would spread light not only on which configurations work, but how they are constructed and maintained over time.

Third, our operationalization of duty-based purpose captures what could be termed as discursive enactment rather than behavioral enactment. The Duty-Orientation Ratio (DOR) measures the linguistic emphasis on stakeholder commitments in regulated annual reports, quantifying the degree to which duty-based purpose has been institutionalized in firms' official identity and accountability apparatus. We do not directly observe resource allocation decisions, stakeholder consultation processes, or how trade-offs are resolved in practice. However, language in mandatory disclosure documents is not costless cheap talk: it creates reputational sanctions, litigation risks, and raises stakeholder expectations. Our measure therefore captures a necessary intermediate stage, the institutionalization of purpose in corporate discourse, that represents the foundation upon which behavioral enactment depends. Future research should integrate observational data on actual managerial decisions to validate the governance-to-behavior link. Case studies examining how boards

deliberate, how CSR committees exercise oversight, and how conflicts between financial and mission objectives are resolved would provide crucial micro-level evidence of whether the configurations we identified actually orient firms to purpose.

6. Conclusions

This study posed a question central to contemporary corporate governance: under what governance conditions does corporate purpose shift from rhetoric to reality? Our configurational analysis provides a structural answer. Purpose shifts from rhetoric to discursive enactment when three elements align: i) enforcement hardware, such as CSR committees and ESG-linked compensation that embed purpose as a procedural constraint; ii) monitoring software, such as board independence or gender diversity calibrated to the firm's ownership structure; and iii) ownership contexts that either disperse control sufficiently to empower independent oversight or concentrate it in ways disciplined by diversity. Where any element is missing, purpose remains rhetoric discourse. The enactment gap closes not through moral exhortation but through constitutive alignment: the precise matching of governance design to organizational context. Our findings reveal that purpose enactment is fundamentally a governance design problem, requiring alignment between the formal apparatus of control and the underlying distribution of power within the firm.

Our configurational analysis has identified three distinct paths to duty-based purpose, each reflecting a different resolution of the governance trilemma. The *Independent Monitoring* path demonstrates that dispersed ownership can sustain purpose when boards possess genuine independence and firms institutionalize dedicated sustainability governance. The *Diverse Stewardship* path reveals that concentrated ownership enables purpose only when disciplined by cognitive diversity, particularly gender diversity, which introduces stakeholder perspectives capable of challenging owner closedness. The *Pluralistic Consensus* path shows that large boards can overcome their coordination challenges when diversity and structural safeguards create space for stakeholder deliberation. Across all three paths, CSR Sustainability Committees and ESG-linked pay consistently appear as non-negotiable elements in our sample: the constitutive 'hardware' without which, in large European firms, purpose does not appear to be credibly enacted.

Ultimately, this research speaks to a broader transformation in corporate capitalism. The question is no longer whether corporations should embrace purpose, but whether they can design governance systems capable of sustaining it. The findings of this study suggest that the answer depends on the willingness of firms to move beyond symbolic gestures and construct the constitutive architecture that purpose demands. In the absence of such architecture, purpose is likely to remain what critics have long alleged: cheap talk, facade, a rhetorical ornament adorning an unchanged structure of power. But where firms succeed in aligning governance hardware with organizational context, purpose can become what its advocates envisioned: a binding fiduciary commitment capable of redirecting corporate power toward the creation of real shared value.

Greenhushing under Institutional Contestation: Evidence from U.S. Listed Firms

SALVATORE ESPOSITO DE FALCO, NICOLA CUCARI, ESTELINA DALIPI, LEONARDO PAONE

Abstract

Frame of the research. *Recent evidence suggests that some firms deliberately under-communicate their sustainability achievements ("greenhushing") while continuing to invest in sustainability, particularly in politicised, controversy-prone environments.*

Purpose of the paper. *This study explains how ESG controversies reshape firms' ESG disclosure strategies by inducing greenhushing and examines how firm size conditions the feasibility and persistence of strategic under-disclosure in a contested institutional environment.*

Methodology. *The study analyses a panel of 76 NYSE- and NASDAQ-listed firms through 2020-2024. Greenhushing is operationalised as a negative ESG disclosure-performance gap, employing fixed-effects regressions with lagged ESG controversies and interactions with market capitalisation.*

Results. *Results show that higher levels of past ESG controversies deepen greenhushing. This tendency intensifies over time. Firm size moderates this relationship, with controversies reinforcing under-disclosure among less visible large firms, while the effect weakens for the largest and most visible firms.*

Research limitations. *The analysis is limited to U.S. listed firms, a specific time window, and a single data provider, which may affect generalisability.*

Managerial implications. *The findings highlight that disclosure strategies should consider controversy exposure, firm visibility, and stakeholder configuration, rather than ESG performance alone.*

Originality of the paper. *This paper provides evidence on greenhushing as an ESG disclosure strategy, operationalising it as a negative disclosure-performance gap, showing that ESG controversies can influence it and firm size conditions this response. The study highlights the role of visibility and stakeholder salience in shaping ESG disclosure for companies that decide to respond to ESG shocks with silence rather than disclosure.*

Keywords: *corporate governance; esg disclosure; greenhushing; esg controversies; market capitalization*

1. Introduction

"*Record ESG, but in secret*." This expression captures a growing tension in corporate sustainability strategy. In 2026, journalists used these words to describe Deutsche Bank's strongest year in sustainable finance and ESG investment volumes since 2021, noting that these achievements received limited visibility in earnings communications compared with traditional financial results (Eticanews, 2026). Rather than amplifying ESG success, firms appear increasingly inclined to keep it in the background.

This tendency extends beyond the financial sector. At the World Economic Forum in January 2026, the CEO of TotalEnergies publicly suggested that European Union sustainability mandates would be diluted, warning that current rules risk generating unnecessary costs as elements of the Green Deal are softened (Reuters, 2026). Advisory reports indicate that, in line with this perspective, many firms continue to achieve relatively strong ESG outcomes while deliberately reducing the prominence of ESG narratives in earnings calls, regulatory filings and external communications (The Economist, 2025; Bloomberg Law, 2025). All these new developments show that there is a growing difference between how well companies are performing in terms of ESG and how they are talking about it (Palea et al., 2025).

This emerging pattern challenges core assumptions in the disclosure literature. Voluntary disclosure has traditionally been understood as a strategic practice shaped by firm characteristics (Uyar and Karamahmutoğlu., 2012) and governance structures (Lagasio and Cucari, 2019; Cucari et al., 2018; Paolone et al., 2023), primarily aimed at enhancing legitimacy and reducing information asymmetry (Adams, 2002; García-Meca & Sánchez-Ballesta, 2010).

As sustainability has become economically and regulatorily material, environmental and ESG

reporting have turned into a widespread and increasingly expected feature of corporate practice, particularly among large firms (Fifka, 2013; Durand et al., 2019). From this perspective, stronger ESG performance should be associated with more extensive and visible disclosure. However, the literature suggests that this alignment cannot be taken for granted. Previous research has documented systematic discrepancies between ESG performance and ESG disclosure (ESGD), revealing that firms may exaggerate or downplay their achievements depending on contextual incentives and perceived risks (Kim & Lyon, 2015; Montgomery et al., 2024). Under-communication is particularly puzzling when it characterises relatively strong performers, as it implies a deliberate decision to forego potential legitimacy gains and weaken ESG signals directed at investors and other stakeholders (Falchi et al., 2022).

Recent research has conceptualised this behaviour as *greenhushing*, understood as the intentional under disclosure of genuine environmental or ESG performance (Font et al., 2017; Falchi et al., 2022). Positioned at the low visibility end of the sustainability communication spectrum, greenhushing reflects a strategic choice to limit exposure rather than to signal virtue.

While the concept has gained traction, empirical knowledge of the conditions that foster greenhushing remains limited, particularly in environments marked by regulatory uncertainty and political contestation. Such environments have become increasingly salient in recent years (Esposito De Falco and Cucari, 2025; Li et al., 2025). Regulatory pressure for sustainability disclosure has intensified, as exemplified by the EU Corporate Sustainability Reporting Directive and related initiatives aimed at standardising climate related information (Bloomberg Intelligence, 2024). At the same time, ESG has become politically contested, especially in the United States, where legislative initiatives and public discourse have raised the reputational and legal risks associated with visible ESG positioning (TD Securities, 2024). In Europe, the apparent softening of key Green Deal elements has raised doubts about the durability of earlier climate commitments (Reuters, 2025). Under these conditions, the strategic calculus of ESG communication is likely to change, potentially altering the relationship between performance and disclosure.

Within this context, ESG controversies represent a particularly relevant yet underexplored factor. Controversies constitute high salience events that affect firm value, stakeholder perceptions, and legitimacy (Aouadi & Marsat, 2018; Bang et al., 2023). According to legitimacy theory, negative events of this kind should trigger legitimacy repair strategies, typically expressed through more extensive disclosure aimed at restoring trust and social approval (Patten, 1992; Suchman, 1995; Cho & Patten, 2007). Emerging insights from the greenhushing literature challenge this expectation, suggesting that ESG controversies can instead raise the perceived costs of public visibility and prompt firms to strategically scale back ESG communication while continuing their underlying sustainability practices (Kim and Lyon, 2015).

Which of these responses firms adopt is unlikely to be uniform and may vary systematically across firms. Firm size plays a central role in shaping both exposure to scrutiny and the capacity to manage communication strategically. Larger firms typically face stronger legitimacy pressures and more intense media attention, yet they also possess greater resources to calibrate disclosure and to absorb reputational shocks (Gray et al., 1995; Hahn & Kühnen, 2013; Baldini et al., 2018). It therefore remains unclear whether ESG controversies tend to narrow the gap between ESG performance and disclosure through increased transparency, or whether they widen this gap by reinforcing greenhushing, and how these dynamics differ across firms of varying size.

Addressing this unresolved issue is essential for understanding contemporary corporate sustainability strategies. Therefore, this study addresses the following research question: *How do ESG controversies and firm size influence the dynamics of greenhushing among under-disclosing U.S. firms between 2020 and 2024?*

To answer this question, we examine how ESG controversies and firm size shape greenhushing behaviour among 76 U.S. listed firms over the period 2020 to 2024. The US is chosen as the setting for this study following Barroso Del Toro, Crissol and Tort-Martorell (2022), who focus on American listed firms because the country's regulatory and economic environment shapes how controversies

affect ESG decisions. The narrative shift around sustainability since the first Trump administration in 2017, together with the complex evolution of ESG described by Sulkowski and Jebe (2022), makes the US a particularly suitable context to examine how disclosure behaviour changes over time. The results show that ESG controversies are associated with reinforced greenhushing among relatively large firms, while for the largest firms, controversies are associated with a smaller disclosure-performance gap, indicating stronger constraints on persistent under disclosure.

This study contributes to the literature on ESGD and greenhushing by clarifying how firms adjust their disclosure strategies following ESG controversies and how these responses vary with firm size. It extends the decoupling literature beyond greenwashing and shows how legitimacy pressures shape ESG communication.

2. Theoretical Background

Greenhushing refers to the deliberate under-disclosure of firms' environmental or ESG performance, whereby companies strategically limit the visibility of sustainability-related information despite maintaining substantive ESG activities. The expression *greenhushing* was coined in 2008 by brand strategist Jerry Stifelman and subsequently introduced into the academic debate to capture this form of strategic silence in sustainability communication. While greenwashing relies on selective over-disclosure, greenhushing operates through selective under-disclosure, with both strategies reflecting deliberate choices about the visibility of ESG information rather than the absence of sustainability engagement (Baldassarre & Campo, 2016; Kutzschbach et al., 2021). Consistent with the greenwashing literature (Bernini & La Rosa, 2024), research suggests that disclosure-based strategies are shaped by external conditions, incentives, and pressures that characterise the institutional context in which firms operate, including regulatory scrutiny, stakeholder expectations, and reputational risk (Hilton, 2025a). This underscores the central role of the institutional setting in determining not only firms' incentives to communicate ESG information, but also the perceived risks associated with increased disclosure visibility. Understanding greenhushing therefore requires situating ESGD within a broader theoretical framework that treats reporting as a strategic response to information asymmetry, stakeholder scrutiny, and institutional pressures rather than as a neutral reflection of underlying performance. Because ESGD involves discretion over what to disclose, how to disclose it, and with what degree of prominence, prior research has consistently argued that no single theoretical framework can fully explain ESG reporting practices, which unfold at the intersection of societal norms, stakeholder demands, governance structures, and reputational considerations (Baldini et al., 2018; Hammami & Zadeh, 2020; Seow, 2024).

Within this theoretical landscape, legitimacy theory and stakeholder theory have emerged as the dominant lenses for explaining voluntary non-financial reporting and CSR disclosure under an implicit social contract between firms and society (Guthrie et al., 2006; Spence et al., 2010; Deegan, 2019). Recent systematic literature reviews confirm the continued centrality of these frameworks, showing that legitimacy- and stakeholder-based explanations account for more than 70% of theoretical applications in the ESGD literature (Del Gesso & Lodhi, 2024). Moreover, legitimacy theory and stakeholder theory are commonly treated as complementary, particularly in ESG contexts, as both focus on how firms respond to external evaluation and scrutiny (Jasni et al., 2020).

Legitimacy theory provides a macro-level explanation by conceptualising disclosure as a mechanism through which organisations seek to maintain or restore societal approval by aligning observable behaviour and communication with prevailing norms and values (Suchman, 1995; Deegan, 2019). In the context of ESG, this implies that disclosure serves not only to inform stakeholders, but also to signal conformity with socially valued standards. Stakeholder theory complements this view by offering a micro-level foundation for disclosure decisions, emphasising firms' accountability to multiple stakeholder groups involved in or affected by corporate operations and value creation, including investors, employees, communities, and public authorities (Guthrie et

al., 2006; Lozano et al., 2015; Rezaee, 2016). This perspective is particularly useful for understanding greenhushing because firms may privilege some audiences over others, and reduce ESG visibility when they expect public communication to trigger scepticism, criticism, or political backlash.

These perspectives frame disclosure as a relational and context-dependent practice through which firms manage heterogeneous and sometimes conflicting external expectations (Kim and Lyon, 2015). Within this framework, greenhushing can be conceptualised as a deliberate form of strategic silence, whereby firms under-disclose ESG information when maintaining visibility is perceived as costly or risky. In particular, under-communication is more likely to emerge when salient stakeholders reward substantive ESG performance while penalising overt ESG communication, especially in politicised or highly scrutinised environments (Font et al., 2017; Ginder et al., 2021). This interpretation positions greenhushing as a rational disclosure response to institutional pressures and stakeholder configurations, rather than as an anomaly or withdrawal from sustainability engagement.

2.1 Literature Review and Hypothesis development

ESG controversies are commonly defined as events or ongoing situations, reported in the media, in which firms are alleged to have generated harmful environmental, social, or governance impacts, including environmental accidents, product-related scandals, social misconduct, and governance failures that attract broad public and investor attention (Aouadi & Marsat, 2018). A growing body of empirical research documents that such controversies have material consequences for firms, affecting financial performance (Aouadi & Marsat, 2018), operational efficiency (Dipierro et al., 2024), credit risk (Petkevich et al., 2024), firm value (Anita et al., 2023), and stock prices (Cui and Docherty, 2020). Investors appear to require compensation for bearing ESG-related controversy risk, consistent with evidence that controversies increase firms' cost of capital and risk premia (Bang et al., 2023).

From a disclosure perspective, legitimacy theory predicts that such negative events constitute legitimacy-threatening shocks that prompt firms to engage in legitimacy-repair behaviour through increased transparency and communication (Patten, 1992; Suchman, 1995). Following environmental incidents or reputational scandals, firms are therefore expected to expand environmental and social reporting in order to signal responsiveness and regain stakeholder trust, particularly among salient audiences (Ashforth & Gibbs, 1990; Cho & Patten, 2007). Research supports this logic by showing that environmentally underperforming firms often disclose more environmental information than stronger performers, using disclosure strategically to manage heightened scrutiny and reputational pressure (Bansal & Clelland, 2004; Alrazi et al., 2015). This stream of research has contributed to the view that ESGD can function as a vehicle for ESG-washing, allowing firms to signal commitment without fully matching it in practice (Alexander & Buchholz, 1978; Barnea & Rubin, 2010).

Recent literature, however, questions that controversies systematically lead to greater disclosure. Research on greenhushing suggests that under conditions of scepticism, high litigation risk, and politicised ESG debates, firms may respond to controversies by reducing the visibility or explicitness of ESG communication rather than increasing it (Font et al., 2017; Ginder et al., 2021; Falchi et al., 2022; Tao, 2024). In such contexts, disclosure itself becomes risky, as additional ESG communication may be interpreted as opportunistic, hypocritical, or politically charged. Evidence from tourism and hospitality, shows that firms often communicate only a subset of their sustainability initiatives to avoid accusations of inconsistency, a practice described as "structural greenhushing" and interpreted as a form of moral muteness adopted under high ethical expectations (Font et al., 2017; Ettinger et al., 2021). These studies portray greenwashing and greenhushing as alternative strategic responses located along a disclosure continuum, rather than as random or idiosyncratic errors, with firms selecting the configuration perceived as less risky given prevailing institutional conditions (Lublóy et al., 2025).

The literature examining ESG controversies and disclosure further reinforces this ambiguity. On the one hand, some studies find that enhanced ESG transparency can mitigate the negative consequences of controversies, for example by improving analysts' forecast accuracy or strengthening organisational resilience following environmental incidents (Schiemann & Tietmeyer,

2022; Marsat et al., 2022). On the other hand, evidence suggests that post-controversy disclosure is often symbolic rather than substantive, indicating that additional communication may be driven by impression management rather than genuine behavioural change (Li et al., 2019).
Building on this we hypothese:
H1: *Higher levels of past ESG controversies are associated with more intense greenhushing.*

Prior research shows that ESGD is strongly shaped by contextual and institutional forces operating at both country and firm level (Ogundajo et al., 2022). Literature shows that variations in ESGD are driven by changes in regulatory frameworks, political systems, investor regimes, and broader socio-cultural conditions, which jointly influence firms' incentives, constraints, and exposure to scrutiny (Baldini et al., 2018; Seow, 2024). From an institutional and legitimacy perspective, ESGD reflects firms' adaptive responses to shifting expectations about acceptable corporate behaviour rather than a stable or purely performance-driven reporting practice.

Within this context, Europe and the United States represent two interconnected but institutionally distinct trajectories of ESG development (Esposito De Falco and Cucari, 2025; Bax et al., 2023). In Europe, ESGD has progressively moved toward formalisation and standardisation, driven by supranational regulation and coordinated policy initiatives (CSRD e CSDDD), aimed at embedding sustainability within corporate governance and capital markets. The expansion of mandatory reporting requirements and harmonised disclosure frameworks has reinforced the perception of ESG transparency as a normative obligation, reducing managerial discretion over whether and how sustainability information should be communicated.

By contrast, ESGD in the US has evolved through a more volatile and contested process (Sulkowski and Jebe, 2022). In the early 2020s, federal climate initiatives, including the US re-entry into the Paris Agreement and the SEC's 2022 proposal on climate-risk disclosure, signalled that expanded ESG reporting was becoming a normative expectation for listed firms (US SEC, 2022). This regulatory momentum was reinforced by growth in investor demand for ESG information, reflected in significant inflows into ESG-labelled funds and the increasing integration of ESG data into investment decision-making (Harvard Law School Program on Corporate Governance, 2022). Consistent with prior evidence, this phase aligned with the view that ESGD can reduce information asymmetry, improve capital-market outcomes, and support long-term value creation (Dhaliwal et al., 2011; Cheng et al., 2014). From 2021 onwards, however, this trajectory became unstable. ESG entered a phase of political contestation at the sub-national level, as conservative politicians, advocacy groups, and think tanks reframed ESG investing and corporate sustainability initiatives as ideologically driven and incompatible with shareholder primacy (Capital Monitor, 2022; Heritage, 2024). This discursive shift translated into an unprecedented wave of state-level legislation restricting the use of ESG criteria in public investment and procurement, and in some cases explicitly penalising firms perceived as "anti-fossil" (American Legislative Exchange Council, 2022; Garrett and Ivanov, 2022). Notable examples include Texas's legislation that penalises companies for divesting from fossil fuels, and Florida's prohibition on considering ESG factors when making state investment decisions (Reuters, 2023). This landscape of conflicting state-level rules creates an environment that is potentially hostile to sustainability communication. The result has been a fragmented institutional environment in which firms face conflicting and geographically uneven expectations regarding ESG communication, reflecting increasing institutional complexity and partial de-institutionalisation of ESG narratives (Wang et al., 2025).

While global investors and federal regulators continue to endorse sustainability-oriented disclosure, powerful domestic actors contest the legitimacy of visible ESG communication, reasserting a shareholder-value logic (Oliver, 1991; Greenwood et al., 2011; Hilton, 2025). Under such conditions, legitimacy cannot be secured through uniform disclosure strategies. Organisational theory suggests that firms respond through selective coupling and institutional repair, maintaining substantive ESG practices internally while recalibrating external communication to minimise legitimacy threats in hostile environments (Pache and Santos, 2013; Micelotta and Washington,

2012).

Greenhushing emerges precisely within this temporal and institutional configuration. When public ESG communication is perceived as increasing political, legal, or reputational risk, firms may rationally reduce the visibility of ESG information, even as underlying practices remain unchanged (Kim and Lyon, 2015; Hilton, 2025b). Survey evidence and practitioner reports indicate that many firms continue ESG integration while deliberately lowering the prominence, explicitness, or labelling of sustainability disclosures (The Economist, 2025; Esposito De Falco, 2025). Importantly, this shift is not instantaneous but unfolds over time as institutional signals become more ambiguous.

The temporal dimension is therefore central. Examining whether and how the greenhushing evolves over time allows us to capture this gradual adjustment process and to assess whether it becomes more pronounced as institutional conflict intensifies.

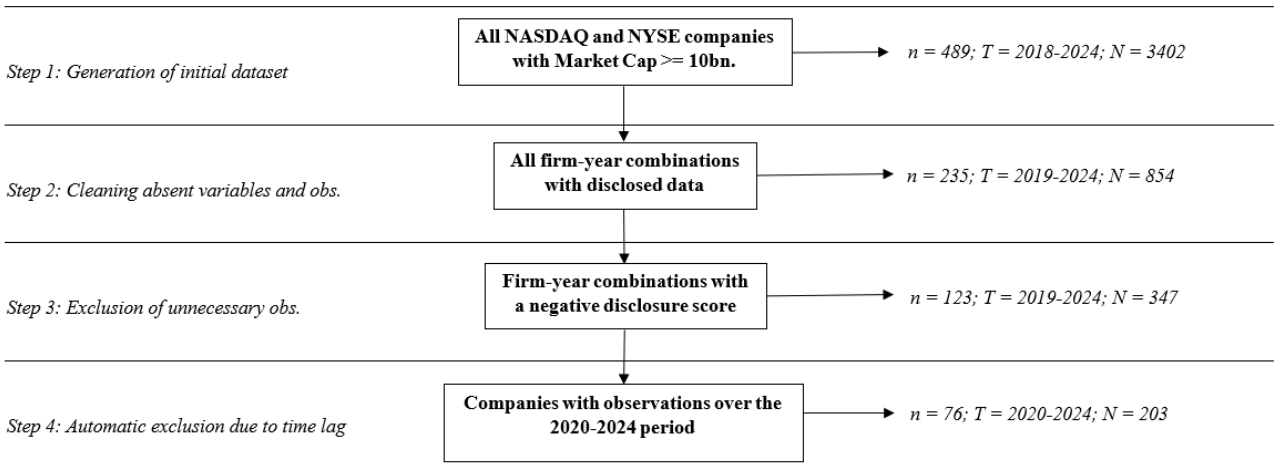
Building on this we hypothese:

H2: *Through 2020-2024, greenhushing has increased among under-disclosing firms, reflecting increased reliance on under-disclosure strategies.*

In this context, firm size is important in shaping firms' ESGD strategies. Larger firms are typically more visible and subject to stronger societal, media, and stakeholder scrutiny, possessing greater organisational resources to develop sophisticated reporting and sustainability management infrastructures (Gray et al., 1995; Adams et al., 1998; Hahn & Kühnen, 2013). Research shows that large companies make more extensive use of tools to organise, analyse, and communicate ethical and sustainable practices, and that both the scope of CSR reporting and related expenditures tend to increase with firm size (Graafland et al., 2003). Evidence further indicates that larger firms are more familiar with sustainability management tools and that this familiarity is associated with more formalised and standardised reporting structures (Hörisch et al., 2015). Similarly, ESG data availability in commercial databases is positively correlated with firm size and market value, reflecting higher visibility and reporting capacity (Baldini et al., 2018). A review by Hahn and Kühnen (2013) concludes that firm size is the only determinant that consistently and positively affects sustainability reporting across studies. At the same time, greater visibility and reporting capacity do not necessarily translate into closer alignment between disclosure and practices. Organisational theory suggests that highly visible firms may be more prone to decoupling between formal structures and substantive activities, using reporting to manage legitimacy and conform to external expectations without proportionate changes in core operations (Meyer & Rowan, 1977; Gallo & Christensen, 2011). Sustainability reports and advanced communication capabilities allow large firms not only to provide richer information, but also to strategically shape narratives and manage impressions in response to external pressures (Baumann-Pauly et al., 2013; Baldini et al., 2018). In this sense, size and visibility simultaneously increase the capacity to disclose and the incentives to strategically manage disclosure, creating fertile ground for both greenwashing and greenhushing. However, larger firms attract greater attention from analysts, media, regulators, and activists, which magnifies both the reputational benefits of credible ESGD and the potential costs of communicative missteps (Cahan et al., 2016; Yu et al., 2020). Therefore, ESG controversies are unlikely to exert a uniform effect on disclosure behaviour across firms of different sizes. For relatively less visible large firms, the concern following a controversy may be to avoid further attention, leading to deeper under-disclosure as a defensive strategy. For large firms, however, the combination of intense scrutiny, litigation exposure, and political salience may render sustained greenhushing after a controversy increasingly risky. Therefore, controversies may prompt greater alignment between ESG performance and communication..

Building on these considerations, market capitalisation is treated as a moderating variable capturing cross-sectional heterogeneity in visibility and stakeholder pressure among large listed firms. Accordingly, the following hypothesis is proposed.

H3. *Firm size moderates the relationship between past ESG controversies and the ESG disclosure-performance gap.*



3. Methodology

3.1 Sample description

The empirical analysis is based on a panel dataset of US listed firms obtained from Refinitiv, drawing on the NYSE and NASDAQ Capital Market indexes over the 2018-2024 period, which were regarded as the two most comprehensive ones. Firms were selected by applying standard filters for primary issues, quoted issues, and active status, in order to ensure consistency in listing characteristics and data comparability over time. The timeframe was chosen following the rise of greenhushing-related literature from the publication of Font et al. (2018) onward. In particular, the shift in the narrative related to sustainability since the advent of the first Trump administration in 2017 has put companies in a tough spot. This, along with the convoluted history of ESG laid out by Sulkowski and Jebe (2022), singles out the US as a uniquely optimal context to understand the temporal evolution of disclosure-related behavior. Moreover, the selection of American firms lines up significantly with companies with a larger than 10 billion USD market capitalization.

Once the temporal and spatial scope of the dataset was specified, it had to be refined to address data availability constraints and to ensure the completeness of all variables required for the analysis. After removing firm-year combinations due to missing information, the sample was reduced and observations for the year 2018 were omitted following a general lack of availability, which further exemplifies the lack of harmonization on ESGD in the US. Given the specific focus of this paper, all companies that were not found employing greenhushing behavior were also subsequently omitted from the dataset. Finally, to account for the temporal relationship between ESG controversies score[1] and subsequent disclosure decisions, the empirical model had to be built based on lagged explanatory variables. Therefore, the first year of observation for each firm cannot be used in the estimation. This leads to the exclusion of 2019 data and results in a final estimation sample of 76 firms observed over five years (2020–2024), for a total of 203 firm-year observations. The resulting panel is unbalanced, which is addressed through fixed-effects estimation techniques. The overall data collection process is summarized in Fig.1.

Figure 1: Data collection

Source: own elaboration

[1] The ESG controversies score, provided by LSEG Workspace (formerly Thomson Reuters' Refinitiv Database), is a recent metric that offers a comprehensive evaluation of a company's sustainability impact and conduct over time. It measures a company's exposure to ESG controversies, capturing adverse events reflected in global media (LSEG Data and Analytics 2023). The score is calculated based on 23 specific controversy areas, such as business ethics, tax fraud, human rights, and environmental issues. Companies with fewer controversies receive higher scores, with 100 representing no controversies. When controversies arise, the score is penalized, and ongoing legal disputes or fines can continue to affect the score over multiple years.

3.2 Variables description

3.2.1 Dependent variable

As the summary of the research variables (Tab. 1) shows, the dependent variable of the analysis is an ESGD score. This was constructed following the methodology proposed by Yu et al. (2020). The objective of this measure is to capture the extent of firms' ESGD relative to their ESG performance, thereby allowing for the identification of greenhushing behavior. The construction of the disclosure score proceeds in several steps. First, a set of Refinitiv variables related to ESGD is extracted separately for each of the three ESG pillars: Environmental (E), Social (S), and Governance (G). These variables include both quantitative indicators and binary disclosure indicators that capture whether specific ESG-related information is publicly reported by the firm. In the second step, all disclosure-related variables within each ESG pillar are normalized using a min–max transformation. For a generic disclosure variable x, the normalized value is computed as:

$$x = \frac{x - min(x)}{max\,(x) - min(x)}$$

Binary variables are transformed into numerical form, with True = 1 and False = 0, and are then included in the normalization procedure. Within each pillar, the normalized disclosure variables are summed to obtain a raw disclosure index. This raw index is subsequently normalized again using a min–max transformation to ensure comparability across firms and years. The result of this procedure is a normalized disclosure score for each ESG pillar, denoted as E_{dis} , S_{dis} , and G_{dis}.

In the third step, the pillar-specific disclosure scores are compared to the corresponding ESG performance scores provided directly by Refinitiv. These scores were subsequently subtracted from the corresponding parts of the ESG score, extracted from REFINITIV, and renamed E_{score}, S_{score}, and G_{score}, which were also normalized using the min-max ratio. For each pillar, the difference between disclosure and performance is computed as:

$$\begin{aligned} \Delta E &= E_{score} - E_{dis} \\ \Delta S &= S_{score} - S_{dis} \\ \Delta G &= G_{score} - G_{dis} \end{aligned}$$

These differences are interpreted as the gap between disclosure intensity and underlying ESG performance. Therefore, they are not meant to provide any information on the quality of disclosure itself. In the fourth step, the overall disclosure score is constructed by aggregating the pillar-level differences:

$$\Delta(ESG\ Disclosure\ Score) = \Delta E + \Delta S + \Delta G$$

This composite measure captures the extent to which a firm's ESGD exceeds or falls short of what would be expected given its ESG performance. Finally, in the fifth step, only observations with negative values of the disclosure score are retained for our analysis. Negative values indicate that a firm's ESGD is lower than its ESG performance, consistent with greenhushing as defined in the related literature, shown in the equation below. Observations with non-negative values are excluded, as they reflect greenwashing-oriented behavior.

$$\begin{cases} \Delta ESG\ Disclosure\ Score > 0 \rightarrow Greenwashing \\ \Delta ESG\ Disclosure\ Score < 0 \rightarrow Greenhushing \end{cases}$$

3.2.2 Other variables

The main independent variable is ESG controversies, which measures the occurrence and intensity of negative ESG-related events involving the firm. ESG controversies capture reputational shocks arising from environmental incidents, social misconduct, or governance failures. They have been

found to impact firm performances (Aouadi and Marsat, 2018) and reputation (Minutiello and Tettamanzi, 2025). As a result, it is estimated that firms will tend to safeguard themselves from further controversies by underdisclosing sustainability information. Therefore, ESG controversies are put in the model in lagged form, to measure how they shape the reaction process over time. In addition, year fixed effects are included in all specifications to control for common time trends, regulatory developments, and changes in ESG reporting standards, as done in previous ESGD-related studies (Gavana et al., 2024).

The second independent variable is the function of time. By measuring variations in the greenhushing score from 2021 to 2024, it is possible to understand how exogenous changes may have impacted on firm behavior. This is done by inserting year dummies and transforming the model in a two-way fixed effects model. Without this function, the explanatory power of year-on-year changes could be absorbed by other variables, or be registered as "background noise" and negatively influence the overall R-squared. However, given the theoretical background and the importance of political shifts in the contemporary American context, variations over time will be taken into account as an integral part of the model. The key assumption is that - as time progresses - greenhushing will become both more intense and more widespread, and consequently easier to predict.

Firm size is introduced as a moderating variable through the natural logarithm of market capitalization, as done previously in ESG literature, by using either market cap, total assets, or a combination of both (Ahmad et al., 2021; Hamdouni, 2025). In particular, market capitalization was chosen as it reflects firms' visibility, access to capital markets, and exposure to external scrutiny. An interaction term between lagged ESG controversies and market capitalization is included to examine whether the disclosure response to controversies varies systematically with firm size.

Finally, the model includes a set of control variables commonly used in the ESGD literature. Consequently, they were implemented to isolate their effects and prevent omitted variable biases. Gender diversity is measured as the proportion of female directors on the board of directors. Board independence - which has been found to impact sustainability metrics (Ciasullo et al., 2020) - is captured through the percentage of independent directors. Firm size from an accounting perspective is controlled for using the natural logarithm of total assets. ESG performance is computed through proxy by using Refinitiv's ESG score and is included to isolate disclosure behavior from performance and check the impact of the latter on the former.

3.3 Model specification and estimation method

The relationship between ESG controversies and ESGD is examined using a firm fixed-effects panel regression model which controls for unobserved, time-invariant firm characteristics that may simultaneously affect disclosure and the explanatory variables. The choice of a fixed-effects model is supported by a Hausman test rejecting the random-effects specification (p-value < 0.005), and is consistent with prior studies on ESGD and corporate governance. The resulting model follows the equation:

$$greenhushing_score_{it} = \beta_1 \times esg_contr_{i,t-1} + \beta_2 \times \log(mkt_cap)_{it} + \beta_3\left[esg_contr_{i,t-1} \times \log\left(mkt_cap_{it}\right)\right] + \beta_4 \times esg_score_{it} + \beta_5 \times gender_div_{it} + \beta_6 \times ind_board_members_{it} + \beta_7 \times \log(tot_assets)_{it} + \alpha_i + \gamma_t + \varepsilon_{it}$$

The baseline specification includes lagged ESG controversies, market capitalization, their interaction term, the set of control variables, firm fixed effects (α), and year fixed effects (γ). The disclosure score is taken at its absolute value, as companies with an underdisclosure gap exclusively were included in the final dataset. Therefore, variables with a positive impact on the score will actually show an increase in greenhushing practices.

3.4 Robustness checks

Several robustness checks were performed to assess the stability of the results. First, alternative lag structures for ESG controversies are employed to verify the persistence of the estimated relationship over time. Second, all models are re-estimated using firm-clustered standard errors to account for serial correlation and heteroskedasticity within firms. Third, multicollinearity is assessed through variance inflation factors, which do not indicate problematic levels of collinearity. Finally, a mechanical endogeneity test is conducted by reversing the direction of causality and replacing lagged ESG controversies with future controversies. The absence of significant effects in these placebo regressions supports the interpretation that ESGD responds to past controversies rather than anticipating future events.

4. Results

4.1 Model selection

The choice of the fixed-effects estimator is supported by the Hausman test, which strongly rejects the null hypothesis of random effects (p-value < 0.05). Multicollinearity concerns were addressed through a variance inflation factor (VIF) test. All VIF values turned up well below conventional thresholds (<< 5), excluding the threat of multicollinearity. Reverse causality issues were also taken into account and accounted for with a placebo test that replaced lagged ESG controversies with future ones. This turned out to be non-significative, as to be expected.

4.2 Baseline fixed-effects results

After selecting the model, multiple regressions were run with all the available variables. Model 1 presents the baseline specification using a one-year lag of ESG controversies. The coefficient on lagged ESG controversies is positive and statistically significant, indicating that, within firms, an increase in ESG-related controversies is followed by an increase in greenhushing levels in the following year. This result suggests that firms respond to reputational shocks by adjusting their disclosure practices, while also keeping their actual sustainability performances unchanged.

Multiple robustness checks were carried out, to test the computational limits of the base model. Attempt n.2 replaces the one-year lag with a two-year lag of ESG controversies in order to assess the

persistence of disclosure responses over time. The coefficient on the two-year lag remains positive and statistically significant, confirming that the disclosure response to ESG controversies extends beyond the immediate aftermath of the shock, and even becoming more significant. The consistency of the results across lag structures indicates that the relationship is not sensitive to the specific timing assumption. The results (Table 2) are consistent with our hypotheses.

