The T-Rex Effect in the Entrepreneurial Ecosystem

FILIPPO MARCHESANI[1], ALICE CIVERA[2], DAVID AUDRETSCH[3]

Abstract. *Large incumbent firms can profoundly shape the economic and institutional structures of the cities in which they operate. In highly attractive and advanced urban environments such as smart cities, the concentration of large firms may alter the configuration of entrepreneurial ecosystems by redistributing key resources, opportunities, and institutional dynamics. Building on the entrepreneurial ecosystem framework, this study introduces the concept of the T-Rex effect, conceptualizing large incumbent firms as dominant actors capable of reshaping ecosystem dynamics. Using a longitudinal panel of 42 Italian cities over a 15-year period and employing a dynamic Generalized Method of Moments (GMM) approach, the analysis investigates how the presence of large firms influences multiple dimensions of the entrepreneurial ecosystem. The findings suggest that while corporate concentration strengthens knowledge flows, talent attraction, and infrastructural resources, it is also associated with lower entrepreneurial activity and weaker liveability and informal institutional dynamics. These results highlight the T-Rex effect, whereby dominant corporate actors simultaneously generate ecosystem spillovers while altering the internal equilibrium of entrepreneurial ecosystems in smart cities.*

Keywords: *Entrepreneurial Ecosystem; Large Firms; Smart Cities; Entrepreneurial Dynamics; T-Rex Effect; Urban Environment*

Framing of the research. Although often portrayed as a powerful predator, the Tyrannosaurus Rex (T-rex) was not a particularly fast runner. Palaeobiological studies suggest that its massive body constrained its running speed, making rapid movement unlikely (Hutchinson & Garcia, 2002). Yet, despite this limited mobility, the Tyrannosaurus profoundly shaped the ecological systems in which it lived, dominating the environment and altering the behavior and ecological positioning of other species within the ecosystem. Drawing inspiration from this ecological metaphor, this study argues that a similar dynamic emerges at the intersection of smart cities, entrepreneurial ecosystems, and urban environments, where large incumbent firms (often characterized by organizational inertia and lower adaptive flexibility) can exert a disproportionate influence on local economic structures. By concentrating substantial resources, talent, and employment within a single city, these actors may reshape the configuration and functioning of entrepreneurial ecosystems in smart cities.

Over the past two decades, cities have increasingly adopted the smart city paradigm as a strategic framework to enhance their economic dynamism, sustainability, and global competitiveness (Albino et al., 2015). Following the early definition proposed by Kourtit & Nijkamp (2012), smart cities have been conceptualized as "urban systems shaped by knowledge-intensive and creativity-driven strategies designed to improve the socio-economic, ecological, logistical, and competitive performance of urban areas. In this perspective, smart cities rely on the interaction of multiple forms of capital, including human capital (e.g., highly skilled labor), infrastructural capital (e.g., advanced digital and communication infrastructures), social capital (e.g., dense and open collaborative networks), and entrepreneurial capital (e.g., innovative and risk-taking business activities)"(p. 93). These elements contribute to shaping cities as complex environments where innovation, knowledge exchange, and entrepreneurial initiatives can emerge and scale. Within this context, cities (Adler et al., 2019; Audretsch & Belitski, 2017; Tavassoli et al., 2021) and smart cities (Barba-Sánchez et al., 2019; Ferraris et al., 2020; Khurana & Dutta, 2024; Marchesani et al., 2025; Marchesani & Kummitha, 2026) are increasingly understood as closely intertwined with the development of entrepreneurial ecosystems .

Urban environments provide the spatial and institutional conditions that enable firms, entrepreneurs, and supporting organizations to interact and co-evolve, thereby generating new economic opportunities and reinforcing local innovation capacity (Fujita & Thisse, 2003; Glaeser, 1999; Glaeser & Gottlieb, 2009). At the same time, the relationship between smart cities and entrepreneurship is inherently dynamic (Tavassoli et al., 2021). Previous research shows that entrepreneurial activity produces both direct and indirect effects on urban economic development. While the direct effects (among the others) arise from the creation of new firms (Marchesani et al., 2025; van den Buuse & Kolk, 2019) and employment (Balland et al., 2020; Betz et al., 2016), indirect effects emerge through broader mechanisms such as increased competition, knowledge spillovers, innovation diffusion, and improved productivity among incumbent firms (Abid & Marchesani, 2025; Adler & Florida, 2021; Feldman & Audretsch, 1999; Florida et al., 2017; Pinkse et al., 2024). Importantly, these dynamics tend to unfold over time and are often amplified in larger urban systems, where agglomeration economies and critical mass facilitate the diffusion of entrepreneurial knowledge and market opportunities (Audretsch et al., 2015).

Taken together, these insights suggest that smart city development, urban environments, and entrepreneurial dynamics are deeply interconnected. The implementation of smart city strategies tends to enhance urban attractiveness and expand

the availability of knowledge, talent, and capital within cities (Ferraris et al., 2020; Kourtit & Nijkamp, 2012; Marchesani et al., 2025). In turn, these conditions can improve the opportunity structure for firms and entrepreneurs, facilitating experimentation, innovation, and the creation of new ventures (Mora et al., 2017; Muñoz & Cohen, 2016; Shearmur & Doloreux, 2021). Within this context, urban environments act as the spatial and institutional arenas where entrepreneurial processes unfold. The concentration of human capital, infrastructures, and collaborative networks enables firms and individuals to interact, exchange knowledge, and mobilize resources (Audretsch et al., 2019, 2023; Audretsch & Fritsch, 1994; Audretsch & Lehmann, 2005; Feldman & Audretsch, 1999). These interactions both (i) influence the emergence of entrepreneurial initiatives and (ii) shape the broader economic trajectory of cities over time.

Considering the intersection between economic and urban environment, entrepreneurial ecosystems represent the systemic configuration of actors, institutions, and resources that co-evolve within a given urban context (Wurth et al., 2022). Such ecosystems are inherently embedded in the environments in which they operate and continuously interact with the economic, institutional, and spatial conditions of the city (Audretsch & Belitski, 2017). As a result, understanding how entrepreneurial ecosystems evolve within smart cities becomes crucial for explaining how urban systems generate long-term economic value and innovation capacity.

In this vein, as noted by Wurth et al. (2022, p. 741), "smart city policies promote entrepreneurship through fostering the ecosystem". At the same time, however, different forms of entrepreneurship and firm typologies may themselves reshape the structure and functioning of the ecosystem. In this sense, ecosystems are not only enabling environments but also evolving outcomes of the actors embedded within them. According to Audretsch & Belitski (2017) entrepreneurial ecosystems are conceptualized as geographically bounded systems in which "institutional and organizational as well as other systemic factors interact and influence the identification and commercialization of entrepreneurial opportunities" (p. 1031).