Tab.2: Results

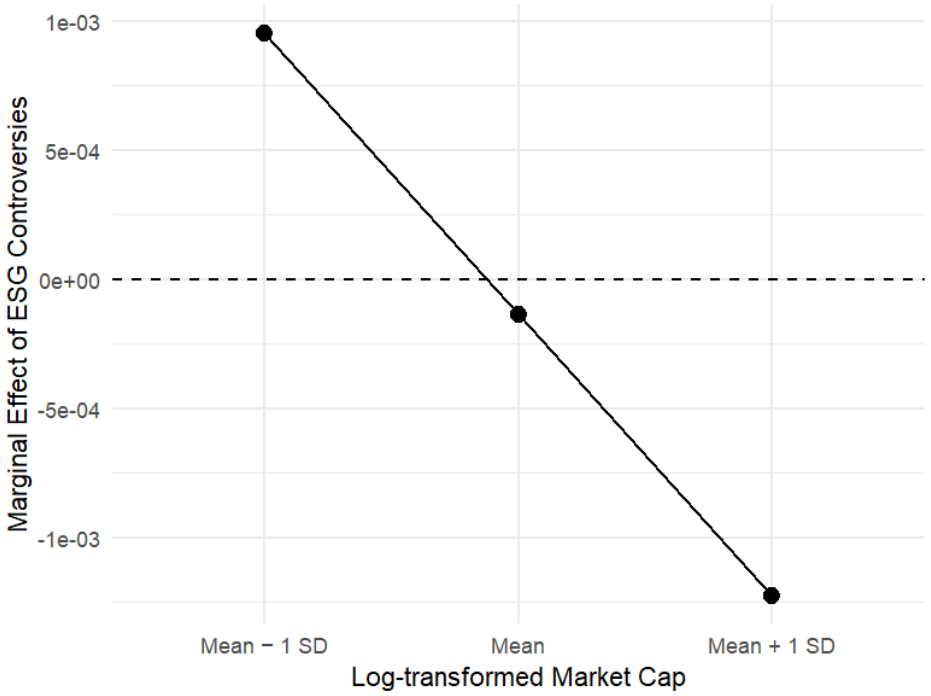
Source: own elaboration

4.2.1 Control variables and time effects

Among the control variables, ESG performance exhibits a positive and highly statistically significant association with ESGD across all specifications, indicating that disclosure remains positively related to underlying ESG performance, even after controlling for firm fixed effects and time trends. Board gender diversity is also positively associated with greenhushing levels and is statistically significant in most specifications. Although this seems to suggest that changes in board composition toward greater gender diversity are linked to higher disclosure levels, this might also be a byproduct of increasing ESG-related performances, which are strongly associated with gender diversity (i.e: Manita et al., 2018; Martinez et al., 2024). Therefore, as our greenhushing score is computed by subtracting performance levels from disclosure ones, this increase in sustainability might be wrongly read by the model as an increase in greenhushing.

Moreover, the proportion of independent board members shows a weaker and less stable association with ESGD, while total assets do not display a statistically significant effect once market capitalization is included. Year fixed effects also reveal a strong upward trend in greenhushing tendencies over the 2021-2024 period, with particularly pronounced increases in the most recent years. This pattern confirms *H2* and the negative impact of the recent political and economic trends on disclosure levels in American firms. Importantly, the main results remain robust after controlling for these common time trends.



4.2.2. Robustness to clustered standard errors

To account for potential serial correlation and heteroskedasticity within firms, the baseline model is re-estimated using firm-clustered standard errors (Table 2). The results confirm that the key findings remain unchanged. In particular, the coefficients on lagged ESG controversies and on the interaction with market capitalization retain their sign and statistical significance. This indicates that the baseline inference is not driven by underestimated standard errors.

4.3 The moderating role of market capitalization

A central contribution of the analysis concerns the interaction between ESG controversies and firm size. In both Model 1 and Model 2, the interaction term between lagged ESG controversies and market capitalization is negative and statistically significant, although the impact (-0.00) is minimal. This finding indicates that the positive relationship between ESG controversies and subsequent ESGD becomes weaker for larger firms. The negative interaction implies that firm size moderates the disclosure response to ESG controversies. While relatively smaller firms increase ESGD following reputational shocks, larger firms exhibit a substantially weaker response. This pattern is robust across alternative lag specifications and suggests that firm size plays an important role in shaping disclosure strategies. To get a better understanding of this interaction between ESG controversies and market capitalization, Figure 3 was created to show the marginal effect of ESG controversies on ESGD at different levels of firm size. Marginal effects are computed using the estimated coefficients from the baseline model and are evaluated at the mean and at plus and minus one standard deviation of market capitalization. Ninety-five percent confidence intervals are constructed using the delta method.

Fig. 3: Marginal effects of ESG Controversies on greenhushing, evaluated at mean of market cap

Source: Own elaboration

The marginal effects analysis reveals a linear downward pattern. For firms with relatively low market capitalization, the marginal effect of ESG controversies on ESGD is positive and statistically significant, indicating a strong increase in greenhushing practices following reputational shocks. As firm size increases, the marginal effect declines steadily and becomes statistically indistinguishable from zero at the mean level of market capitalization. For firms with high market capitalization, the marginal effect turns negative, thus changing the sign of the interaction. These results provide two clear insights on the model. The first one is that market capitalization plays a crucial moderating role in the relationship. Indeed, the changes it causes is not simply quantitative, but qualitative too. Consequently, the use of the moderating variable is justified from a statistical point of view, as well as a theoretical one. Second, it shows that larger firms appear less responsive in their disclosure behavior following ESG-related controversies, which shows a lower impact of negative public opinion compared to relatively smaller firms. This is consistent with previous studies (Cahan et al., 2016; Yu et al., 2020) on the impact that firm size and overall "power" can have on disclosure processes, thus confirming the expected results of *H3*.

5. Discussion

This study advances understanding of ESGD by examining how firms characterised by greenhushing adjust their communication strategies following ESG-related controversies and how these adjustments vary with firm size. The findings indicate that greenhushing is neither a residual reporting outcome nor a purely firm-specific anomaly, but a systematic and context-dependent response to external shocks and evolving institutional conditions. Thus, ESGD emerges as a strategically managed activity rather than a neutral reflection of underlying sustainability performance (Suchman, 1995; Deegan, 2019; Guthrie et al., 2006).

A central implication of the results concerns how firms engaging in greenhushing reassess disclosure risk following ESG-related controversies. The analysis shows that higher levels of past

ESG controversies are associated with a subsequent increase in the ESG disclosure-performance gap, supporting H1. Traditional legitimacy-based arguments would predict the opposite pattern, namely an expansion of disclosure following legitimacy-threatening events in order to restore social approval (Patten, 1992; Suchman, 1995). Research grounded in this logic has documented cases in which firms increase environmental or social reporting after accidents or scandals to signal responsiveness and regain stakeholder trust (Ashforth and Gibbs, 1990; Cho and Patten, 2007). The evidence of our study, however, aligns more closely with the emerging greenhushing literature, which suggests that controversies can raise the perceived costs of ESG communication and induce firms to limit disclosure visibility rather than expand it (Font et al., 2017; Ginder et al., 2021; Falchi et al., 2022; Tao, 2024). In politicised or sceptical environments, additional ESGD may heighten scrutiny or invite accusations of hypocrisy, thereby undermining rather than restoring legitimacy. From this perspective, ESG controversies do not merely threaten legitimacy, they also reshape firms' disclosure calculus by increasing the risks associated with visible ESG talk (Kim and Lyon, 2015).

This reassessment of disclosure risk does not occur in isolation, but unfolds over time as institutional conditions surrounding ESG continue to evolve. The year fixed effects indicate a clear increase in under-disclosure over the period examined, thus supporting H2. Our results suggest that greenhushing has intensified over time, consistent with broader changes in the institutional environment surrounding ESG. As ESGD becomes more contested and partially de-institutionalised, firms may respond through selective coupling, maintaining substantive practices internally while recalibrating external communication to preserve legitimacy across heterogeneous audiences (Pache and Santos, 2013). Relatedly, institutional repair work highlights how organisations adjust symbols and narratives under pressure without abandoning underlying practices (Micelotta and Washington, 2012). The observed temporal increase in under-disclosure is consistent with these mechanisms, particularly in contexts characterised by political polarisation and regulatory uncertainty (Oliver, 1991).

Finally, the feasibility of strategic silence depends on firm visibility and scale. The results show that market capitalisation significantly moderates the relationship between ESG controversies and the disclosure gap, directly addressing H3. This finding is consistent with prior evidence that larger firms are more visible and subject to stronger stakeholder scrutiny, while also possessing greater resources to manage disclosure strategically (Gray et al., 1995; Hahn and Kühnen, 2013; Baldini et al., 2016). Among less visible firms within the under-disclosing segment, controversies are associated with a stronger widening of the disclosure gap, consistent with a defensive turn toward reduced visibility to contain attention. For the largest and most visible firms, however, the effect of controversies weakens and may become negligible, indicating that persistent greenhushing becomes increasingly difficult to sustain under conditions of continuous scrutiny. Importantly, this does not imply that large firms are less dependent on stakeholders. Rather, it suggests that the configuration of salient stakeholders and the constraints they impose differ systematically with scale and visibility, altering the strategic feasibility of sustained silence following ESG controversies.

6. Conclusions

These findings of this paper recast ESG reporting as an adaptive equilibrium at the intersection of legitimacy pressures, stakeholder configurations, and political contestation, where firms adjust the level of sustainability practices to manage controversy risk and stakeholder expectations.

6.1 Contribution to the literature

The paper has three main literature contributions. First, it refines ESGD theory by operationalising greenhushing as a negative disclosure-performance gap and documenting, on a large sample, that firms may respond to ESG shocks not through exaggeration but through silence. This complements the dominant focus on greenwashing and reframes disclosure strategy as spanning both over- and under-communication. Moreover, it suggests a refinement of legitimacy theory, which has already

been heavily suggested by Deagan (2019). In particular, we find that under conditions of institutional conflict, firms may instead pursue legitimacy through reduced visibility, thus indicating that silence can function as a strategic legitimacy mechanism. This is not accounted for by seminal works that define legitimacy theory, therefore implying the need for further debate.

Second, by integrating legitimacy and stakeholder perspectives within a politically polarised U.S. context, the study shows that controversies do not uniformly prompt transparency as a form of legitimacy repair. When salient stakeholders penalise explicit ESG communication, visibility itself becomes costly. This has significant implications that are heavily rooted in stakeholder theory, and in particular on the criteria for stakeholder selection, a branch of this approach exemplified by Bridoux and Stoelhorst's (2014) seminal work. In particular, it is worth noting that when certain stakeholder groups penalise ESG visibility, firms may prioritise selective stakeholder alignment, leading to under-disclosure strategies.

Third, the findings enrich institutional and governance research by identifying firm size as a key moderator: relatively less scrutinised large firms deepen under-disclosure following controversies, whereas the largest and most exposed firms exhibit limited capacity to sustain silence. This will be especially important for future quantitative research on greenhushing practices, which will have to consider size and influence in a way that is seldom done by past studies.

6.2 Managerial implications

For managers, ESG communication must be jointly controlled with ESG controversy history (at least last 3 years), visibility in terms of market capitalization, and salient stakeholders in terms of their material sensitivity, to avoid both exaggerated claims and over-silence. External auditors also should define a minimum, assured disclosure baseline. For investors, sparse disclosure should not be always taken as weak performance, and engagement should target both inflated claims and unusual silence. For regulators, formal mandates should be complemented with enforcement, assurance, and prominence requirements for core ESG indicators, especially for large or controversy-prone firms, to curb greenhushing without stifling discretion.

Moreover, there is a significant number of external stakeholders that are directly impacted by disclosure practices. Indeed, civil society actors, including NGOs and the media, may also face increasing challenges in monitoring corporate sustainability behaviour, as greenhushing reduces the availability and salience of information necessary for public scrutiny. Finally, for standard-setters and assurance providers, the findings underscore the importance of developing frameworks capable of detecting not only over-disclosure greenwashing but also systematic under-disclosure, thereby supporting more reliable and comparable ESG reporting ecosystems. We argue that rising lack of trust by external stakeholders will provide an even further challenge for managers in an already chaotic environment.

6.3 Limitations and future research

Despite the advancements made by this paper, the focus on U.S. listed firms from 2020 to 2024 and reliance on a single dataset may embed contextual and provider-specific biases. Restricting the sample to under-disclosers sharpens identification of greenhushing but limits direct comparison with greenwashing and may overlook dynamics near the disclosure threshold. The quantitative design cannot fully capture qualitative dimensions of ESG communication, such as tone or framing. Moreover, despite lags, fixed effects, and robustness checks, the observational approach constrains strong causal inference. Therefore, cross-country analyses could assess whether controversy-driven greenhushing generalises to different regulatory and political regimes. Mixed-method designs combining disclosure-performance gaps with textual analysis could uncover subtler forms of narrative softening or depoliticisation. Extending the time horizon and modelling major regulatory inflection points would clarify whether greenhushing is a temporary adaptation to institutional turbulence or an enduring feature of contemporary ESG capitalism.

When Corporate Governance becomes Necessary: Board Mechanisms and Innovation Efficiency

SALVATORE ESPOSITO DE FALCO, NICOLA CUCARI, GIACINTO CONIGLIO

Abstract

Frame of the research. *Research on corporate governance and innovation has predominantly relied on sufficiency-based models that estimate average effects of board mechanisms, offering limited insight into whether certain governance mechanisms are indispensable for innovation outcomes. This limitation is particularly salient in knowledge-intensive and highly regulated contexts such as the healthcare industry, where innovation efficiency is critical.*

Purpose of the paper. *This study investigates whether board-level corporate governance mechanisms constitute necessary conditions for achieving innovation efficiency, understood as the effective transformation of R&D investments into patented innovation outputs.*

Methodology. *The paper employs Necessary Condition Analysis (NCA) to examine whether board size, board independence, board gender diversity, board tenure, and CEO duality represent necessary consitions for innovation efficiency. Ceiling line estimation, permutation tests, and bottleneck analysis are employed.*

Results. *The findings identify board independence as the only necessary condition for high innovation efficiency. Firms with insufficient board independence are unable to achieve high efficiency levels, regardless of R&D intensity. Other board mechanisms display weaker or non-significant necessity patterns.*

Research limitations. *The study is constrained by a limited sample size, a short observation period, and a focus on the healthcare sector, which may affect generalisability.*

Managerial implications. *The results suggest that board independence represents a non-negotiable governance foundation for innovation efficiency, while other board attributes should be adapted to firm-specific contexts.*

Originality of the paper. *The study advances governance and innovation research by introducing necessity logic, reconceptualising innovation efficiency as a governance-relevant outcome, and demonstrating the non-compensatory role of board independence.*

Keywords: *corporate governance; board of directors; innovation efficiency; nca; healthcare*

1. Introduction

Innovation, defined as the development of new products, services, processes, or organisational models (Kahn, 2018; Annesi *et al.*, 2020), is a fundamental determinant of firm competitiveness and long-term survival in complex and uncertain environments (Almrshed *et al*., 2023; Becheikh *et al*., 2006; Johannessen *et al*., 2001). Its strategic importance became particularly evident in the aftermath of the COVID-19 pandemic, which profoundly reshaped global economic structures and forced organisations to reconfigure business models (Seetharaman, 2020), supply chains (Raj *et al*., 2022), and innovation processes (Amankwah-Amoah, 2021; Akay *et al.*, 2022).

Within this landscape, the healthcare sector occupies a distinctive position. The need for rapid and effective innovation intensified, positioning innovation capability as a central lever for resilience and competitive advantage (Chesbrough, 2020). During the pandemic, major U.S. healthcare and pharmaceutical firms sustained record levels of R&D investment, such as Merck & Co. (USD 13.56 bn), Johnson & Johnson (USD 12.15 bn), and Pfizer (USD 9.41 bn), underscoring the sector's central role in sustaining global innovation (FDI Intelligence, 2021). Yet healthcare innovation remains characterised by unusually high risk, substantial resource requirements, and uncertain market success (Jalonen, 2012; Stern, 2017; Nawrocki & Jonek-Kowalska, 2022). These challenges have intensified in the post-pandemic years, when healthcare firms must simultaneously ensure financial resilience, improve operational robustness, and respond to demographic trends such as ageing populations and rising chronic disease prevalence (Flessa and Huebner, 2021; Oderanti *et al*., 2021; Nawrocki and Jonek-Kowalska, 2022). So the growing societal expectations for an improved quality of life and increased life expectancy further amplify the demand for innovation (Segarra-Oña *et al*., 2020; Saheb

and Izadi, 2019), which is supported by ongoing digital transformation and rising R&D costs.

However corporate governance has emerged as a key determinant of firms' innovative behavior (Sapra *et al*., 2014; Asensio-López *et al*., 2019). Over the past two decades, research has progressively moved beyond the governance-performance link and has examined the role of governance structures in shaping innovation outcomes (Barker and Mueller, 2002; Lin *et al*., 2011; Belloc, 2012). Recent contributions highlight that innovation should not be viewed only as a technological or operational process, but as an evolving dynamic process shaped by the quality of corporate governance (Bobillo *et al*., 2018; Liu *et al*., 2025). Several governance mechanisms have been shown to influence innovation strategies, including board size (Blibech and Berraies, 2018), board independence (Berezinets *et al*., 2018), gender diversity (Harjoto *et al*., 2018), board tenure (Chen, 2013), and CEO duality (Goodstein and Boeker, 1991; Sierra-Morán *et al*., 2024; Kor, 2006).

Despite these contributions, two major research gaps remain. First, existing research is fundamentally limited in how it conceptualises and measures innovation. Most prior studies (e.g. Bravo and Reguera-Alvarado, 2017; Chen, 2014; Cumming and Leung, 2021) use innovation inputs (e.g. R&D expenditure) or outputs (e.g. patents) as standalone indicators. However, these indicators only capture the volume of innovation efforts, not their productivity (Hagedoorn and Cloodt, 2003). As Cruz-Cázares et al. (2013) have highlighted, examining innovation inputs and outputs in isolation provides an incomplete and often misleading picture of innovation performance because it fails to reflect the efficiency with which firms convert R&D efforts into tangible innovation outcomes. Innovation inputs represent sunk costs unless they generate successful innovations, and innovation outputs alone say little about the effort required to obtain them (Tidd and Bessant, 2009; Koellinger, 2008). Consequently, only a limited number of studies examine innovation efficiency — the ability of firms to transform R&D inputs into meaningful innovation outputs — leaving a limited understanding of how governance mechanisms influence this productivity dimension.

A second limitation relates to the theoretical and empirical approaches that have traditionally been used to study governance and innovation. Existing research relies on linear, additive models (typically regressions), which assume that governance mechanisms operate independently and have equal marginal effects. However, as scholars have argued, corporate governance does not operate through isolated mechanisms, but rather as a "governance bundle" (Rediker and Seth, 1995, p. 87) or a "system of interdependent elements" (Aguilera et al., 2008, p. 482). Subsequent contributions (Dalton *et al*., 2003; Aguilera *et al*., 2012; Misangyi and Acharya, 2014; Greckhamer et al., 2018; Cucari, 2019; Furnari *et al*., 2021) have further reinforced the view that governance systems are configurational, meaning that mechanisms interact with, reinforce or even substitute each other. These contributions have emphasised that the effectiveness of governance depends not on the attributes of individual mechanisms, but on their configuration.

This perspective challenges the assumptions underlying regression-based approaches. Organisational processes, and innovation in particular, often exhibit "necessary but not sufficient" dynamics. This means that certain conditions must exceed a minimum threshold for innovation to occur, even though they are not sufficient to guarantee high performance. This logic is similar to the concept of bottlenecks, threshold constraints and non-compensatory mechanisms, whereby the absence of a single critical governance attribute can prevent innovation, despite the presence of other favourable conditions. For example, substantial investment in R&D may be ineffective if board independence is insufficient to ensure adequate oversight, whereas strong oversight alone cannot produce innovation without complementary organisational capabilities. However, traditional regression models cannot detect such asymmetric and non-compensatory patterns, as they estimate average additive effects and cannot test whether a predictor serves as a necessary condition.

To address these gaps, we address the following research question: *Which corporate governance mechanisms function as necessary conditions for innovation efficiency in healthcare firms?*

This study applies Necessary Condition Analysis (NCA) (Dul, 2016; Dul, 2024), a methodology specifically developed to identify factors that act as non-compensatory constraints: if the condition is absent or too low, the outcome cannot occur, regardless of the presence of other favourable factors.

Rather than modelling sufficiency *"does X increase Y?"*, NCA tests necessity "*if X is absent, Y is always absent"*.

This approach is particularly suited to studying innovation efficiency in healthcare, where regulatory compliance, organisational capabilities, and financial resources often operate as hard constraints that limit firms' ability to transform R&D input into innovation output.

We analyse 315 firm-year observations from 63 NASDAQ-listed U.S. healthcare firms over 2020–2024, applying NCA to assess whether specific board mechanisms impose ceiling constraints on firms' innovation efficiency. This time window captures a unique phase in which innovation pressures and governance practices were profoundly reshaped by pandemic-related disruptions. Our findings reveal a highly asymmetric relationship between governance and innovation. Of the board mechanisms examined, board independence is the most important factor in achieving high innovation efficiency. Firms with insufficient independent oversight are unable to reach higher levels of innovation efficiency, regardless of their R&D investment levels. Other board attributes, such as board size, gender diversity and tenure, display weaker necessity patterns that do not withstand permutation testing. Meanwhile, CEO duality does not impose any binding constraints on innovation efficiency.

The study makes three contributions. First, it provides one of the few empirical analyses that link governance mechanisms to innovation efficiency rather than innovation intensity in the healthcare sector. Second, it introduces Necessary Condition Analysis to this field of research, demonstrating the value of identifying governance-related constraints on innovation. Third, it provides practical guidance for managers and policymakers. By identifying the minimum governance thresholds required for efficient innovation, the findings offer actionable insights for configuring boards to avoid innovation bottlenecks.

2. Governance Mechanisms as Necessary Conditions for Innovation Efficiency

In corporate governance systems, the board of directors provides the formal link between shareholders and those responsible for the firm's day-to-day management, and constitutes the primary locus of control within the organisation (Fama and Jensen, 1983; Adams *et al*., 2008). From this perspective, the board's core function is to monitor managerial behaviour and safeguard shareholders' interests. However, an increasing amount of research on governance and strategy suggests that the role of the board extends beyond control and oversight. This research positions governance mechanisms as strategic resources that influence a firm's capacity to develop and implement complex strategies (Zahra and Pearce, 1989; Baysinger and Hoskisson, 1990; Zattoni and Pugliese, 2012). The composition and structure of the board have a significant influence on the approval of strategic initiatives, as well as on the possession by organisations of the cognitive capacity, expertise, and evaluative capabilities required to execute them effectively, particularly in innovation-intensive contexts (Forbes and Milliken, 1999; Hillman and Dalziel, 2003). Through its monitoring and advisory roles, the board therefore shapes strategic priorities, constrains managerial discretion, and defines the organisational conditions under which long-term investments, including R&D, are evaluated and governed.

Early studies on corporate governance and innovation already recognised that board mechanisms influence firms' innovation-related decisions (Baysinger *et al.*, 1991; Lacetera, 2001; Hoskisson *et al.*, 2002), yet subsequent research has largely examined these relationships through average effects on innovation inputs or outputs (Balsmeier *et al*., 2014), rather than asking whether certain governance mechanisms constitute necessary conditions for innovation. In R&D-intensive and highly regulated contexts such as the healthcare industry, this distinction is particularly salient. Innovation efficiency depends on whether firms possess a minimum set of governance mechanisms that make the disciplined transformation of R&D investments into valuable innovation outputs organisationally feasible. Among these, board size represents a fundamental structural constraint shaping the board's

ability to coordinate monitoring and advisory functions. While larger boards may increase access to expertise and information, the associated coordination frictions, slower deliberation, and diffusion of responsibility undermine accountability and weaken the board's capacity to evaluate complex R&D portfolios in a timely manner (Nguyen and Huynh, 2023; Li *et al*., 2024). In innovation environments characterised by high uncertainty and irreversible investment decisions, even modest reductions in the effectiveness of monitoring can prevent firms from discontinuing low-quality projects and reallocating resources efficiently. This makes achieving high innovation efficiency impossible, regardless of R&D intensity (Messai and Jouini, 2025; Shabbir *et al*., 2024). Board independence is a second critical governance prerequisite. Independent directors improve the quality of monitoring, curb managerial opportunism and ensure more rigorous project selection, thereby reducing the tendency to escalate commitment in uncertain research trajectories (Rosenstein and Wyatt, 1990; Almulhim, 2023). Evidence that increased independence reduces R&D spending while simultaneously improving patent output suggests that independence does not stimulate innovation volume, but rather enables firms to extract more value from existing R&D investments (Balsmeier *et al*., 2017; Chou and Johennesse, 2021). Without a minimum level of independence, boards lack the authority and informational distance required to correct decisions that allocate resources inefficiently. This makes it structurally infeasible to innovate efficiently, even when technological capabilities are present.

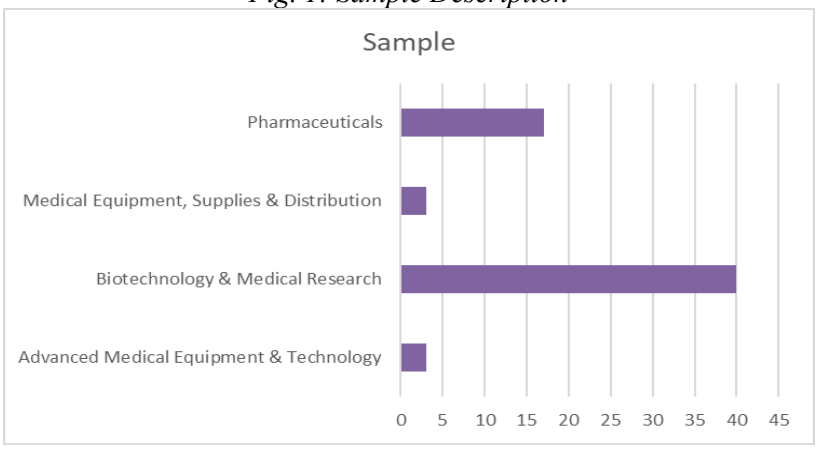
Board gender diversity further operates as a necessary organisational condition by expanding cognitive variety (Müller-Horn *et al.*, 2024), improving deliberation quality (Nielsen and Huse, 2010), and enhancing strategic evaluation in innovation governance (Memon *et al*., 2025). Empirical evidence shows that gender-diverse boards are associated with higher innovation productivity rather than merely higher output volumes, reflecting superior conversion of R&D inputs into impactful outcomes (Griffin *et al*., 2021). Importantly, this relationship is best understood through the lens of critical mass theory. Prior research suggests that when women represent only a small minority on the board, their ability to influence strategic discussions is constrained by tokenism, limited voice, and conformity pressures. Only once a critical mass is reached do female directors acquire sufficient legitimacy, interaction intensity, and decision-making influence to shape board processes and strategic outcomes meaningfully (Torchia *et al*., 2011; Schwartz-Ziv, 2017; Slomka-Golebiowska *et al*., 2023; Al-Shaer *et al*., 2026).

Board tenure introduces a temporal constraint that further shapes the feasibility of innovation efficiency. A minimum level of tenure is required for directors to accumulate firm-specific and technological knowledge necessary to understand complex R&D processes (Kor, 2006), yet prolonged tenure fosters entrenchment, conformity, and reduced monitoring vigilance, impairing boards' willingness to challenge legacy projects and adapt research portfolios to emerging opportunities (Vafeas, 2003).

Finally, CEO duality defines a critical boundary condition for innovation governance by restructuring authority and information flows at the apex of the firm. Unified leadership can streamline decision-making, reduce information frictions, and enhance strategic coherence in innovation-intensive settings, thereby improving the productivity of R&D investments (Li and Yang, 2019; Yu, 2023; Hsieh *et al.*, 2024). However, duality can also weaken formal monitoring and increase exposure to discretionary biases, potentially undermining innovation efficiency in the absence of sufficient transparency and reporting structures (Krause *et al*., 2014; Nuanpradit, 2024).

3. Methodology

3.1 Research design and sample



The empirical analysis adopts a panel data research design, in line with previous studies on corporate governance and innovation (e.g. Lacetera, 2001; Abu Alia *et al*., 2024), in order to capture cross-sectional heterogeneity and the temporal evolution of firms' innovation efficiency. The dataset

covers the period from 2020 to 2024. This timeframe was deliberately chosen to exclude the most acute phase of the pandemic, in order to avoid any distortions associated with extraordinary crisis conditions. At the same time, it captures the post-pandemic phase of strategic recovery, organisational restructuring and renewed innovation efforts in the healthcare sector. During this period, healthcare firms substantially increased their R&D investments in order to rebuild technological capabilities and enhance operational resilience (Shukla *et al*., 2020; Robinson, 2021; Marques *et al*., 2021; Sharma *et al*., 2021).

The sampling procedure followed a transparent and systematic process. First, the full population of healthcare companies listed on the NASDAQ stock exchange was retrieved from the LSEG Data & Analytics database, resulting in an initial universe of 743 firms. This comprehensive starting point ensured that the study did not rely on any ex ante selection criteria that could bias the sample. Second, all firms were screened for the availability of complete financial, governance, and innovation-related data over the entire 2020–2024 period. Because the analysis requires consistent time-series observations for all variables, firms with missing data were excluded to preserve comparability and internal validity. After applying these data-quality filters, 63 firms met the full inclusion criteria, yielding a fully balanced panel of 315 firm-year observations (Figure 1).

Importantly, firms were excluded solely due to incomplete disclosure rather than firm-specific characteristics, thereby reducing concerns regarding systematic selection bias. The final sample comprises U.S. healthcare firms operating across heterogeneous but innovation-intensive subsectors, including biotechnology and medical research, pharmaceuticals, and medical equipment and technology. These firms exhibit substantial variation in size, governance structures, and innovation profiles, ranging from small R&D-intensive biotechnology companies to larger, more established pharmaceutical and medical technology firms. Consistent with the characteristics of innovation-driven healthcare industries, a large share of sample firms report negative profitability during the observation period, reflecting long development cycles, high R&D intensity, and delayed commercialisation of innovation outputs. This heterogeneity enhances the suitability of the sample for examining innovation efficiency, as it captures firms operating under markedly different organisational and economic conditions while facing similar innovation-related challenges. The use of a high-quality balanced panel is particularly important for reliably identifying both average relationships and necessity-based constraints.

3.2 NCA Technique

To investigate whether specific board-related governance mechanisms operate as prerequisites for innovation efficiency, the study employs NCA, a method specifically designed to detect non-compensatory, constraint-like relationships (Dul, 2016; Dul *et al.*, 2020; Dul, 2024). A necessary condition is a factor whose absence systematically prevents the outcome: "*if X is absent, Y is always*

absent." Unlike sufficient conditions—which may be compensated for by other favourable factors—necessary conditions are indispensable thresholds that cannot be substituted. This logic aligns with bottlenecks and non-compensatory mechanisms widely discussed in organisational research (Goertz *et al.*, 2013; Karwowski *et al*., 2016) but seldom tested empirically in the governance–innovation domain.

NCA identifies these constraints by examining the boundary of the XY scatterplot rather than its centre, as done in regression-based models. If the upper-left region of the plot is empty, high levels of the outcome never occur when the predictor is low, indicating the presence of a necessary condition (Richter *et al*., 2020). The boundary separating the populated area from this empty "ceiling zone" is the ceiling line, which marks the maximum attainable level of the outcome for any given value of the predictor.

Ceiling lines are estimated using two techniques. The CE-FDH estimator constructs a non-parametric, stepwise frontier and is considered the most conservative, while the CR-FDH estimator provides a linear approximation that offers smoother and more interpretable results (Dul, 2016). For CR-FDH, ceiling accuracy values of 95% or higher indicate a reliable necessity relationship. The importance of a necessary condition is captured by the effect size (d), defined as the proportion of the empirical outcome space restricted by the ceiling. Following Dul (2016) and Van der Valk *et al.* (2016), effect sizes are interpreted as small ($0 < d < 0.10$), medium ($0.10 \leq d < 0.30$), large ($0.30 \leq d < 0.50$), or very large ($d \geq 0.50$). Statistical significance is evaluated using permutation tests, which assess whether the observed ceiling zone could arise by chance (Dul *et al*., 2020).

Because NCA is suited to cross-sectional data, applying it directly to panel structures may distort ceiling shapes by multiplying observations for each firm (Dul, 2021). To avoid this, the balanced panel was transformed into a cross-sectional dataset by computing firm-level means for all variables, following established methodological recommendations. All analyses were conducted in R using the nca package 4.0.4.

3.3 Outcome, conditions and measurements

3.3.1 Outcome variable: Innovation efficiency

This study measures innovation efficiency through a composite indicator that captures both the inputs and outputs of the firm's innovation process. Specifically, the dependent variable is defined as the ratio of the number of patents to R&D expenditures, thereby quantifying the firm's ability to convert research investments into codified technological outcomes. This approach extends beyond the limitations of single dimensional innovation indicators. While R&D expenditure is widely used as a proxy for a firm's innovative efforts, representing deliberate investments aimed at generating new scientific or technical knowledge and bringing substantially improved products or processes to market (Jermias, 2008), it captures only inputs and not whether these investments result in successful innovation.

Prior studies consistently rely on R&D intensity as an indicator of innovative effort (Bublitz and Ettredge, 1989; Coff, 2003; O'Brien, 2003), recognizing that R&D spending reflects a firm's intention to build technological capabilities and sustain competitive advantage. Conversely, patent counts represent realized innovative output by capturing the novelty and codification of technological inventions; however, there are not single metrics that alone fully capture all the aspects of innovation (Hagedoorn and Cloodt, 2003).

By combining these two components into a patent-to-R&D ratio, this study adopts a productivity-oriented measure of innovation efficiency, consistent with prior research emphasizing the complementarity of input- and output-based indicators (Artz et al., 2010; Chircop et al., 2020; Hsieh et al., 2024). This composite indicator aligns with the broader innovation-measurement literature, which underscores the need for multifaceted indicators capable of capturing the complexity of innovation processes and the interplay of resources, technological capabilities, and realized outcomes (Patel and Pavitt, 1995; Grupp and Schubert, 2010; Dziallas and Blind, 2019).

Given the inherent difficulty of measuring innovation, particularly in contexts where companies

are reluctant to disclose sensitive innovation data (Chesnais, 1992) and where no single "catch-all" indicator exists (OECD, 2005), composite measures provide a more robust assessment of innovation performance.

The measure adopted here is especially appropriate for the healthcare sector, where R&D activities are highly resource-intensive, characterized by long development cycles, regulatory uncertainty, and substantial technological risk (Katila, 2000). In these industries, patents serve not only as formal protection mechanisms but also as strategic signals of technological capability, partnership potential, and market value. Thus, innovation efficiency, operationalized as the firm's effectiveness in transforming R&D inputs into patented outputs, offers a conceptually grounded and empirically validated proxy for capturing the innovation performance most relevant to this study's context.

3.3.2 Condition variables: Governance Mechanisms

To examine whether corporate governance mechanisms act as necessary conditions for innovation efficiency, the study focuses on five board-related mechanisms: Board Size, Board Independence, Board Gender Diversity, Average Board Tenure, and CEO Duality (Table 1). These conditions, sourced from LSEG Data & Analytics, capture structural and compositional dimensions of the board that may impose threshold constraints on firms' innovative efficiency.

Tab. 1: Variables Description, Source: LSEG Data & Analytics

	Name	**Type**	**Definition**	**Source**
Condition variables	Board Size	Continuous	The total number of board members at the end of the fiscal year	LSEG
	Independent Board Members Score	Continuous (%)	Percentage of independent board members as reported by the company	LSEG
	Board Gender Diversity Score	Continuous (%)	Percentage of females on the board	LSEG
	Average Board Tenure	Continuous	Average number of years each board member has been on the board	LSEG
	CEO Duality	Binary (0/1)	Binary value: 1 is True and 0 is False	LSEG
Outcome variable	Innovation Efficiency	Continuous	Number of patents / R&D Expenditures	LSEG

Source: our elaboration

4. Results

Table 2 reports the results of the NCA analysis for the five board-related governance mechanisms. For each mechanism we estimated two ceiling lines, the conservative non-parametric CE-FDH and the linear CR-FDH. The ceiling plots (Figures 2–6) graphically display the empirical upper frontier and the empty ceiling zone above it; these plots are the core diagnostic of NCA because they show whether high values of the outcome (innovation efficiency) ever occur when the predictor is low.

Across the board mechanisms, the most striking finding is the necessity of board independence.

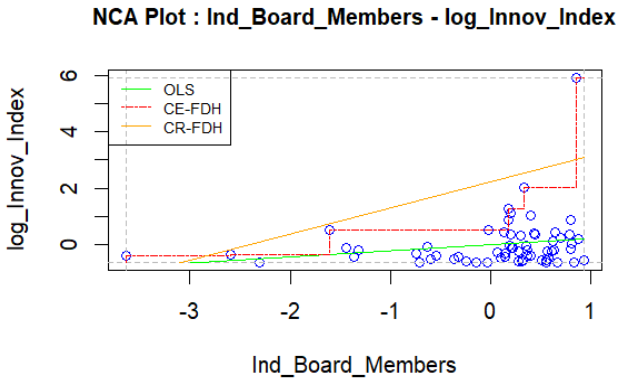
The ceiling plot for independent directors (Figure 2) exhibits a pronounced empty area in the upper-left part of the scatter, and the effect sizes are very large for both estimators (CE-FDH: d = 0.839; CR-FDH: d = 0.747). In substantive terms, the observed distribution implies that firms with low shares of independent directors do not achieve the higher levels of innovation efficiency observed in this sample.

Other board mechanisms display moderate necessity patterns. Board Size (Figure 3), Board Gender Diversity (Figure 4), and Average Board Tenure (Figure 5) all display visible ceiling zones, although less pronounced than for board independence. These patterns indicate that firms must meet minimum thresholds of board capacity, gender diversity, and accumulated board experience to avoid structural constraints on innovation efficiency. The trajectory of the ceiling lines suggests that insufficient levels of these conditions prevent firms from reaching higher innovation outcomes.

In contrast, CEO Duality (Figure 6) shows no evidence of necessity. The scatterplot lacks a discernible upper-boundary constraint, the ceiling line is flat, and the effect size is zero (d = 0). The scatter lacks an upper-left empty zone and the ceiling is effectively flat, which implies that whether the CEO also serves as board chair does not constrain firms' ability to achieve higher innovation efficiency in our data.

Across all variables, ceiling accuracies exceed 93%, and visual inspection confirms that the estimated ceiling lines appropriately trace the upper frontier of the data. This provides strong support for the robustness and reliability of the necessity patterns identified.

4.1 Permutation Test



In line with the recommendations of Dul (2020) and Dul et al. (2023), we performed permutation tests to determine whether the observed effects differed significantly from those expected by chance. The p-values are reported in Table 2. The results show that only independent board members yield statistically significant necessity effects (p = 0.05 and 0.012). Board size, gender diversity, and board tenure yielded non-significant p-values, and CEO duality was not statistically significant (p = 1.00). Thus, permutation testing confirms that, in our sample, board independence is the only robust necessary condition for innovation efficiency.

Tab. 2: NCA Results

Conditions	Method	c-accuracy	Ceiling Zone	Scope	Effect size	Fit	p-value (Permutation Test)
Board Size	CE-FDH	100%	11.455	30.013	0.382	100%	0.123
	CR-FDH	93.7%	8.571	30.013	0.286	74.8%	0.135
Independent Board Members	CE-FDH	100%	25.282	30.130	0.839	100%	0.012
	CR-FDH	96.8%	22.495	30.130	0.747	89.0%	0.005
Board Gender Diversity	CE-FDH	100%	9.912	25.857	0.383	100%	0.408
	CR-FDH	95.2%	7.998	25.857	0.309	80.7%	0.439
Average Board Tenure	CE-FDH	100%	10.464	28.702	0.365	100%	0.178
	CR-FDH	93.7%	7.876	28.702	0.274	75.3%	0.176
Ceo Duality	CE-FDH	100%	0.000	6.601	0.000	100%	1.000
	CR-FDH	100%	0.000	6.601	0.000	NA	1.000

4.1 Bottleneck Table

In line with Dul's (2016) recommendations, we present the bottleneck table based on the CR-FDH ceiling (Table 3). The CR-FDH method produces a linear ceiling that yields smooth, interpretable thresholds, expressed as a percentage of the observed range. At the 10% outcome level, only modest thresholds are required: a limited presence of board size (6.7%), independent directors (26.7%), gender diversity (4.5%), and board tenure (6.1%). These lower requirements indicate that initial innovation performance can be supported by relatively minimal governance mechanisms. As innovation output increases, however, the minimum necessary levels rise sharply. For instance, at outcome levels of 30–50%, firms are required to have substantially higher board size (17.6%–28.6%), greater independence (57.9%–89%), increased gender diversity (17.7%–30.9%), and more substantial board tenure (16.8%–27.4%). At innovation levels of 60% and above, Independent Board Members' condition become ‘not acceptable’ (NA), indicating that no feasible threshold could be computed due to data sparsity in the upper-right corner of the distribution, an expected behaviour of the linear CR–FDH estimator when observations are limited at high outcome levels.

Tab. 3: Bottleneck Table (CR-FDH)

Y	Board Size	Independent Board Member	Board Gender Diversity	Average Board Tenure
0	1.2	11.2	NA	0.8
10	6.7	26.7	4.5	6.1
20	12.1	42.3	11.1	11.4
30	17.6	57.9	17.7	16.8
40	23.1	73.5	24.3	22.1
50	28.6	89.0	30.9	27.4
60	34.0	NA	37.5	32.8
70	39.5	NA	44.1	38.1
80	45.0	NA	50.7	43.4
90	50.4	NA	57.3	48.8
100	55.9	NA	63.9	54.1

5. Discussion

This study examined whether board-level corporate governance mechanisms are necessary organisational conditions for achieving high levels of innovation efficiency in healthcare firms. Moving beyond the dominant regression-based approaches that focus on average effects, we adopted a logic of necessity to determine whether specific governance structures must be present to an extent sufficient for innovation efficiency to be attainable.

This perspective is particularly relevant in research and development (R&D)-intensive and highly regulated industries, where the successful implementation of innovation-oriented strategies depends not only on investment in resources, but also on governance structures that enable disciplined strategic execution, timely project evaluation and effective reallocation of resources across competing innovation trajectories.

The most notable finding relates to board independence. Large effect sizes and statistically significant permutation tests suggest that firms with a low proportion of independent directors do not achieve the higher levels of innovation efficiency observed in the sample. From a strategy implementation perspective, this finding suggests that independent directors play a critical role in ensuring that not only are innovation strategies formulated, but they are also executed efficiently. By enhancing monitoring quality and constraining managerial discretion, independent boards reduce escalation of commitment in uncertain R&D trajectories and facilitate the timely termination or redirection of projects that no longer align with strategic priorities (Almulhim, 2023). A point that had been unclear in earlier literature is clarified by the necessity logic. Board independence does not just improve the outcomes of innovation on average. Instead, it is a minimum governance condition. Without this condition, it is not possible to implement innovation strategies in an effective way. This is because the strategies need efficient allocation and reallocation of R&D resources. This interpretation reconciles previous findings that independent boards often reduce R&D spending while increasing patent output (Balsmeier et al., 2017), suggesting that independence primarily affects the productivity, rather than the scale, of innovation investments.

The bottleneck analysis further reinforces this interpretation by showing steep threshold requirements for independence as innovation efficiency increases. At moderate and high outcome levels, firms must appoint a very high proportion of independent directors to avoid constraints on innovation efficiency. In highly regulated healthcare environments, where project termination decisions are politically and economically costly, independent directors are essential for enabling disciplined strategy implementation. Specifically, they help to ensure that innovation portfolios remain aligned with strategic objectives over time, thereby preventing the persistent misallocation of resources to projects that no longer contribute to the firm's competitive positioning.

Although other board characteristics (board size, gender diversity and board tenure) display visible ceiling patterns, they do not qualify as statistically robust necessary conditions. These results suggest that, while these mechanisms may facilitate efficient innovation, they are not strict prerequisites. With regard to board size, the observed ceiling zone is consistent with previous arguments that boards that are too small may lack the cognitive and informational capacity required to govern complex R&D portfolios effectively (Lacetera, 2001). Similarly, although there is a moderate necessity pattern for board gender diversity, it fails to reach statistical significance.

However, this result does not contradict the growing body of evidence linking gender-diverse boards to higher innovation productivity (Griffin et al., 2021). Rather, it suggests that gender diversity improves the quality of deliberation and problem-solving during strategy execution, acting as a strategic enhancer rather than a binding condition without which innovation efficiency cannot be achieved.

The pattern of board tenure is similar. While insufficient tenure may limit directors' understanding of complex technological processes, the results suggest that a minimum tenure level is not strictly necessary for innovation efficiency to be achieved. This finding reflects the dual nature of tenure, as highlighted in previous research: the informational benefits coexist with the risks of entrenchment

and conformity (Vafeas, 2003; Kor, 2006).

Finally, there is no necessary relationship between CEO duality and innovation efficiency. This finding supports the notion that leadership structure is a contingent governance choice rather than a structural prerequisite. Although unified leadership can improve strategic coherence in certain innovation contexts (Hsieh et al., 2024), NCA findings suggest that firms can attain high innovation efficiency regardless of whether the CEO also serves as board chair. This finding is consistent with mixed prior evidence and highlights the importance of considering CEO duality as a context-dependent governance configuration rather than a universal enabler or constraint.

5.1 Theoretical Implications

This study makes three primary theoretical contributions to the literature on corporate governance and innovation.

First, it advances the corporate governance and innovation literature by introducing necessity logic through the application of NCA. Prior research has predominantly relied on additive models that estimate average effects of board characteristics on innovation outcomes, implicitly assuming symmetry and compensability among governance mechanisms. As highlighted by Belloc (2012), this tradition has struggled to explain why firms with similar size, market power, and R&D investment often display markedly different innovation performance, largely because governance has been treated as a "black box" or as a set of isolated, exogenous attributes. By contrast, our findings demonstrate that governance mechanisms operate asymmetrically: some conditions, such as board independence, function as non-compensatory prerequisites rather than incremental drivers. This necessity-based view reframes corporate governance not only as a system of control, but as an enabling architecture for strategy implementation, by delineating the minimum governance conditions under which innovation strategies can be effectively executed through efficient R&D allocation. In doing so, the study helps reconcile prior mixed evidence and clarifies why similar innovation investments can yield vastly different efficiency outcomes.

Second, the study contributes to the growing configurational perspective on corporate governance by showing that innovation efficiency depends on governance bottlenecks rather than isolated mechanisms. The results suggest that governance systems should be understood as bundles in which certain elements define feasibility boundaries. Board independence, in particular, emerges as a structural condition that enables other governance mechanisms to operate effectively, supporting the view that boards play a strategic and coordinating role, rather than serving solely as control. This insight resonates with recent calls to reconnect board research with stewardship oriented perspectives, which emphasise the board's role in enabling long-term value creation and strategic action rather than focusing exclusively on control (Belkacemi et al., 2025).

Third, the study contributes to innovation research by conceptually and empirically distinguishing innovation efficiency from innovation intensity. By operationalising innovation efficiency as the conversion of R&D inputs into patented outputs and analysing it through a necessity lens, the study demonstrates that efficiency captures governance-relevant aspects of innovation performance that are obscured by traditional input- or output-based measures. This reconceptualisation aligns innovation measurement more closely with the strategic oversight role of boards and opens new avenues for governance research focused on productivity rather than scale. By operationalising innovation efficiency as the conversion of R&D inputs into patented outputs, this study responds to calls for more integrative innovation constructs that capture both effort and outcome (e.g., Zahra, 1996; Wincent et al., 2013; Zona et al., 2013). Analysing this construct through a necessity lens further demonstrates that efficiency captures strategically salient aspects of innovation performance that are directly aligned with the board's oversight and implementation role, opening new avenues for governance research focused on productivity and strategic feasibility rather than innovation scale alone.

5.2 Managerial Implications

The findings offer several actionable implications for managers and policymakers.

First, the results highlight board independence as a non-negotiable governance foundation for innovation efficiency. Firms seeking to improve the productivity of their R&D investments should prioritise achieving and maintaining sufficiently high levels of board independence. Independence is not merely a compliance or legitimacy concern, but a structural condition that enables the effective implementation of innovation strategies by supporting disciplined monitoring, strategic project evaluation, and the timely termination or redirection of underperforming research initiatives. Without such governance capacity, innovation strategies risk remaining symbolic rather than operationally executable.

Second, the absence of robust necessity effects for board size, gender diversity, and tenure suggests that there is no one-size-fits-all governance template for innovation efficiency. Managers should view these mechanisms as levers that can enhance innovation governance but are not substitutes for independence. This flexibility is particularly relevant for smaller or younger firms that may face constraints in board composition but can still achieve high innovation efficiency by strengthening independent oversight.

Third, the findings caution against overemphasising leadership structure reforms, such as separating or unifying CEO and chair roles, as primary drivers of innovation efficiency. Since CEO duality does not constitute a binding constraint, firms should base such decisions on contextual considerations rather than assuming universal innovation benefits.

Conclusion

This study set out to investigate whether board-level corporate governance mechanisms act as necessary organisational conditions for innovation efficiency in healthcare firms. Departing from traditional sufficiency-based approaches, the analysis adopted a necessity perspective to identify governance structures that must be present at minimum levels for firms to effectively transform R&D investments into valuable innovation outputs.

The central finding is that board independence constitutes a robust and statistically significant necessary condition for innovation efficiency. Firms lacking sufficient independent oversight are structurally constrained from achieving high innovation efficiency, regardless of their innovation inputs. Other board mechanisms (board size, board gender diversity, and board tenure) exhibit supportive but non-binding roles, while CEO duality does not constrain innovation efficiency.

Some limitations should be acknowledged. First, the sample size is relatively small, which may limit the generalisability of the findings and reduce statistical power for detecting weaker necessity effects. Second, the temporal horizon is short, restricting the ability to capture long-term governance dynamics and delayed innovation outcomes. Future research should extend the analysis to larger samples, longer time spans, and firms operating in industries beyond healthcare to assess the external validity of the necessity patterns identified. Additionally, future studies could integrate complementary configurational approaches, such as fuzzy-set qualitative comparative analysis (fsQCA), to explore how combinations of governance mechanisms jointly enable high innovation efficiency.

An Agent-Based Modeling Approach to Multilevel Emergent Dynamics in OSCM

DAVIDE BONFIO[1], ANDREA FURLAN[2], STEVE WJ KOZLOWSKI[3]

Abstract

Frame of the research. Organizations and supply chains are multilevel systems in which micro-level interactions among heterogeneous actors give rise to higher-order operational outcomes. Yet OSCM research remains dominated by single-level, variance-based designs that are poorly suited to capture emergence as an unfolding cross-level process.

Purpose of the paper. This paper advances a process-based, multilevel approach to theorizing and analyzing emergent dynamics in OSCM by integrating multilevel theory with agent-based modeling, with the aim of specifying, interrogating, and refining generative mechanisms that link micro behaviors to macro-level unit properties.

Methodology. We develop a conceptual framework that positions ABM as a computational instantiation of multilevel process theorizing, capable of representing heterogeneity, local interaction rules, and top-down contextual constraints. We then demonstrate the approach through an agent-based model of the Sales and Operations Planning executive meeting, in which strategic consensus conditions information disclosure, integration, and the accumulation of shared team knowledge over time.

Results. The paper shows how ABM can render cross-level mechanisms explicit and testable by simulating how localized interaction patterns, under varying contextual constraints, generate emergent properties at the collective level. In the S&OP setting, the model illustrates how consensus operates as a higher-level constraint shaping disclosure and integration processes that, in turn, drive the emergence of team knowledge.

Research limitations. The demonstration is grounded in a stylized representation of the S&OP meeting and is intended to establish generative plausibility rather than provide direct empirical validation, which should be pursued in subsequent work through calibration and triangulation.

Managerial implications. The framework supports managers in diagnosing which meeting conditions and interaction structures foster knowledge integration, offering a basis for designing S&OP routines that promote productive information exchange and collective learning.

Originality of the paper. The paper contributes a theory-building template for OSCM research that couples multilevel process theorizing with ABM, enabling disciplined explanation of emergent operational phenomena beyond variance-based inference.

Keywords: *Computational process theory, layers of theoretical explanation, agent-based simulation, multilevel emergence, sales and operations planning.*

1. Introduction

Organizations and supply chain networks are inherently complex and multilayered entities where activities and interactions occur across multiple levels (Carter et al., 2015; Pavlov & Micheli, 2023), spanning across individuals, teams, organizations, and interorganizational networks. The operations and supply chain management (OSCM) literature has increasingly recognized this multilevel and processual nature of its core phenomena, as reflected in research on purchasing and supply (Meschnig et al., 2018), delivery delays (Awaysheh et al., 2021), new product development (Swink & Song, 2007; Yan & Dooley, 2013), and operational improvement (Stefanini et al., 2020). Despite this growing recognition, a misalignment persists between the research strategies used in the OSCM literature and the multilayered nature of its core phenomena.

In their review of OSCM publications, Carter et al. (2015) examined studies published between 2002 and 2014 showing that, although sophisticated methodological tools (e.g., statistical modeling via Hierarchical Linear Modeling, HLM, or Structural Equation Modeling, SEM) are increasingly available, explicit multilevel designs remain underutilized. Compared to other management disciplines (e.g., marketing or organizational behavior), most OSCM research still theorizes and tests

[1] Department of Economics and Management, University of Padova, davide.bonfio@phd.unipd.it

[3] Department of Psychology, University of South Florida, skozlowski@usf.edu

hypotheses at a single level of analysis, leaving cross-level relationships and interactions underexplored. This misalignment is also consequential for theory building. As noted by Bendoly and Oliva (2025), meaningful contributions can take different forms, ranging from identifying regularities among empirical observations to focusing on phenomena that contradict existing knowledge. Those two different perspectives shift the motivation for the research question from "*what do we expect to see*" to "*how can we explain what we are seeing*" (Bendoly & Oliva, 2025). Therefore, a multilevel, process-oriented approach becomes necessary because it is designed to connect observed regularities to their lower-level generative mechanisms (Bendoly & Oliva, 2025; Kozlowski & Klein, 2000; Kozlowski et al., 2026).

In this paper, building on the call for methodological refinement in OSCM research (Bendoly & Oliva, 2025; Cornelissen et al., 2024), we advance a theoretical and methodological approach to study emergent phenomena in OSCM. After a literature review on multilevel research in OSCM, we propose the multilevel theory (MLT) of Kozlowski and Klein (2000) as a meta-theoretical framework to account for the different emergence patterns that organizational phenomena follow. We advocate for an epistemological shift from variance-based to process-based theorizing, enabling researchers to develop appropriate theories for uncovering emergent processes (Mohr, 1982; Kozlowski et al., 2026). As a research tool, we contend that Agent-Based Simulation (ABS) is among the most suitable tools to conduct research on multilevel emergent phenomena (Grand et al., 2025; Kuljanin et al., 2024).

We also provide an example of how to conceptualize and compute an ABS to study a multilevel bottom-up phenomenon. Specifically, we investigate the role of management cognitive alignment, conceptualized as Strategic Consensus (SC, Tarakci et al., 2013), on the emergence of team knowledge during executive meetings of the Sales and Operations Planning (S&OP) process. To do so, we adopt a bottom-up multilevel perspective and investigate how micro-level determinants (i.e., generative mechanisms) at the individual level (i.e., communication skills, information processing skills, and speaking rate), and a team-level factor (i.e., Strategic Consensus), influence the process of team knowledge emergence. We conclude by providing a roadmap for designing and implementing ABS in multilevel research and outlining validation logics suitable for OSCM.

2. Literature review

2.1 Methodology

To contextualize our proposal within the existing OSCM literature, we conduct a Systematic Literature Review (SLR) to accomplish two main objectives. First, to evaluate whether the results presented by Carter et al. (2015) on the substantial lack of multilevel inquiry within the OSCM literature still hold a decade later. Consistent with established SLR practice in the OSCM literature (Carter et al., 2015; Zupic & Čater, 2015), we searched Elsevier's Scopus using a structured query applied to titles, abstracts, and keywords. The query was developed in three steps. First, we included emergence terms to capture bottom-up pattern formation, then we added multilevel terms to capture nested structures and cross-level mechanisms, and finally, we restricted our search for journals to leading OSCM outlets (Carter et al., 2015). We limited the publication window from 2015 to 2025 to evaluate developments since Carter et al. (2015). Each retained study was coded by focal phenomenon and methodological approach to support descriptive and thematic synthesis (Zupic & Čater, 2015). In Section 1 of the Online Appendix, we provide a detailed explanation of the methodology and a comprehensive analysis of the sample papers.

2.2 SLR results and literature gap

The final sample comprises 43 articles, approximately 4.3 per year, closely mirroring Carter et al. (2015) results. This indicates that, despite sustained calls for multilevel process research, the volume of explicit multilevel inquiry in OSCM remains limited. Based on the methodology employed, we divided the papers into three methodologically homogeneous clusters.

Cluster 1, *multilevel econometrics methods*, includes hierarchical modeling, HLM, multilevel SEM, and related variance partitioning designs used to test cross-level associations. These studies are analytically suited for separating within-unit from between-unit variance and estimating cross-level effects, but they typically operationalize emergence as a measurable outcome or relational pattern, rather than modeling the interaction dynamics through which it unfolds. Accordingly, they are best aligned with post-emergence inference, where the emergent construct is already stabilized and measurable.

Cluster 2, *qualitative designs*, includes interviews, comparative cases, and longitudinal case studies that trace how micro actions and interpretations accumulate into evolving system outcomes. Papers in this cluster articulate generative mechanisms and temporal sequencing, and develop constructs and boundary conditions when emergence is inherently processual. The main limitation is context dependence and interpretive findings, which can constrain generalization without complementary analytic generalization.

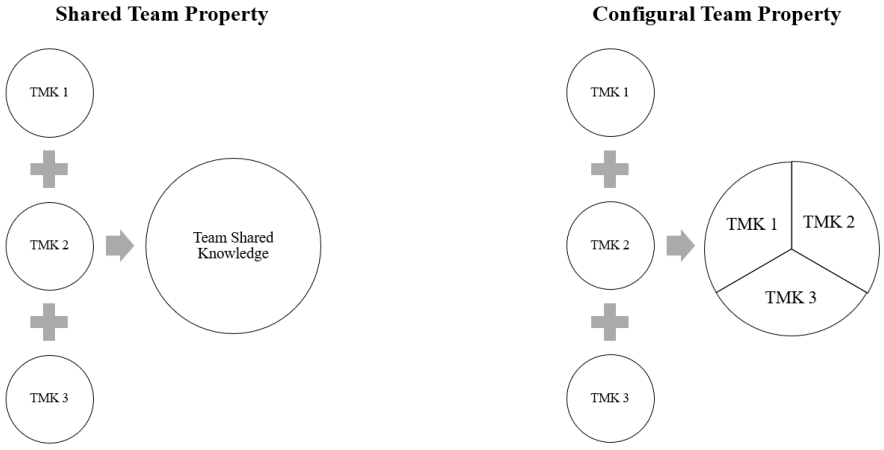
Cluster 3, *complex systems approaches*, includes simulation and network analytic work that represents local interaction rules and examines macro-level pattern formation, disruption propagation, and structural evolution. Interestingly, the sole paper in our sample using an Agent-Based Model (ABM) in emergent multilevel research is Clement and Puranam (2018), which examines how contextual, top-down organizational design can shape the bottom-up evolution of intraorganizational social networks over time. The phenomenon of interest is the emergence of stable interaction patterns from decentralized microlevel agents' choices, where agents repeatedly decide with whom to interact, learn from prior outcomes, and adapt their ties under limited information and enforcement. ABM fits this multilevel emergent research because it lets socialization arise from individual interactions, where agents use the quality of those interactions, such as performance feedback, to judge whether engaging with a given individual is worth repeating. It shows how individual interaction rules and local learning generate macro network structure and performance, and it isolates the conditions under which even imperfect formal structures function as coordination "scaffolds" that help agents discover, sustain, and regenerate productive relationships as the system evolves.

To conclude, the results of our SLR corroborate Carter et al.'s (2015) evidence on the relative scarcity of multilevel research in OSCM, identifying only a limited number of contributions over the past decade. Beyond this quantitative gap, our review also suggests that existing studies approach multilevel emergence through a variety of conceptual lenses and methodological strategies. Although these contributions provide valuable insights into specific aspects of multilevel phenomena, the literature remains somewhat fragmented, with limited integration between how emergence is theorized and how it is empirically investigated across levels of analysis. As a result, opportunities remain to further clarify the conceptual foundations of multilevel emergence and to strengthen the alignment between theoretical argumentation and the methodology employed to test it. Building on these observations, the next section introduces our proposal for theorizing and studying multilevel emergent phenomena in OSCM.

3. Multilevel Theory

To address the methodological gap in emergent multilevel research, we propose the MLT conceptualized by Kozlowski and Klein (2000) as a meta-theoretical framework. MLT can serve as an ontological framework for OSCM that largely follows a variance-based, cross-sectional logic, emphasizing statistical relationships among variables to infer causality (Ketokivi, 2019; Carter et al., 2015). As is well known, variance-based approaches are ill-equipped to capture the temporal and recursive dynamics that characterize emergent processes (Mohr, 1982; Kozlowski et al., 2026; Grand et al., 2025). MLT conceptualizes organizations as hierarchical systems composed of interacting entities at the micro, meso, and macro levels that are dynamically connected through top-down and bottom-up processes (Kozlowski & Klein, 2000). Within this framework, higher-level phenomena

are not simply aggregations of lower-level components, but emergent outcomes of interdependent lower-level constituents and interactions that unfold across time and levels of analysis. As specified by Kozlowski et al. (2013), emergent phenomena are:



- *Multilevel* because they originate at the lower level and manifest as collective outcomes at higher levels, thus linking micro-, meso-, and macro-level dynamics.
- *Time-dependent* because they develop, stabilize, or transform over cycles of interaction, adaptation, and feedback, which may occur rapidly or over extended periods depending on their nature.
- *Process-oriented* because their main focus lies in the dynamic interaction mechanisms among entities, such as social coordination and feedback, that generate higher-level properties.
- *Context-sensitive* because higher-level contextual factors (e.g., structure, culture, or environment) shape and constrain the dynamic process of emergence, influencing how and under what conditions collective properties unfold.

Kozlowski and Klein (2000) emphasize that bottom-up phenomena can unfold following different patterns of emergence, ranging from convergent (compositional) to divergent (compilational). In compositional emergence, individual contributions are homogeneous and isomorphic, yielding a shared unit property that maintains functional and structural equivalence across levels. This form of emergence reflects uniformity and stability, where the higher-level constructs mirror their lower-level constituents in both form and meaning (Kozlowski & Chao, 2012). Compositional emergence gives rise to shared constructs, unit-level properties grounded in within-unit consensus or homogeneity. By contrast, compilational emergence captures heterogeneity and asymmetry in individual contributions, where the collective phenomenon arises through complex patterns of differentiation and interdependence (Stewart et al., 2005; Kozlowski & Klein, 2000). In such cases, the collective property is functionally equivalent but structurally distinct across levels, emerging from specific configurations of individual states and behaviors rather than uniform aggregation. Thus, compilational emergence unfolds into configural constructs, which capture unit-level phenomena that depend on patterned heterogeneity, such as the distribution or variability of within-unit attributes of its lower-level constituents. Consequently, the operationalization of configural constructs must be tailored to the type of emergence process, reflecting the system's interactional logic (Kozlowski & Chao, 2012). Finally, emergence is not a one-time event but a dynamic process that can evolve, shifting from divergent, compilational states to convergent, compositional ones as they unfold (Kozlowski et al., 2013; Kozlowski & Chao, 2012).

As an example of the differences between shared and configural proprieties, we can think of two different conceptualizations of team knowledge in inventory management (Figure 1). If team knowledge is conceptualized as shared unit propriety, the emergent construct reflects the extent to which relevant information is commonly held across members involved in inventory decisions (e.g., current on-hand inventories, open orders, and promotion calendars). Shared team knowledge can be operationalized as the percentage of information shared among team members.

On the other hand, if team knowledge is conceptualized as configural propriety, it will consist of the complementary knowledge that unit members possess. A configural perspective of team knowledge corresponds to the configuration of team members' non-overlapping information sets whose joint pattern will represent the team's knowledge. In a configural conceptualization, what matters is team members' knowledge configurations, given that this perspective highlights the complementary array of unique knowledge. Adopting this lens, team knowledge outcomes (e.g., bullwhip attenuation, lower backorders, and better service-level) are the result of the complementary structure of heterogeneous information sets rather than from the sharedness of the same dataset.

Figure 1: Representation of team knowledge as a shared and configural team property.

Note: TMK = Team Member's unique Knowledge

From this perspective, multilevel process theorizing integrates the temporal focus of process theory with the structural layering of MLT. This dynamic view of multilevel emergence directly addresses the OSCM call for more informed multilevel research within the field (Carter et al., 2015).

4. Why is multilevel bottom-up emergent research needed in OSCM

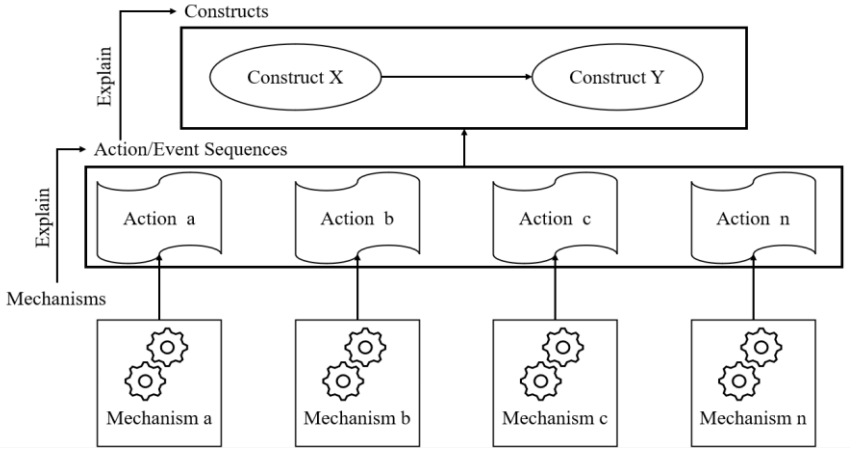
Among the multilevel studies in OSCM, a top-down approach prevails, which tends to overlook how lower-level dynamics generate emergent constructs (Carter et al., 2015; Ketokivi, 2019). Top-down processes refer to the way higher-level systems shape the actions and configurations of lower-level units; e.g., how the configuration of the supply chain structurally affects its organizations, shaping coordination mechanisms, decision rights, and the locus of innovation (Dyer & Singh, 1998; Flynn et al., 2010; Gereffi et al., 2005; Sturgeon, 2002).

In contrast, bottom-up processes describe how lower-level constituents coalesce over time to produce higher-level manifestations, such as organizational capabilities (Roscoe et al., 2019). Moreover, bottom-up research can aid in exploring how teams and organizations accumulate knowledge (Grand et al., 2016; Kozlowski & Bell, 2020), support/hinder individuals' proactive effort (Twemlow et al., 2023; Carraro et al., 2024), manage relationships with buyers/suppliers (Shamsollahi et al., 2021), and inquire into how individual decision heuristics shape systemic efficiency (Croson & Donohue, 2006).

Understanding the interplay between these distinct but interdependent perspectives is essential for explaining how organizations both shape and adapt to these primary driving forces in complex systems. As Kozlowski and Klein (2000) argue, understanding organizational systems requires tracing how micro-level interactions among individuals give rise to higher-order properties by simultaneously accounting for the influence that higher-order contextual factors exert over the micro dynamics. The lack of a coherent theoretical and methodological framework for examining bottom-up emergence is particularly striking, given that organizational performance, and generally most organizational outcomes, emerge from the dynamic interactions of individuals within teams (Bendoly et al., 2006; Marks et al., 2001; Mathieu et al., 2008).

4.1 Variance-based and process-based perspectives

Understanding bottom-up organizational processes and inferring causality with respect to emergent dynamics requires an epistemological shift, distinguishing between variance-based and process-based theorizing. As Mohr (1982), Maxwell (2004), and Bendoly and Oliva (2025) argue, the theoretical difference between variance and process-based explanations lies not in whether they seek causality but in how they conceptualize and test it.



Building on this distinction, Kozlowski et al. (2026) propose a typology, the Layers of Theoretical Explanation, that distinguishes three levels of analysis that differ in causal explanatory depth (Figure 2). At Layer 1, theorizing focuses on constructs and their empirical associations. Layer 2 lowers the focus of explanation by describing the sequence of actions and events through which outcomes unfold over time. Layer 3 deepens the explanation by specifying the generative mechanisms that produce those sequences, which ultimately give rise to observed outcomes.

Within this typology, variance-based explanations operate at Layer 1 by identifying systematic covariations among variables. They operate under the logic that differences in the values of independent variables account for differences in dependent outcomes, usually assuming temporal stability, measurable constructs, and generalizable relationships. The typical research design of variance-based research is "construct X is correlated with construct Y, and this relationship is moderated or mediated by constructs A, B, or C." Such studies rely on what can be termed construct-centered causal reasoning (Kuljanin et al., 2024), which assumes that, once alternative explanations are ruled out or statistically controlled (Mohr, 1982; Antonakis et al., 2010), the presence of X accounts for the presence of Y. In other words, in the absence of any other explanation, Y would not occur without X. Although this logic allows researchers to infer associations among variables, it does not shed light on the underlying drivers through which a particular configuration of X brings about specific manifestations of Y. Causality here is treated as a "black box," where the mechanisms linking variables are not directly observed, but rather inferred from regularities across cases (Kozlowski et al., 2026).

On the other hand, process-based theories focus on events, time-sensitive sequences, and the underlying mechanisms that generate outcomes (Mohr, 1982; Kozlowski et al., 2013; Kuljanin et al., 2024). As Mohr (1982) contends, process theorizing seeks to uncover the causal processes that connect events, observing how specific conditions and interactions lead to a specific phenomenon. Process theorizing mainly focuses on explicating organizational phenomena as action/event sequences that unfold over time (Mohr, 1982; Kuljanin et al., 2024; Kozlowski et al., 2026), emphasizing the situated context, the actors involved, and the temporal ordering through which outcomes emerge. In doing that, causal explanation is refined by focusing on "*what happened*" and "*in what order.*"

We acknowledge that process-based research is not new within OSCM, much of which has been conducted qualitatively (e.g., Oliva & Watson, 2011; Kaipia et al., 2017). Qualitative research is typically case-based and draws on techniques such as narratives, interviews, ethnography, and participant observation to develop a rich, interpretive, and holistic understanding of an emergent phenomenon, making it especially useful for theory building (Kozlowski & Chao, 2012). In addition, those studies present the advantage of lowering the explanation focus by one layer (from Layer 1 to Layer 2 in Figure 2), offering a closer examination of actions and the sequences of events through which processes unfold. However, this approach provides limited insight into *why* particular actions are enacted or specific events unfold in a given sequence. Moreover, given their interpretive nature (Kozlowski & Chao, 2012), direct observation of actions and event sequences introduces a potential measurement problem (Kuljanin et al., 2024), as interpretations are inevitably filtered through the observer's understanding, reinterpretation, and cognition (Kozlowski & Chao, 2012; Kozlowski et al., 2013). Even when process data are complemented with interviews or other ethnographic techniques, there is also the risk of overgeneralizing idiosyncratic findings derived from specific cases without testing their generalizability (Eisenhardt, 1989). Nonetheless, qualitative process and variance-based studies represent valuable starting points for identifying relevant variable correlations (Kozlowski et al., 2013) as epiphenomena, which need to be complemented by the study of underlying generative mechanisms.

Figure 2 Layers of Explanation Offered by Process Theories.

Note: Adapted with permission from Kuljanin, G., Braun, M. T., Grand, J. A., Olenick, J. D., Chao, G. T., & Kozlowski, S. W. (2024). Advancing organizational science with computational process theories. The Leadership Quarterly, 35(4), 101797. https://doi.org/10.1016/j.leaqua.2024.101797

To this end, computational-process theorizing (CPTs) takes a foundational theoretical focus on the generative mechanisms or drivers producing a determined pattern of actions and event sequences. Specifically, CPTs aim to disaggregate the variables of interest to their lowest layer of explanation, uncovering the mechanisms responsible for actions and events (Layer 3 in Figure 2). This distinction is described by Pentland (1999, p.722), who noted that "to describe a process, one needs event sequences. But to explain a process, one needs to identify the generative structures that enable and constrain it." In other words, CPT lowers the layer of explanation to the causal mechanisms generating certain patterns of action or events responsible for the correlation of two constructs X and Y. CPT theories rely on mechanistic, temporal, and configurational forms of explanation (Grand et al., 2016; Grand et al., 2025), better suited to domains where causation is emergent, non-linear, and context dependent. Focusing on the generative mechanisms consists of focusing on the *drivers* leading to specific actions or sequences of events underpinning construct relationships.

In sum, CPTs complement narrative process explanations with formal specifications expressed through mathematical equations, logical statements, and computer simulations (Davis et al., 2007). These computational formulations overcome limitations of variance-based and narrative process-based theory, such as relying on natural language, suffering from ambiguity, a lack of standardization, and interpretive variability, which hinder consistent evaluation of theoretical plausibility and causal adequacy (Frankenhuis et al., 2023; Smaldino, 2017). Moreover, by explicitly stating theoretical intentions, empowering simulation and internal validation, referred to as generative sufficiency (Epstein, 1999), allows researchers to clearly determine driving mechanisms of how processes evolve and interact across multiple levels and contexts. This refinement moves inquiry beyond answering *what* questions, toward explaining *how* and *why* phenomena occur.

The distinction between variance and process-based perspectives can be illustrated through the example of a clinical trial for a new drug. In a randomized controlled trial, participants are randomly assigned to treatment or control groups (Hariton & Locascio, 2018; Moher et al., 2010). By manipulating the independent variable, the drug to be tested, researchers observe its effects on patients. Outcomes may be different, as the drug could be 100% effective or cause adverse effects in certain subgroups (Sun et al., 2014). In the latter and more common case, knowing that for subgroup Z the drug causes adverse effects identifies a correlation but not provide insights about its cause (Rubin, 2005; Bradford Hill, 1965). To uncover this, researchers adopt a mechanistic perspective, examining how the compound interacts with biological processes, such as whether it inhibits or overstimulates enzymes, produces reactive metabolites, or alters biomarkers indicating organ stress (Danhof et al., 2008; Edwards & Aronson, 2000; Lin et al., 2019; Lavertu et al., 2021). Tracing these mechanisms reveals how molecular interactions lead to clinical outcomes and informs clinicians

about reformulation or dosage adjustments (Lavertu et al., 2021). Applying a similar logic to OSCM means moving beyond correlations between constructs, such as between supply chain integration and firm performance, to uncover the causal drivers and temporal dynamics through which these relationships emerge and evolve within organizations (Antonakis et al., 2010; Ketokivi & McIntosh, 2017; Ho et al., 2017).