However, entrepreneurial ecosystems do not evolve solely through the interaction of start-ups, entrepreneurs, and supporting institutions. A growing body of research highlights that large incumbent firms represent central actors within entrepreneurial ecosystems, shaping resource allocation, institutional arrangements, and local opportunity structures (Changoluisa & Fritsch, 2020; Herzog et al., 2024; Markman & Waldron, 2014; Rohrbeck et al., 2009). According to the framework proposed by Stam and Van de Ven (2021), entrepreneurial ecosystems consist of interconnected resource endowments and institutional arrangements, including talent, knowledge, finance, leadership, demand, and physical infrastructure, whose interactions ultimately determine the level of productive entrepreneurship (p. 813). Within these systems, large corporations frequently act as anchor organizations that influence multiple ecosystem components simultaneously (Engel et al., 2018). Empirical evidence shows that corporations contribute to ecosystem development by attracting highly skilled workers, investing in local infrastructure, and participating in public–private initiatives aimed at improving urban attractiveness and quality of life (Baumol, 2002; Herzog et al., 2024; Marchesani & Ceci, 2025). They also support entrepreneurial activity through accelerators, incubators, mentoring programmes, and venture investments, thereby expanding the financial and knowledge resources available to start-ups (Florida et al., 2017) while also function as a talent magnet, recruiting highly skilled workers and providing advanced training opportunities that enhance the overall human capital base of the region (Marchesani et al., 2023).

However, recent evidence suggests that the influence of large firms is more ambivalent than traditionally assumed. While corporations inject resources into the ecosystem, they may also absorb a disproportionate share of skilled talent, raise wage expectations, and reshape local opportunity structures, potentially constraining entrepreneurial activity (Gilbert et al., 2008; Lucarelli et al., 2025). Despite these insights, three important gaps remain in the literature. First, ecosystem research has predominantly focused on the presence of actors and resources, while the specific structural role of large incumbent firms within the ecosystem configuration remains underexplored (Herzog et al., 2024, p. 1296). Second, existing studies largely examine the resource-enhancing effects of corporations, whereas the potential systemic imbalances within the urban environment generated by dominant corporate actors have received limited theoretical attention (Baumol, 2002; Keskin & Markus, 2022; Sternberg & Arndt, 2001). Third, while smart city research emphasizes urban attractiveness as a driver of entrepreneurial activity, little is known about how the localization of large corporations within highly smart cities reshapes entrepreneurial ecosystems and their internal dynamics (Ferraris et al., 2020; Khurana & Dutta, 2024; Marchesani & Ceci, 2025). Addressing these gaps is crucial for understanding the evolving relationship between urban environment and entrepreneurial ecosystems. When large firms concentrate substantial employment and strategic resources within a city, they may simultaneously stimulate economic growth while structurally reshaping labour markets, institutional priorities, and opportunity structures within the ecosystem. Against this background, this study asks the following research question: "How does the concentration of large incumbent firms within smart cities influence the structural configuration of entrepreneurial ecosystems?"

To address this question, we conceptualize the T-Rex effect as the structural influence exerted by large incumbent firms that concentrate a substantial share of employment and strategic resources within a single urban ecosystem. In highly attractive urban environments such as smart cities, these firms often emerge as dominant actors capable of shaping labour markets, knowledge flows, and institutional priorities. Similar to apex actors within ecological systems, large corporations may simultaneously generate positive spillovers (such as knowledge diffusion, infrastructure development, and increased demand) while also absorbing critical ecosystem resources including talent, capital, and institutional attention. As a result, their presence may alter the internal balance of entrepreneurial ecosystems, reinforce certain dimensions while constrain others.

Purpose of the paper. Despite the growing body of research on smart cities and entrepreneurial ecosystems, limited attention has been devoted to understanding how the presence of large incumbent firms reshapes the internal structure of urban entrepreneurial systems. Existing studies largely emphasize the resource-enhancing role of corporations, while the potential systemic imbalances generated by dominant actors within highly attractive urban environments remain underexplored. In particular, little is known about how the concentration of large firms within smart cities influences the configuration of entrepreneurial ecosystem dimensions such as talent, knowledge, infrastructure, and finance. This study addresses this gap by introducing the T-Rex effect, conceptualized as the structural influence exerted by large incumbent firms that centralize substantial employment and strategic resources within a city. Using a longitudinal analysis of 42 Italian cities over 15 years, the paper examines how increasing levels of corporate dominance reshape both the overall entrepreneurial ecosystem and its key structural components. By doing so, the study advances research on smart cities and entrepreneurial ecosystems by highlighting how dominant corporate actors may simultaneously generate spillovers while constraining entrepreneurial opportunity structures.

Methodology. Using a longitudinal panel of 42 Italian cities over a 15-year period, we examine how the concentration of large incumbent firms (250+ employees) affects the structural configuration of entrepreneurial ecosystems. The empirical analysis is conducted using the Generalized Method of Moments (GMM) estimator (Lee & Yu, 2014; Roodman, 2009), which allows us to account for potential endogeneity, dynamic effects, and unobserved heterogeneity across cities. The analytical framework follows the systemic conceptualization of entrepreneurial ecosystems proposed by Stam and Van de Ven (2021), which emphasizes the interaction between resource endowments and institutional arrangements in shaping productive entrepreneurship. Consistent with this approach, we operationalize the ecosystem through seven core dimensions capturing the main structural conditions of urban entrepreneurial systems: (1) Industry and Economic Environment, (2) Leadership, (3) Knowledge and Human Capital, (4) Physical Infrastructure, (5) Livability and Leisure, (6) Informal Institutions, and (7) Finance.

Each dimension is measured through a combination of indicators and composite indices constructed from multiple variables. The indicators are derived from national and international data sources, allowing us to capture both the structural characteristics and the dynamic evolution of entrepreneurial ecosystems across cities. These dimensions represent the key pillars through which urban environments interact with the entrepreneurial ecosystem structure and determine the capacity of cities to generate and sustain entrepreneurial activity. By examining the impact of large firms across each dimension, the empirical design enables us to assess both the overall ecosystem configuration and the specific mechanisms through which dominant firms reshape ecosystem components.

Results. Preliminary results indicate that the presence of large incumbent firms is positively associated with the overall configuration of the entrepreneurial ecosystem, while revealing differentiated effects across its core dimensions. In particular, cities hosting a higher concentration of large firms tend to experience improvements in knowledge and human capital, talent attraction, and the strengthening of the industry and economic environment as well as physical infrastructure supporting entrepreneurial activity.

These dynamics appear to enhance the availability of resources such as skilled labor, innovation networks, and market opportunities. However, the results also reveal emerging structural imbalances across ecosystem dimensions. In particular, higher levels of corporate concentration are associated with a decline in entrepreneurial activity and a weakening of informal institutional conditions within the city, such as informal networks, public participation and community-based support mechanisms. This pattern suggests that increasing corporate dominance may reshape the internal equilibrium of entrepreneurial ecosystems in smart cities, reinforcing some resource-based pillars while simultaneously constraining entrepreneurial dynamism and grassroots ecosystem interactions.

Research limitations. This study presents several limitations that open avenues for future research. First, the analysis focuses on Italian cities, which may limit the generalizability of the findings to other national contexts characterized by different institutional and economic structures. Second, while the study adopts a longitudinal panel design, the operationalization of entrepreneurial ecosystem dimensions relies on available secondary indicators, which may not fully capture the complexity of informal institutional dynamics. Third, the measurement of corporate dominance is based on employment concentration of large firms, which may overlook other forms of influence such as financial power, technological leadership, or platform dominance. Fourth, although the empirical strategy accounts for potential endogeneity using dynamic panel techniques, causal interpretations should be considered with caution given the structural complexity of urban entrepreneurial ecosystems. Finally, the study focuses on city-level dynamics, which may mask important micro-level interactions among entrepreneurs, institutions, and corporate actors that shape ecosystem evolution over time. Future research could address these limitations by exploring different geographical contexts, incorporating alternative measures of corporate influence, and examining ecosystem dynamics through multi-level or qualitative approaches.

Managerial implications. The preliminary findings provide implications for entrepreneurs, urban policymakers, city managers, and ecosystem stakeholders involved in smart city development. While attracting large corporations may strengthen key ecosystem resources such as knowledge, talent, and infrastructure, excessive corporate concentration may

also generate structural imbalances within the entrepreneurial ecosystem. Policymakers should therefore design governance mechanisms that balance the benefits generated by large incumbent firms with policies that sustain entrepreneurial diversity, informal institutional support, and opportunity distribution within the city. This may include strengthening local entrepreneurial networks, supporting start-up ecosystems, and ensuring that large corporate actors remain integrated within the broader urban innovation system rather than dominating it.

Originality of the paper. This study contributes to the literature on smart cities and entrepreneurial ecosystems by introducing the concept of the T-Rex effect, which conceptualizes the structural influence of large incumbent firms within urban entrepreneurial ecosystems. By examining how corporate dominance reshapes multiple ecosystem dimensions simultaneously, the paper moves beyond traditional spillover-based perspectives and highlights how large firms may both reinforce and constrain entrepreneurial ecosystem dynamics. In doing so, the study provides a novel framework for understanding how dominant corporate actors reshape the internal equilibrium of entrepreneurial ecosystems in smart cities.

Training for Automotive Company Creation: a case study for university students' entrepreneurial action and education

GIULIA TAGLIAZUCCHI[1], LINDA GABBIANELLI[2], LUIGI ROVATI[3], BERNARDO BALBONI[4]

Abstract. *This paper investigates how learning-by-doing approaches within an interdisciplinary program can foster student entrepreneurship and contribute to the regional ecosystem of innovation. Grounded in the literature on the entrepreneurial university, the study interprets higher education institutions not only as knowledge producers but as institutions that integrate structural transformation with educational innovation to nurture entrepreneurial mindsets and venture creation. This entails a shift from knowledge production for its own sake toward addressing concrete societal and economic challenges, repositioning universities as active agents within innovation ecosystems rather than isolated knowledge producers (Audretsch, 2014). Within this transformation, the university assumes a strategic developmental role by aligning its educational mission with innovation-driven outcomes.*

Empirically, the paper presents as a case study the program called Training for Automotive Company Creation (TACC), organized by the University of Modena and Reggio Emilia (Emilia Romagna region, IT), designed as a lean and problem-driven entrepreneurial pathway that brings together students, lecturers, and mentors in an experiential learning environment. The program is structured around early-stage problem identification of burning issues in the automotive industry and team development, followed by iterative prototyping and validation, culminating in the creation of a comprehensive project work and, in some cases, the creation of junior spin-offs. This architecture reflects principles of human-centered and interdisciplinary learning, emphasizing experimentation, user focus, and action under conditions of uncertainty. The program indeed adopts a design thinking approach, that is here discussed in its distinctive features and as an approach suitable to foster entrepreneurial competence development. Rather than a linear methodology of problem-solving, design thinking indeed represents a set of practices and cognitive orientations that emphasize framing and reframing of problems, thus generating multiple solution alternatives, then prototyped and tested, and learning through feedback loops. Its diffusion in higher education answers to the need of bridging technical expertise with the competencies required in entrepreneurial mindset and education (Klenner et al., 2022; Micheli et al., 2019).

The results highlight two interrelated dimensions central to the program's effectiveness: (1) team formation and functioning, particularly the role of interdisciplinary collaboration and self-organized team building in shaping entrepreneurial dynamics; and (2) the impact of the approach on entrepreneurship education, especially in terms of managing ambiguity, fostering leadership, and supporting transformational learning processes. By examining TACC and its experiential methodologies the paper contributes to the debate on how universities can act to empower students to become proactive entrepreneurs. Overall, the study depicts a transferable model for institutions seeking to embed entrepreneurship more deeply into their academic structures. In doing so, it provides not only pedagogical guidance for educators but also strategic insights for university managers and technology transfer practitioners aiming to cultivate an innovation-oriented and ecosystem-driven university environment.

Keywords: *entrepreneurial education; junior spin-offs; academic entrepreneurship; design thinking.*

Framing of the research. A key contribution to defining the so-called third mission of the university comes from Perkmann et al. (2013), who distinguish between academic engagement and academic entrepreneurship. The former refers to knowledge-based collaborations between academic researchers and external organizations, while the latter focuses on technology transfer through the creation of startups and spin-offs aimed at commercializing academic research (Shane, 2004). This distinction clarifies that the entrepreneurial turn in higher education is not limited to firm creation, but encompasses a broader spectrum of relational and institutional mechanisms that connect universities with industry and society. The entrepreneurial university model therefore requires stronger collaboration between academia, industry, and government. Such collaboration entails structural and organizational transformations, including the establishment of entrepreneurship centers and technology transfer offices (Grimaldi et al., 2011; Baglieri et al., 2018), the integration of new institutional purposes and hybrid business models (Miller et al., 2014), and the development of managerial and collaborative capabilities among both students and faculty (Linton and Klinton, 2019). However, structural adaptation alone is insufficient, and requires also to innovate the educational approach. Today, universities are then expected not only to generate knowledge but also to adapt their structures, activities, and values to promote entrepreneurship among students (Audretsch, 2014).