4.2 OSCM limitations addressed by MLT

An overemphasis on variance-based and equilibrium-oriented modeling has often treated organizations as predictable rather than adaptive systems (Pavlov & Micheli, 2023), generating a multitude of correlational findings linking constructs at the aggregate level while overlooking the generative mechanisms and interactive processes through which such relationships develop or dissipate over time. Even with panel data, causality posited between variables is still inferred, because panel data provide repeated snapshots of the variables of interest, observed at multiple points in time (Kozlowski et al., 2026). These limitations are a relevant constraint in OSCM research since, as Sterman et al. (2015) emphasize, operations contexts are feedback-rich and time-dependent, rendering static, correlational models insufficient to explain temporal dynamics. Empirical meta-analytic evidence further shows that the effects of supply chain complexity on performance are contingent and divergent, contradicting the notion of simple, linear, and time-invariant causal relationships (Akın Ateş et al., 2022).

A direct consequence of variance-based theorizing is that organizational research frequently aggregates phenomena or processes data to higher levels (e.g., team averages or firm aggregates) without clearly theorizing the mechanisms of aggregation or emergence (Kozlowski & Klein, 2000; Carter et al., 2015). This exposes empirical analysis to the ecological fallacy (Klein et al., 1994; Bliese, 2000; Bliese et al., 2007), in which inferences about lower-level dynamics are drawn from higher-level assessments, leading to invalid generalizations across levels (Ketokivi, 2019). This simplification neglects the inherently multilevel nature of organizational systems, spanning across different levels. Consequently, the field has limited insight into how lower-level entities and their interactions contribute to and affect higher-level outcomes. Misplacing the generative mechanism at the wrong level might lead to inaccurate inference of a specific relationship or, even worse, to wrong inference (Klein et al., 1994; Hitt et al., 2007).

Empirical research suggests that this type of oversimplification obscures the underlying drivers of OSCM phenomena. In a multiplant study, Ketokivi and Schroeder (2004) show that the same manufacturing practices can yield different results depending on whether they align with a plant's strategic priorities. As a result, operational performance improves when practices fit the plant's competitive features rather than when a generic best practice bundle is applied uniformly. In addition, Turkulainen and Ketokivi (2012) reinforce this point by demonstrating that the apparent benefits of cross-functional integration are not invariant across levels of analysis. Cross-level integration relates differently to distinct performance outcomes when they are clearly specified and targeted at the right level.

A process-oriented, multilevel perspective explicitly distinguishes between within-level processes and cross-level relationships, revealing how micro-level variation contributes to collective patterns and, conversely, how macro-level contexts constrain or enable local action (Kozlowski & Klein, 2000). Process-based bottom-up MLT provides a framework to overcome the limits of variance-based, top-down explanations and level-of-analysis confusion in OSCM. In fact, MLT requires explicit observation of each construct at its focal level, specifying how higher-level phenomena emerge (composition vs. compilation), and specifying the cross-level mechanisms in place (e.g., top-down constraints, bottom-up interactions, and feedback loops) that unfold over time (Kozlowski & Klein, 2000). In sum, MLT converts the call to encompass more levels of analysis (Mathieu & Chen, 2011; Hitt et al., 2007) into a research design suited for explaining emergence, aligning measurement, and identifying cross-level effects, strengthening causal claims (Kozlowski et al., 2026), and yielding actionable interventions (Braun et al., 2022).

5. MLT methodological proposal: Agent-Based Simulations

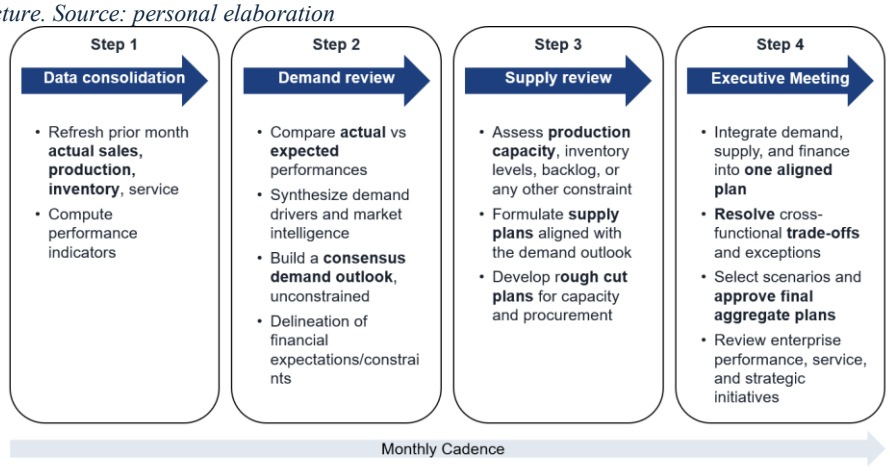
ABSs represent a valid tool to conduct emergent multilevel inquiry (Kozlowski et al., 2013; Kozlowski, 2015; Kuljanin et al., 2024; Grand et al., 2016; Grand et al., 2025). In general, computational modeling serves as a rigorous methodological framework for articulating, testing, and refining the logical and causal structure of theories by translating their components into formal, executable representations (Borsboom et al., 2021; Eronen & Bringmann, 2021; Guest & Martin, 2021; Kozlowski et al., 2013). In short, computational modeling can be thought of as a technique for specifying and testing the proposed logic and rationale of a theory, as it requires that the computer to serve as an input-output calculator that executes predefined instructions (code) following prescribed rules (formal logic and mathematics), to be capable of reproducing the theory's mechanisms in a fully operational form (Grand et al., 2025).

ABSs are computational tools that represent a system as a collection of autonomous, decision-making agents that interact according to defined rules (Epstein, 1999; Kozlowski et al., 2013; Grand et al., 2025). Each agent evaluates its environment and acts based on these rules, producing system-level patterns that can reveal complex, emergent phenomena. By encoding decision-making and interaction rules as executable algorithms, ABS provides a means of examining how individual-level mechanisms generate collective outcomes. By simulating interactions among agents and their relationships, ABS enables the exploration of adaptive and evolving processes that are often unobservable through purely analytical methods (Bonabeau, 2002). By explicating micro-level generative mechanisms, ABS enables scholars to explore how entities coevolve, revealing the emergent pathways that underlie operational and supply chain phenomena. In doing so, ABS embeds the principles of contextual constraints, temporality, and multilevel interdependence central to organizational science, offering OSCM a rigorous methodological foundation for studying emergence as a dynamic, evolving process rather than a static correlation.

Because computational models must be expressed in precise logical or mathematical terms that computers can interpret and execute, this approach demands the complete and precise specification of a theory's core concepts, processes, generative mechanisms, and contextual assumptions, provided by CPTs. As Vancouver and Weinhardt (2012) emphasize, a working computational model assures that a theory is internally consistent, accounts for the phenomena it claims to represent, is sufficiently specified, and remains unambiguous in the dynamics it portrays. Furthermore, computational modeling enables systematic exploration of theoretical assumptions and implications through simulation, allowing researchers to examine how variations in parameters and conditions influence predicted outcomes, uncover emergent phenomena from complex interactions, and generate empirically testable predictions (Grand et al., 2025; Kuljanin et al., 2024; Kozlowski et al., 2013; Vancouver et al., 2020). Thus, computational approaches enhance theoretical precision and internal validity, simultaneously expanding the capacity to interrogate and evolve theories through dynamic, emergent inquiry. This logic aligns closely with the structure of CPT, which formalizes how activities, events, and mechanisms interrelate to produce emergent phenomena.

Appendix A provides two ancillary arguments that are relevant, but not central to the point of the paper. First, an analysis of how ABSs mitigate endogeneity issues, and second, a comparison between ABS and another computational model typically used in OSCM, i.e., System Dynamics. Table 1 provides a synthesis of multilevel theory, process-based theorizing, and ABSs, highlighting their interconnections.

	MLT	Process theorizing	ABS
Purpose	Meta-theoretical framework for nested systems, linking micro, meso, and macro levels through bottom-up emergence and top-down constraints, clarifies construct locus and cross-level linkages.	Explains emergent phenomena through ordered sequences, mechanisms, and feedback over time.	Implements mechanisms as executable rules, enabling simulation and falsifiable implications.
Causality focus	Pinpoint causal drivers at the appropriate level, specifies within level processes and cross-level relationships, guide aggregation logic and measurement alignment, mitigates ecological and atomistic fallacies.	Moves beyond construct covariation and specifies how and why phenomena unfold.	Evaluates generative sufficiency, mechanisms must reproduce target macro regularities.
Emergence focus	Differentiates different forms of emergence, among which are compositional and compilational emergence. Categorizing global, shared, and configural unit properties allows shifts from divergence to convergence over time and acknowledges equifinality in emergent pathways.	Treats emergence as dynamic, recursive, context sensitive, not a one-time aggregation.	Captures heterogeneity and network structure, avoids perfect mixing assumptions. Tests whether the theorized emergence form (e.g., composition, or compilation) and cross-level constraints are sufficiently described by the computed generative mechanisms to generate the intended unit property under heterogeneity, network structure, and feedback conditions.
How do the three dimensions integrate?	MLT specifies levels and emergence form, process theorizing specifies temporal mechanisms and event sequences, and ABS formalizes the generative mechanisms to evaluate generative sufficiency and boundary conditions.		



6. Unpacking S&OP effectiveness: an ABS approach

In this section, we provide an example of how to build an ABS to investigate multilevel phenomena in OSCM. In particular, we aim to study the effect of strategic consensus (i.e., the extent to which executives share the same strategic priorities) on the information sharing process leading to team knowledge emergence during the S&OP executive meetings. This phenomenon is particularly suitable to be analyzed through an ABS since it requires identifying the microlevel determinants and dynamics shaping the process of information sharing, leading to team knowledge emergence. To provide an actionable framework on how to conduct multilevel emergent research using ABSs, we articulate the discussion and conceptualization of our model into a seven-step roadmap.

6.1 First step - Team knowledge of the executive team in S&OP

S&OP represents a managerial control and coordination tool through which organizations periodically, usually monthly (Grimson & Pyke, 2007), aggregate and reconcile different functional plans into a coherent set of medium- to long-term plans with a forecasting horizon of 3-18 months, balancing forecasted demand, supply, and production, as well as meeting financial objectives (Figure 3).

Figure 3 S&OP structure. Source: personal elaboration

S&OP can be thought of as an integrative process that entails information acquisition, validation, and interpretation across functions whose differentiated incentives and priorities require managing a set of trade-offs in resource allocation (Shapiro, 1977; Oliva & Watson, 2011; Kristensen & Jonsson, 2018). Its scope is simultaneously operational and strategic, including upstream preparation activities (e.g., the generation of function specific analyses, forecasts, and performance indicators), and a structured sequence of cross-functional meetings that progressively aggregate, evaluate, and agree on these inputs, condensing them into a restricted number of feasible scenarios and plans (Grimson & Pyke, 2007; Thomé et al., 2012; Danese et al., 2018).

The executive meeting is the last step of the monthly S&OP process, where functional forecasts and proposals are reconciled, inconsistencies are resolved, and competing plans are synthesized into a limited set of aggregated plans that can be agreed and communicated as a stable commitment (Thomé et al., 2012; Tuomikangas & Kaipia, 2014; Wu et al., 2025). The reconciliation stage is crucial because S&OP must consolidate demand forecasts and functional plans that often conflict with cross-functional priorities. Integrating information originating in different parts of the organization involves overcoming functional specialization, which is known to generate tensions and conflicts over divergent preferences and priorities (Oliva & Watson, 2011; March & Simon, 1958).

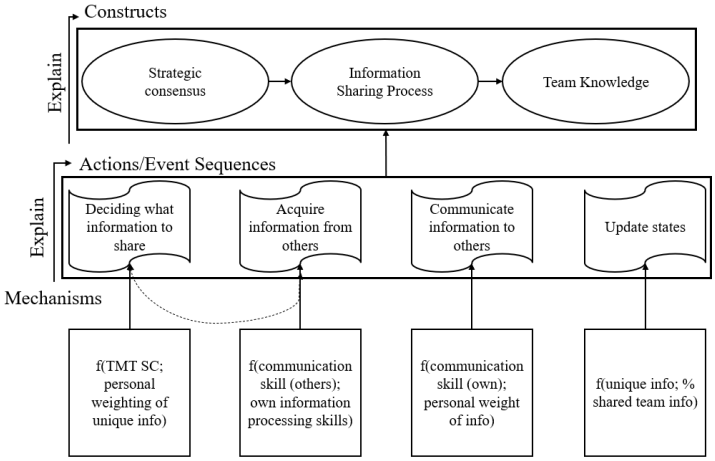
Prior research shows that the quality of S&OP outcomes is also dependent on the extent to which executives share the same strategic priorities, since alignment affects what information is disclosed, when it is disclosed, and which inferences are deemed legitimate in converting heterogeneous functional views into integrated decisions (Oliva & Watson, 2011; Goh & Eldridge, 2019; Kristensen & Jonsson, 2018).

As noted by Thomé et al. (2012), much of S&OP literature remains descriptive and focused on how to implement this managerial tool, rather than shedding light on the characteristics and drivers of its effectiveness (e.g., stage of the maturity model, Grymson & Pyke, 2007). An underexplored aspect of this gap is how SC influences the information sharing process, which ultimately determines the amount of shared knowledge that is held by the team (Kozlowski & Chao, 2012). Unpacking the microdynamics of information sharing is relevant for deepening our understanding of S&OP performance determinants, since the amount of shared information reduces forecasting error (Cui et al., 2015), mitigates supply chain disruptions (Lee et al., 2000), and generally improves S&OP effectiveness (Oliva & Watson, 2011; Tuomikangas & Kaipia, 2014).

Our study examines whether higher levels of SC (Tarakci et al., 2013) among executives during the S&OP executive meeting enhance information sharing and, in turn, increase the team's shared knowledge. Drawing on OSCM evidence that richer, more transparent information sharing improves forecast accuracy and planning quality (Lee et al., 2000; Cui et al., 2015; Oliva & Watson, 2011; Tuomikangas & Kaipia, 2014; Abolghasemi et al., 2025), we argue that SC provides a common mental frame that aligns priorities, reduces defensiveness, increases prosocial behaviors, and encourages executives to share their unique, privately held insights (Becker et al., 2025). Consistent with research on emergent team cognition, such disclosure enables individually held knowledge to be shared at the team level, transforming idiosyncratic functional expertise into collectively available knowledge (Kozlowski & Chao, 2012).

Based on this rationale, we assert this proposition, which we evaluate by means of an ABS:

"Higher strategic consensus will enhance the information sharing process within the executive team, thus increasing the amount of shared team knowledge."



From a methodological standpoint, ABS is particularly well-suited to investigate this emergent phenomenon because it can capture heterogeneity across executives. For example, it can model differences in executives' cognitive abilities or in the amount of function-specific information that executives receive between successive S&OP meetings, thereby linking individual cognition and interaction to the emergence of team-level knowledge. Recent OSCM studies reinforce this internal perspective on S&OP effectiveness, showing that performance depends on how information is acquired, processed, and disclosed within the firm, and that well-designed alignment mechanisms can

unlock the benefits of information sharing by making cross-functional coordination timely and actionable (Kaipia et al., 2017, Goh & Eldridge, 2019, Oliva & Watson, 2011).

6.2 *Second step – A process theory of knowledge team emergence in S&OP executive meetings*

In this section, we seek to identify the mechanisms behind the multilevel nature of the relationship between SC and team knowledge. We first present the core variables and summarize findings from prior literature. Subsequently, we articulate our CPT, depicted in Figure 4, as a determinant sequence of actions and events and their generative mechanisms.

Figure 4 Process-based model of our ABS

We represent the executive team of the S&OP as composed of three executives (Oliva & Watson, 2011), namely the Chief Marketing Officer (CMO), Chief Operations Officer (COO), and Chief Financial Officer (CFO). Executives enter the meeting possessing a distinct private information vector that reflects the informational domain of their respective function:

- CMO contributes demand-related signals such as promotions and market trends;
- COO provides production and capacity constraints;
- CFO introduces financial parameters such as margin targets, cash constraints, and working-capital limits.

Collectively, these distributed information sets constitute the information configuration of the firm's mid- to long-term planning horizon. Having described the primary agents comprising our model, we next define the variables involved in our models, i.e., strategic consensus, team knowledge, agent parameters, and the process governing information sharing.

6.2.1 Variables and Agent Parameters

Strategic Consensus is defined as "*the shared understanding of strategic priorities among managers at the top, middle, and/or operating levels of the organization*" (Kellermanns et al., 2005, p. 721). In our CPT, SC functions as a contextual variable shaping information exchange. High levels of consensus align the mental frameworks through which executives interpret and prioritize information, thus fostering mutual trust and shared interpretive schemas that encourage full information disclosure (Kellermans et al., 2008; Xiang et al., 2013; Turner et al., 2014; DeChurch & Mesmer-Magnus, 2010).

Recent work on managerial mental representations (MMRs) indicates that within stable teams, SC tends to endure because the MMRs on which it relies display cognitive permanence and consistency over time (Becker et al., 2025). Permanence refers to shared representations that are easily reactivated and remain decision-relevant, lowering the cognitive cost of transparent exchange across cycles (Becker et al., 2025). When team composition remains constant, these shared cognitive structures consolidate into stable mental schemas that guide perception and decision making, maintaining consensus even under moderate environmental change (Becker et al., 2025). The stability and permanence of such representations, understood as their sustained relevance and reactivation

potential, support ongoing alignment of strategic understanding within teams (Becker et al., 2025). Moreover, even when cognitive structures evolve, those that are widely shared tend to exhibit change inertia, becoming embedded in organizational norms and decision processes that reproduce collective understanding (Benner & Ranganathan, 2017).

Team Knowledge is defined as the shared knowledge integrating individual team members' knowledge and expertise, and arising from collaborative interactions and exchanges (Kozlowski & Chao, 2012). Therefore, team knowledge is the result of team members' mutual learning, which is a multilevel emergent phenomenon (Kozlowski & Bell, 2020), particularly relevant in teams with distributed expertise in which team members must learn from one another to integrate complementary insights (Kozlowski & Bell, 2020). In our model, team knowledge is specified as a compositional construct capturing the overlapping amount of information held in common by executive members stemming from the information-sharing process. Conceptually, this aligns with composition emergence, where convergent interaction processes yield isomorphic contributions across levels, so that when information is shared, it becomes commonly held at the collective level (Kozlowski & Chao, 2012).

Internalized knowledge is the task-relevant knowledge that individuals learn and integrate and remains privately held within members as they acquire and retain it through individual learning processes (Grand et al., 2016). *Externalized (encoded) knowledge* is knowledge that is articulated and shared with others, becoming collectively held and mutually acknowledged through team sharing and agreement, and therefore available as public, actionable team knowledge (Grand et al., 2016). *Share rate* is the ratio of information shared by each agent relative to the total unique information available for that agent.

Following Johnson and Hollenbeck (2007) and Grand et al. (2016), we conceptualize team knowledge emergence as an interpersonal process, whereby team members build shared information through interaction, communication, and mutual adjustment. Accordingly, following Grand et al. (2016) we describe the amount of externalized (encoded) knowledge as the result of two agents' characteristics: information processing skills (receiving agents) and communication skills (speaking agent).

Information Processing Skills refer to the individual capacity to select task-relevant information, internalize and encode it into durable mental representations, decode information received from others, and integrate new inputs with prior knowledge so that an increasingly coherent schema guides judgment and action. In team cognition, this set of microprocesses is typically formalized as data selection, encoding, decoding, and integration (Grand et al., 2016; Kozlowski & Bell, 2020).

Communication Skills refer to the individual capacity to transform internalized knowledge into collectively held knowledge through high-quality message externalization (Grand et al., 2016). *Unique functional information* refers to the set of novel function-specific information that each executive holds when entering S&OP executive meetings, whereas *Speaking Rate* is the probability that a given member will elect to speak first in the team meeting (Grand et al., 2016). A higher level of speaking rate is correlated with the tendency to speak first in the team meeting.

Information weights (*information saliency* and *prosocial orientation*) refer to the importance attached to each piece (bit) of private information held by each executive. Building on the motivated information processing model (De Dreu et al., 2008), we conceptualize the weight associated with each information bit as a combination of two components: epistemic motivation and social motivation. Importantly, in our model both components are attributes of each bit of information in a given context, rather than stable traits of the manager.

Epistemic motivation is defined as "the willingness to expend effort to achieve a thorough, rich, and accurate understanding of the world, including the group task or decision problem at hand" (De Dreu et al., 2008, p. 23). In our setting, epistemic motivation is operationalized through *information saliency*, which captures how temporally proximate and decision-relevant the consequences of a specific information bit are. Thus, information whose effects will materialize in 18 months has lower

saliency than information whose effects will manifest within the next three months. For example, a sales director may enter the executive S&OP meeting with evidence that the largest customer has pulled forward a promotion by six weeks, shifting a substantial demand spike into the next two months. If the plan is not adjusted promptly, service levels will collapse and expedited deliveries will be required. This information bit has high saliency because its consequences materialize within the immediate planning window; directly constrain near-term capacity, inventory, and cash; and alter the optimal aggregate plan in the short forecasting horizon.

Social motivation constitutes the second component of the information weight and captures the orientation embedded in the handling of a specific information bit, i.e. whether it is framed and disclosed in a proself or prosocial manner. Consistent with De Dreu et al. (2008), a *proself orientation* reflects a focus on individual or functional outcomes, whereas a *prosocial orientation* reflects a concern for collective, firm-level outcomes. In our framework, a proself versus prosocial orientation is not modeled as a stable individual disposition, but as an information-specific attitude that may vary depending on the type of information and the incentives attached to it.

This distinction is particularly relevant in the S&OP context, where participants must reconcile potentially conflicting functional objectives. A higher prosocial orientation associated with a given information bit increases its transparency and the willingness to share it openly, thereby helping resolve tensions between local and firm-wide goals (De Dreu et al., 2008; Kellermanns et al., 2005). For instance, a COO may possess information that a critical production line will undergo preventive maintenance next month, reducing capacity and threatening on-time delivery. If handled in a proself manner, this information may be withheld or downplayed to avoid blame or protect local performance metrics, allowing the constraint to surface later when mitigation options are costly. Conversely, if handled prosocially, the same information bit would be disclosed early with explicit quantification of the expected capacity loss and proposed cross-functional mitigation actions (e.g., pre-building inventory, reallocating production, or substituting components). Even if such disclosure worsens short-term functional KPIs, it improves overall firm performance and reduces total system costs. Accordingly, we compute the weight of each information bit as the joint product of its *saliency* (epistemic component) and its *prosocial orientation* (social component). In this way, the information weight emerges from the interaction between the decision-relevance of the information and its collectively oriented handling within the executive team.

During S&OP meetings, managers continuously recalibrate the weight attached to their own privately held information in response to what others disclose. We name this process *information weight recalibration*. We conceptualize the situation as one in which a manager enters the meeting endowed with a set of private information bits, each associated with an initial weight (reflecting its saliency and prosocial orientation). Upon receiving others' inputs, the manager updates the weight assigned to each information bit. The extent of this adjustment depends on perceived information complementarity, relevance, and the level of uncertainty implied by the task environment (Bonaccio & Dalal, 2006; Harvey & Fischer, 1997; Yaniv, 2004). As the discussion unfolds, disclosed information may alter the perceived contribution of one's own information bits. A given piece of information may become more critical, for example, because it resolves residual uncertainty or complements others' disclosures, or less consequential, for instance, if it is inconsistent with the emerging shared interpretation of the situation (Gigone & Hastie, 1993). Through this iterative process, the relative influence of each information bit evolves dynamically over the course of the meeting.

Finally, to reflect the evolving nature of the planning environment across S&OP cycles, the simulation embeds an information updating cycle to allow executives' information sets to change over time. Specifically, after each S&OP executive meeting, participants may receive different quantities of new information, and each information bit may differ in both saliency and prosocial orientation. As a result, the model captures a dynamic environment in which functional areas are exposed to heterogeneous between-cycle updates that vary not only in volume but also in relevance and collective orientation.

6.2.2 Process description

The process underlying team knowledge emergence in S&OP executives' meetings occurs across a series of meetings within a stable TMT and unfolds as a set of interacting executives exchanging their unique function-specific knowledge. We simulate 60 executive meetings over a period of 5 years (one meeting per month). Each executive begins with a unique information set and a subjective weighting scheme that captures both salience and prosocial dimensions, together with heterogeneous communication and information processing abilities. Rolling S&OP meetings represent the point at which interaction and information sharing occur. The logic we compute is that the privately held set of information for each executive has an attached weight, such that a lower weight means a lower disposition to share a particular bit of information. In each meeting, each participant must choose between sharing or withholding every unique information bit they possess in their information set, comparing their subjective information weight to a cognitive threshold that decreases with a higher level of SC. If the weight of the information bit is higher than this threshold, the executive will share the information bit. In other words, a higher level of SC should facilitate the sharing of unfavorable information, as the TMT is aligned toward the strategic priorities of the firm. Conversely, when consensus is low, divergent strategic priorities amplify the perceived risk of misalignment and opportunistic interpretation, leading executives to withhold or strategically filter information in defense of functional interests.

Every time an information bit is shared, the amount of information internalized by each participant depends jointly on the speaker's communication skill and the receiver's information processing skill, following a cognitive ability-based team knowledge emergence model (Grand et al., 2016). Because information disclosed during the S&OP meetings is interconnected across functions, listening and internalizing information from other participants may trigger a recalibration of each manager's privately held information. Therefore, executives may revise the weights they assign to their own information bits in light of newly internalized information, and this revision can trigger additional disclosure in subsequent meetings as perceived complementarities and reduced uncertainty change what becomes worth sharing. Or, it might have the opposite effect of decreasing the willingness to share a particular information bit by decreasing the relative weight attached to it. Between meetings, executives also update their unique information as a result of the new functional information emerging from each function's data analysis (Grimson and Pyke, 2007), representing the process and team knowledge dynamic emergence.

These dynamics are described by four linked generative mechanisms explaining how shared knowledge emerges and how SC affects this dynamic (Figure 4). First, SC and personal weighting of private information will determine the initial amount of information that each executive is willing to share during the executive meeting. The second and third generative mechanisms occur simultaneously, since whenever a speaking agent is disclosing its own private information, the amount of information conveyed will depend on its own communication skills and its personal information weight. Contextually, all information shared by a speaking agent will be encoded by the receiving agents based on their information processing skills and the speaking agent's communication skills. This encoding process can also induce agents to revise the weight they assign to their own information when complementarities emerge (dotted line in Figure 4). Fourth, after all agents have disclosed their unique information, team knowledge is calculated as the proportion of information that becomes commonly shared across agents relative to the total information available. Between meetings, agents update their information sets to incorporate new information emerging from their respective functions.

6.3 Third step – From process theory to CPT. Define agents and model rules/constraints

Pseudocode is a central step in CPT development, being a representational layer connecting the narratively articulated process description to an executable computational model. Kuljanin et al. (2024) define pseudocode as "a higher-level representation of a computational process theory, which may include a listing of computational steps, diagrams, equations, etc., with varying specificity"

(Kuljanin et al., 2024, p. 10). This representation is also framed as a simple, plain language description of the sequence of actions and events that a computer program should perform, whose primary purpose is to clarify the steps, requirements, and logical structure of an algorithm, while remaining independent from any particular programming language (Grand et al., 2025). This use of pseudocode is presented as a means to sharpen causal inference by forcing precise specification of actors and the dynamics involved in a process, where and when phenomena unfold, why the process operates as proposed, and how its actions and events are linked, rendering process theories both conceptually transparent and subject to rigorous computational evaluation (Kozlowski et al., 2026). In our case, Tables 2 and 3 present the operationalization of the variables and our pseudocode as step-by-step high-level code to clarify the generative mechanisms and the hypothesized process of information sharing and team knowledge emergence.

Table 2: Variables Operationalization

Variable	Operationalization	Rationale
Strategic Consensus	Range between 0 and 1. Drawn randomly	Tarakci et al. (2013) measure ranges from 0 to 1.
Cognitive Threshold to Share Information	Range between 0 and 1. Threshold=(1-Strategic Consensus)	With this operationalization, a higher level of Strategic Consensus will lower the cognitive threshold of agents to share information, increasing the information shared.
Team Knowledge	Ratio between the total commonly held information and the total information available. Range between 0.1 and 1 $\sum \frac{Total\ Internalized\ Information}{Total\ Info\ Available}$	A compositional representation of team knowledge reflecting the amount of commonly held knowledge among S&OP participants (Kozlowski & Chao, 2012; Kozlowski & Klein, 2000). To represent the minimum amount of shared information within the TMT on a firm's specific information, we put a lower threshold of 10% to Team Knowledge.
Internalized (Encoded) Information	$Encoded\ Information = Shared\ Information * CommunicationSkill[Speaking\ Agent] * InformationProcessingSkill[Receiving\ Agent]$	The amount of information internalized by the receiving agents, function of the agents' cognitive abilities
Shared Rate	Ratio between each agent's total externalized information and the total information available	The amount of information each agent shared.
Information Processing Skill	Drawn randomly from a normal distribution with a floor at the 70th percentile	Adams et al. (2018) find that large company CEOs have cognitive ability above 82 percent of the population, while Wai and Rindermann (2015) show extreme right tail overrepresentation among Fortune 500 CEOs, consistent with many being in top percentiles, including around the top 1 percent. Accordingly, representing C-level managers' cognitive ability by drawing from the top percentiles of a normal distribution better matches observed selection than sampling on the whole distribution.
Communication Skill	Drawn randomly from a normal distribution with a floor at the 70th percentile	
Speaking Rate	Range between 0 and 1. Drawn randomly	Agents' parameters representing the proclivity to speak first during a meeting.
Recalibration of information Weights	While listening to others' information, if the information is particularly relevant (assigned weight over 0.5), each agent can recalibrate their information weight, ranging between ±10%	Representing a dynamic of information weight recalibration similar to the one reported by Yaniv (2004) and Bonaccio & Dalal (2006).
Unique Information	Vector of information	A vector containing each agent's set of unique functional information.
Saliency	Range between 0 and 1. Drawn randomly	Weight component representing Epistemic Motivation
Prosocial	Range between 0 and 1. Drawn randomly	Weight component representing Social Motivation
Information weight	Function of saliency and prosocial. Ranging from 0.25 and 1 $\frac{(1+prosocial)^2 + (1+saliency)^2}{8}$	This operationalization reflects that if one of the two components is high, the overall weight will be higher than a simple linear combination. It represents one of the two components taking over the other in computing the cognitive weight attached to a particular information bit.
Updates Matrix	Matrix containing all the possible update combinations between cycles. N. of new information (1;3;5) Saliency (0.1;0.5;0.9) Prosocial (0.1;0.5;0.9)	Since the timestep has been bound to 60, to ensure heterogeneity in the update condition, we predefine a 27-condition matrix, whose combinations allow us to represent a dynamic and evolving environment in each simulation.

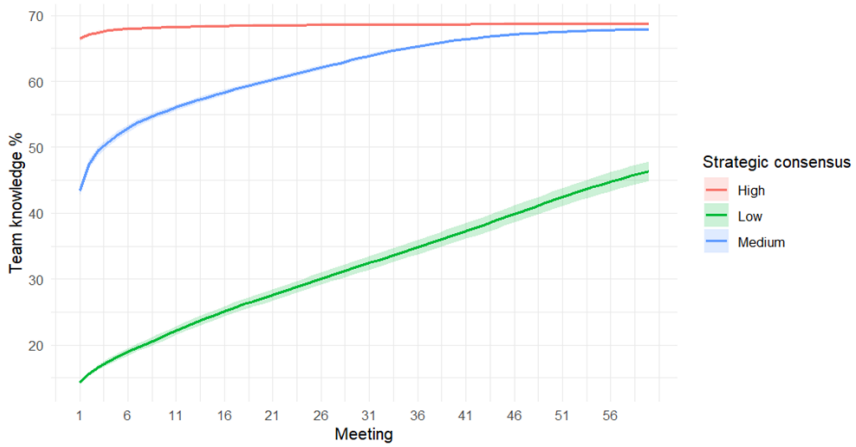
Table 3 Pseudocode for Computational Simulation of Team Knowledge Emergence during SOP Meetings

Model/theory component	Step	Actions/ Sequence
Setting of Initial Conditions	1	Initialize each agent's parameters: - Start a vector of unique information, - Weight each information bit, depending on information saliency and "prosocial" value of a particular information - Information processing skills - Communication skills - Speaking rate
	2	Set the Strategic Consensus level drawing from a normal distribution Set the cognitive threshold to decide whether to share information or not
	3	Set counter m of the model to 0 Set counter of total-meetings = 60 (Repeat until 60 cycles have been computed)
	4	Set all different possible combinations of emergent new information bundles (saliency/prosocial/ number of new bits of information per new cycle) a) Update the number of new pieces of information acquired before the next meeting b) Update new information saliency and prosocial
Model algorithm specification	5	WHILE current held monthly meetings < total monthly meetings in the forecasted horizon:
	6	FOR each agent of the team, select the speaking order based on their speaking rate (extraversion).
		FOR each unique information bit, decide whether to share it or not, based on the comparison between the information weight and the threshold for sharing.
	7	Based on communication skills, the selected agent shares unique information with the rest of the team.
		FOR each not speaking agent:
	8	Receiving agents internalize the information shared by other agents based on their information processing skills (received information is internalized by the receivers based on their information processing ability)
	9	Based on information weight (proxy of complementarity), if the information shared by other agents is strongly relevant, it might alter the relative weight that a receiving agent assigns to its own information; update the receiving agent's information weights accordingly.
	10	Compare the amount of information internalized by each agent and compute the amount of shared info (% of shared information with respect to the total information available)
	11	Update the amount of unique information for each agent (new information + withheld information) → New bits of information are drawn randomly from the pool of predetermined combinations of new info bits/saliency. Store all the agents' parameters and team knowledge into a database to compute further statistical analysis.
	12	Iterate m = m + 1
	13	If m = 60, end simulation.

6.4 Fourth step - Model Coding

After specifying the CPT and presenting the pseudocode, we operationalized the model as an ABS computed in RStudio. In line with recommended practice, the code maps each pseudocode element onto concrete functions, logical conditions, and iterative control structures, improving transparency and reproducibility of the theorized dynamics (Grand et al., 2025; Kuljanin et al., 2024). The ABS simulated 3000 distinct teams to characterize the distribution of emergent outcomes across heterogeneous team compositions and contextual conditions. Repeated simulation across many independent teams is appropriate for evaluating the implications of CPTs, because it reveals how outcomes vary as a function of initial states and process parameters, not only whether a single run produces a plausible trajectory (Grand et al., 2025). Our code is available in the online Appendix. For clarity, we present it in three parts, (a) agent parameters, (b) model function, and (c) general model.

Agent parameters specify the model's initial conditions (Grand et al., 2025) with respect to the actors, their attributes, and the relevant contextual parameters that define the starting state of each simulated team. These initialization choices are crucial because they establish boundary conditions that shape what the model can generate (Grand et al., 2025; Kuljanin et al., 2024). In practice, initialization encodes the distribution of starting states across the 3000 teams, ensuring that cross-team variation in outcomes can be attributed to the intended differences in inputs and process parameters.



In the function and general model files, we computed the sequence of actions and events that enact the emergent dynamic, specifying their order, their decision rules, and the intensity with which they recur through time. A central requirement in computational process modeling is to make the

temporal structure explicit, including the sequencing of activities and the state transition logic that connects one step to the next (Grand et al., 2025). Accordingly, the main simulation code advances the model timesteps, triggers actions in the prescribed order, updates agent and system states, and stores outcomes for analysis. This structure supports the interpretation of emergent outcomes as consequences of the theorized mechanisms operating through time, rather than underspecified variables or dynamics with imprecise execution.

6.5 Fifth step - Simulate Emergence

The simulation unfolded over 60 discrete time steps, with each time step representing one S&OP meeting, thereby allowing us to trace how repeated cycles of interaction progressively accumulate into commonly held knowledge. We chose 60 cycles to represent a TMT tenure of five years, which is the average executive tenure (Messersmith et al., 2014; Carpenter, 2002; Zhang, 2019). To ease interpretation through visualization, we grouped teams according to their level of SC, defining Low consensus teams as those with values between 0 and 0.33, Medium consensus teams as those between 0.33 and 0.66, and High consensus teams as those between 0.66 and 1. This grouping enables the plotted trajectories (Figure 5) to be read as average emergent paths under systematically different consensus conditions, highlighting how differences in initial alignment translate into distinct rates of knowledge accumulation and distinct saturation levels across the 60 meetings. Finally, to assess the representativeness of our code, we conducted a series of sensitivity analyses, ensuring that the results are not driven by the model's parameter initialization, but by the within-team dynamics. All the sensitivity analyses are available in Section 2 of the online Appendix.