As knowledge increasingly drives innovation, universities play a crucial role not merely in transferring technology but in cultivating an entrepreneurial mindset. By integrating innovative approach to entrepreneurial education and

interdisciplinarity, universities can ultimately empower students to become proactive entrepreneurs within local and regional ecosystems (Etzkowitz et al., 2000). In this sense, the entrepreneurial university emerges as a systemic configuration in which education and third mission activities converge to generate technological innovation and social value. The transition toward an entrepreneurial university then implies a reconfiguration of courses or the integration of specific programs that are designed to foster entrepreneurial cognition and behavior (Klenner et al., 2022). In this perspective, innovation in higher education becomes a central lever through which universities operationalize their entrepreneurial mission, and the educational program grounded in experiential and interdisciplinary learning become central. Innovative approaches, when embedded within university structures that support experimentation and external engagement, contribute to strengthening the university's third mission not only at an institutional level but also at the level of individual capability development.

Among the approaches that have gained relevance in both management research and higher education research, design thinking is one of the most notable (Sarooghi et al., 2019). Originally rooted in design practice, it has progressively expanded into management, social sciences, and entrepreneurship as a tool for addressing complex and ill-defined problems, to generate customer value and market opportunities (Micheli et al., 2019). It has been conceptualized as a structured yet flexible problem-solving paradigm that combines user-centeredness, iterative experimentation, and abductive reasoning (Baltador et al., 2024; Linton and Klinton, 2019). Design thinking indeed represents a human-centered non-linear approach for developing innovative solutions that integrates user needs, technological feasibility, and viable business strategies (Lynch et al., 2021; Vignoli ey al. 2023). Micheli et al. (2019) highlight that "doing" design thinking involves the integration of three core dimensions: (1) a human-centered orientation grounded in empathy and deep user understanding; (2) an experimental logic based on prototyping and iterative testing; and (3) collaborative and interdisciplinary work structures that challenge traditional functional silos. These elements are particularly relevant in context where uncertainty, ambiguity, and resource constraints require actors to move beyond purely analytical reasoning toward abductive and action-oriented approaches, like in entrepreneurial contexts

Design thinking emerges then as particularly relevant for fostering an entrepreneurial education and mindset, as it trains students to sense opportunities, act rapidly, and mobilize resources under conditions of uncertainty (Baltador et al., 2024; Kazakeviciute et al., 2016; Sarooghi et al., 2019). Through iterative and practice-based processes, students develop critical tangential skills, including teamwork, communication, networking, empathy, and the ability to manage ambiguity in complex contexts (Micheli et al., 2019; Vignoli et al., 2023). Empirical evidence highlights how this approach enables transformational learning: students are often pushed beyond their disciplinary comfort zones and encouraged to move from a rule-based, purely analytical orientation toward a more creative and value-driven perspective (Klenner et al., 2022; Micheli et al., 2019). Although initial difficulties may arise due to time pressure and team dynamics, the experiential nature of the method allows participants to overcome the limits of traditional analytical models and to internalize entrepreneurial ways of thinking and acting. Moreover, the design thinking approach is inherently interdisciplinary, requiring collaboration across fields such as engineering, business, and the arts to achieve breakthrough innovation. This interdisciplinary dimension aligns with evidence from case-based studies (Klapper and Tegtmeier, 2010; Sorici et al., 2023), which confirm the importance of cross-disciplinary education and field experimentation in developing entrepreneurial competencies and supporting start-up creation.

Purpose of the paper. How can universities effectively foster student entrepreneurship while strengthening their role as drivers of innovation in knowledge-based societies? This paper addresses this broad question by examining how higher education institutions assume a more entrepreneurial and engaged position within regional knowledge ecosystems through cross-disciplinary and action-oriented educational programs. Specifically, the study investigates how structured entrepreneurial pathways can support student-led venture creation. In this preliminary analysis, we present the analytical framework and methodological approach adopted, and we introduce the case study of the Training for Automotive Company Creation (TACC) program at the University of Modena and Reggio Emilia (Unimore), located in the Emilia-Romagna region of Italy. By analyzing the experiences of participating students, the paper aims to explore the mechanisms through which problem-driven learning environments can enhance entrepreneurial competencies and contribute to the university's third mission within its regional ecosystem.

Methodology. We adopt a qualitative case study approach (Yin, 2003; Eisenhardt, 1989), suitable for investigating complex phenomena within their real-life context. The empirical setting is the Training for Automotive Company Creation (TACC) program, promoted by the University of Modena and Reggio Emilia. TACC is selected as a significant case, given its consolidation over multiple editions and its explicit orientation toward venture creation within a structured university–industry partnership framework. The case study design allows an in-depth exploration of how this entrepreneurial educational program operates and how it influences students' entrepreneurial mindset development.

Data collection relies on multiple sources to ensure triangulation and enhance construct validity (Yin, 1994). First, we conducted participant observation during program activities, including workshops, mentoring sessions, team formation processes, and final project presentations. This enabled direct observation of team dynamics, interdisciplinary collaboration, and iterative learning processes. Second, we carried out document analysis of internal program materials, project outputs (business models and business plans), and communication materials. These sources provide insight into the formal structure of the program, its educational approach, and its evolution over time. Third, data about junior spin-off creation, stemming from projects evolved during the TACC program, at university level are analyzed.

Data analysis followed an iterative strategy consistent with case study research (Eisenhardt, 1989; Yin, 2003). The empirical material collected through participant observation and document analysis was systematically analyzed. First, field notes and program documents were subjected to open coding in order to detect emerging themes grounded in the textual data. This initial phase allowed the identification of key analytical categories, such as management of uncertainty, problem framing, prototyping practices, leadership emergence. Second, we connect empirical evidence with the theoretical framework on entrepreneurial universities and design thinking. This process enabled pattern matching between observed practices and conceptual constructs derived from the literature. Last, longitudinal assessment of venture creation and performance is performed. The analytical approach thus combines inductive insights with theory-driven interpretation. Triangulation across data sources—observational evidence, internal documents, and project outputs—was used to enhance internal validity and reduce potential bias. Particular attention was devoted to cross-edition comparison, allowing a process-oriented interpretation of how the program evolved over time.

Results. TACC is promoted by the University of Modena and Reggio Emilia and MUNER Motor Valley University of Emilia Romagna, in partnership with AVL and Confindustria Emilia Area Gruppo Giovani Imprenditori, Rete Professionisti Motorsport, and Fondazione di Modena, with several other sponsors. Since its launch in 2018, TACC has progressed through five editions, in each improving its educational structure and approach. TACC combines workshops with managers and entrepreneurial mentors, corporate visits, and participation in fairs, offering a rich entrepreneurial learning experience between its two phases. The first phase is focused on team creation and idea elaboration. The second phase is focused on prototyping, in terms of technical feasibility and business viability. TACC is open to PhD students, students of Master's Degree and 5-year combined Bachelor' s/Master's degree. To date, TACC has gathered applications from over 360 students, with 150 students from the departments of Communication, Economics, Engineering, Law, Physics and Mathematics participating in it.

The uniqueness of TACC lies in its lean and problem-focused approach, which is consistent with the principles of design thinking. The program is structured around an initial phase centered on problem identification and business model architecture, followed by a prototyping phase aimed at translating validated assumptions into concrete and viable solutions within a limited time frame. This sequence shifts attention from abstract theorization to action-oriented experimentation, encouraging students to engage directly with real market and user-related constraints. In doing so, the program reinforces an entrepreneurial mindset understood as the capacity to perceive opportunities, act, and mobilize resources rapidly under conditions of uncertainty.

The emphasis on early problem framing, rather than solution elaboration, exposes participants to complex and ill-defined challenges, requiring them to define the boundaries of the problem autonomously rather than relying on predefined analytical schemes. This deliberate exposure to ambiguity supports the development of cognitive flexibility and tolerance for uncertainty, key attributes of entrepreneurial behavior. The subsequent prototyping and validation phase institutionalizes an iterative logic based on testing hypotheses, feedback collection, and progressive refinement. Students learn to transform ideas into tangible artifacts, gather immediate market responses, and adjust their solutions accordingly. This process operationalizes the principle of learning through experimentation and normalizes failure as an informative step within the innovation cycle rather than as a negative outcome.

The activities culminate in a supervised project work developed with lecturers and mentors, including the elaboration of a business model, a business plan, and the organizational design of the new venture. This structured deliverable consolidates analytical rigor with creative exploration, ensuring that experimentation is anchored to strategic coherence and economic feasibility. The combination of conceptual modeling and field validation strengthens students' abilities in strategic thinking, prioritization, and project management under time pressure. The human-centered orientation of the program further reinforces its entrepreneurial impact. By emphasizing user needs and latent demand, students are trained to ground innovation in empathy and value creation rather than in purely technical sophistication. This focus strengthens their capacity to identify viable market opportunities and to articulate convincing value propositions, particularly in pitching contexts.

Through this process, students develop essential entrepreneurial competencies, including effective communication, networking capabilities, shared leadership, and collaborative decision-making, effectively converting interpersonal and professional tensions into powerful drivers for creative problem-solving. Beyond skill acquisition, the educational impact of design thinking assumes a transformative dimension. As highlighted in the literature (Klenner et al, 2022; Micheli et al., 2019), engaging students in the resolution of complex and ill-defined problems shifts their perspective from a passive, rule-based and predominantly analytical stance toward a proactive orientation centered on real-world value creation. This transition is not merely methodological but cognitive and identity-related, as students progressively internalize an action-oriented logic grounded in experimentation and responsibility for outcomes. Through this approach, participants develop critical transversal competencies, including critical thinking, effective communication, and the capacity to act decisively under time pressure and conditions of extreme uncertainty. In this sense, design thinking operates not only as a problem-solving methodology but also as a catalyst for entrepreneurial agency, reinforcing the alignment between pedagogical innovation and the broader objectives of the entrepreneurial university.

Team building represents a core structural element of the program. Unlike traditional didactic formats, students autonomously form teams through a call for ideas followed by a voting process. This mechanism enhances ownership and intrinsic motivation while simulating early-stage entrepreneurial dynamics. This evolutionary configuration of teams

around problem-seeking processes emerges as a distinctive element of the program. In the first phase of TACC, teams initially emerge around a problem or an early-stage idea. Participants who have already explored a specific problem domain present their proposal to the cohort, allowing other students to join their initiative and collaboratively develop it through a design thinking approach. However, identifying a problem beforehand is not a prerequisite for participation; rather, it represents an initial aggregation mechanism that helps orient participants toward specific thematic areas. Between the first and the second phase of the program, teams are allowed—and often encouraged—to reconfigure. Participants may decide to abandon the original idea, join another group whose concept has demonstrated greater potential, or merge competences with other participants around more promising problem–solution trajectories. As a consequence, not all initial ideas progress to the prototyping phase; only those that withstand early validation continue to evolve, and teams progressively reorganize themselves around these emerging opportunities. These dynamic reverses the traditional logic in which teams are expected to generate ideas regardless of their viability. Instead, the TACC model adopts a problem-driven architecture, in which the team adapts to the most promising problem–solution configurations rather than forcing an idea to fit a pre-existing group structure.

This adaptive mechanism reinforces participants' entrepreneurial competence by exposing them to processes of opportunity recognition, resource recombination, and strategic decision-making under uncertainty. Opportunity seeking therefore emerges as the outcome of the iterative exploration process embedded in the program rather than as a starting assumption. Similarly, the potential creation of new ventures represents a downstream result of this multi-phase learning trajectory, in which validated problems, recomposed teams, and experimentally tested solutions progressively converge toward viable entrepreneurial initiatives. In addition, interdisciplinarity is actively promoted by encouraging the participation of students from different knowledge domains. Although heterogeneous teams may initially experience communication frictions and divergent perspectives, these tensions are intentionally leveraged through structured problem exploration processes that enable participants to progressively develop a shared understanding and a common working language across disciplines. The interdisciplinary configuration reflects the design thinking ethos, which relies on the integration of diverse cognitive frameworks—such as engineering, business, and creative disciplines—to generate breakthrough solutions. By challenging students from different backgrounds to align their mental models, the program intentionally simulates the cognitive dissonance inherent in real-world innovation ecosystems.

Finally, TACC extends beyond simulation by supporting the actual creation of junior spin-off companies. This dimension ensures that entrepreneurial learning produces tangible organizational outcomes. The spin-offs function as concrete manifestations of the iterative learning journey, translating educational processes into real ventures embedded in the university ecosystem. There are 7 spin-offs established following the TACC program, from 2020 to date, and still in activity at the end of 2024. Two more junior spin-offs are in the actual phase of creation at the end of 2025, while 3 more potential junior spin-off may constitute as results of the final awards from the latest TACC Edition (ended in February 2026). All the ventures are classified as deep-tech or high-tech. Overall, the TACC approach does more than just simulate entrepreneurship; it builds effective and potentially long-lasting ventures. This evidence suggests that the educational approach based on iterative validation and problem framing importantly reduces the risk of failure in the early years of a new ventures, allowing for the creation of a technological solution that is in line with the market needs, and that can be adapted to these evolving needs. This is reinforced by the problem-driven and evolutionary team configuration typical of TACC, that increases the likelihood of venture creation by allowing ideas, competences, and participants to progressively realign around the most promising problem–solution opportunities, enabling entrepreneurial competences to be actively enacted rather than merely designed or simulated within a protected learning environment. The tensions that emerge within teams and the coordination dynamics participants are required to manage closely resemble those of a venture in its early stages of formation, as do the challenges of bridging the gap between an initial idea, the development of a viable solution, and its eventual market introduction.