Figure 5 Output of ABS. 3000 simulated teams. Source: output from R code

6.6 Sixth step - Establish Generative Sufficiency and Model Validation

To assess the model's generative sufficiency (Epstein, 1999), we have to evaluate the ability of the ABS to reproduce the theoretically expected qualitative pattern across conditions. Because our simulation is grounded in a compositional conceptualization, we compute the variables for statistical analysis (i.e., team knowledge, share rate) as a group average across cycles. In our ABS, we expect a between-group difference in team knowledge across High, Medium, and Low SC, to an extent that is unlikely to be attributable to noise alone (Epstein, 1999; Kuljanin et al., 2024; Grand et al., 2016; Grand et al., 2025). To test ABS's generative sufficiency, we first computed an ANOVA to assess whether there was a statistical difference between these three subgroups. In addition, we also performed a pairwise group comparison with Tukey's method to further evaluate whether the differences between groups in their amount of team knowledge are statistically significant and with the predicted sign. The results of these analyses are provided in Tables 4 and 5. The one-way ANOVA provided strong evidence that the consensus manipulation was generatively relevant in the simulated data, $F(2, 2997) = 9905.47$, $p < .001$, with R-squared = .8686, indicating that most of the variance in team knowledge is explained by the grouping variable. The Tukey post-hoc tests reinforce this

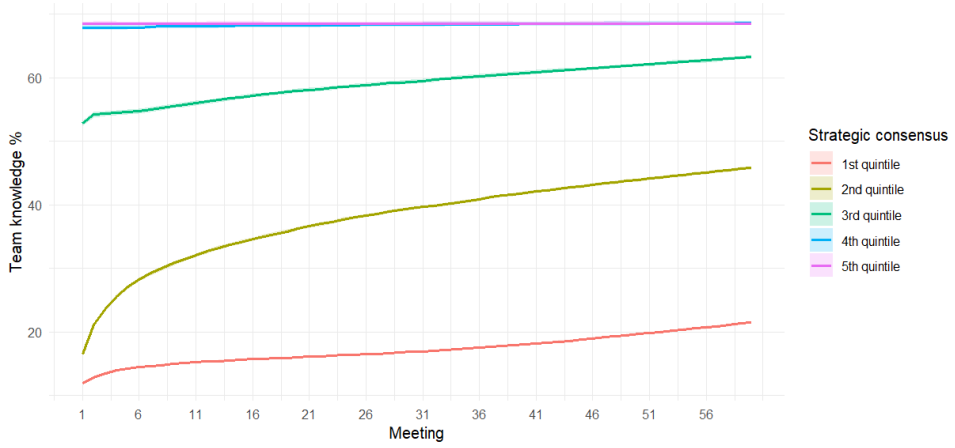
conclusion by showing that all pairwise contrasts were significant and correctly ordered, Medium is lower than High by 12.53 %, Low is lower than High by 46.74%, and Low is lower than Medium by 34.21%, all $p < .001$, which yields the expected finding that a higher level of SC leads to a higher level of team knowledge. To strengthen the empirical grounding of the ABS, we calibrated agents' parameters so that they reflect executives' characteristics as closely as possible (see Table 2). Combined with the theoretical plausibility of the generative mechanisms, this strengthens confidence in the model's ability to explain the outcomes of interest.

Table 4: ANOVA output. Source: output from Stata 18

Source	Partial SS	df	MS	F	P > F
Model	1164174.8	2	582087.39	9905.47	0.0000
Group	1164174.8	2	582087.39	9905.47	0.0000
Residual	273348.79	2997	58.764211		
Total	176116.34	2999	446.91268		
Observation n.	3000				
R-squared	0.8686				
Root MSE	7.66578				

Table 5: Tukey test output. Source: output from Stata 18

Groups	Contrast	Std. err.	t	P > |t|
Medium vs High	-12.5322	.3416307	-36.68	0.000
Low vs High	-46.74792	.3433605	-136.15	0.000
Low vs Medium	-34.21572	.3435292	-99.60	0.000



6.7 Seventh step - Analyze process and outcome patterns over time

6.7.1 Simulation Analysis

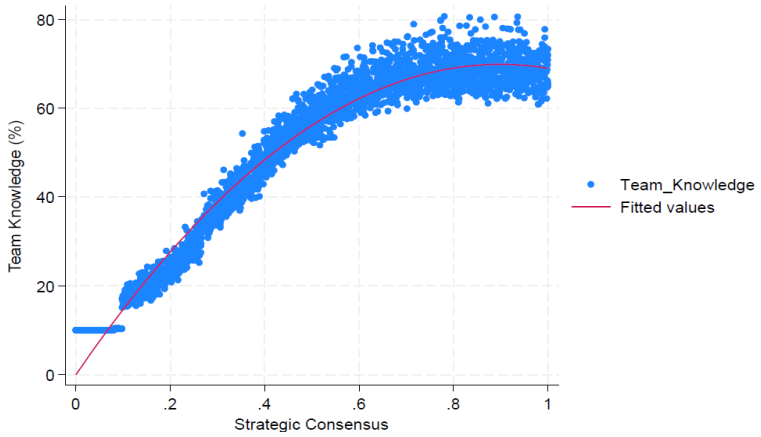
The simulation result presented in Section 6.5 depicts the dynamic emergence of team-shared knowledge within a TMT across S&OP meetings. Although Figure 5 presents a visualization of the dynamic emergence of Team Knowledge, it is not highly informative *per se*. What we can grasp from Figure 5 is that team knowledge increases over time, but it does so at significantly different rates and toward different saturation levels depending on SC. In particular, the trajectories depicted suggest that teams characterized by Medium and High levels of SC tend to stabilize, with the highest consensus conditions approaching a clear plateau and exhibiting only marginal increase thereafter. Thus, the figure implies a pattern of diminishing marginal returns at the Medium to High level of SC, where additional increases in consensus translate into relatively small improvements in team knowledge, whereas the difference between low and moderate consensus remains relevant across the entire time horizon.

To further unpack the results shown in Figure 5, we reran the simulation, this time not drawing SC values randomly between 0 and 1, but manually assigning them to better isolate the effect of SC. Specifically, we divided the distribution into quintiles and assigned the median values to each quintile (i.e., 0.1, 0.3, 0.5, 0.7, 0.9), generating a set of simulations depicting the effect of increasing the level of SC on team knowledge building. In this analysis, we simulated 2500 teams, 500 teams in each quintile. The results, shown in Figure 6, disaggregates the effect of different levels of SC, such that the lowest quintile starts with the smallest knowledge base and improves gradually, the second quintile exhibits faster early growth but remains well below the mid and high conditions, the median quintile continues to accumulate knowledge more steadily across meetings, and the fourth and fifth quintiles begin at substantially higher levels and rapidly reach a ceiling point, with the top two trajectories nearly overlapping for most of the simulation. Considering the findings portrayed in Figures 5 and 6 together, the pattern suggests that SC shapes both the early stages of team knowledge accumulation and the speed with which teams convert interaction over time into commonly held shared knowledge. It is worth noting that the graph suggests a team knowledge convergence over a longer time horizon; for longer periods of time, it would be unlikely that the TMT would remain constant. Consequently, changing team composition would have consequences for SC and would, therefore, affect within-team dynamics and subsequent team knowledge emergence.

Figure 6: Output of ABS's sensitivity analysis. 2500 simulated teams, 500 for each category. Source: output from R code

Results of the quintiles analysis, paired with the scatter plot and fitted values in Figure 7, reinforce the idea that the association between strategic consensus and team knowledge is nonlinear. Greater gains appear when moving from low to moderate consensus, where an increase in team knowledge flattens, and may even begin to decrease as consensus becomes very high. A similar nonlinear pattern emerges in the relationship between information sharing and team knowledge. As shown in Figure 8, increments in share rate (i.e., the team average of the ratio between each agent's externalized information and their total unique information over the simulated period), are associated with a steep increase in team knowledge at low levels of share rate, but the slope progressively flattens as share rate rises, with the curve reaching a saturation point.

Figure 7: Scatter Plot and Fitted Value of Team Knowledge and Strategic Consensus. Source: personal elaboration with Stata 18



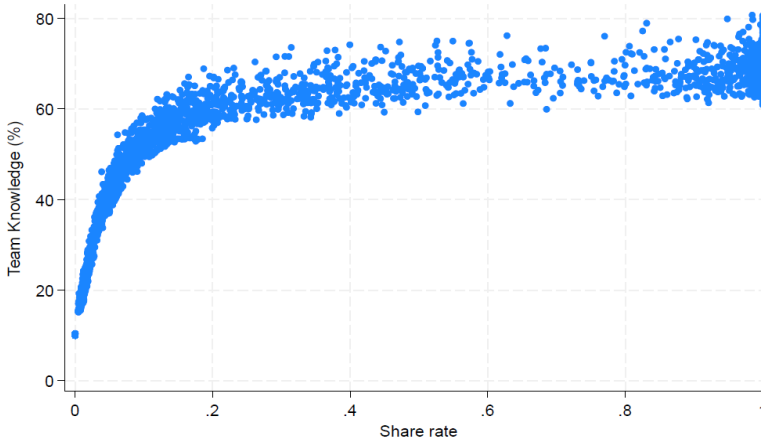


Figure 8: Scatter Plot of Team Knowledge and Share Rate. Source: personal elaboration with Stata 18

To address our proposition that a higher level of SC will increase the amount of information sharing within the TMT, thus increasing team knowledge, we ran a path analysis to examine whether the effect of SC on team knowledge is mediated by the share rate. Because Figure 7 suggested a curvilinear association, we also included a quadratic term for SC, allowing us to test whether its effect is monotonically positive even at higher levels. The concave relationship between share rate and team knowledge suggests that a linear operationalization of share rate is not the most appropriate (Box & Cox, 1964). Therefore, in our analysis, we model the share rate using a logarithmic transformation, which provides a good representation of the relationship depicted in Figure 7. Results of the path analysis are reported in Table 6.

Table 6: Results of path analysis for the SC mediation effect on Team Knowledge. SE calculated with the Satorra-Bentler estimator. N- of teams: 3000

	Coefficients	**SE**	**P>|z|**
ln(Share Rate)			
Strategic Consensus	15.241	.441	0.000
Strategic Consensus^2	-7.930	.346	0.000
Constant	7.275	.124	0.000
Team Knowledge			
ln(Share Rate)	.244	.098	0.013
Strategic Consensus	171.715	1.795	0.000
Strategic Consensus^2	-100.840	1.080	0.000
Information Processing Skills	55.333	1.366	0.000
Communication Skills	54.483	1.363	0.000
Constant	-87.576	1.957	0.000

As we can see from the results, SC has a strong positive correlation with team knowledge, β = 171.72, $p < 0.001$, consistent with the proposition, but the squared term revealed a significant nonlinear dynamic. Specifically, SC squared had a negative direct effect on team knowledge, β = -100.84, signaling diminishing returns and a negative effect at very high levels of consensus. In addition, SC squared also had a mediated negative indirect effect on team knowledge via share rate, as its effect on share rate is β = -7.93, $p < 0.001$, and share rate increased team knowledge, $\beta = 0.244$, $p < 0.05$, yielding an indirect effect of approximately $-7.93 \times 0.244 = -1.94$. Because the share rate is operationalized in logarithmic form, the coefficient represents a proportional change in team knowledge. Specifically, a one-unit increase in *ln(share rate)*, equivalent to an *e-fold* increase in share rate, is associated with a 0.244 percentage point increase in team knowledge. Thus, the total effect of the squared term on team knowledge is negative through both paths, with the indirect, mediated component complementing the negative direct component. Together, they confirm the curvilinear pattern in the scatterplot, whereby team knowledge increases with strategic consensus but stabilizes and slightly declines at the highest levels of consensus. To conclude, path analysis shows an excellent model fit, with RMSEA = 0.023, a very high p-close of 0.956, CFI and TLI both equal to 1.000, and SRMR = 0.003, indicating that the specified nonlinear relationships align closely with the data.

6.7.2 Simulation Discussion

Across the ABS runs and the complementary statistical tests, the results support a central intuition: SC helps top teams integrate privately held information into team knowledge, but its effects are not strictly linear. In the simulation, teams in higher consensus conditions achieve higher team knowledge than medium and low consensus teams. The ANOVA and post hoc comparison indicate that these differences are large and systematically ordered, consistent with the idea that consensus strengthens the social and cognitive conditions for alignment. This finding aligns with core S&OP research that treats the process as an integrative planning mechanism, where cross-functional alignment, structured meetings, and shared targets help synchronize demand and supply decisions, and thereby improve collective understanding of the plan and its assumptions (Grimson & Pyke, 2007; Thomé et al., 2012; Tuomikangas & Kaipia, 2014).

At the same time, the time series trajectories and the quintile reruns show that the strongest gains occur when moving from low to moderate consensus, where gains flatten at high levels, with the top quintiles rapidly approaching a ceiling and becoming difficult to distinguish. In other words, consensus appears to shape the speed of knowledge accumulation, yet it also introduces saturation, which is consistent with a curvilinear relationship implied by the fitted scatterplot.

The path analysis clarifies the effects and sharpens the boundary conditions. The linear component of SC positively predicts share rate, and share rate positively predicts team knowledge, which is the mediation logic embedded in our proposition. Higher strategic consensus increases information sharing within the TMT, which in turn increases team shared knowledge. This is consistent with team information processing research showing that information sharing and elaboration are foundational for building shared mental models and common understanding (Mesmer Magnús & DeChurch, 2009; Mohammed et al., 2010).

Accounting for the curvilinear pattern by including SC squared helps explain why the benefits of consensus taper off at higher levels. In the model, SC is specified to have a linear positive effect on the propensity to share information, because higher consensus lowers the cognitive threshold that determines whether an information bit is disclosed. However, ABS dynamics depict a saturation effect. In fact, for high values of SC, additional increments in SC have diminishing marginal returns to the accumulation of team knowledge, because lowering the cognitive threshold over a certain point will not increase the portion of the information being exchanged (reflected by the team share rate), as it is already known. The squared term, therefore, captures this diminishing return, exerting a negative direct effect on team knowledge and an additional negative indirect effect through share rate. When combined with heterogeneity in agents' communication and information processing abilities, this saturation dynamic can even produce conditions in which very high levels of consensus yield smaller, and even negative, marginal contributions to team knowledge.

Conceptually, this suggests that excessive consensus may limit the informational gains generated through interaction. When teams become highly aligned, the incremental value of additional exchanges declines, and the integration of diverse perspectives becomes less pronounced. This interpretation is consistent with evidence that groups often fail to pool unique information, particularly when agreement is socially rewarded and dissent is costly (Stasser & Titus, 1985). It also aligns with the groupthink literature, which argues that concurrence seeking suppresses critical evaluation and the generation of alternatives, leading to high consensus but low informational richness (Janis, 1972). Similarly, Knudsen and Srikanth (2014) show that strong alignment in specialists' mental models can induce "joint myopia," narrowing collective search and increasing the likelihood of suboptimal performance.

Viewed through an S&OP lens, the nonlinear relation between SC and team knowledge has important implications, because S&OP performance depends upon sustained integration of new information into the aggregate plan. Extremely high SC may generate fast and stable emergence of team knowledge, yet simultaneously inhibit the critical recombination of discrepant demand, supply, and market information that protects forecast accuracy and plan quality over time. In this sense, the same consensus that reduces coordination costs can raise the risk of overconfidence, insufficient scenario exploration, and weaker information integration, which would be expected to manifest downstream as diminishing improvements in plan accuracy even as perceived alignment remains high.

The first managerial recommendation appears to be almost self-evident, as it suggests composing the TMT with managers with above-average relational skills (i.e., communication and information processing skills) as they directly improve the amount of information encoded at the team level. Second, and a bit counterintuitive, is not to pursue maximal consensus, but to prefer a consensus high enough to enable coordination and shared understanding, while preserving structured techniques for dissent and evidence-based challenge. Such techniques include explicit scenario comparisons, rotating devil's advocate roles, pre-meeting reviews that surface exceptions, and decision rules that require revisiting assumptions when new information conflicts with the current plan.

As shown by the intervention described by Tarakci et al. (2013), it is possible to increase SC of a TMT with an exogenous intervention. Our ABS findings reframe SC as a lever that must be balanced with effective information integration, and it provides a process-based explanation for why teams can underperform on accuracy when they become too cognitively aligned (Janis, 1972; Mesmer Magnús & DeChurch, 2009; Knudsen & Srikanth, 2014).

7. How to compute an ABS: a "To-do" list

To conclude, we provide a step-by-step guide (see Table 7) on how to conduct multilevel emergent CPT research, detailing the steps we used to outline our research on team knowledge emergence in S&OP executive meetings.

Table 7: Stepwise guide on how to compute an ABS. Acknowledge that this is an "idealized" way to build a CPT and ABS

Step	Description
1. Observe an emergent multilevel phenomenon	Identify a phenomenon and determine if the generative mechanisms driving this posited relationship are known. ABSs and process theory can be used to deepen the understanding of an already established correlation, an observation of a given phenomenon, or a processual causal relationship that seems plausible to explain an organizational phenomenon.
2. Build a process theory	If generative mechanisms are yet to be uncovered, identify the actions/event sequence determining the observed relationship in type (negative/positive) and intensity (relative magnitude of the correlation). If some prior literature exist, use the correlations and nomological networks to guide the identification of the underlying process.
3. Translate the process theory into a CPT. Define Agents and model rules/constraints	Starting from the pattern of actions/events sequence, compute a CPT based on logical statements and mathematical functions to eliminate any kind of uncertainty and ambiguity on driving mechanisms and model rationale. Design agents and encode their decision rules, goal functions, and contextual constraints. Translate the narrative process theory into agent action and sequences Write a complete pseudocode.
4. Model Coding	Operationalize the pseudocode into an ABS using code (e.g., Python or R). Model operational logics: - Initial Conditions; - Specify order, nature, and intensity of actions/events.
5. Simulate Emergence	Run ABS to observe how agents' characteristics and interactions lead to higher phenomena emergence over time. Manipulate context variables and external factors
6. Validate Generative Sufficiency	Assess if micro rules reproduce the observed macro regularities. If necessary, iteratively refine the narrative theory, CPT and then the pseudocode and code. This step tests the plausibility and representativeness of our model's generative mechanisms.
7. Analyze both process and outcome patterns over time	Track trajectories, feedback loops, and tipping points, not just end-state performance. Plot the data into clear graphs and store the generated data in a database. Enhance the theory around an emergent phenomenon by uncovering and theorizing at the mechanism level, clearly identifying the cause of a given phenomenon without the need for inference.

7.1 Observe an emergent multilevel phenomenon

The starting point of emergent multilevel research is a detailed specification of a focal phenomenon that plausibly reflects the generative mechanisms of its emergence over time (Epstein, 1999). In organizational science, including OSCM, this first step is not just a descriptive phase. Rather, it is a bounding exercise that clarifies context, the relevant actors and levels, and the temporal

window over which the phenomenon unfolds, because process explanations depend on specifying *what* happens, *where*, *when*, *how,* and for *whom* (Kozlowski et al., 2026). In this phase, researchers should not fall into what Bendoly and Oliva (2025) call the "fallacy of cited references;" namely, the mistaken belief that theoretical arguments must be legitimized primarily through the explicit citation of established theories. Bendoly and Oliva (2025) caution that while positioning with prior work matters, the logic of an explanation should remain defensible even if citations are stripped away. This is because references can reinforce an argument, but cannot substitute for warranted mechanisms and boundary conditions. The initial phase of conceptualization in multilevel emergence research should therefore draw on observation, intuition, and/or abductive reasoning, and need not be overly grounded in prior literature (Bendoly & Oliva, 2025; Kozlowski & Klein, 2000).

7.2 Build a process theory

Process theory development requires moving from covariance statements toward an explicit action and event sequence that can plausibly generate the observed phenomenon. This involves progressing downward across the Layers of Theoretical Explanation (Kozlowski et al., 2026) from construct relations to the process sequence layer, and ultimately to the mechanism or deep structure layer that enables and constrains the process action sequence (Kuljanin et al., 2024; Kozlowski et al., 2026). The core goal is a narrative explanation that identifies the actors involved in the sequence, the ordering and timing of events, and the conditional dependencies that render the process intelligible as something other than a retrospective story. Moreover, identifying an action or event sequence is insufficient unless the underlying generative mechanisms are specified as drivers of agents' actions, guiding how and with whom they interact. These mechanisms also shape the direction and strength of relationships and the stochastic processes through which multilevel phenomena unfold (Kozlowski et al., 2026).

7.3 Translate the process theory into a CPT. Define agents, model rules, and constraints

Translating narrative process theory into a CPT entails transforming qualitative process accounts into unambiguous, executable statements about how system states update from one-time point to the next (Kuljanin et al., 2024; Grand et al., 2016, 2025). This step is crucial as it forces researchers to clearly specify what the features of the model are (e.g., the initial conditions), how many actors to represent, what characteristics they possess and their parameter values, what they can do, and which environmental structures enable or constrain action (Grand et al., 2025). In agent-based terms, these model features constitute the microspecification, namely the initial agent environment and behavioral specifications that govern local interactions (Epstein, 1999). Pseudocode is an intermediate representation between a narrative process theory and an operationalized computational model, because it maps the process narrative into a stepwise representation of actions and events with sufficient granularity to be translated into code, while still being readable as theory (Kozlowski et al., 2026). In this step, the focal point is to clarify every ambiguity source over the computed model, as it is a direct threat to interpretability. In fact, two implementations of the same process can diverge dramatically in code and results if core actions and event ordering are underspecified (Grand et al., 2025).

7.4 Model Coding

Coding operationalizes the pseudocode into an executable simulation, thus turning the theory into an algorithmic object whose implications can be examined under controlled conditions (Kozlowski et al., 2026). The primary methodological feature is correspondence or fusion between the ABS coding and the theory, specifically the generative mechanisms. This careful mirroring requires clarity and attention to specifying initial conditions; state variables; and the order, nature, and intensity of actions and events as they occur within each iteration of the model (Rand & Rust, 2011). Initial conditions can be thought of as theoretical boundary conditions that shape what the

ABS can and cannot explain, thus determining what the ABS's "computational world" contains and how the mechanisms operate (Grand et al., 2025).

Similarly, coding requires fully specified operational definitions for each action and event, including how actions are initiated, how they update the states of actors and their environment, and how stochastic elements influence the model when probabilistic processes are represented (Grand et al., 2025). Thus, building an ABS entails defining agents as "purposive" actors embedded in contexts, encoding decision rules or goal functions that operationalize the underlying generative mechanisms, and specifying relevant constraints (e.g., resource limitations, role structures, or network interdependencies).

7.5 Simulate Emergence

Simulation is the phase in which the ABS is run, enabling observation of whether local interactions among agents, under specified constraints and contexts, yield the expected higher-level phenomenon over time. This is the distinctive value proposition of ABSs for emergence-based research questions, as it renders the unfolding process itself observable, rather than inferred from cross-sectional accounts (Kozlowski et al., 2016). In practice, simulation should be treated as systematic experimentation over theoretically meaningful parameter ranges and contextual conditions, not as a single illustrative run.

Agent representativeness can be progressively refined through empirical inputs, after which the simulation can be used as a platform for virtual experiments that explore contextual manipulations (Kozlowski et al., 2016). This logic also enables the manipulation of exogenous shocks, institutional constraints, or network structures to assess robustness and identify boundary conditions (Grand et al., 2025).

The appropriate timeframe is idiosyncratic to the phenomenon under study, as it depends on the frequency and magnitude of interactions (Kozlowski et al., 2013; Kozlowski, 2015; Kozlowski et al., 2026). Importantly, the relevant output is the joint pattern of trajectories and process dynamics: how micro-level interactions aggregate, interact, and feed back into the evolving environment (Kozlowski et al., 2026).

7.6 Establish Generative Sufficiency and Model Validation

Establishing generative sufficiency and model validation must be understood as two different requirements. To establish generative sufficiency, researchers must determine whether the model specification is sufficient to generate macro patterns of interest. Following Epstein's (1999) criterion on generative sufficiency, if the macro pattern does not emerge from the ABS, the proposed explanation mechanism is disqualified. However, assessing generative sufficiency does not imply that a single successful reproduction is sufficient. Rather, it supports generative plausibility while motivating comparative evaluation against alternative microspecifications and sensitivity analyses. More precisely, generative sufficiency constitutes an internal plausibility check, namely, whether the specified mechanisms can reproduce the target pattern under the ABS's boundaries and assumptions (Kozlowski et al., 2026).

Validating an ABS involves comparing synthetically generated data and patterns with available empirical evidence. In other words, validation serves as an external plausibility check, assessing whether the specified mechanisms can reproduce observed phenomena under the proposed constraints and boundary conditions. Accordingly, validation is an empirical endeavor, achieved through systematic confrontation with observed evidence rather than reliance on a single test.

However, because many empirical observations take the form of aggregate differences or correlations derived from cross-sectional data, validating the micro-to-macro dynamics implied by ABSs may be challenging. For this reason, empirical validation should be treated as a cumulative and revisable process, in which confidence in the model is progressively strengthened through triangulation across multiple patterns, datasets, and levels of aggregation, where possible. When data

are unavailable, model parameters and dynamics should be calibrated to align as closely as possible with known features of the real-world.

Depending on whether an ABS is used for theory building or for explaining empirical phenomena, the required type of analysis differs. When ABS aims at theory building, its value lies in operationalizing CPTs, whose implications for a phenomenon's generative mechanisms can be simulated over time to assess the plausibility of the proposed process account (Kozlowski et al., 2026).

Given its exploratory and novel nature, appropriate data tracing underlying action–event sequences (e.g., fine-grained process data) may not exist, as the purpose of theory building is precisely to develop and refine a novel, coherent causal account of how and why the phenomenon unfolds (Kozlowski et al., 2026). Accordingly, theory building with ABS does not require empirical data as input or as a benchmark, provided that the model's dynamics are theoretically credible, explicitly specified, and internally coherent with the proposed causal explanation (Kozlowski et al., 2026). This position aligns with the broader view that theorizing progresses along a continuum, from early-stage propositions to increasingly detailed accounts of causal mechanisms (Bendoly & Oliva, 2025).

When the ABS is used normatively or to explain an empirically observed phenomenon, researchers should validate the model against available empirical evidence. In this normative use, validation becomes necessary, even if the empirical evidence is scant or indirect. In this case, ABS requires both verification and validation as distinct processes: test the generative sufficiency to ensure the ABS reflects the conceptual model, and validation to assess correspondence with real-world patterns and evidence (Rand & Rust, 2011). Thus, whereas generative sufficiency asks whether the model "works" as a coherent generator of the theorized dynamics, ABS validation offers a stronger, externally anchored test of whether the same mechanisms can reproduce independent empirical findings (Kozlowski et al., 2026), when such evidence is available and commensurate with the model's claims. When empirical data exist, scholars can strengthen model evaluation by estimating or calibrating parameters and quantifying the correspondence between simulated predictions and observed patterns. In doing so, it is useful to distinguish between qualitative sufficiency (i.e., whether an effect emerges and in the expected direction), and quantitative sufficiency (i.e., whether the magnitude and temporal dynamics of the effect align with empirical observations; Ballard et al., 2021). At the same time, the feasibility of quantitative validation depends on the availability of sufficiently granular, longitudinal, or process-tracing data.

7.7 Analyze both process and outcome patterns over time

ABS allows not just the analysis of the end state phenomenon, but the evaluation of dynamic signatures by which the phenomenon emerges, stabilizes, oscillates, or collapses. This entails tracking trajectories with different agent parameters and contextual constraints, identifying feedback loops, and locating tipping points where small micro-level changes produce discontinuous macro effects, which are the kinds of implications that narrative dynamic theories often leave unspecified (Vancouver & Weinhardt, 2012). Consistent with CPTs, analysis should treat constructs as summaries of action streams, but the focus of the analysis must remain anchored in the underlying process rules that generated those summaries (Kozlowski et al., 2026). Accordingly, researchers should store rich time-indexed outputs, including micro determinants of interactions, meso-level coordination patterns, and macro outcomes, enabling both descriptive visualization and formal analytical analyses.

Step 7 also closes the theory-building loop, because discrepancies between predicted and observed process outcomes can be used as a stepping-stone to refine the narrative explanation. Ideally, a well-crafted ABS can elucidate how and why the phenomenon occurs by pointing to the mechanism-level responsible for generating macro phenomena, thereby reducing reliance on inference from static covariances and improving the design logic for interventions tested through virtual experimentation and refining the aim and scope for possible subsequent empirical study (Braun et al., 2022; Kozlowski et al., 2016; Epstein, 1999).

8. Conclusion

This manuscript addresses an evident gap in OSCM research. Many of the phenomena theorized are multilevel, dynamic, and time-dependent, yet research strategies largely prefer single-level and variance-based methodologies, producing construct associations that often leave the generative "how" and "why" under-specified.

Building on multilevel theory and computational process theory, we propose a complementary path for theory building in such settings, shifting the explanatory target from covariation to generative mechanisms, specifying the sequences of actions and state transitions that can generate a focal macro regularity, and then evaluating those mechanism explanations through executable computational models. In this approach, ABS is a tool that forces unambiguous operationalization, makes temporality explicit, and supports systematic experimentation over boundary conditions, while evaluating internal credibility through generative sufficiency and robustness checks.

Our S&OP ABS example clarifies both the value and the limits of strategic consensus as an alignment mechanism in executive planning. Across 3,000 simulated teams observed over 60 S&OP cycles, higher SC increases team shared knowledge primarily by increasing information sharing, consistent with the logic embedded in our proposition. At the same time, the emergent trajectories and the curvilinear findings show that the benefits are not monotonic. At very high levels, SC begins to reduce the share rate and exerts an additional negative component on team knowledge, yielding diminishing returns and, at the extreme, slight inhibition of team knowledge emergence. This pattern is consistent with groupthink and hidden profile mechanisms, where strong concurrence seeking narrows search, suppresses unique information pooling, and yields agreement that is socially smooth but informationally thin.

This result is a particularly consequential risk in S&OP, where planning quality depends on integrating discrepant demand, supply, and financial signals over repeated cycles. The central implication is therefore not that consensus is undesirable, but that its effectiveness is bound to a threshold, beyond which more consensus can undermine the information integration it initially facilitated. By making this nonlinear tradeoff mechanistically explicit, and by showing how it can emerge from micro-level disclosure and integration dynamics under repeated interaction, the manuscript overcomes some limitations in the extant literature, offers a coherent roadmap for multilevel bottom-up theorizing in OSCM, and provides an actionable framework for future research on emergent phenomena.

APPENDIX A:
ABS and Endogeneity

Traditional econometric approaches seek to mitigate endogeneity biases through identification strategies, such as instrumental variables, lag structures, or fixed effects, focusing on strengthening the assumptions of variable exogeneity. Ketokivi and McIntosh (2017) contend that these problems in OSCM research arise from the complex and interdependent nature of organisations and supply chains, so we should accept, up to a certain point, a certain degree of endogeneity. Moreover, they argue that "the conclusion about endogeneity is based not on statistical theory but on substantive, theoretical considerations" (Ketokivi and McIntosh, 2017, p. 5). Building on this view, the question is not only how to remove endogeneity, but how to design dependence in ways that make causal inference testable in its generative mechanisms.

Ho et al. (2017, pp. 511-512) identified three primary sources of endogeneity in OSCM research. These are:

1. Omitted variables occur when one ignores the possibility of some unobserved variable affecting both the outcome and key explanatory variables in the estimation models.
2. Simultaneity or reverse causality occurs when there are multiple dependent variables, each influencing at least one other dependent variable.
3. Measurement and selection biases, resulting from imperfect data, non-random sampling, and the endogenous nature of variables of interest.

Rather than attempting to isolate exogenous variation, ABSs can simulate the endogenous interdependencies among agents, allowing simultaneity and feedback to emerge as intrinsic system properties (Kuljanin et al., 2024). Underlying causes of omitted variables bias can be explicitly modelled as agent attributes or environmental parameters rather than absorbed into a regression error term. Similarly, measurement error and selection bias become matters of model specification and validation, where researchers define the generating process and can simulate different samples

or test several measurement conditions. Thus, instead of attempting to rule out endogeneity through instruments or controls, ABSs address it by explicitly embedding the causal mechanisms that generate dependence among variables at the "co-variance layer" (Figure 2).

Nonetheless, it is worth specifying that ABSs do not eliminate endogeneity problems. The question becomes whether those mechanisms are credible and plausible representations of the real processes that generate the outcome of interest, and whether alternative mechanisms could yield the same results, indicating that we are overlooking some determinant mechanisms. In this sense, ABSs do not "solve" endogeneity through identification strategies but reframe it as a theory-level problem focused on the adequacy of the proposed causality. In other words, addressing endogeneity becomes a matter of ensuring that in the "world" the model is intended to represent, the mechanisms are theoretically plausible as generators of the observed phenomena.

In a generative model, explanation is incomplete unless a micro-specification is sufficient to produce the phenomenon to be explained (Epstein, 1999). If the proposed mechanisms are plausible, simulated outcomes should reproduce key empirical patterns at the aggregate level (Epstein, 1999). If they are meaningful in real phenomena, the model must represent them, or the model's generative sufficiency requirement would not be satisfied. Yet, because the same aggregate regularities can sometimes be reproduced by different micro-level specifications and interactions (i.e., generative equifinality), generative sufficiency alone cannot prove which mechanism is causally correct. In a case of generative equifinality (i.e., different micro-level specifications generate similar macro-level patterns), the choice of the most appropriate model should be based on the plausibility and representativeness of generative mechanisms and, where possible, backed up by empirical evidence (Epstein, 1999). Accordingly, model validation becomes a relevant test, as it evaluates whether the proposed mechanisms can reproduce empirical regularities beyond those implied by the model's own assumptions. In those cases, we argue that the model should be the one whose agent rules are better supported by extant theory and empirical evidence (Epstein, 1999), ideally supplemented by validation using observed data.

Empirical anchoring strengthens this approach, as parameters can be estimated from empirical data and models' outputs can be compared to observed time series patterns (Ballard et al., 2021). Finally, rigour guidelines for ABSs recommend verification, validation, calibration, and sensitivity analyses, so that models and their results do not depend on researcher assumptions but are both theoretically grounded and empirically sound (Rand & Rust, 2011).

Computational models in OSCM: System Dynamics and ABS

In response to the growing recognition that modern operations are inherently dynamic, nonlinear, and cross-functional, the OSCM field has increasingly advocated for the adoption of system dynamics (SD) modelling to complement traditional static and variance-based approaches. As Sterman et al. (2015) note, many operational challenges emerge from feedback processes, information delays, bounded rationality, and behavioural responses that generate variability, coordination failures, and policy resistance. SD provides a formal means to represent these feedback-rich systems and to test how structural and behavioural factors jointly drive performance over time. For example, recent studies have employed SD models to examine supply chain risk management and readiness (Stumpf et al., 2023), the propagation of financial risk under alternative payment-term policies (Esenduran et al., 2022), the coordination of humanitarian search-and-rescue operations (Kosmas et al., 2022), and the mitigation of medical supply disruptions during crises (Falagara Sigala et al., 2022). These studies demonstrate SD's value in representing aggregate feedback loops and policy-level decision structures, helping to explain the dynamic variation of the observed. However, SD and other Differential Equation (DE) based approaches typically rest on aggregation and perfect-mixing assumptions (Rahmandad & Sterman, 2008), treating agents as homogeneous and their interactions as averaged over the system.

As Rahmandad and Sterman (2008, p. 998) argue, "Nonlinear DE models can easily encompass a wide range of feedback effects, but typically aggregate agents into a relatively small number of states (compartments)." To examine the implications of these assumptions, they developed a series of simulations comparing a traditional differential equation diffusion model with an equivalent Agent-Based Models across multiple network topologies (i.e., fully connected, random, Watts-Strogatz small world, scale-free, and lattice) and under different levels of heterogeneity in agents' contact rates. Their simulations revealed that the two modelling approaches produce nearly identical average dynamics under perfect mixing and homogeneous conditions. However, once network structure or agent heterogeneity is introduced, diffusion in the ABS becomes slower, more variable, and granular, while DE models continue to predict smooth, deterministic trajectories that miss early burnout or localised saturation effects.

In the OSCM literature, ABSs have been used to represent heterogeneous agents (firms, orders, or facilities), each with distinct attributes and interaction rules within explicit network structures, thus depicting granular effects or heavy-tailed performance (e.g., Swaminathan et al., 1998). More recently, in their study on ripple effects and the effect of blockchain in enhancing supply chain resiliency, Lohmer et al. (2020) used a model to compute heterogeneous and interconnected firms to evaluate how specific and digitally enabled collaboration of firms along the supply chain can mitigate disruption propagation. By employing ABS, the authors were able to represent a tiered network composed of suppliers, producers, wholesalers, and retailers. Under high process efficiency, the ABS reveals localised effects in the baseline and shows that collaboration reduces disruption costs by up to ≈$13M, shortens recovery by up to ≈90 days, and limits propagation of a disruption to a smaller subgroup of tied organisations (effects that depend nonlinearly on disruption duration and process times). Since these outcomes depend on *who* is facing disruption, *where* a specific firm is placed along the network, and *how fast* partners can enact smart-contract exchanges, the mechanism is inherently agent- and topology-specific. An SD stock-and-flow representation would have mainly captured only smoothed averages of

inventory, backlog, and cash static states, obscuring the subnetwork improvements and contextual conditions (e.g., under low collaboration efficiency) that the ABS can make explicit.