Research limitations. As this research is still at an early stage, several limitations must be acknowledged. First, the findings are based on a single case study and capture a specific temporal phase of the program's development. The program is currently being updated and will broaden its disciplinary scope, while maintaining its educational approach. A long-term assessment of outcomes is necessary to evaluate the sustainability of the new ventures created by students, the persistence of entrepreneurial competencies among participants, and the overall replicability of the model. Longitudinal monitoring would allow a more robust evaluation of impact and help distinguish short-term educational effects from sustained entrepreneurial trajectories. Second, the study focuses on a single institutional context embedded in a specific regional ecosystem characterized by a strong industrial base and support structures for innovation. This setting may indeed limit the generalizability of the findings. The results should therefore be interpreted in light of the broader national framework of innovation policies, university–industry collaboration, and startup support mechanisms. Cross-national comparisons with analogous initiatives in other higher education systems would strengthen the empirical validity of the study and allow the identification of transferable best practices as well as context-dependent factors. Such comparative research would contribute to a more systematic understanding of how universities can effectively operationalize their entrepreneurial mission within diverse innovation ecosystems.

Managerial implications. Overall, entrepreneurship programs can function not only as venture creation platforms but also as strategic tools for cultivating an innovation-oriented culture within the university and reinforcing its role within the regional ecosystem. This study offers several managerial implications for universities. First, entrepreneurship

educational initiatives should be strategically embedded within the institutional framework rather than treated as isolated programs. Alignment between governance and resource allocation is essential to ensure continuity and impact of these types of programs. Second, experiential and problem-driven learning educational formats should be prioritized. Programs structured around iterative validation, prototyping, and real-world challenges appear more effective in fostering entrepreneurial competencies than traditional classroom-based approaches. Clear phase articulation and structured mentorship can help students navigate uncertainty while maintaining strategic coherence. Third, interdisciplinary collaboration requires active facilitation. While cross-departmental teams enhance creativity and opportunity recognition, they also generate coordination challenges. Formal support and facilitation mechanisms should be designed, such as mentoring, credit recognition between departments, alignment of teaching calendars and timetables for participation by multiple departments, to strengthen inter-disciplinary team creation. Fourth, entrepreneurial programs may benefit from structuring teams around problem exploration rather than fixed project assignments, allowing team composition to evolve as ideas are validated. This adaptive configuration enables resources and competences to progressively concentrate around the most promising opportunities, fostering the development of entrepreneurial competences through real decision-making, coordination, and uncertainty management.

Originality of the paper. This study contributes to the literature by positioning TACC as an empirically grounded example of how "entrepreneurship in practice" can be systematically embedded within higher education. Rather than focusing solely on institutional structures or policy frameworks, the case highlights the micro-foundations of entrepreneurial learning, showing how pedagogical design, interdisciplinary team formation, and iterative experimentation can be integrated into a coherent educational architecture oriented toward venture creation.

The combination of documented student-led projects, the establishment of active spin-offs, and the longitudinal observation across multiple program editions provides process-based insights into how entrepreneurial competencies are developed and consolidated over time. This allows the paper to move beyond descriptive accounts of entrepreneurship education and to identify concrete design principles that support both learning outcomes and tangible entrepreneurial results. The case further generates actionable knowledge regarding best practices for fostering cross-departmental collaboration, structuring team dynamics, and managing the tensions inherent in interdisciplinary work. It also sheds light on recurrent obstacles—such as coordination challenges, ambiguity management, and time pressure—and on the mechanisms adopted to address them through mentorship, structured workshops, and iterative validation processes.

From the perspective of the entrepreneurial university, design thinking contributes to bridging the gap between knowledge generation and value creation. It enables students to translate disciplinary expertise into actionable entrepreneurial competencies first, and then opportunity recognition and venture development processes, aligning technological feasibility with user desirability and business viability. Moreover, by institutionalizing experimentation and tolerating failure as part of learning, universities can cultivate an entrepreneurial culture. By participating in this program, students consolidate entrepreneurial cognition and collaborative capabilities within a robust educational program. In this sense, TACC does not merely teach entrepreneurship; it institutionalizes a transformational learning environment in which students progressively shift from a rule-based and passive stance to a proactive, creative, and value-oriented entrepreneurial mindset.

We are Change.
Il linguaggio degli innovatori deep tech nel contesto europeo

CHIARA BARTOLI[1] FEDERICA BRUNETTA[2]

Abstract. *Lo studio investiga le modalità attraverso cui gli innovatori emergenti costruiscono la propria legittimazione, sia all'interno sia all'esterno della venture. Attraverso l'adozione di un approccio qualitativo basato sull'analisi computazionale del linguaggio dei founder di imprese deep tech in fase early stage a livello europeo, il lavoro identifica gli aspetti linguistici che caratterizzano le loro narrazioni. Dall'analisi emergono cinque temi che risultano rilevanti nella costruzione identitaria della startup come attore di cambiamento nella società e nell'economia. La startup è capace di fare leva sulle tecnologie digitali per proporre soluzioni sostenibili i cui impatti superano la dimensione del mercato. In tal modo, le startup deep tech affermano la propria legittimazione interna ed esterna come agenti di cambiamento, ed in cui il ruolo centrale non è più assegnato al founder, ma piuttosto alla startup intesa come comunità di intenti, dove significati e valori vengono costruiti congiuntamente e si riflettono nelle attività esterne della startup.*
Keywords*: Innovators, Deep tech, European Union, Entrepreneurship, Venture building*

Il contesto della ricerca. Gli innovatori si confrontano ogni giorno con l'esigenza di articolare un complesso sistema di significati che consenta di superare l'incertezza che caratterizza una nuova iniziativa imprenditoriale. Questa attività implica la costruzione della fiducia e l'accettazione di innovazioni che mettono in discussione modelli consolidati, veicolandone le caratteristiche distintive affinché ne venga compreso il significato profondo e le loro idee possano guadagnare l'accettazione esterna (Hargadon and Douglas, 2001). La struttura del linguaggio rappresenta dunque un fattore determinante per acquisire la legittimazione delle idee innovative, perché è il mezzo attraverso i quale il founder veicola il significato delle proprie idee al pubblico esterno (Cornelissen and Clarke, 2010), ed è particolarmente rilevante in presenza di idee che non sono state ancora implementate (Falchetti, 2022).

Per questo, gli studiosi di management hanno dedicato particolare attenzione all'analisi del ruolo della comunicazione degli imprenditori emergenti (McSweeney et al., 2022). Recenti lavori si concentrano in particolare sui segnali linguistici della comunicazione dei founder, dimostrando come questi rappresentino fattori capaci di influenzare gli outcome delle nuove idee imprenditoriali (Singhal and Kapur, 2023). In particolare, lo stile linguistico è un importante predittore del successo delle attività di crowdfunding in situazioni di pitching (Koh et al., 2020; McSweeney et al., 2022). Nel contesto dell'imprenditoria sociale, è stato inoltre dimostrato che l'uso di un linguaggio concreto e di uno stile interattivo, facilita i processi di fundraising (Parhankangas and Renko, 2017). Studi hanno inoltre approfondito l'aspetto del linguaggio degli imprenditori nascenti nel contesto di attività di fundraising sociale, guadando alla dimensione di genere ed al contenuto emozionale. Ulteriori studi si sono concentrati alla veicolazione di significati di innovazione e risk taking (Mckenny et al., 2018). Ulteriori studi hanno inoltre iniziato ad investigare la dimensione cognitiva legati alla narrativa utilizzata nella presentazione delle idee innovative, concentrandosi sui diversi effetti che hanno i discorsi degli innovatori sui processi valutativi dell'idea da parte degli stakeholders (Falchetti et al., 2022).

Occorre inoltre considerare che nella fase nascente il founder è chiamato ad organizzare le risorse, che in un settore emergente sono spesso scarse, e delineare i confini dell'organizzazione, facendo delle scelte che riguardano l'inserimento di nuovo personale e l'utilizzo delle risorse in condizioni estremamente incerte (Liebregts, 2025). A ciò si aggiunge l'esigenza di integrare i valori della sostenibilità nell'organizzazione nascente e di rispondere alle crescenti, ma altrettanto divergenti, aspettative degli stakeholder, bilanciando sostenibilità e performance, offerta di soluzioni adatte ad affrontare le sfide della sostenibilità, sia ambientale che sociale, e creazione di valore economico (Glinik et al., 2024).

Le aspettative esterne si riflettono anche nei comportamenti interni dell'organizzazione, trasformando le richieste che provengono dall'esterno in obiettivi organizzativi che contribuiscono a plasmare i valori e le norme interne che definiscono il corso dell'azione futura nuova venture (Hampel and Dalpiaz, 2025). Questo elemento contribuisce ad accrescere il livello di incertezza organizzativa, dal momento che le organizzazioni devono gestire risorse spesso limitate all'interno di contesti emergenti e molto instabili.

La tensione tra aspettative esterne e comportamenti interni influenza anche l'uso della retorica da parte degli innovatori come strumento di legittimazione interna e di adattamento dell'organizzazione ai feedback esterni.

La duplice prospettiva di costruzione di significati all'interno e all'esterno dell'organizzazione fa quindi parte del processo di legittimazione identitaria delle startup di fronte all'incertezza e alla crescente complessità dell'ambiente esterno.

Obiettivi dello studio. Nonostante i molti passi avanti fatti nella comprensione del ruolo del linguaggio nel processo di accettazione dell'innovazione, permangono ancora aspetti inesplorati che riguardano i contenuti della comunicazione, i

[1] La Sapienza University of Rome, e-mail: chiara.bartoli@uniroma1.it
[2] Luiss Guido Carli University, e-mail: fbrunetta@luiss.it

significati e i simboli utilizzati per trasmettere il messaggio dei nuovi imprenditori, soprattutto in presenza di innovazioni disruptive.

Tali messaggi diventano fondamentali anche per comprendere il rapporto tra legittimazione esterna e costruzione interna della startup. Si tratta tuttavia di una prospettiva integrata che non è stata ancora pienamente approfondita dalla letteratura manageriale, soprattutto in specifici contesti regionali e di fronte all'incremento degli shock esterni derivanti dalle twin transition, ovvero le transizioni gemelle del green e del digitale (Uhrenholt et al., 2022), e che ridefiniscono il ruolo delle startup, soprattutto quelle che operano nel segmento deep tech.

Alla luce di tali considerazioni, il presente lavoro persegue il fine di comprendere gli elementi del linguaggio che ne determinano l'identità, con particolare riguardo agli innovatori disruptive nel contesto UE, per comprendere le narrative prevalenti e come gli innovatori articolano il rapporto tra legittimazione interna ed esterna dell'organizzazione.

Metodologia. Lo studio adotta un approccio qualitativo basato sull'analisi computazionale delle narrazioni e sull'analisi linguistica. Per l'analisi sono stati utilizzati i software LIWC22 e T-LAB Plus. Il software LIWC22 (Linguistic Inquiry and Word Count) è riconosciuto come lo strumento di analisi del linguaggio più comunemente utilizzato per indagare il rapporto tra l'uso delle parole e le variabili psicologiche (Chen et al., 2014; Malal, 2014). L'analisi con LIWC22 è stata inoltre integrata con una Textual Analysis basata sulle co-occorrenze, effettuata con il software T-LAB Plus (Lancia, 2004). Questa integrazione ha permesso di elaborare analisi di correlazione tra parole e di comprendere meglio il contesto delle narrazioni degli innovatori. La raccolta dei dati per l'analisi è avvenuta in modo automatico mediante web scraping utilizzando la piattaforma MaxQDA. In particolare, sono stati raccolti i post LinkedIn dei fondatori di imprese deep tech con sede in EU che si trovano in una fase iniziale di sviluppo, con un'attività non superiore ai 3 anni. Per la selezione delle startup, ci si è avvalsi della piattaforma Dealroom, selezionando le prime 100 startup che hanno ricevuto gli importi più elevati di investimenti tra quelle fondate nel periodo di riferimento. Per ogni startup sono stati raccolti tutti i post pubblicati negli ultimi 2 anni dal founder. Per l'analisi è stato adottato un approccio adduttivo al coding per la costruzione delle categorie teoriche (Vila-Henninger et al., 2022),

Risultati. L'analisi della struttura dei testi attraverso LIWC22 mostra l'utilizzo di un tono prevalentemente positivo da parte degli innovatori (4%). Prevale la componente emozionale e positiva del linguaggio (1,05% di linguaggio emozionale positivo contro 0,05% di linguaggio emozionale negativo). La struttura è incentrata sulla prevalenza della parola "Noi" nel testo (2,5%). Ciò anticipa l'importanza del contenuto sociale del linguaggio che presenta la percentuale più elevata di termini (10%). L'analisi delle principali parole chiave lemmatizzate (con il più elevato numero di occorrenze nel testo) e delle co-occorrenze tra parole chiave, effettuata attraverso il software T-Lab, ha consentito l'identificazione di 5 temi che descrivono il contenuto della legittimazione identitaria degli innovatori, e che sono presentati di seguito.