In sum, because SD can effectively shed light on macro-level dynamics and feedback complexity, such models are well-suited for analysing aggregate feedback and policy. However, their ability to reproduce emergent phenomena arising from heterogeneity, lower-level interactions, or network structure is limited (Rahmandad & Sterman, 2008). In contexts where agents are heterogeneous, there are non-linear connections, or uneven agents' contributions, and nuanced dynamics shape agents' behaviour, SD provides only an approximation of the process. In contrast, because ABS captures the generative dynamics through which micro-level interactions scale into system-wide outcomes, it provides more nuanced insight into how heterogeneous phenomena unfold over time. Consequently, although SD can offer a representation of dynamic complexity, it is not fully capable of capturing the generative, bottom-up processes through which collective patterns emerge in complex adaptive systems. To advance computational methodologies, OSCM scholars should complement SD with bottom-up ABSs to enable process-oriented inquiry that represents how interaction structure and heterogeneity jointly shape system evolution within operational settings.

Track: Sustainability

A Comparative Cross-European Investigation into Social Sustainability Disclosure among Leading Football Clubs

SILVIA COSIMATO, NUNZIA CAPOBIANCO, ROBERTO VONA, FEDERICA GRUMETTI

Abstract

***Purpose of the paper**. This study is intended to investigate how leading European football clubs approach the disclosure of social sustainability initiatives. Given the "culture of silence" and social challenges traditionally affecting the industry, this research aims to identify the primary themes and practices communicated by clubs to meet the rising demand for stakeholder accountability and compliance with evolving European regulations.*

***Methodology.** The study has been conducted by implementing an inductive qualitative thematic analysis to examine official documents issued by the main football clubs active in three of the main European leagues (Serie A, La Liga, and Bundesliga). The analysis followed a six-step iterative process to identify recurrent patterns of meaning and was cross-validated through a data triangulation process involving multiple researchers to ensure internal validity.*

***Results.** Results revealed five overarching themes recurring in European clubs' disclosure (Social Value, Environmental Protection, Talent Legacy, Governance & Ethics, and Operations & Mobility), but also a significant geographic divide that characterized this industry. Thus, if German clubs tend to adopt a systemic, compliance-based approach, Spanish and Italian ones tend to prioritize values-driven, community-oriented social practices. Furthermore, a maturity gap has emerged between major and smaller clubs regarding the adoption of high-level reporting standards.*

***Originality of the paper.** This study contributes to the managerial literature by offering a holistic, cross-European comparison of social sustainability disclosure in the football industry. It provides a novel thematic map that bridges the gap between theoretical frameworks like Legitimacy Theory and the practical managerial shifts required by the Corporate Sustainability Reporting Directive (CSRD).*

Keywords: *Social Sustainability, Football Industry, Sustainability Disclosure, Thematic Analysis.*

1. Introduction

Since the beginning of the XXI century, the public concern about organizations' environmental and social impacts has globally risen (Hoerber, 2025). More recently, this concern has also interested the sports industry, sparking debate about whether and how sustainability and sustainable development are addressed. This debate has been inspired by the seminal pillars of the Brundtland Report (1987), and its well-recognized aim to meet the needs of the present generation without compromising the ability of future generations to do the same. This opens to the dynamism that inherently characterizes sustainable development, inspired by the lessons learnt over time in terms of sustainability operationalization (Azapagic and Perdan, 2011). Despite the long debate around sustainability, it remains a complex and multi-dimensional concept, which scholars (Ben-Eli, 2018; Greenland et al., 2022) tend to approach considering five different foundational elements: 1) social/socio-cultural, 2) economic, 3) environmental, 4) political, and 5) technological. The first three elements, or the constitutive pillars of the Triple Bottom Line (TBL) (Elkingthon, 1997), are well established among institutions and organisations, mainly thanks to the publication and the promotion of the United Nations "2030 Agenda for Sustainable Development", and the definition of the Environmental, Social, and Governance (ESG) principles. ESGs were first conceptualized in the 2004 UN report "Who Cares Wins" (Senadheera et al., 2022), inspired by well-established sustainability frameworks and initiatives, such as the Global Reporting Initiative (GRI) and the UN Global Compact, and considered as an evolution or the operationalization purpose of the traditional paradigm of Corporate Social Responsibility (CSR) (Tarczynska-Luniewska et al., 2024). The rise of ESGs marked the concrete evolution from the voluntary and often ambiguous nature of CSR to a more standardized and measurable evaluation framework (Chutiphongdech et al., 2026). At the operational level, this supported organizations in better managing sustainable initiatives, also thanks to a set of specific evaluation criteria.

Over the last few decades, efforts towards sustainability have also grown in the sports industry, which is globally recognized as one of the most economically and culturally prominent industries (Woratschek et al., 2014). Even though the public pressure to prevent social and environmental misconduct (McCullough and Bramley, 2025), the guidelines of the UN's 2030 Agenda for Sustainable Development Goals (SDGs) and the ESG (Hugaerts et al., 2021) have contributed to expanding research on sport sustainability, it still lags behind other domains, such as operations, finance, or manufacturing (Gregori-Faus et al., 2025). The starting point of the managerial debate on this topic is the 2012 London Olympics, the first international sports event ISO-certified (ISO 20121 based on the British standard BS 8901) because organized around specific sustainability criteria (Söderman, 2023). Nevertheless, sport sustainability remains a blurred concept that scholars (Johnson Morgan and Summers, 2012) have differently approached, focusing on one or another sustainability dimension according to different and often siloed interpretative frameworks. The most common ones are the Social Exchange Theory (Cook et al., 2013), which analyses the social aspects (e.g., people participation) of sustainability initiatives related to sporting events (Liang et al., 2026), the Stakeholder Theory (Freeman, 1998), which offers a better understanding of the decision-making processes aimed at balancing the interests of the stakeholders involved in the initiatives defined above (Daddi et al., 2025). The analysis of the environmental dimension of sustainability is often conducted according to the Value-Belief-Norm (VBN) framework (Stern et al., 1999), which supports the analysis of how environmental initiatives of sport organizations influence fans' pro-environmental behaviors (Pelcher et al., 2023). These frameworks usually complement the holistic approach of the seminal ones, such as the UNSDGs and the TBL.

In sport management research on sustainability has mainly focused on economic and environmental issues, neglecting the social ones (McCullough and Kellison, 2020). In this domain, economic sustainability has been based on multi-stakeholder value-based collaborative processes, intended to create value from different financial sources (Paredes et al., 2019). Compared with the previous concept, environmental sustainability is an expanding topic, characterized by studies mainly focused on the assessment of the environmental impact of sports events, often neglecting the importance of environmentally responsible business practices (Cury et al., 2023). Finally, the research on sports' social sustainability is still nascent, even though this industry has a positive influence on it through its principles of discipline, culture of wellbeing, and teamwork orientation (Barbu et al., 2022), and a negative one due to several social challenges, such as crises, misconduct, and even scandals, which have negatively affected athletes' and supporters' well-being (Breitbarth et al., 2023).

In the sports industry, research on social sustainability cannot ignore some complex phenomena, such as the social stigma (Tyler and Slater, 2018) and the culture of silence (Wilcox, 1987). The first one is related to the myth and rhetoric of success, which pressure athletes to hyper-perform physically (Petersen et al., 2024), sometimes negatively affecting athletes' mental health and strength (Ryan, 2013). The second further affects the social sphere of sports' sustainability, being linked to one of the most critical paradoxes of the current society. Thus, it deals with the silence that pervades the sports industry's social issues such as bullying, harassment, alimentary and psychological disorders (Sartore-Baldwin et al., 2017).

To counteract this situation, research on sports' social sustainability should also put more effort into connecting the theory and practice; for example, promoting disclosure practices pointing to enact a more transparent and reliable communication of social sustainability initiatives (Rith and Spinelli, 2024; Stokowski and Carter, 2025). Thus, this paper aims to contribute to bridging this gap by investigating if and how one of the most prominent sports worldwide, football, approaches social sustainability and its disclosure, also identifying the main initiatives and topics that characterize their social sustainability efforts. In doing so, the analysis will also contribute to advancing and better framing the existing definitions of and approaches to sport social sustainability. Three main research questions inspired the study:

RQ1: Do the European major football clubs disclose information about social sustainability?
RQ2: How do they approach social sustainability disclosure?

RQ3: Which are the social sustainability themes that these clubs mostly disclose?

To address these questions, an inductive thematic analysis (Terry et al., 2017) has been conducted on the official documents published by the major European football clubs to identify the main themes at the core of their approach to social sustainability disclosure. The analysis of the achieved results will support policymakers and sports managers in strategically approaching social sustainability and its disclosure, challenging misconduct and segregation, and promoting a culture of inclusion and equity. The paper is organized as follows. The first section is dedicated to the critical description of the sustainable approach to sport management, and of the way football clubs deal with social sustainability disclosure. Follows the presentation of the implemented methodology and of the achieved findings, which have been subsequently discussed. Closed, the presentation of theoretical, managerial, and policy implications, together with study limitations and future research paths.

2. Theoretical background

2.1 A sustainable approach to Sport Management: A Focus on the football industry

As in many other sports, sustainability is gaining prominence also in professional football due to the institutional and social pressure (Daddi et al., 2025). However, the literature on the sustainable approach to football management is still nascent and characterized by the need for further investigation for a better understanding of its determinants.

Approaching sustainability in this industry is as complex as in many other domains, due to the intertwined interactions between its social, environmental, and economic dimensions and the actors involved in the related processes and activities (Lozano and Barreiro-Gen, 2023). To better understand football sustainability, the growing pressure and expectations that affect this industry cannot be ignored due to its high visibility, public scrutiny, and expanding regulatory and societal demands. This has led international institutions to develop sustainability-oriented strategies, standards, and agendas intended to encourage more responsible practices (Konstantopoulos and Manoli 2024). One of the most prominent sustainability-oriented strategies has been launched by the UEFA (*Union of European Football Associations*) to pressure its 55 member associations to take action towards specific environmental and social goals. This strategy (*Strength through Unity: Football Sustainability Strategy*) "sets out 11 key policies and 66 indicators, effectively introducing sustainability reporting as a compliance and governance instrument in the sector" (Agostino and Thomasson, 2025, p.381). This and other top-down initiatives reflect the institutional growing awareness about the fact that long-term sustainability legitimacy mainly depends on football clubs "to align commercial success with environmental stewardship and social responsibility" (L'Abate et al., 2026, p.3).

Some studies, focused on the pressure of stakeholders and governance dynamics on clubs' sustainability, pointed out the enduring difficulties in integrating this paradigm in the environmentally and socially-oriented processes of a highly commercialized and multi-actor industry such as football (Trendafilova and McCullough 2018). Thus, most of the studies focus on the economic dimension of sustainability, while the environmental and social dimensions remain under-investigated (Pellegrino and Stasi, 2025). Despite the growing research on football's environmentally sustainable practices, often linked to event organization (Tettamanzi et al. 2024), the literature still calls for a better understanding of its commitment to social sustainability and its integration within the culture and strategies of clubs. This research need is because most of the existing studies demonstrated that often "sustainability issues are pursued more coincidentally than with a clear strategy" (Baumgartner & Ebner, 2010, p. 76). It follows that social sustainability remains conceptually elusive, empirically fragmented, and normatively contested (Agostino and Thomasson, 2025), because often associated with other constructs such as "social responsibility" or "community engagement". Despite this conceptual ambiguity, this study approaches social sustainability as "a life-enhancing condition within communities, and a process within communities" (McKenzie, 2004, p.4). This definition

aligns with the inherent nature of football clubs, which are, on the one hand, strongly connected to the local communities they represent and, on the other, highly influenced by the social context in which they have been created (Hyndman and Liguori, 2024). Thus, the clubs have traditionally assumed a social role, acting not only as sports organizations but also as social organizations (Agostino and Thomasson, 2025) by promoting local culture, heritage, and identity, engaging people in the revitalising of urban/local areas (Yiapanas, 2025).

More recently, financial and social scandals have put the football industry under public scrutiny, calling for concrete changes in managerial practices based on the enactment of responsible programs aimed to promote ethics, inclusion, and transparency (Robertson et al., 2025). This calls for further investigations on the football clubs' impact and contribution to societal grand challenges

To respond to this call, especially in managerial studies, should be more focused on the promotion of societal accountability and on the engagement of stakeholders (e.g., staff, suppliers, fans, athletes, etc.) in specific sustainability-oriented strategies and actions. To achieve this goal, organizations must necessarily better manage and communicate their "responsibility and awareness of the impacts that sport events have on societal issues" (Chutiphongdech et al., 2025, p.3), and on the overall community well-being. Thus, a better disclosure will also contribute to counteract the so-called "culture of silence", which traditionally affects sport and above all football organizations, characterized by a passive tolerance of domination that prevent some social groups from speak up and speak out about misconduct and abuses, making them reluctant to expressing their opinion, feelings, and desires (Mitchel, 2012; Sartore-Baldwin et al., 2017).

2.2 The disclosure of social sustainability in the football industry

Over the last few decades, public pressure towards sustainability has stimulated growing interest in sustainability reporting and disclosure (Troshani and Rowbottom, 2024).

Even though the concept of sustainability disclosure is gaining international attention as central to managerial research and practice, a comprehensive approach to its main determinants still lacks (Wahyuningrum et al., 2023). This is mainly due to the enduring prejudice that sustainability performance and its disclosure are not among the sport organizations' and, especially, football clubs' primary objectives, remaining something used to instrumentally enhance corporate reputation when it is under criticism (Liu and Wu, 2023). Even though the growing stakeholder pressure led scholars and practitioners to focus on environmental and economic sustainability reporting and disclosure, the social dimension remains fragmented and elusive (Abhayawansa et al., 2022). Thus, little research investigates how social sustainability is operationalized, reported, and disclosed within football clubs. This is mainly due to the high fragmentation and the lack of standardized approaches to reporting and communicating social sustainability initiatives. To contribute to bridging this gap, the disclosure of social sustainability of European football clubs has been investigated, highlighting how the major European clubs contextualize and approach social sustainability disclosure. In doing so, the guidelines set by the specific sustainability disclosure regulations have been considered, such as the Non-Financial Reporting Directive[1] (NFRD) (European Parliament and Council of the European Union, 2014), and the most recent Corporate Sustainability Reporting Directive (CSRD) (European Parliament and Council of the European Union, 2022).

Football clubs tend to disclose mostly on financial and environmental matters, rather than on social ones, which remain conceptually and empirically fragmented (Agostino and Thomasson, 2025). This happens even though international bodies (e.g., the UN Global Compact, the Climate Disclosure Standards Board, UEFA, and Global Reporting Initiative or GRI) have offered some general guidelines (Adegbie et al., 2020). In particular, the EU issued "more comprehensive and detailed reporting requirements, such as the principle of double materiality, the integration of sustainability information into management reports, mandatory external assurance, digital tagging of reported data,

[1] This Directive, enacted in 2017, states that EU public interest entities characterized by a specific size and financial criteria must disclose non-financial information, including diversity data.

and, crucially, the obligation to report in line with the European Sustainability Reporting Standards (ESRS)" (Raimo et al., 2025, p.5). However, this activity remains highly voluntary and presented in the annual report of football clubs following a generic spirit of integration (Raimo et al., 2021). This is often inspired by some institutional initiative, such as European Union and global reporting guidelines issued by the International Sustainability Standards Board (ISSB) and the Global Reporting Initiative (GRI) (Raimo et al., 2025). Together with these, clubs also use some specific "tools" (e.g., sustainability reports, corporate websites, or social media) to communicate sustainable initiatives, integrating them in the traditional reports (e.g., Corporate Sustainability Reporting Directive, Corporate Sustainability Due Diligence Directive, GRI standards, and ESGs). This depicts clubs' tendency to narratively approach social sustainability disclosure, rather than in a normative and strategic way (Milne and Gray, 2013).

The nascent but growing effort of football clubs in disclosing social sustainability practices (e.g., gender diversity, assaults and scandals, equity, inclusion, bullying, etc.) is also due to the need for gaining reputational advantages by counteracting the negative influence of misconduct, scandals, and the culture of silence that negatively affect sports (Caccialanza et al., 2024; Clarkson and Philippou, 2024). Thus, according to Agostino and Thomasson (2025), social sustainability disclosure is not a "neutral act of transparency but a political and selective construction of organisational legitimacy" (p.381). This led to approaching social sustainability disclosure in the football industry not only as a mere communication act, but rather as a relational act merging the stakeholder theory and the legitimacy theory approach **(**Deegan, 2014). Thus, the disclosure of clubs' social commitment not only responds to stakeholders' information (supporters, institutions, local community, etc.) needs, but also contributes to activating a legitimation process that better commits clubs to their local context, thanks to the social work they do for the community. This is in line with the extant literature, which considers sustainability disclosure a key mechanism for achieving or improving corporate accountability (Sarfaty, 2015; Teplitz, 2025) or organizations' responsibility for something that explains and justifies the acts and omissions for which they are responsible to people with a legitimate interest (ISEA, 1999). Freeman (1984) incorporated accountability to a wide range of stakeholders, considering it as inherently related to whether stakeholders have sufficient, accurate, understandable, and timely information for starting decision-making processes.

3. Methodology

3.1 Research Method

This study investigates and compares the disclosure of social sustainability initiatives of the clubs active in the main European leagues (*Serie A, La Liga,* and the *Bundesliga*), identifying the themes or practices they mainly communicate. In doing so, an inductive thematic analysis (Joffe, 2011; Terry et al., 2017) has been conducted to identify and analyse the most recurrent patterns of meaning related to the topic under investigation. This method examines narrative materials, fragmented into small units of analysis to be described and qualified. Thematic analysis supports researchers in dealing with individuals' and/or organizations' attitudes, concerns, or feelings about a specific phenomenon (Vaismoradi et al., 2013). The flexibility of this method offers a qualitative interpretation of the collected data and information, identifying and comparing common elements across an entire set of textual resources. According to Braun and Clarke (2006), this methodological approach is suitable "for identifying, analysing and reporting patterns (themes) within data" (p. 79). This method is mainly implemented when researchers want to use a relatively low level of interpretation, in contrast to grounded theory or hermeneutic phenomenology, in which a higher interpretive complexity is needed.

3.2 Research Design

The thematic analysis has been conducted on a sample of primary European football clubs, collecting and screening their sustainability reports to identify, classify, and compare, according to

the thematic analysis protocol, the social sustainability initiatives, issues, and actions they mostly disclose. The analysis of the textual resources (sustainability reports) was organized around the following open-ended iterative process (Finfgeld-Connett and Johnson 2013): 1) searching, 2) sorting, 3) selecting, 4) acquiring, 5) reading, 6) identifying, and 7) refining.

The searching process was conducted by analysing titles and eventual keywords to understand if the selected documents align with the topic at the core of the study. This led to sorting and selecting the final sample to be analysed. In doing so, some inclusion criteria were set. The publication timeline, which spans from January 2021 to January 2026. January 2021 has been selected as the starting period because of the enactment of some sustainability-oriented regulations (e.g., the SFDR). Other inclusion criteria were the publishing language (English) and the authorship (Serie A, La Liga, and Bundesliga clubs). The Serie A, La Liga, and Bundesliga were selected according to a convenience sampling strategy (Etikan et al., 2016), justified by 1) the prominence of these leagues within the European football industry, 2) data availability and accessibility, and 3) their representativeness of three different organizational, economic, and cultural models. This ensures high data quality, transparency, and accessibility (Bryman, 2016), as well as a comparative analysis of different contexts and managerial approaches implemented in highly professional and competitive contexts; thus, the Bundesliga is organized in an 18-team format and 34 matches, while the Serie A and La Liga are organized in a 20-team format and 38 matches (Etikan et al., 2016). After the application of the inclusion criteria to the initial sample of 48 clubs, the final sample was made up of 23 clubs, because these 1) are committed to sustainability practices, 2) publish sustainability reports regularly, and 3) an English version of these reports is freely available online.
The thematic analysis was conducted following the guidelines defined by Braun and Clarke (2006): 1) data familiarization, 2) code generation, 3) themes' construction, 4) themes' reviewing, 5) themes' defining and naming, and 6) report production.

Two researchers worked independently on the selected sample to familiarize themselves with it and generate the initial codes. Then, a list of preliminary themes and subthemes based on similarities across texts was defined. Researchers also re-assessed each text, changing and/or adding codes if necessary. This led to reconciling discrepancies and re-coding data for gaining consensus on the defined thematic categorizations. When no agreement was achieved, the thematic map was modified until all texts were represented by a final list of themes and subthemes. When thematic grouping was comprehensively agreed upon, the themes were named, and representative quotes were selected and described.

Data triangulation process ensured the internal validity of the analysis; thus, a data triangulation strategy was implemented, based on cross-referencing sample reports with external regulatory frameworks (European and national), official press release, professional articles, and interviews, etc. This led to the cross-validation of findings, comparing and corroborating them through multiple data sources (Denzin and Lincoln 2011). Thus, the robustness of the analysis was ensured not only by cross-referencing sustainability reports with external sources but also by maintaining inter-coder consistency to mitigate subjective bias during the thematic labeling process (Flick, 2018; Patton, 2014). This made it possible for two different researchers to categorize the emerging themes in the same way.

3.3 Thematic Analysis structure

To start the thematic analysis, some content units (or "observation" in inferential statistics) were defined, and the sentence was set as the unit of analysis. Two researchers worked independently, checking the texts to correct any eventual coding errors. As stated, the internal validity of the analysis was ensured through the data triangulation process (Houghton et al. 2013), which allows the test of the thematic analysis observations and the minimization of researchers' subjective influence.

The thematic analysis has been conducted following Braun and Clarke's (2006) approach, which points to inductively defining some primary themes, specified by some related sub-themes, essential to provide more granular detail to the analysis. The software Atlas.it was used to analyse the selected

reports, while two researchers reviewed the achieved results. Some codes (or key concepts) were defined to describe the content of the paragraphs of the selected reports, grouped according to the reported topic. These codes were then grouped and used to define the final themes and sub-themes, presented in the following paragraph.

4. Findings

As stated, the inductive thematic analysis was conducted following Braun and Clarke's (2006) iterative process, which led to the definition of the main semantic themes that characterize the analyzed sample of sustainability reports issued by some of the main European football clubs. In doing so, the identification of some codes led to the clustering of five primary themes and some sub-themes extracted from the analyzed texts (Tab.1).

Tab. 1: Comparative Thematic Table and Key Components.

Codes (Key Components)	**Primary Themes**	**Sub-themes**	**Unit Analysis Findings (sample)**
Foundations, Solidarity, Inclusion, Dialogue	*Social Value*	Social Accounting (Spanish/German clubs) Sport for Change (Italian clubs)	Maximizing social influence through "Sport for Development"
Net Zero, Circular Economy, Photovoltaics, Water	*Environmental Protection*	Technocratic Data (German clubs) Natural Resource Defense (Spanish/Italian clubs).	Focus on "Scope 1, 2, 3 emissions" and "resource conservation".
Youth, Wellbeing, Education, Development, Growth.	*Talent Legacy*	Youth education (All clubs) Social inclusion (All clubs)	Maximizing social influence through "Sport for Personal Development and Wellbeing"
Transparency, Governance, Stakeholders, Materiality, Compliance.	*Governance & Ethics*	Governance used to maintain fan trust (All clubs) Materiality reporting (German/Italian clubs)	"Double materiality" and reporting for specific stakeholder groups.
ResearchLab, Green, Circular, vehicles, supply chain, innovation.	*Operations & Mobility*	Insfrastructures' green innovation (Spanish/German clubs)	Viewing sustainability as a challenge to change and innovate infrastructures (e.g., the sustainable arena).

Source: authors' elaboration.

The primary themes are: 1) Social Value, 2) Environmental Protection, 3) Talent Legacy, 4) Governance & Ethics, and 5) Operations & Mobility. These themes have been derived after having counted the occurrences of the defined codes (key concepts), which have been grouped, according to their meaning and number of occurrences, into 5 primary themes. This has led to the recognition of the "dominating" themes that mutually characterize the analyzed reports. The frequency is defined as "high" when the primary themes have a recurrence frequency higher than the average of the dataset, "medium" when the patterns are recurrent but less than the average, and "low" when the themes are interesting but characterized by a lower frequency (Tab.2).

Tab. 2: Primary themes recurrency frequence

Primary Themes	**Recurrence (High/Med/Low)**	**Avg. Sentence Count**
Social Value	High	146
Environmental Protection	High	94
Talent Legacy	Medium	74
Governance & Ethics	Medium	55
Operations & Mobility	Low	44

Source: authors' elaboration.

Two of the five themes have a clear environmental orientation (*environmental protection* and *operations & mobility*). Even though this study is focused on the social dimension of sustainability, the environmental-based themes have been considered because they support the integrity of the analysis and data coherence. In doing so, it is also possible to avoid the so-called social washing, which distorts the representation of the investigated phenomenon, isolating the social dimension of sustainability and the related communication. Moreover, the occurrence and the analysis of the main environmental themes highlight the intertwined and holistic nature of sustainability as well as the clubs' integrated approach to sustainability and its disclosure. Dealing with these themes, the first is *Environmental Protection,* which groups issues/activities related to environmentally friendly practices (e.g., climate neutrality, waste management, and resource preservation). This theme occurred 94 times in the analyzed reports, and those with the most occurrences were published by two German clubs (FC Augsburg and Wolfsburg), while those with fewer occurrences were the reports of two Spanish clubs (Athletic Bilbao and Valencia CF). The other environmentally friendly theme was *Operation & Mobility,* which groups issues/activities related to the sustainable management of operations and mobility infrastructures (e.g., green stadium infrastructure, EV charging, and supply chain). This theme occurred only 44 times, and the reports in which it recurred mostly were issued by a Spanish and a German club (Real Madrid and FC Augsburg), while the reports with fewer occurrences were issued by a German and an Italian club (Bayer Leverkusen and AC Milan).

Focusing on the social sustainability-oriented themes, the most recurrent theme is *Social Value*, which occurred 146 times in the analyzed reports and is characterized by practices intended to create and share social value among stakeholders (e.g., Philanthropy, social inclusion, human rights, and community equity). The reports in which this theme mainly occurred were issued by Athletic Bilbao and AC Milan, while Wolfsburg and Hoffenheim issued those with fewer occurrences. Follows the theme *Talent Legacy* with 74 occurrences, which is characterized by issues/activities related to youth education and support (e.g., youth academy education, safeguarding, and "dual-career" support). The reports in which this theme mostly occurred were published by Bayer Leverkusen and FC Augsburg, while those in which it has fewer occurrences were published by Juventus and Bayern Munich.

The last theme recognized during the analysis was *Governance & Ethics,* with 55 occurrences and characterized by issues/activities related to business ethics (e.g., ESG committees, risk management, and legal compliance). Atlético Madrid and Juventus published the reports in which this theme mostly occurred, while Valencia CF and Athletic Bilbao published those with fewer occurrences. The following table depicts the themes' recurrence and distribution across the sample (Tab.3).

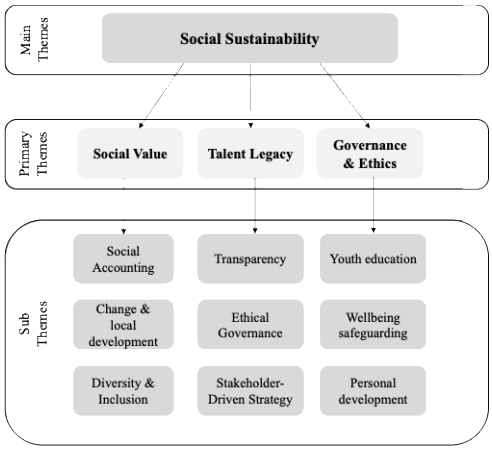
Tab.3: Comparative Thematic Table and Recurrence

Final Theme	Description	Most Recurrent	Least Recurrent
Social Value	Philanthropy, social inclusion, human rights, and community equity.	Athletic Bilbao, AC Milan	Wolfsburg, Hoffenheim
Environmental Protection	Climate neutrality, waste management, and resource preservation.	FC Augsburg, Wolfsburg	Athletic Bilbao, Valencia CF
Talent Legacy	Youth academy education, safeguarding, and "dual-career" support.	Bayer Leverkusen, FC Augsburg	Juventus, Bayern Munich
Governance & Ethics	ESG committees, risk management, and legal compliance.	Atlético Madrid, Juventus	Valencia CF, Athletic Bilbao
Operations & Mobility	Green stadium infrastructure, EV charging, and supply chain.	Real Madrid, FC Augsburg	Bayer Leverkusen, AC Milan

Source: authors' elaboration.

The five primary themes were also further investigated to better specify them by recognizing the practices that each of the analyzed clubs has disclosed to communicate the effort they are putting into each of the retrieved sustainability areas. Themes and subthemes are described in Table 4.

Tab. 4: Thematic Map.



Thematic Map		
Primary Theme	**Sub-theme**	**Action/s**
Social Value	Social Accounting	Athletic Bilbao effort to monetizing intangible social impact.
	Change & local development	Valencia's response to the 2024 floods, AC Milan: Using the jersey as a tool for bridge-building
	Diversity & Inclusion	FC Bayern promotion of equity in the workplace and stands through the "*mitnand*" philosophy.
Environmental Protection	Technocratic Data	German clubs focus on ISO 14001 and technical Psi.
	Climate Action	The effort toward carbon neutrality, and the BVB's Scope 1/2 goals by 2040.
	Natural Resource Defense	Spanish and Italian clubs' actions intended to water-saving/drought-prevention.
Talent Legacy	Youth education	Almost all clubs' efforts to use football as a "tool" for the personal growth.
	Wellbeing safeguarding	The promotion of mental health programs, as in the case of Bayer Leverkusen.
	Personal development	The development of a "dual-career" promoted by German clubs.
Governance & Ethics	Transparency	Almost all clubs consider governance as a tool to maintain stakeholders' trust.
	Ethical Governance	Almost all clubs are involved in compliance, transparency, and anti-corruption actions.
	Stakeholder-Driven Strategy	Almost all clubs are involved into a materiality analysis to align their goals with stakeholders' expectations.
Operations & Mobility	Circular resources	Waste management and energy efficiency, as for Wolfsburg's "Zero Waste" vision.
	Sustainable Infrastructures	The modernization of physical assets to reflect "Green" values, as for Real Madrid's innovation in infrastructures.
	Resource saving	Efforts toward carbon neutrality, as for German clubs.

Source: authors' elaboration.

The primary themes were organized into two main categories: 1) *sub-themes* or the content and topics covered by the reports, and 2) *action/s* or the investigated clubs' approach to the identified contents related to social sustainability.

Drawing on Brown and Clark (2006), a graphical thematic map has been proposed to better depict the themes inductively retrieved and the hierarchical relationships between them (main themes, primary themes, and sub-themes) (Fig.1). This led to addressing the first research question at the core of this analysis (*Which are the sustainability-related themes that these clubs mostly disclose?*).

Fig. 1: Graphical representation of the thematic map based on socially-oriented themes.

Source: authors' elaboration.

To better support the retrieved sub-themes, some relevant example quotes have also been identified. In terms of Diversity & Inclusion, AC Milan reported "Fondazione Milan (…) uses sport as a lever for inclusion and participation to trigger social change", while on Climate Actions, Bayern Munich reported "We have achieved a 35% total emissions reduction compared to our 2019 baseline and received SBTi verification". Dealing with Youth Education, Bayern Leverkusen affirmed, "Bayer 04 Leverkusen promotes the dual career of its young talents, linking sporting development with vocational and school education". Finally, reporting on Sustainable Infrastructures, Real Madrid affirmed, "Real Madrid has increased the number of charging points for electric vehicles by four, installing 70 additional points".

5. Discussion

The debate around the football industry's disclosure of social sustainability practices is increasingly attracting societal and managerial interest globally (Trail and McCullough, 2020). As the results demonstrated, this has pushed major European clubs to integrate social sustainability practices into sports strategic management and corporate communication. All the analyzed clubs recognize the importance of social sustainability disclosure in inspiring, engaging, and communicating with local communities. Thus, "sport and sustainability are increasingly being linked together in efforts to promote environmental stewardship and social responsibility" (Safarpour et al., 2025, p.3). This led to addressing the first research question (*Do the European major football clubs disclose information about social sustainability?*). Drawing on these considerations, this paper has investigated the approach of some of the major European football clubs to social sustainability disclosure, offering a holistic picture of the practices they are implementing and communicating.

First, the analysis pointed out the existence of a clear geographic divide among the three analyzed leagues (Bundesliga, La Liga, and Serie A), which is mainly due to the influence of national/local context. However, Serie A and La Liga demonstrated some similarity, if compared with the Bundesliga. This is in line with Hydman et al. (2024), who underlined that football clubs historically act as a guide for local communities, influencing their social development and being influenced by the related societal context. Therefore, the geographic divide that emerged from the analysis is not merely a spatial difference, but rather a structural difference in social contracts (Chen and Choi, 2005), and in the way they mediate between the interests of the stakeholders involved in the social initiatives (Daddi et al., 2025). Therefore, this divide among the three analysed leagues is mainly due to the existence of different local exchange norms, inspired by the related specific socio-cultural context. Thus, assuming the Social Exchange Theory perspective (Cook et al., 2013), at the national level, the investigated clubs demonstrated a certain level of social reciprocity, based on the fact that when a club effectively intervenes in a community's social development, create a commitment based on a common social identity, a strong sense of belonging, and community cohesion. This pushes the local community to provide clubs with social capital, legitimacy, and loyalty.

Tab. 5: Geographical divide in social sustainability disclosure.

League	Local Context	Examples
Bundesliga	High emphasis on fan ownership (50+1 rule) and community accessibility.	The "cost" (ticket prices) is kept low to maximize the "reward" (fan inclusion), ensuring a high volume of social exchange.
Serie A **La Liga**	Historical ties to regional identity and local political patronage.	The exchange is often centred on regional prestige; the club acts as a vessel for local pride against central authorities, a high-value intangible reward.

Source: authors' elaboration.

Drawing on these considerations, clubs have evolved into multifaceted institutions able to inspire and holistically contribute to local sustainable development, encompassing its economic, environmental, and social dimensions (Risaliti and Verona, 2013). It follows that sustainability reporting, and the activity of social sustainability disclosure, are more than a mere communicative exercise, but it is rather a situated act of contextualization (Røvik, 2016), where socially related concepts can be reported and legitimized by a specific organizational, regulatory, and sociocultural context (Agostino and Thompson, 2025). This justifies the different approaches demonstrated by the clubs of three European Leagues. In particular, the Bundesliga demonstrated a systemic and compliance-based approach to sustainability and social sustainability, often leading the way, especially in the implementation of environmentally friendly practices and in their strategic integration. This integrated and systemic approach to sustainability lays its foundations on the Deutsch Strategy for Sustainability (*Deutsche Nachhaltigkeitsstrategie*), defined in 2002 and constantly updated to UN goals. This highlights that social sustainability disclosure acts as a proxy for legitimation, because clubs tend not to just report facts, but rather align social sustainability to their specific organizational, regulatory, and sociocultural context (Archel et al., 2009). Thus, by legitimizing socially related activities and projects through disclosure, clubs make a situated act of contextualization (Ferraro et al., 2026). This led to addressing the second research question (*How do they approach social sustainability disclosure*?).

Football clubs, like all profit and non-profit organizations, must comply with clear and strict legal requirements, as the results demonstrate, highlighting the emphasis on technical certifications and the need for reaching specific quantitative goals (e.g., climate neutrality by 2040, and the maintenance of the EMAS certification for the Allianz Arena since 2006). This emerges from the German approach to social sustainability, which clubs consider a real asset to be used to strengthen local identity and to stakeholders' engagement, supported by a well-established materiality analysis (Adam et al., 2025).

La Liga (Spain) and Serie A (Italy) clubs demonstrated quite a different approach to social sustainability; thus, their reports are more focused on social, societal, and community-oriented practices than on environmentally friendly ones. This is also testified by the clubs' foundations' direct and primary involvement in sustainability disclosure. In particular, Spanish clubs tend to adopt a global, values-driven approach, leveraging their international influence to promote universal sustainability goals (e.g., Real Madrid was the first club to join the UN Global Compact) and sustainable innovation (e.g., the restyling of the Santiago Bernabéu, which features innovative water recycling and energy-efficient LED technology). This aligns with the extant research, which focuses on the importance of sport organizations' disposition to approach sustainability efforts and disclosure according to a value-driven perspective (Yiapanas, 2025). This emerges from football clubs' disclosure of their disposition to ground their business and athletic activities in ethical values, rather than merely in financial performances (Fernández-Villarino, 2021; Jones, 2023).

Finally, the approach of Italian football clubs is characterized by institutional rigor and sophisticated reporting, because they often treat sustainability and social sustainability with the same level of accountability as financial performance. This emerges from these clubs' disposition to disclose the implemented governance, transparency, and anti-corruption measures, embedded in the general sustainability strategy. This finding is justified by the past scandals that affected Italian clubs, which are currently deeply committed to properly communicating their institutional integrity, as in the case of Juventus, which, in doing so, is also advancing in the application of the main formal accounting standards like CSRD (Corporate Sustainability Reporting Directive) and Social Monetary Accounting. This finding aligns with the research stream that considers sustainability as a system-based paradigm, in which economic viability, social equity, and environmental integrity are embedded within corporate governance strategies (Yadav and Yadav, 2024). Drawing on these results, the approach to social sustainability disclosure of the three leagues can be described as follows. The Bundesliga's approach can be defined as "systemic and compliance-oriented" because inspired by a substantive approach to legitimacy. This is due to clubs' adherence to the *Deutsche Nachhaltigkeitsstrategie*, the rigorous certifications (e.g., EMAS, etc.), and the alignment with

national systemic goals. La Liga's approach can be described as "global and value-driven" because inspired by a normative approach to legitimacy, due to the mission and the values that inspire clubs towards social sustainability. Thus, La Liga clubs tend to act as moral leaders in the international football community. Finally, Serie A's approach to social sustainability disclosure can be defined as "institutional rigor and accountability" because it relates to a restorative approach to legitimacy. This is justified by the need and desire to restore accountability after some scandals, and restore, through sophisticated reporting, the social contract, and prove to stakeholders that the clubs are now transparent and accountable.

Tab. 6: Geographical divide in social sustainability disclosure

League	Core Approach	Focus	Examples
Bundesliga (compliance)	Systemic & Compliance-oriented	Regulatory Legitimacy: Focus on strict legal requirements, technical certifications, and quantitative environmental goals. Sustainability is treated as a strategic asset for local identity.	EMAS certification (Allianz Arena), Climate neutrality by 2040, Deutsche Nachhaltigkeitsstrategie, Materiality analysis.
La Liga (values)	Global & Value-Driven	*Moral/Ethical Legitimacy:* Prioritizes social and community-oriented practices over environmental ones. Leverages international influence to promote universal values and ethical business.	UN Global Compact (Real Madrid), Club foundations' involvement, Santiago Bernabéu restyling (water/energy innovation).
Serie A (accountability)	Institutional Rigor & Accountability	*Governance Legitimacy:* Focus on transparency, anti-corruption, and institutional integrity to rebuild trust following past scandals. Sustainability is treated with the same rigor as financial reporting.	CSRD application, Social Monetary Accounting, Governance and anti-corruption measures (e.g., Juventus).

Source: authors' elaboration.

Going through the differences between the analysed clubs, it is worth noting that some differences in the way they approach social sustainability disclosure also emerge when comparing small and big clubs. This implies a clear dualism between local versus global identity, because smaller clubs (e.g., TSG Hoffenheim) tend to emphasize their local roots as a unique challenge in competing with the "global giants" (e.g., Real Madrid, Barcelona, Juventus, Bayern Munich, etc.), focusing on their role as inspirational examples for the UN SDGs. This opens to another interesting finding, clubs' maturity level in sustainability reporting and disclosure. Thus, also in this case, the major clubs (Juventus, AC Milan, Real Madrid, Barcelona, Dortmund, Bayern Munich, etc.) have demonstrated the ability to deeply align with high-level reporting standards (e.g., ESRS or Social Accounting, etc.), treating social impact with the same rigor as financial accounting. This led to some reflections on the maturity level of European football clubs in disclosing social sustainability. As for many other sectors, football clubs that approach sustainability strategically, considering it a guiding principle for each organizational process and for maintaining an integral legitimacy, tend to demonstrate a higher level of disclosure maturity (Bonrath et al., 2022; Anis and Avrilia, 2024). This also implies a clear shift from an unstructured to a more strategic and systemic approach to sustainability management and communication, with a focus on the interdependencies among economy, society, and environment, and on related resource management (Setyawan, 2025).

6. Implications, limitations, and final remarks

Analysing how the major European football clubs approach the disclosure of social sustainability efforts and initiatives, this study offers multifaceted, interesting theoretical and practical implications for supporting and inspiring clubs towards a more rigorous, strategic, and shared approach.

The first theoretical implication emerging from the analysis delves into the contribution to sustainability disclosure research and focuses on the contribution of the Legitimacy Theory (Deegan, 2014), by reframing social sustainability disclosure from a passive transparency tool to a proactive, and strategically organized situated act of contextualization (Røvik, 2016; Agostino and Thompson, 2025). This suggests that legitimacy is not a static "license to operate" but a dynamic construct negotiated within specific regulatory and sociocultural boundaries. Consequently, for football clubs, disclosure should serve as a mechanism to "translate" sustainability imperatives into local social capital, thereby validating the organization's existence according to the specific local expectations (e.g., the German compliance model vs. the Spanish value-driven model).

The second theoretical implication concerns the need and the efforts that clubs must dedicate to accountability, moving beyond traditional financial reporting and disclosure to incorporate societal matters that represent a wider range of stakeholders' (e.g., fans, athletes, local communities, etc.) needs and issues. This also supports and extends the application of the Stakeholder Theory (Freeman 1984) to the sport domain, by demonstrating that the "social contract" of a football club has expanded beyond traditional boundaries. Thus, accountability is no longer limited to the financial stewardship of shareholders but must now address a multidimensional ecosystem of fans, athletes, and local communities. The findings suggest that in the sports industry, "social utility" is a core performance metric. This necessitates a shift in stakeholder management where societal issues are not peripheral "externalities" but central to the club's strategic survival.

Finally, a third contribution to the theory emerged from this analysis, which is the identification of five semantic themes (Social Value, Environmental Protection, Talent Legacy, Governance & Ethics, and Operations & Mobility). This contributes to the conceptualization of sustainability as a system-based paradigm, validating the shift from an unstructured approach to a more strategic, systemic model where economic viability and social equity are deeply embedded within corporate governance strategies (Dilling, 2010).

In terms of managerial and policy implications, this study suggests the need for a paradigm shift from a narrative-based to a strategic and systemic approach to sustainability disclosure. In this sense, football managers should no longer approach this activity instrumentally, considering it a tool for reputation repairing, but they should rather integrate it into core decision-making processes (Chopra et al., 2024). This implies a systemic approach to sustainability and social sustainability, and in doing so, managers should manage social impact data with the same rigor applied to financial accounting, and use specific frameworks (e.g., Social Monetary Accounting, ESRS, etc.) to meet increasing stakeholder expectations for accountability. This will also support clubs in holistically exploiting the potential of sustainability to promote innovation, also at the social and societal level (Yiapanas, 2025).

From a policy perspective, this research highlights a significant geographic divide, where national strategies influence the general level of disclosure maturity of European clubs (Anis and Avrilia, 2024). In this sense, policymakers should leverage the main sustainability directives and standards to harmonize the enduring fragmentation existing at the local and national level, ensuring that social sustainability becomes a normative requirement rather than a voluntary and random activity. This will support the mitigation of the culture of silence mentioned before and the promotion of a more transparent, equitable, and inclusive football industry.

Despite its insights, this study is limited by its qualitative nature and the small sample of analysed reports. The reliance on official documents may also reflect a selective construction of organisational legitimacy, rather than actual performance. Future research should employ longitudinal quantitative methods to track the progress of football clubs in social sustainability disclosure and in the quality of communication and reporting. Additionally, investigating the perspective of diverse stakeholder groups (e.g., fans, athletes, and local communities) through primary data collection would provide a more holistic understanding of whether disclosed initiatives translate into tangible social and environmental improvements.

Assessing the Financial Impact of Climate-Related Risks in the Automotive Industry

FEDERICA GASBARRO[1], FORSTER JUNIOR SHITSI[2]

Abstract

Frame of the research. *The automotive industry is facing increasing exposure to climate-related risks that threaten its financial stability and competitiveness.*

Purpose of the paper. *This study examines how the severity of these risks interacts with risk types and a firm's value chain position to influence its performance.*

Methodology. *Using climate risk data and economic indicators from major automotive manufacturers between 2018 and 2021, we apply a quantitative framework that links risk classifications with severity scores and the value chain.*

Results. *Findings indicate that financial impacts are strongly dependent on the type and magnitude of risk. Physical and regulatory risks exert the most significant economic toll, particularly when severity is high. Market and technological risks tend to have minor or context-dependent effects, with certain firm positions, such as upstream suppliers under market risk, experiencing relative insulation.*

Research limitations. *This research has some limitations. First, it relies on self-reported CDP disclosures, which may vary in accuracy or reflect strategic bias. Second, the analysis is confined to the automotive sector.*

Managerial implications. *From a managerial perspective, the heterogeneity of climate risk impacts demands differentiated strategies across the value chain.*

Originality of the paper. *This research advances the understanding of climate-related financial exposure in the automotive industry and provides a practical framework for assessing risks in carbon-intensive sectors.*

Keywords: *Climate-related risks, financial impact, automotive industry, risk severity, value chain*

1. Introduction

The unfolding reality of climate change has emerged as one of the most profound economic disruptors of the 21st century, reshaping the competitive landscape across virtually every sector (Dietz et al., 2016). For industries with extensive global footprints, the challenge is not merely about complying with environmental norms but about safeguarding operational continuity, protecting asset value, and sustaining profitability in the face of escalating climate-related risks. Climate change manifests through two broad and interconnected dimensions of risk: physical and transition (Carney, 2017). Physical risks encompass both acute events, such as extreme storms, floods, droughts, and heatwaves, as well as chronic environmental shifts, including progressive temperature increases and rising sea levels. These phenomena can directly damage infrastructure, interrupt production processes, disrupt supply chains, and impose unplanned repair and maintenance costs, all of which translate into revenue loss and operational inefficiencies. Transition risks, on the other hand, stem from the global pivot toward a low-carbon economy, encompassing the tightening of regulatory requirements such as emissions standards and carbon pricing (regulatory risk), shifts in consumer preferences toward cleaner products (market risk), and technological disruptions that render existing processes and assets obsolete (technology risk) (Gasbarro et al., 2017; Krueger et al., 2020). For instance, the introduction of aggressive carbon pricing mechanisms can sharply increase manufacturing costs and depress the market valuation of carbon-intensive assets, particularly when firms lack proactive adaptation strategies (Matsumura et al., 2014).

The automotive sector is uniquely and acutely exposed to this evolving risk landscape. As one of the most carbon-intensive manufacturing industries, it is simultaneously grappling with unprecedented regulatory scrutiny, market realignment toward electric mobility, and the operational

[1] University of Brescia – Italy e-mail: federica.gasbarro@unibs.it
[2] University of Brescia – Italy e-mail: f.shitsi@unibs.it

challenges of globalized and complex supply networks. Automakers and their suppliers are facing not only the imperative to decarbonize production processes but also the financial volatility brought by shifting demand patterns, raw material price fluctuations, and rapid technological innovation cycles (IEA, 2021). The shift toward vehicle electrification, combined with stricter emissions regulations in major markets, has accelerated the need for operational and technological transformation (Sierzchula et al., 2014). Despite its vulnerability, the automotive sector remains underrepresented in the empirical literature on climate-finance linkages. Previous studies increasingly highlight the financial consequences of climate risk exposures: evidence suggests that heightened exposure to climate-related hazards tends to weaken corporate returns (Zhang et al., 2023), while firms that adopt robust carbon-management practices often demonstrate enhanced profitability and resilience (Busch et al., 2016; Matsumura et al., 2014). This dynamic implies that unmanaged climate risks are not only an environmental liability but also a material financial hazard.

However, the current state of academic inquiry reveals essential gaps. Much of the literature on the financial impacts of climate-related risks has concentrated on sectors such as finance, energy (Dietz et al., 2016; Ilhan et al., 2021), and utilities, leaving the manufacturing sector, particularly the automotive industry, relatively underexplored. Even when manufacturing is examined, the analytical scope is often confined to firm-level exposures without sufficient consideration of the broader supply-chain context. This omission is critical because climate-related risks rarely occur in isolation; instead, they propagate along value chains. A flood or typhoon affecting a raw materials supplier can create cascading production delays for upstream manufacturers, while sudden shifts in downstream demand, such as a surge in electric vehicle adoption, can reverberate upstream, altering production schedules, procurement strategies, and investment decisions (Ghadge et al., 2020). Furthermore, the financial consequences are influenced not only by the type of risk but also by its severity, defined as the likelihood and magnitude of the anticipated climate event (Chakraborty et al., 2019). However, no empirical studies have systematically integrated the interplay between risk type, supply chain position, and risk severity into a unified analytical framework.

This study addresses these gaps by conducting a multi-dimensional analysis of climate-related risks in the automotive sector, linking physical, regulatory, market, and technological risk categories to firms' reported financial impacts while explicitly accounting for supply-chain positioning and risk severity. Drawing on firm-level climate disclosures from the Carbon Disclosure Project (CDP) between 2018 and 2021, this research applies a combination of analysis of covariance (ANCOVA) and robust regression techniques to quantify these relationships. The novelty of this approach lies in its integration of risk typology, value-chain location, and risk severity into a single empirical model, allowing for a more granular and operationally relevant understanding of how climate change is reshaping the financial dynamics of one of the world's most strategically significant manufacturing sectors. By doing so, the study not only advances theoretical perspectives on climate-finance interactions but also offers practical insights for managers, investors, and policymakers seeking to mitigate financial vulnerability and strengthen resilience within the global automotive value chain. The remainder of the paper is structured as follows: Section 2 reviews the relevant literature and develops the hypotheses; Section 3 details the data sources and analytical approach; Section 4 presents the empirical results, focusing on statistically significant effects and coefficient interpretations; and Section 5 discusses the findings in light of existing empirical evidence and outlines implications for practitioners and policymakers.

2. Literature review and hypothesis development

2.1 Financial impact of climate-related risks

Climate-related risks, both physical and transitional, can materially affect revenues, asset values, and long-term business viability. Physical hazards, such as floods, droughts, and hurricanes, directly damage assets, disrupt supply chains, and reduce productivity, leading to revenue loss, higher

insurance costs, and asset impairments (Krueger et al., 2020; Linnenluecke et al., 2013). Chronic risks, including temperature shifts and sea-level rise, impose long-term pressure on operations and resource availability (Bolton et al., 2020).

Transitional risks, on the other hand, arise from the global low-carbon transition and are especially critical in the automotive industry (Kim et al., 2024). These include regulatory risks stemming from emission standards and carbon pricing, market risks arising from shifting consumer preferences, and technological risks associated with disruptive innovations such as electric mobility. Regulatory changes often increase compliance costs, impair the performance of carbon-intensive assets, and create legal or reputational exposure (Engau & Hoffmann, 2011). Evidence suggests that carbon pricing and emission trading schemes can negatively impact stock performance when firms are unable to adapt (Er Kara et al., 2021; Palea & Santhià, 2022).

Most prior research on climate-related financial impacts has concentrated on the financial sector, particularly banks (Chalabi-Jabado & Ziane, 2024; S. Li & Pan, 2022), with some coverage of the energy (Palea & Santhià, 2022) and health sectors (Toumi, 2025). Within these contexts, evidence consistently shows that physical risks tend to depress financial performance, while the effect of transition risks is more nuanced. For example, Chalabi-Jabado & Ziane (2024), using a 10-year CDP dataset of 147 banks across 37 countries, found that physical risks reduced returns on assets, equity, and capital. In contrast, proactive integration of transition risks into strategy often yielded positive effects. Other related studies, including Pagliari (2021), Li and Pan (2022), and Huang et al. (2022), confirm that physical climate risks present a systemic threat to financial stability, particularly for banks with exposure to climate-vulnerable sectors.

However, the impact of transition risks on financial performance is less consistent. Chalabi-Jabado & Ziane (2024) and Sun et al. (2020) found a positive effect, which they attributed to firm proactiveness in incorporating transition risk into their risk framework, hence, reversing the potential challenges of regulatory changes (regulatory risks), changes in consumer demand (market risks), and technology dynamics (technological risks). Roncoroni et al. (2021) and Cortes and Straham (2017) found negative impacts, which Li and Pan (2022) explained by linking it to the failure or not of banks to fully incorporate transition risk, of any form, into their strategic and operational decision-making processes.

Palea & Santhià (2022) demonstrate that transition risks linked to policy uncertainty and regulatory tightening exert downward pressure on firm profitability and asset values in the automotive sector. Similarly, Toumi (2025) employed a Bloomberg dataset of firms from 51 countries, comprising 169 financial and non-financial sectors, and found a significant positive effect of climate physical risk on all three financial performance indicators: Tobin's Q, return on assets, and return on equity. Song et al. (2025) confirmed the significant differences in the financial impact of various climate-related risks across 47 sectors in China, revealing both negative and positive effects. The literature indicates that climate-related risk types — physical, regulatory, market, and technological — exert distinct financial pressures. In the automotive sector, these risks influence cash flows, asset valuations, and revenue stability. We therefore hypothesize:

H1. The financial impact of climate-related risks differs significantly across risk types (physical, regulatory, market, and technological).

2.2 Risk value chain

Climate-related risks extend across the entire value chain, propagating both upstream and downstream rather than remaining within a firm's direct operations. Research highlights how disruptions from physical dangers, such as natural hazards or resource shortages, can threaten suppliers and buyers alike (Dasaklis & Pappis, 2013; Furlan et al., 2017), hence underscoring the importance of considering climate-related risks along the value chain. In direct operations, capital outlays for technology and infrastructure remain central (Jin et al., 2025). Empirical studies confirm that cost structures vary depending on where the risk originates along the supply chain (Li et al., 2024; Mao et al., 2017).

The interdependencies across the chain create reciprocal challenges. Poor environmental practices by suppliers can raise indirect emissions and damage reputations downstream (Cousins et al., 2004; Delmas & Montiel, 2009). In addition, Carbon-intensive supply chains may also heighten financial risks if suppliers pass down rising costs from carbon pricing (Lash & Wellington, 2007). Non-compliance may even trigger regulatory shutdowns, pushing firms to prefer suppliers with more substantial climate commitments. Consequently, many companies now demand carbon transparency and embed climate-related criteria into their procurement processes (Jira & Toffel, 2013). Taken together, while risk exposure varies along the chain, the financial implications of climate-related risks remain broadly significant, leading us to propose the following hypothesis:

H2. The financial impact of climate-related risks differs significantly across risk value chains.

Prior studies suggest that the financial materiality of climate risks may depend on the interaction between risk typology and value chain position. For example, regulatory risks such as emission limits may exert greater financial pressure on downstream firms with high consumer visibility and stringent compliance demands, whereas upstream suppliers may internalize hidden costs due to raw material volatility or relocation efforts (Khan & Khan, 2025; Qing et al., 2024). Physical risks, on the other hand, may disproportionately affect firms that rely on climate-vulnerable infrastructure, regardless of their position in the supply chain (Jin et al., 2025; X. Li et al., 2024). Subsequently, we follow from H1 and H2, and hypothesis that:

H3. The interaction between risk type and value chain position has a significantly different effect on financial performance.

2.3 Severity of climate risks

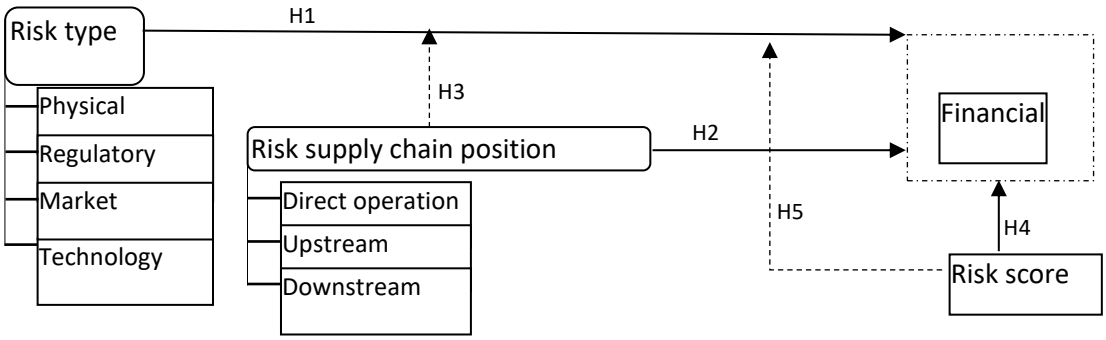
A growing body of empirical research demonstrates that firms with severe climate face valuation penalties, as investors price in future liabilities (Chalabi-Jabado & Ziane, 2024). In contrast, proactive firms with climate strategies tend to receive valuation premiums (Jin et al., 2025).

The risk score of firms is measured by components of risk perception, including risk impact, which encompasses a combination of the relative likelihood of occurrence, time priority, and the relative impact magnitude. Previous studies refer to this composition as risk exposure (X. Li et al., 2024) or risk exposure score (Sakhel, 2017). While studies have examined the effect of climate change exposure on firm value (Almaghrabi, 2023; Jin et al., 2025; Ongsakul et al., 2023), few studies have analyzed the financial impact of climate-related risk severity, while empirical studies on the effect of climate risk score or risk severity on financial implications are lacking. Several empirical studies support the notion that higher climate-related risk scores, whether physical, regulatory, market, or technological, are associated with adverse financial outcomes for firms.

For instance, Jin et al. (2025) found a 4.14% reduction in firm value with a one-standard-deviation increase in climate change exposure in a study of non-financial firms in the Asia-Pacific region. This justifies empirical findings by prior studies on the effect of increased climate risk on firm's vulnerability with resulting increase in cost of capital (Lemma et al., 2019), effect on capital structure (Ahmad et al., 2023; Huang et al., 2022), and reduction in stock market reactions (Hossain & Masum, 2022; Matsumura et al., 2014). Huang et al. (2022) found an adverse effect of climate risk exposure of companies on corporate finance. Similarly, Almaghrabi (2023) found a negative impact on firm cash flow volatility and profitability, while Ongsakul et al. (2023) found erosion of company value among US firms due to firm-specific climate change exposure. These findings support the expectation that climate risk scores have a statistically significant adverse effect on financial performance. Hence, the hypotheses:

H4. There is a direct, negative, and significant financial impact of risk severity (as measured by the risk score) on firms.

Following hypothesis H4, it is essential to consider how the severity of climate risks affects firms differently depending on the type of risk involved. Different risk types, such as physical risks like



flooding or regulatory risks like stricter emissions rules, lead to other costs and financial effects. For example, severe physical risks often require substantial investments in infrastructure, resulting in long-term cash outflows, while severe regulatory risks may lead to immediate compliance costs and penalties. Research indicates that physical risks can sometimes signal future resilience and be viewed positively by markets, whereas severe regulatory risks typically lower a firm's value (Lash & Wellington, 2007; X. Li et al., 2024). In the automotive sector, where supply chains face multiple climate risks, the financial consequences of severe risks vary based on their type. Physical risks may prompt firms to undertake costly supply chain adjustments, while market or technological risks may drive innovation with varying cost and revenue implications. Moreover, enterprise risk management studies highlight that the same severity level can have very different financial impacts depending on whether the risk affects supply continuity, regulatory compliance, or reputation (Delmas & Montiel, 2009; Mao et al., 2017). Thus, the impact of climate risk severity on financial performance depends strongly on the interaction between risk type and severity (Khan & Khan, 2025). Based on the argument regarding the economic impact of risk types and risk severity, we propose the following hypothesis.

H5. The financial impact of climate-related risks varies significantly depending on the interaction between risk type and risk severity (risk score).

In the automotive sector, climate-related risks affect financial performance through interconnected pathways. Physical, regulatory, market, and technological risks vary in their impact depending on a firm's value chain position: upstream, OEM, or downstream. These effects are further shaped by the severity of risks, as measured by their likelihood, timing, and magnitude of impact.

The hypotheses (H1–H5) reflect these relationships, positing both direct effects (H1, H2, H4) and interaction effects (H3, H5) between risk type, value chain position, and risk severity. As shown in Figure 1, the framework illustrates how these dimensions collectively influence financial impacts.

Fig. 1 Conceptual framework: climate-related risks and financial impacts in the automotive value chain

Source: our elaboration

3. Methodology

3.1 Research design and context

This study uses a quantitative, archival approach. We analyze self-reported climate-risk disclosures by automotive-sector firms to examine how risk characteristics relate to financial outcomes. The sample comprises global automotive companies that responded to the Carbon Disclosure Project (CDP) climate questionnaire between 2018 and 2021. The automotive industry is an ideal setting for this investigation because it is highly carbon-intensive and subject to both stringent regulations and rapid technological advancements.

The analysis focuses on one dependent variable, which is the log of the reported financial impact

of a climate-related risk (lnFI). Using a single-outcome design (ANCOVA and robust regression) lets us model risk-type and supply-chain effects while adjusting for continuous covariates. Methodologically, the approach extends Sakhel's (2017) framework on the cost of response by integrating a covariate in a model that captures both direct effects and interactions between risk types, value chain positions, and risk score, offering a more detailed picture of sectoral vulnerabilities and firm-level financial impacts. Our design also enables us to assess how the economic impact of climate-related risks varies by risk type and risk value chain, with subsequent depth, the directional effects, and the magnitude of the risk characteristics on the company's finances.

3.2 Data sources and sample

We used data from the CDP's climate change disclosure database, which collects self-reported information on climate-related risks and opportunities from firms worldwide. We select observations in which the firm's primary activity is in the automobile manufacturing and transportation equipment industries. The selection of the automotive sector ensures consistency with the sector's emission profile, technological transition pressures, and supply chain complexity. The final dataset is an unbalanced panel of firm-year-risk type observations, as firms reported multiple climate-related risk types (e.g., physical, regulatory, market, or technology) for each year, identified as having the potential to have a substantive financial or strategic impact on their business. This repeated and nested structure reflects the reality of how firms experience and report distinct climate risks over time, making the data suitable for interaction-based modeling. We excluded observations missing key variables (financial impact and risk scores). Differences in CDP question formats between 2018–2019 and 2020–2021 data were harmonized during data cleaning.

3.3 Study variables and construction

The key variables in this study capture the types of climate-related risks firms face, their position in the value chain, the estimated financial impact, and the risk characteristics, including the time horizon, likelihood, and magnitude of effects, as determined by questions C2.3a_C2, C2.3a_C3, C2.3a_C7, and C2.3a_C9 (see Appendices A1 and A2). Although the structure of some questions varied slightly across years, the data were harmonized to ensure consistency, using the 2021 format as the reference.

Financial Impact (lnFI)

This is the firm's potential or monetary loss if the risk materializes. CDP responses include either a point estimate (C2.3a_C11) or a reported range (C2.3a_C12 and C2.3a_C13). We take the midpoint of any range. We log transform this to lnFI. This transformation helps normalize the skewed distribution of monetary values. A higher lnFI indicates a larger potential loss (a worse outcome).

Risk type (RiskT)

This is a categorical variable with four levels: physical, regulatory, market, and technological risk. This categorization is based on how risk types are captured in the latest CDP database (2020 and 2021). In our study, acute physical and chronic physical risks are combined into "physical risk"; current regulations, emerging regulations, and legal issues into "regulatory risk"; market risks and reputation into "market risk"; and technology-related issues remain . This categorization reflects recent updates in climate risk reporting frameworks and is consistent with the emerging academic consensus on multidimensional climate risk typologies (e.g., Li et al., 2024; Busch et al., 2022). The risk data for 2018 and 2019 are physical and transition risk. However, we used the data on the primary climate-related risk drivers (C2.3a_C4) in recategorizing the risk types to align with the 2020-2021 format.

Risk value chain position (rvchain)

This variable identifies a firm's position in the value chain as upstream (e.g., suppliers), in direct

operation (including the midstream or OEM segment), and downstream. To ensure consistency across years, the 2018 and 2019 data were reclassified to align with the 2020–2021 structure, grouping "supply chain" and "investment" under upstream, and "customer" under downstream.

Climate risk score

The risk score (riskE) is a composite metric derived using three dimensions reported by firms: time horizon (rT), likelihood of occurrence (rL), and magnitude of financial impact (rM), based on responses to CDP questions C2.3a_C7 to C2.3a_C9. In the survey, each parameter is assessed using predefined Likert-type scales, although the number of scale points varies by parameter. For instance, the likelihood of occurrence is rated on an 8-point scale ranging from "exceptionally unlikely" to "virtually certain." At the same time, the magnitude of impact is evaluated on a 5-point scale, ranging from "low" to "high", and the time frame is evaluated on a 4-point scale, ranging from "unknown" to "long-term" . Following a normalized scoring approach, each component is expressed as a fraction of its maximum possible value on the corresponding Likert scale, as shown in Equation (1). For example, a magnitude score of 3 on a 5-point scale is computed as 3/5 = 0.6, resulting in a normalized score between 0 and 1.

$$T_{(k,t,i)}=(〖rT〗_{(k,t,i)}/N_{rT}) ; L_{(k,t,i)}=(〖rL〗_{(k,t,i)}/N_{rL}) ; \text{and } M_{(k,t,i)}=(〖rM〗_{(k,t,i)}/N_{rM}), \quad (1)$$

where T_(k,t,i) refer to the normalized risk time horizon (rT) of risk type k in year t for company i, and N denote the maximum possible value on the corresponding Likert scale.

Because our study considers the risk value chain in its analysis, we deviate from computing a single score for each risk type, as in Sakhel (2017) and Li et al. (2024), to computing risk scores for each risk type within each risk value chain. Our data structure assumes a many-to-many form, where a particular company can have multiple entries of a specific kind of risk, as this may relate to different value chains; hence, the impacts on finance may vary for the same risk type across various value chains. We compute a composite risk score for each identified risk type, defined as the product of the normalized time, likelihood, and magnitude scores, as depicted in Equation (2).

$$〖RiskS〗_{(k,t,i)}=T_{(k,t,i,)}*L_{(k,t,i)}*M_{(k,t,i)}, \quad (2)$$

where 〖riskS〗_(k,t,i) is the composite risk score for risk type k in year t for firm i, hereafter referred to as the risk score for simplicity. This enables cross-risk comparability of severity levels and provides a continuous measure of climate vulnerability, which serves as a covariate in the empirical model.

3.4 Analytical strategy and model selection

Our primary analysis employs analysis of covariance (ANCOVA) based on our study variables and the objective of examining whether different risk types significantly impact a company's finances differently, while controlling for risk severity (measured by risk score), a continuous variable. Interaction terms between risk type and chain position are included to test H3, and between risk type and risk severity to allow severity to have differential effects by risk. ANCOVA adjusts for the impact of Risk Score (risk severity) while comparing mean lnFI across groups. This yields tests of our main hypotheses: for example, a significant main effect of Risk Type would support H1.

We first checked ANCOVA assumptions. Univariate normality of lnFI was acceptable. Homogeneity of variances across groups was confirmed (Levene's test $p>0.10$) after log transformation. However, a Breusch-Pagan test indicated mild heteroskedasticity ($p\approx0.03$). To ensure robust inference, we supplemented ANCOVA with robust regression models using the same predictors (risk type, value chain, severity, and interactions). Robust regression downweighs outliers

and relaxes normality assumptions, providing a robustness check on significance and coefficient estimates.

The adopted regression model is expressed in equations (3) and (4). We added the interaction term between RiskT and riskS in (4) to test whether the effect of risk scores differed by type of risk.

$$\ln〖FI〗_{itk}=ß_0+ß_1\ 〖RiskT〗_k+ß_2\ 〖rvchain〗_{it}+ß_3\ (〖RiskT〗_{ik}*〖rvchain〗_{ik})+ß_4\ 〖RiskS〗_{itk}+ε_{itk} \quad (3)$$

$$\ln〖FI〗_{itk}=ß_0+ß_1\ 〖RiskT〗_k+ß_2\ 〖rvchain〗_{it}+ß_3\ (〖RiskT〗_{ik}*〖rvchain〗_{ik})+ß_4\ 〖RiskS〗_{itk}+\ ß_5\ (〖RiskT〗_{ik}*〖RiskS〗_{ik})+ε_{itk} \quad (4)$$

where y_itk is the outcome variable y (i.e., lnFI) of firm i in year t for risk type k; ß_0 is the intercept and ß_i (i=1, 2, …, 5) is the effect of the respective predictor on the outcome variables (lnFI); 〖RiskS〗_itk is a standardized risk score, and ε_itk is the error term.

All analyses were performed in Stata 15. We report both ANCOVA F-tests (Table 3) and the robust regression coefficients (Table 4), focusing on statistically significant findings ($p<0.05$). In interpreting coefficients, recall that lnFI is log loss: a positive coefficient means the factor increases the logged financial impact (larger losses), whereas a negative coefficient means it reduces lnFI (i.e., lower losses, relatively better outcome).

4. Empirical results

4.1 Descriptive statistics

The descriptive results in Tables 1 and 2 reveal that both financial impact and risk severity vary by risk type and value chain segment. Technology-related risks have the highest average financial impact and severity, particularly in direct operations and downstream. Physical and Regulatory risks are more prevalent in direct operations, while Market risks are concentrated downstream. Financial impact and risk severity are moderately positively correlated (r = 0.30, see Table 3A), suggesting that more severe risks tend to have higher financial consequences. Most risk cases are reported in direct operations, highlighting this segment as a key vulnerability point in the value chain.

4.2 Analysis of covariance results

From Table 3, we find significant main effects of RiskT [$F(3, 394) = 2.63$, $p = 0.049$]. This supports H1, that different risk categories yield different financial impacts. The covariate RiskS is highly significant [$F(1, 394)=35.86$, $p<0.001$], indicating that, across the board, firms projecting more severe risk report larger losses. In contrast, the main effect of value chain position is not significant, contrary to H2's position that chain position alone does not change impact.

Of the interactions, the RiskT × RiskS interaction is significant [$F(3,394)=3.36$, $p=0.019$]. This means the effect of risk severity on lnFI differs by risk category, suggesting severity amplifies impacts more strongly for some risks than others. The RiskT × rvchain interaction is marginal [$F(6,394) = 2.09$, $p = 0.053$], suggesting some variation in how certain risks affect different segments, but this is at the threshold of conventional significance. The ANCOVA confirms that risk type and severity are key drivers of financial impact, while simple chain-position differences are weak.

4.3 Robust Regression results

To probe these relationships in detail, the findings from Table 3 and Table 4 provide nuanced insights into how climate-related risks, risk value chain, and risk severity affect financial impact. Risk severity emerged as the strongest predictor of financial impact across all models, with a highly significant and positive effect. This underscores that, irrespective of risk category or supply chain position, more severe risks are associated with greater financial costs.

Table 4 offers more granular insights into how different types of risks affect financial outcomes, both independently and in combination with the risk value chain and severity. M4 and M5 are the results for (3) and (4). M1 to M3 are the base models, which include the interaction between RiskT and the rvchain in M3. In M4, the physical and regulatory risk types are consistently associated with higher financial impact relative to climate-related technology risk (the baseline category). For instance, physical risks exhibit a statistically significant coefficient of 5.280 ($p < 0.05$), suggesting that physical climate-related risks can have disproportionately large financial consequences relative to technology risks.

The rvchain is not significant and aligns with the ANOVA outcome. In M4, however, companies in direct operations (Coefficient = 3.090, $p < 0.05$) face higher financial impacts compared to those

in downstream positions. The closer a firm is to the point of climate exposure (e.g., production or resource extraction), the greater the potential financial burden.

The RiskT x rvchain terms indicate that a value chain position strongly influences the financial impact of different risks. Across models M4–M5, all interaction coefficients are negative, suggesting that being upstream or in direct operations reduces the marginal impact of non-technology risks compared to downstream firms. This effect is especially pronounced and significant for Regulation × Direct operation (M4: -3.199*, M5: -4.118**) and Market × Upstream (M4: -4.246*, M5: -5.171**), indicating that OEMs are more exposed to regulatory shocks. At the same time, upstream suppliers are relatively shielded from market shocks. Physical risk interactions are consistently negative but less robust, implying weaker moderating effects. Overall, the results indicate that not all risks are transmitted evenly across the value chain, and the combination of risk type and chain position is crucial in explaining financial vulnerability.

The RiskT x RiskS interactions reveal that regulatory risks become particularly financially burdensome as severity increases. Specifically, Regulatory × RiskS was 10.123 ($p<0.01$), highlighting a multiplicative effect between regulation and severity. This suggests that firms exposed to regulatory uncertainty or stringent climate policy may face compounding financial effects when those risks are also severe.

Source: our elaboration

Figure 2 displays the predictive margins of financial impact (lnFI) by risk type and value chain position, based on the interaction effects from the regression model. The analysis reveals important distinctions in financial exposure across different segments of the value chain. Specifically, downstream firms report the highest predicted financial losses in relation to physical risks, while upstream firms appear more sensitive to technology-related risks. Direct operations, by contrast, exhibit more stable financial impacts across all risk types.

Notably, the non-parallel trend lines confirm the presence of an interaction effect between risk type and value chain position, echoing the marginally significant ANCOVA interaction result. This finding highlights that the impact of climate-related risks on financial performance is not uniform, but varies substantially depending on a firm's position along the value chain and the nature of the risk it faces. These insights underscore the importance of developing targeted risk management strategies that are tailored to both risk typology and operational context.

Fig. 2 Predicted margins of financial impact by risk type and risk value chain

5. Discussion

The findings of this study provide new empirical evidence on how climate-related risks differentially influence financial impact in the automotive industry, and how both risk value chain and risk severity shape these effects. Consistent with H1, the ANCOVA results reveal that risk type has a significant effect on financial impact, even after controlling for severity. This aligns with prior research suggesting that physical and regulatory climate-related risks tend to exert disproportionate financial pressure on firms (Dietz et al., 2016; Krueger et al., 2020). The consistently significant impacts from physical risks align with industry observations that manufacturers are vulnerable to extreme events. When floods, storms, or other hazards strike, they can halt assembly lines and damage expensive machinery, resulting in significant revenue losses and costly repairs. This is well-documented: severe weather disruptions have repeatedly forced automakers to suspend production, supporting our result that physical risks entail large financial losses. Regulatory risks also impose significant burdens. A tightening of emission standards or the introduction of new carbon taxes can strand existing assets and increase compliance costs, which our results confirm through the strong positive effects on regulatory risk (especially at high severity). This echoes the notion that climate policy uncertainty escalates financial risks. For instance, Engau & Hoffmann (2011) argue that unpredictable environmental regulations deter investment; our finding that regulatory risk interacted with severity to magnify losses is consistent with that view. In essence, when firms judge a regulation to be highly probable and impactful, the compounded effect on their balance sheets is severe.

The absence of a significant main effect for value chain contradicts H2 and aligns with earlier studies (Li et al., 2024; Mao et al., 2017), echoing findings from the supply chain literature that risk

impact depends on the interaction between value chain position and risk type rather than chain position alone (see also M5 of Table 4). For M4, the results on the value chain are rather illuminating. Only Direct-operation firms (OEMs) consistently report relatively higher financial impact, reflecting their capital-intensive plants in potentially hazard-prone locations, tight production schedules, and limited flexibility to climate shocks. For example, a flooded factory halts output but incurs fixed costs.

The results also support H3. In contrast, the negative Market x Upstream effect suggests suppliers are more resilient to pure market shocks. With multiple customers, lower fixed costs, and diversified sales, suppliers can adjust more easily to changing market conditions. This supports the findings of Khan & Khan (2025), Qing et al. (2024), Jin et al. (2025), and Li et al. (2024) on physical risks and RVChain. These findings highlight that shocks affect tiers differently, underscoring the need for targeted risk management.

The strong and positive covariate effect of risk severity corroborates the fourth hypothesis (H4) and is consistent with earlier studies, which demonstrate that the magnitude of losses escalates as risks intensify (Bolton et al., 2020; Bolton & Kacperczyk, 2021; Gölgeci et al., 2019). Our results also underscore the overriding importance of risk severity. Across all models, a higher composite risk score dramatically increased lnFI. These findings corroborate those of Huang et al. (2022) on the negative financial implications of risk severity. This confirms that firms' own assessments of risk magnitude and likelihood are meaningful predictors of economic outcomes. It suggests that companies' internal risk evaluations carry weight: when a risk is rated as high-severity, the expected financial impact is substantially larger. This aligns with the broader finance literature, which suggests that firms facing extreme, likely hazards suffer greater valuation penalties (Linnenluecke et al., 2013). In practical terms, it highlights that detailed climate risk assessments (as recommended by frameworks like TCFD) are vital. Firms need granular, quantitative estimates of the potential severity of each risk.

The interaction patterns deepen this understanding. The significant RiskT × RiskS effect suggests that severity amplifies financial losses more sharply for some risk categories, particularly regulatory risks, than for others. This is in line with evidence that regulatory shocks, such as sudden compliance costs or stringent emissions caps, can disproportionately strain financial performance when severity is high.

The marginally significant RiskT × rvchain interaction, supported by robust regression results, further indicates that certain combinations of risk type and value chain stage result in either heightened or reduced financial impacts relative to the baseline (technology risk × downstream). Negative coefficients for interactions such as regulatory × direct operations or market × upstream imply that, compared to downstream firms facing technology risks, these groups experience relatively lower financial costs. Theoretically, this suggests that specific operational contexts may afford structural or strategic buffers against specific risk categories, possibly due to upstream flexibility in sourcing or more direct operational control over mitigation measures. Empirically, this partially supports H3 by confirming that the financial burden of climate risks depends on the intersection of risk type and chain position. However, the direction of impact may sometimes run counter to expectations based on generalized vulnerability models. In the context of existing research, our findings contribute several insights. They extend findings like those of Zhang et al. (2023), who report that general climate risk tends to reduce returns. We show that this effect is concentrated in specific risk categories (physical and regulatory) and contingent on firm attributes. They also complement literature (Er Kara et al., 2021; Palea & Santhià, 2022) showing that proactive climate management correlates with better financial performance. In this sense, our evidence suggests that firms experiencing the most significant economic impacts may be those that have not effectively hedged or adapted to their climate-related risks. In contrast, those with lower (or even negative) coefficients may be managing risk effectively. For example, the supplier firms showing a negative impact under market risk might have already taken measures (like flexible contracts) to buffer those effects.

Taken together, these findings bridge and extend the literature by demonstrating that climate-

related financial impacts in the automotive sector are not only risk- and severity-dependent but also contingent upon operational positioning. While prior work has established the differentiated nature of climate risk exposure across sectors, our results highlight that within a single industry, these differences are further shaped by the nuanced interactions between the typology of climate risks, risk severity, and the location within the value chain where the firm operates. This highlights the importance of developing targeted, context-specific adaptation and mitigation strategies, rather than adopting one-size-fits-all approaches.

6. Conclusion and Implications

6.1 Conclusion

This study aimed to investigate how different types of climate-related risks —physical, regulatory, market, and technological—impact the financial performance of firms in the automotive sector, and how these effects are influenced by value-chain position and the perceived severity of risks. Using firm-level disclosures from CDP (2018–2021) and applying ANCOVA and robust regression models, we provide systematic evidence that bridges risk typology, value chain dynamics, and severity assessments within a single analytical framework.

This study provides robust empirical evidence on how climate-related risks —physical, regulatory, market, and technological —interact with value-chain position and perceived severity to shape the financial impacts faced by firms in the automotive sector. The findings reveal that physical and regulatory risks exert the greatest financial toll, particularly when severity is high, underscoring the disruptive potential of extreme weather events and stringent policy shifts. In contrast, market and technological risks tend to have more minor or context-dependent effects, with certain firm positions, such as upstream suppliers under market risk, experiencing relative insulation.

Notably, risk severity emerged as the most consistent and powerful predictor of financial impact, confirming that firms' own assessments of a risk's likelihood, magnitude, and time horizon taken together are meaningful indicators of potential losses. These results extend beyond generalized sectoral vulnerability models by demonstrating that the materiality of climate risks is contingent not only on risk type and severity but also on the operational role a firm plays in the value chain.

Compared to earlier studies, which have predominantly focused on financial and energy firms or examined climate risks in isolation, this research contributes a sector-specific and value-chain-sensitive analysis of the automotive industry, an industry central to global decarbonization efforts. By jointly modeling risk type, value-chain position, and risk severity, we move beyond generalized sectoral vulnerability models to offer more granular and empirically grounded evidence of financial materiality. This extends prior findings, including those of Dasaklis & Pappis (2013), Li et al. (2024), and Jin et al. (2025), by demonstrating that climate risk impacts are heterogeneous, contingent, and shaped by firms' operational roles in the supply chain.

By integrating these dimensions, this study advances the literature on cleaner production and climate finance, offering a more granular understanding of where and how climate risks become financially material. The evidence underscores that one-size-fits-all approaches to climate risk management are insufficient. Instead, industry actors must adopt targeted, position-specific strategies to strengthen resilience and protect long-term financial performance.

6.2 Managerial and Policy Implications

From a managerial perspective, the heterogeneity of climate risk impacts demands differentiated strategies across the value chain. For original equipment manufacturers (OEMs) operating at the point of production, investments in physical resilience such as flood defenses, asset hardening, and production flexibility are critical. Firms with high exposure to regulatory risk should strengthen compliance readiness, engage proactively with policymakers, and integrate adaptive planning into capital investment decisions. Upstream suppliers, particularly those relatively shielded from certain

market risks, may prioritize supply diversification, contractual flexibility, and customer portfolio management to buffer demand shocks.

For policymakers and investors, these results underscore the need for targeted and nuanced intervention. Large OEMs may benefit from targeted incentives for resilience upgrades and decarbonization efforts, while smaller suppliers could require financial support to manage market volatility. Climate disclosure frameworks, including the CDP and the EU's Corporate Sustainability Reporting Directive, should encourage firms to report not only emissions and aggregate risks but also the interaction between value-chain position and risk type. This information is material for capital allocation, risk pricing, and designing policies that maximize sectoral stability during the climate transition.

6.3 Limitations and Directions for Future Research

This research has some limitations. First, it relies on self-reported CDP disclosures, which may vary in accuracy or reflect strategic bias. Future work could triangulate these with independent datasets on actual financial losses from specific climate events or market shifts. Second, the analysis is confined to the automotive sector; extending the framework to other industries could reveal whether similar interaction patterns hold in sectors with different asset structures or supply-chain dynamics. Comparative, multi-industry studies could thus broaden the external validity of these findings.

The Corruption Configuration Cube (CCC): A Configurational Governance Framework for Corruption Analysis

SERGIO ERNESTO VALENTINI[1]

1. Introduction

Corruption is increasingly recognized not only as a legal or ethical deviation, but as a structural threat to economic sustainability, organizational legitimacy, and governance resilience. Across both public and private sectors, corruption distorts resource allocation, undermines institutional trust, inflates transaction costs, and weakens long-term value creation processes (Bahoo et al., 2020; OECD, 2023). Within management and governance research, corruption has traditionally been analysed through compliance-oriented and institutional perspectives, primarily focusing on monitoring systems, regulatory enforcement, and incentive misalignment (Klitgaard, 1988; Johnston, 2005). While these approaches have generated important insights, they often conceptualize corruption as a discrete governance failure rather than as a multidimensional organizational phenomenon embedded within decision-making structures, strategic adaptation processes, and evolving systems of moral agency.

Recent transformations in the global governance environment further amplify these limitations. Organizations increasingly operate within fragmented institutional settings characterized by geopolitical instability, regulatory asymmetries, stakeholder pressure, and overlapping governance regimes. Simultaneously, the growing diffusion of artificial intelligence, algorithmic management systems, and digitally mediated decision architectures is reshaping how organizational decisions are produced, delegated, and controlled. Emerging research on digital governance and AI-mediated organizational systems suggests that these transformations generate new integrity vulnerabilities, including opacity in decision-making, diffusion of accountability, and forms of moral distancing within technologically mediated governance environments (Martin, 2019; Kellogg et al., 2020; Raisch & Krakowski, 2021). In such contexts, corruption can no longer be interpreted exclusively as intentional misconduct by isolated individuals but increasingly appears as a systemic governance pathology emerging from the interaction between organizational incentives, institutional pressures, technological mediation, and weakened ethical oversight.

At the same time, existing corruption models remain only partially equipped to capture these evolving dynamics. Classical analytical frameworks, such as the Fraud Triangle (Cressey, 1953), the Corruption Triangle, the Corruption Diamond (Johnston, 2005), and institutional opportunity-structure models (Klitgaard, 1988; Mungiu-Pippidi, 2015), have contributed significantly to explaining corruption through opportunity architectures, incentive systems, rationalization mechanisms, and governance weaknesses. More recent streams of research in behavioural ethics and organizational misconduct have also demonstrated how unethical practices may become normalized through moral disengagement, bounded ethicality, and organizational cultures that prioritize performance over ethical reflexivity (Bandura, 1999; Ashforth & Anand, 2003; Treviño et al., 2006). However, despite their explanatory relevance, these approaches tend to under-theorize coercive corruption dynamics, fear-based compliance, blackmail mechanisms, and the progressive erosion of moral agency within complex governance environments.

This limitation becomes particularly relevant in contexts where corruption is not driven primarily by voluntary exchange or opportunistic calculation, but by asymmetrical power relations, coercive pressures, reputational vulnerability, and governance-induced fear. Existing management literature has only marginally explored how corruption may emerge through mechanisms of domination, forced compliance, or strategic adaptation under conditions of organizational insecurity. As a result,

[1] Transparency International Italia, Email Address: sergio.valentini@gmail.com

corruption is frequently treated as a transactional or behavioural anomaly rather than as a multidimensional governance configuration involving agency structures, legitimacy of instruments, and power asymmetries within organizational systems.

To address this gap, the present paper introduces the Corruption Configuration Cube (CCC), a multidimensional conceptual governance framework designed to analyse corruption as a configurational governance phenomenon rather than as an isolated act or compliance deviation. The framework integrates three analytical dimensions: (1) agency structure, ranging from coercion to voluntariness; (2) legitimacy of instruments, ranging from formally legitimate to intrinsically illegitimate means; and (3) transactional directionality, ranging from offer-based to request-based corruption. By combining these dimensions within a unified configurational architecture, the CCC enables corruption to be conceptualized as a heterogeneous strategic and governance phenomenon characterized by different organizational dynamics, sustainability risks, and integrity failures.

The paper contributes to the literature in three principal ways.

First, it extends existing corruption research by integrating coercion, fear dynamics, and moral agency governance into corruption analysis, dimensions that remain comparatively underdeveloped within management studies.

Second, it contributes to governance and sustainability research by reframing corruption as a systemic sustainability failure linked to organizational design, strategic incentives, and decision architectures rather than solely to compliance deficiencies.

Third, the paper advances emerging debates on governance complexity and the agentic economy by exploring how digitally mediated decision systems and distributed organizational agency may reshape corruption vulnerabilities in contemporary organizations.

The remainder of the paper is structured as follows. The next section reviews the principal corruption models within management and governance literature and identifies the main conceptual limitations of existing approaches. The paper then introduces the methodological positioning of the study and develops the Corruption Configuration Cube (CCC) framework. Subsequently, the analysis discusses the governance and sustainability implications of the model, including its managerial relevance and potential empirical operationalization. The final section concludes by outlining the theoretical contributions, limitations, and future research directions of the study.

2. Literature Review and Theoretical Gap

2.1 Corruption in Management and Governance Research

Corruption has traditionally been examined across economics, political science, criminology, and public administration as a phenomenon associated with institutional inefficiency, abuse of power, and regulatory failure. Within management and governance research, however, corruption has progressively evolved from being considered a peripheral compliance issue to being recognized as a strategic and organizational challenge capable of undermining long-term value creation, stakeholder trust, and sustainability performance (Bahoo et al., 2020; OECD, 2023).

Early management approaches largely interpreted corruption through agency and control perspectives, emphasizing opportunistic managerial behaviour, information asymmetries, and failures in monitoring systems (Klitgaard, 1988). In this view, corruption emerges when organizational actors exploit discretionary power under conditions of weak accountability and insufficient oversight. Consequently, anti-corruption efforts have historically focused on compliance architectures, internal controls, auditing systems, and regulatory enforcement mechanisms.

Although these approaches remain highly relevant, contemporary governance environments have exposed their limitations. Organizations increasingly operate across fragmented institutional settings characterized by regulatory asymmetries, geopolitical instability, stakeholder activism, and complex transnational supply chains. At the same time, the expansion of ESG governance and sustainability-oriented management has broadened the understanding of corruption beyond legal misconduct,

reframing it as a systemic threat to organizational legitimacy and sustainable development (Bahoo et al., 2020; Shaheer et al., 2019).

Recent research in behavioural ethics and organizational misconduct has further demonstrated that corruption cannot be fully explained through formal control deficiencies alone. Studies on moral disengagement, ethical fading, and normalization processes show how organizational cultures, performance pressures, and cognitive framing mechanisms may progressively legitimize unethical conduct within otherwise formally compliant systems (Bandura, 1999; Tenbrunsel & Messick, 2004; Ashforth & Anand, 2003). Corruption increasingly appears not as an isolated deviation, but as a phenomenon deeply embedded within organizational routines, strategic incentives, and governance architectures.

This shift becomes particularly relevant within emerging digitally mediated governance environments. The diffusion of artificial intelligence, algorithmic management systems, and data-driven organizational decision-making introduces new forms of opacity, distributed accountability, and moral distancing within corporate governance structures (Martin, 2019; Raisch & Krakowski, 2021). In such contexts, corruption risks may emerge not only from intentional misconduct, but from systemic vulnerabilities embedded within technologically mediated decision architectures that prioritize efficiency, optimization, or competitive survival over ethical reflexivity.

Despite the growing sophistication of corruption research, much of the management literature still conceptualizes corruption primarily through voluntary exchange logics, opportunistic incentives, or institutional weakness. Comparatively limited attention has been devoted to coercive corruption dynamics, fear-based compliance, blackmail mechanisms, and the erosion of moral agency under conditions of organizational pressure and asymmetrical power relations. This omission becomes increasingly problematic in governance environments where corruption operates not only through incentives and opportunity, but also through domination, retaliation, and coercive adaptation processes. Contemporary ESG and sustainability debates have further expanded the scope of corruption research by emphasizing the relationship between integrity failures, stakeholder legitimacy, and long-term organizational resilience. Corruption increasingly appears not only as a legal or reputational issue, but also as a sustainability risk capable of undermining environmental governance, social trust, and responsible value creation processes. This perspective reinforces the need for governance frameworks capable of analysing corruption as a multidimensional organizational phenomenon linked to systemic governance quality, rather than merely to compliance deficiencies, or isolated individual behaviour.

2.2 Classical Corruption Models

The international literature has produced several influential analytical models aimed at explaining the emergence and persistence of corruption across individual, organizational, and institutional contexts. Although these frameworks differ in scope and level of analysis, they collectively contributed to establishing corruption as a structured governance phenomenon rather than merely an individual ethical failure. One of the foundational models is the Fraud Triangle[2] developed by Cressey (1953), which explains fraudulent behaviour through the interaction of three conditions: pressure, opportunity, and rationalization. According to this framework, corruption becomes possible when individuals experience situational pressures, encounter organizational opportunities for misconduct, and cognitively justify unethical behaviour through rationalization mechanisms. The model has had

[2] The Fraud Triangle *(Cressey, 1953)* is individual-centred, approaching fraud from a criminological micro-level of analysis It explains unethical behaviour as a product of individual moral reasoning under constraint. Widely used in auditing, compliance, internal control, it's suited to analysing non-systemic or episodic corruption and financial fraud.
. It identifies three necessary conditions for fraudulent or corrupt behaviour:
- Pressure / Motivation: Economic needs, professional pressure, personal ambitions, or organizational stressors that lead individuals to consider illicit behaviour as a viable option.
- Opportunity: Weak internal controls, lack of segregation of duties, opacity of procedures, or technical possibilities that enable misconduct without immediate detection.
- Rationalization: Moral or cognitive justifications that allow individuals to neutralize ethical dissonance.

a major influence on auditing, compliance, and corporate governance research because of its simplicity and operational applicability. Subsequent developments adapted this logic to broader corruption contexts. The Corruption Triangle[3] shifted attention from moral rationalization toward strategic calculation by emphasizing opportunity, perceived risk, and expected benefit. This perspective conceptualizes corruption as a decision-making process shaped by cost-benefit evaluations under conditions of imperfect accountability and enforcement. The model proved particularly influential in public administration and procurement studies, where corruption is often analysed as an adaptive response to incentive structures and regulatory weaknesses.

More systemic approaches emerged through the Corruption Diamond[4]proposed by Johnston (2005), which conceptualizes corruption as the outcome of interacting structural conditions involving opportunities, incentives, control systems, and social norms. Unlike individual-centered approaches, the Diamond highlights how corruption may become institutionally embedded within political systems, organizational networks, and informal governance structures. This perspective contributed significantly to comparative corruption research by showing how different "corruption regimes" emerge from distinct institutional and cultural configurations.

Similarly, institutional opportunity-structure models, particularly those associated with Klitgaard[5] (1988) and later developed by Mungiu-Pippidi (2015), explain corruption through the interaction of monopoly power, discretionary authority, and weak accountability systems. These approaches conceptualize corruption as a structural governance pathology generated by institutional configurations that systematically enable misconduct. Their relevance lies in shifting anti-corruption analysis from moral exhortation toward governance design and institutional reform.

Collectively, these models have generated major theoretical and practical advances. They demonstrate that corruption is shaped by incentives, organizational structures, social norms, governance architectures, and cognitive rationalization processes. Moreover, they have informed anti-corruption strategies focused on transparency, compliance, accountability, and institutional strengthening.

However, despite their explanatory power, classical corruption models share several limitations. First, they predominantly conceptualize corruption as a voluntary or incentive-driven phenomenon, implicitly assuming relatively symmetrical agency relations between actors. Second, they tend to focus on opportunity structures and strategic calculation while underexploring how fear, coercion, retaliation, and domination shape corrupt behaviour. Third, they frequently treat governance failures

---

[3] *The Corruption Triangle* adapts Cressey's framework to administrative and political corruption, shifting the analytical focus from moral justification to strategic calculation, from an individual and organizational point of view, as a decision-oriented model. The model foregrounds power, incentives, and strategic behaviour over moral rationalization. It is particularly effective in analysing public-sector corruption and procurement, and identifies actionable intervention points: reducing opportunities, increasing perceived risk, and limiting benefits. The core elements of the triangle are:

- Opportunity: The practical ability to influence decisions or extract favours due to discretionary power, procedural opacity, or control deficiencies.
- Perceived Risk: The subjective assessment of the likelihood of detection and sanction (not the actual risk).
- Expected Benefit: Economic, political, personal, or organizational gains resulting from corrupt actions.

[4] The Corruption Diamond *(Johnston, 2005)* conceptualizes corruption as a property of interacting structural factors rather than individual deviance. It focuses on four dimensions of systemic, political-institutional drivers and enablers:

- Opportunities: Vulnerable public resources, regulatory assets, privileged access, and institutional weaknesses.
- Incentives Pressures: Economic interests, distorted political competition, clientelist networks, and elite collusion.
- Control + Accountability: Enforcement institution's effectiveness, independence of judiciary, media, civil society.
- Norms + Culture: Social tolerance of favoritism, gift-giving, nepotism, informal practices. This enables cross- country comparisons to identify distinct corruption regimes and inform long-term institutional reform strategies.

[5] The Corruption Opportunity Structure framework *(Klitgaard; Mungiu-Pippidi; Heywood)* approaches corruption from an institutional viewpoint, explaining corruption as a function of configurations that generate opportunities for misconduct. Identifying high-risk sectors and processes, this model serves as a diagnostic tool for institutional assessment and forms the basis of prevention policies focused on structural reform and it builds upon Klitgaard's corruption formula: ***Corruption = Monopoly of Power + Discretion - Accountability***

- Monopoly: Concentration of decision-making authority and lack of competition or alternatives.
- Discretion: Wide margins of interpretation, opaque procedures, and personalized decision-making.
- Accountability: Effectiveness of audits, transparency mechanisms, judicial enforcement, media oversight, and whistleblowing systems.

as problems of insufficient monitoring or institutional weakness rather than as failures in the governance of moral agency and decision architectures.

As governance systems become increasingly complex, technologically mediated, and politically fragmented, these limitations suggest the need for conceptual frameworks capable of integrating structural, cognitive, relational, and coercive dimensions within a unified analytical perspective.

Table 1. Comparative Positioning of Classical Corruption Models and the CCC

Model	Level of Analysis	Core Dimensions	Main Strengths
Fraud Triangle	Individual	Pressure - Opportunity - Rationalization	Simplicity; useful for audits and compliance
Corruption Triangle	Individual / Organizational	Opportunity - Risk - Benefit	Effective for public decision-making and procurement
Corruption Diamond	Systemic	Opportunity - Incentives - Control - Norms	Strong for comparative and macro-level analysis
Opportunity Structure	Institutional	Monopoly - Discretion - Accountability	Ideal for risk mapping and policy design

CCC Positioning vs existing literature (Author's elaboration)

2.3 The Overlooked Dimension: Coercion, Fear, and Moral Agency Collapse

A major limitation of existing corruption research concerns the under-theorization of coercive and fear-based corruption dynamics. Most classical corruption models implicitly assume that corrupt exchanges are fundamentally voluntary, incentive-driven, or strategically opportunistic. Even when pressure is acknowledged, it is typically interpreted as economic stress, performance pressure, or institutional incentive distortion rather than as coercive domination or forced compliance. This approach endures despite the extensive criminological literature and judicial evidence establishing corruption as the primary instrument and strategic *modus operandi* through which criminal organizations and organized crime cartels operate, infiltrating legitimate markets and subverting competitive integrity.

Both empirical evidence and emerging governance research suggest that corruption frequently operates through mechanisms of intimidation, retaliation, reputational blackmail, extortion, and asymmetrical power dependence. In such contexts, organizational actors may engage in corrupt conduct not because they actively seek illicit advantage, but because they perceive compliance as necessary for professional survival, organizational belonging, or protection against retaliation.

Research on moral disengagement and ethical fading partially addresses these dynamics by showing how individuals cognitively neutralize ethical responsibility under organizational pressure (Bandura, 1999; Tenbrunsel & Messick, 2004). Similarly, Ashforth and Anand (2003) demonstrated how corruption may become normalized through institutional routines and collective rationalization processes. Nevertheless, these approaches still focus predominantly on normalization and rationalization rather than on coercive governance structures themselves.

This omission becomes increasingly problematic in contemporary governance environments characterized by heightened uncertainty, organizational insecurity, and concentrated power asymmetries. Under such conditions, corruption may emerge as a defensive adaptation mechanism rather than as a purely opportunistic choice. Fear of exclusion, career retaliation, reputational destruction, or economic marginalization can progressively erode moral agency, encouraging individuals to prioritize short-term survival over long-term ethical commitments (Valentini, 2026).

The issue is particularly relevant in relation to whistleblowing systems and organizational silence. Studies on organizational misconduct (Kish-Gephart et al., 2024) increasingly show that when governance systems fail to protect dissent, fear itself becomes a governance mechanism capable of sustaining corrupt practices through implicit coercion and collective conformity (Molds, 2023). Corruption operates not only through rewards and incentives, but also through vulnerability, dependency, and domination (Schmid et al., 2022).

Furthermore, emerging forms of digitally mediated governance may intensify these dynamics. Algorithmic management systems, opaque decision infrastructures, and AI-assisted performance

evaluation processes can contribute to the diffusion of accountability and moral distancing, making it more difficult for organizational actors to identify responsibility, resist unethical directives, or challenge corrupt practices. In such contexts, corruption increasingly appears as a systemic governance pathology embedded within organizational decision architectures rather than solely as intentional individual misconduct.

These developments reveal a significant theoretical gap within existing corruption literature. While current models explain how corruption becomes possible, they insufficiently explain how governance systems progressively weaken moral agency, normalize coercive adaptation, and generate corruption through fear-based organizational dynamics.

Recent research on organizational moral agency further supports the relevance of governance structures in shaping ethical conduct. Vriens et al. (2024) demonstrate that organizational architectures characterized by excessive fragmentation, formalization, and functional separation may weaken individuals' capacity for moral deliberation and ethical responsibility. Their findings suggest that governance systems themselves can either support or undermine moral agency within organizations. This perspective is particularly relevant for corruption analysis because it shifts attention from isolated unethical actors toward organizational configurations capable of progressively normalizing ethical disengagement and compliance under pressure.

2.4 Research Gap and Conceptual Need for the Corruption Configuration Cube (CCC)

The preceding discussion highlights an important limitation within contemporary corruption research. Existing analytical models have significantly advanced the understanding of corruption by identifying key drivers such as opportunity structures, institutional weakness, rationalization mechanisms, incentive systems, and governance failures. Nevertheless, these approaches remain only partially capable of capturing corruption as a multidimensional governance phenomenon emerging from the interaction of agency structures, coercive dynamics, legitimacy of instruments, and transactional power asymmetries.

More specifically, current corruption frameworks tend to analyse corruption either as an individual behavioural outcome or as a structural institutional pathology, while rarely integrating cognitive, relational, coercive, and governance dimensions within a unified conceptual architecture. As a result, forms of corruption rooted in fear, blackmail, retaliation, domination, and forced compliance remain comparatively under-theorized within management and governance studies.

This gap becomes increasingly relevant in contemporary organizational environments characterized by governance fragmentation, technological mediation, distributed decision-making, and intensified competitive pressure. In such settings, corruption cannot be fully understood solely through compliance failures or opportunistic calculation. Instead, it increasingly reflects failures in the governance of moral agency and in the design of organizational decision architectures capable of protecting ethical autonomy under conditions of uncertainty and power asymmetry.

Moreover, institutional complexity increasingly exposes organizations to overlapping regulatory expectations, conflicting stakeholder demands, and hybrid governance pressures that blur traditional boundaries between legitimate influence, strategic adaptation, and corrupt conduct. Under such conditions, corruption risks may emerge not only through direct illegality, but through ambiguous governance environments characterized by opacity, asymmetrical dependence, and accountability diffusion.

Recent governance scholarship increasingly frames organizational misconduct as the outcome of systemic governance failures rather than isolated ethical deviations. In particular, Paruchuri et al. (2024) argue that governance breakdowns often emerge through the interaction of board structures, accountability failures, and organizational responses to misconduct crises. This perspective aligns with the present study's configurational approach by suggesting that corruption should be analysed as an emergent property of governance systems rather than solely as individual opportunism.

To address these limitations, this paper introduces the Corruption Configuration Cube (CCC) as a multidimensional conceptual framework aimed at reconceptualizing corruption as a configurational governance phenomenon.

Rather than explaining corruption through linear causal relationships, the CCC conceptualizes corruption as the interaction of three analytical dimensions: (1) agency structure, ranging from coercion to voluntariness; (2) legitimacy of instruments, ranging from formally legitimate to intrinsically illegitimate means; and (3) transactional directionality, ranging from offer-based to request-based corruption.

The framework extends existing corruption models in three principal ways. First, it explicitly incorporates coercion and fear-based dynamics into corruption analysis, treating them not as marginal anomalies but as structurally relevant governance configurations. Second, it integrates governance, sustainability, and behavioural ethics perspectives within a unified multidimensional architecture. Third, it shifts corruption analysis from static behavioural explanations toward configurational and systems-oriented governance approaches capable of capturing the complexity of contemporary organizational environments.

The CCC should be understood not as a replacement for existing corruption models, but as an integrative analytical framework designed to connect and extend them within a broader governance and sustainability perspective.

Recent developments in AI governance and algorithmic management further complicate traditional corruption analysis. Emerging research demonstrates that algorithmic decision-making systems may generate new governance vulnerabilities linked to opacity, distributed accountability, and weakened human oversight (Martin & Waldman, 2023; Stark & Vanden Broeck, 2024). In increasingly automated organizational environments, decision authority is progressively embedded within data-driven infrastructures and algorithmic management systems, potentially reducing transparency and diluting individual responsibility. Studies on algorithmic governance further suggest that technologically mediated decision systems may intensify moral distancing, reinforce asymmetrical power relations, and constrain employees' capacity for ethical dissent or autonomous judgment (Adams-Prassl et al., 2023; Rinta-Kahila et al., 2023). These developments reinforce the need to conceptualize corruption not only as intentional misconduct, but also as a systemic governance pathology emerging from complex organizational decision architectures.

Table 2. Emerging Governance Drivers Reinforcing the Need for the CCC

Governance Trend	Limitation of Classical Models	CCC Contribution
Algorithmic management	Accountability diffusion	Agency structure dimension
ESG governance complexity	Ambiguous legitimacy	Legitimacy of instruments
Institutional fragmentation	Overlapping incentives	Configurational approach
Organizational coercion	Under-theorized fear dynamics	Coercion-voluntariness axis
Distributed decision systems	Moral distancing	Moral agency integration

CCC's Contemporary Governance Relevance (Author's elaboration)

3. Methodology

3.1 Research Design

This study adopts a conceptual and theory-building research design aimed at developing an integrative analytical framework for the interpretation of corruption as a multidimensional governance phenomenon. Rather than testing predefined hypotheses through empirical observation, the paper seeks to advance theoretical understanding by synthesizing and reconfiguring existing streams of literature into a unified conceptual architecture. The study follows the tradition of conceptual research in management and organization studies, where theory development emerges

through analytical integration, reinterpretation of existing constructs, and identification of overlooked relationships among phenomena (Jaakkola, 2020).

The conceptual orientation of the paper is particularly appropriate given the fragmented nature of contemporary corruption research. Existing studies on corruption are often distributed across distinct disciplinary domains - including economics, public governance, criminology, behavioural ethics, sustainability, and strategic management - with limited integration among organizational, cognitive, institutional, and coercive dimensions. As a result, current models frequently explain isolated aspects of corruption while lacking an overarching framework capable of capturing the configurational complexity of corruption within contemporary governance systems.

The purpose of the present study is not to replace existing corruption models, but to integrate and extend them through the development of the Corruption Configuration Cube (CCC), a multidimensional framework designed to analyse corruption through the interaction of agency structures, legitimacy of instruments, and transactional directionality. Thus the CC framework can support analytical interpretability across heterogeneous corruption contexts.

3.2 Literature Selection and Analytical Approach

The development of the CCC framework is grounded in an integrative review of interdisciplinary literature on corruption, governance, organizational misconduct, behavioural ethics, and sustainability management. The review combines foundational theoretical contributions with more recent research addressing emerging governance dynamics associated with digitalization, algorithmic decision-making, ESG governance, and institutional complexity.

The literature selection process followed three complementary criteria. First, the analysis included seminal corruption models that have historically shaped governance and organizational research, such as the Fraud Triangle (Cressey, 1953), institutional corruption approaches (Klitgaard, 1988), the Corruption Diamond (Johnston, 2005), and opportunity-structure perspectives. These models were selected because of their foundational role in explaining corruption through incentives, rationalization, institutional weakness, and governance asymmetries.

Second, the review incorporated literature from behavioural ethics and organizational misconduct studies, particularly research examining moral disengagement, ethical fading, normalization of deviance, and organizational corruption processes (Bandura, 1999; Ashforth & Anand, 2003; Tenbrunsel & Messick, 2004). This stream was included to better understand how corruption may become embedded within organizational routines, decision-making systems, and governance cultures (Molds, 2023).

Third, the analysis integrated recent contributions from management and governance scholarship addressing contemporary transformations in organizational environments, including AI governance, algorithmic management, ESG accountability, and institutional fragmentation (Martin & Waldman, 2023; Raisch & Krakowski, 2021; Stark & Vanden Broeck, 2024). These studies were considered particularly relevant because they highlight emerging governance vulnerabilities associated with distributed accountability, technologically mediated decision architectures, and the erosion of moral agency in increasingly complex organizational systems.

The analytical process adopted an abductive and configurational logic. Rather than deriving the framework deductively from a single theory or inductively from empirical data, the study progressively identified recurring analytical dimensions across different research streams and reorganized them into a coherent multidimensional structure. This approach is consistent with conceptual theory-building methodologies aimed at generating integrative frameworks capable of explaining complex organizational phenomena through the interaction of multiple dimensions rather than through linear causal relationships.

3.3 Framework Development Process

The development of the Corruption Configuration Cube (CCC) occurred through a three-stage analytical process.

In the first stage, the study systematically analysed the explanatory assumptions underlying the principal corruption models discussed in the literature. Attention was devoted to identifying the dominant explanatory variables used to conceptualize corruption, including opportunity structures, rationalization mechanisms, institutional weakness, incentive systems, and governance failures. This phase revealed that most existing approaches predominantly conceptualize corruption as either an opportunistic behavioural choice or an institutional pathology generated by insufficient accountability structures.

In the second stage, the analysis focused on identifying dimensions that remained comparatively underdeveloped within existing corruption frameworks. Through comparison across governance, behavioural ethics, and organizational misconduct literature, three recurrent analytical gaps emerged. The first concerned the limited treatment of coercion and fear-based corruption dynamics. The second involved the insufficient distinction between formally legitimate and intrinsically illegitimate instruments used within corrupt exchanges. The third related to the directional structure of corruption transactions, particularly the distinction between offer-driven and request-driven corruption mechanisms.

In the third stage, these dimensions were reorganized into a unified configurational framework through the construction of three orthogonal analytical axes: (1) agency structure, ranging from voluntariness to coercion; (2) legitimacy of instruments, ranging from formally legitimate to illegitimate means; and (3) transactional directionality, ranging from offer-based to request-based corruption. The interaction among these dimensions generated the conceptual architecture of the Corruption Configuration Cube (CCC).

The configurational structure of the framework reflects the assumption that corruption cannot always be adequately explained through isolated variables or linear models. Instead, corruption configurations emerge from the interaction between governance pressures, power asymmetries, organizational incentives, and moral agency conditions. Consequently, different combinations of the three dimensions may produce qualitatively distinct forms of corruption characterized by different governance implications, sustainability risks, and organizational dynamics.

3.4 Methodological Positioning and Scope

The present study should be interpreted as an exploratory conceptual contribution rather than as an empirically validated predictive model. The purpose of the CCC is primarily analytical and heuristic: to provide a multidimensional interpretive framework capable of supporting future empirical investigation, governance analysis, and organizational diagnosis.

Consistent with conceptual theory-building research, the framework aims to generate analytical categories and relationships that may subsequently be operationalized through qualitative, comparative, or quantitative methodologies. In particular, the CCC may support future studies focused on corruption mapping, governance risk assessment, organizational misconduct analysis, whistleblowing systems, and AI-mediated governance environments.

At the same time, the conceptual nature of the study necessarily entails limitations. The framework has not yet been empirically tested across organizational contexts, and the boundaries between different corruption configurations may vary depending on institutional, cultural, and sectoral conditions. Moreover, some dimensions may interact dynamically rather than remaining fully independent in practice. Nevertheless, the configurational approach adopted in this paper offers a foundation for future refinement and empirical validation.

By explicitly integrating coercion, legitimacy structures, and transactional directionality within a unified governance framework, the methodology adopted in this study seeks to advance corruption research beyond purely compliance-oriented or incentive-based interpretations, contributing instead to a broader understanding of corruption as a multidimensional governance and sustainability phenomenon.

4. The Corruption Configuration Cube (CCC): Analytical Framework

4.1 Conceptual Logic of the Framework