1) Il ruolo del fondatore come leader

Analizzando le connessioni dei lemmi (keyword) con il termine "myself" emerge la forte vicinanza con keyword che esprimono il senso di appartenenza a un gruppo e di lavoro congiunto, rappresentati da parole come "we", "cofounders", "friends", "working". Inoltre, si evince il ruolo dell'imprenditore come guida e fonte di ispirazione per gli altri, grazie al legame di Myself con parole come "inspiring". Allo stesso tempo, il legame con la parola "care" definisce anche il ruolo sociale del leader e la connessione con gli altri membri dell'impresa. Allo stesso tempo, il fondatore rappresenta la proiezione della startup verso l'esterno, come dimostrato dalle parole "eventi" e "celebrare". Questi aspetti sono evidenti se si osserva l'ego network della keyword "leadership", associata a parole come "together" e "team", segnalando l'importanza da parte dell'imprenditore della condivisione del progetto imprenditoriale sia all'interno sia all'esterno dell'impresa, in particolare con gli stakeholder istituzionali come gli "investor" e con l'ecosistema.

Fig 1 Ego network delle associazioni per la parola chiave "Leadership"

2) Il valore del team

Per quanto riguarda l'analisi di come l'imprenditore vede il mondo e gli altri, e che consente di comprendere il comportamento rispetto alla venture e il senso attribuito al team work, questa ruota attorno alla parola "Noi" legata al senso del fare insieme e quindi al ruolo che il team ha nella costruzione e nello sviluppo futuro della venture (attraverso parole come "innovation", "future", "building"). È una dimensione centrale anche nella gestione dei processi di innovazione. Tuttavia, il ruolo del team include anche gli attori esterni all'impresa, richiamati da parole come "open source" e "world wide". L'aspetto del rapporto con l'esterno emerge anche osservando la parola "team", collegata alla keyword "partner" e al "talent", e quindi alle competenze dei membri del team, a cui viene attribuita particolare rilevanza. In questo ambito emerge il ruolo del "researcher" e quindi la centralità delle attività di ricerca e sviluppo come leva di crescita.

Fig 2 Ego network delle associazioni per la parola chiave "We"

Fonte: elaborazione con TLAB

3) L'innovazione disruptive

L'innovazione è interpretata come rottura con il passato e legata al tema della tecnologia, intesa come concetto dinamico e trasformativo della realtà organizzativa, rappresentata dalla vicinanza della parola chiave "Tecnologia" ai lemmi "accelerate", "building" e "splitting". La tecnologia è centrale per comprendere il ruolo dell'innovazione. La tecnologia è considerata una leva per cogliere le opportunità di accelerazione. In particolare, il discorso si concentra sulle tecnologie di frontiera, come il "quantum". La tecnologia presenta un forte legame anche con i concetti legati allo sviluppo futuro della venture (ad esempio attraverso la vicinanza della parola "quantum" a "scaling") e con il processo di generazione dell'innovazione. Lo scaling è interpretato come superamento della frontiera dell'innovazione in cui si esprime il ruolo attivo della startup nelle attività produttive, nella costruzione di nuove soluzioni ("solutions"), di nuovi "prodotti" e nei processi.

Fig 3 Ego network delle associazioni per la parola chiave "Technology"

Fonte. elaborazione con TLAB

4) il risk taking resiliente

Il tema del risk taking si lega all'ambiente esterno, interpretato in chiave resiliente, come mostrato dalla relazione con la keyword "resilience". Il rischio viene collegato prevalentemente al concetto di rischio finanziario, inteso come motore di crescita e di innovazione e come fattore centrale per la scalabilità dell'iniziativa imprenditoriale. Per questo motivo, nel discorso diventa centrale la coltivazione della relazione con gli attori dell'ecosistema finanziario, come le banche, i fondi e i venture capital, con cui si costruisce la fiducia dialogando e stimolando l'attenzione.

Fig 4 Ego network delle associazioni per la parola chiave "financing"

Fonte: elaborazione con TLAB

Se si considera invece la correlazione con la keyword "challenge", emergono altri aspetti rilevanti: la necessità di affrontare contesti complessi che includono le dinamiche geopolitiche e che incidono sulle dinamiche del business ("pressure", "urgent") e che richiedono un approccio congiunto ("we").

5) La sostenibilità trasformativa

Il tema della sostenibilità presenta un legame con la dimensione ambientale. L'analisi delle co-occorrenze rispetto alla parola "green" rivela che questa ha una relazione stretta con le pratiche di mercato mediante il collegamento con i lemmi "ecodesign" e "fair consumption". Ciò richiama il ruolo etico della startup, la sua responsabilità verso la promozione di comportamenti di consumo (fair consumption) e verso l'obiettivo di ridurre l'impatto carbonico ("decarbonization"), ma anche verso le tecnologie green. Il legame è forte anche con alcune tecnologie disruptive richiamate in contesti elementari quali "hydrogen" e "nano technologies

Prime implicazioni teoriche e manageriali. I primi risultati del lavoro fanno emergere il ruolo peculiare degli innovatori nel contesto europeo e nell'ambito del settore deep tech, un contesto caratterizzato da elevata incertezza ma anche da un' accelerazione nei processi di innovazione. L'analisi del linguaggio fa emergere nuove categorie di significati che si affiancano alle tradizionali retoriche dell'innovatività e del rischio (Mckenny et al., 2018). Il linguaggio costruisce infatti nuovi contesti identitari che caratterizzano gli imprenditori del deep tech, proiettando la funzione dell'io imprenditore oltre la dimensione del mercato e quella sociale, tipica degli studi in contesti di crowdfunding.
La costruzione dell'identità, funzionale alla legittimazione degli innovatori, è infatti legata al ruolo determinante che questi rivestono come motori di innovazione orientata alla sostenibilità e, in particolare, alla risoluzione dei grandi problemi legati alle due transizioni del green e del digitale. Il linguaggio consente di delineare il ruolo della strategia della startup a forte connotazione tecnologica non solo come motore di crescita del valore per gli azionisti e di affermazione sul mercato, ma soprattutto come attore di trasformazione in chiave di rottura nell'economia e nella società, capace di imprimere un cambiamento positivo con soluzioni legate alla tecnologia che sono in grado di modificare le abitudini di consumo e di costruire approcci più sostenibili. Si tratta di una visione che va oltre i confini della startup stessa e di quelli del perimetro europeo, assumendo una valenza globale.

Inoltre, il linguaggio costruisce significati che legano l'interno all'esterno dell'organizzazione, in una dinamica che è di scambio continuo. Un nuovo ambito che emerge è anche il ruolo assegnato al team, che è protagonista dell'azione degli innovatori. Questo è frutto di una visione comunitaria sottolineata dal valore assegnato al "Noi" e quindi fortemente condivisa. In questo contesto, i dipendenti della startup sono parte attiva della sua crescita e promotori del suo ruolo trasformativo nella società. Negli innovatori deeptech emerge quindi una forte condivisione progettuale da cui derivano la visione e gli obiettivi della startup, piuttosto che essere frutto di un condizionamento esterno (Hampel and Dalpiaz, 2025).

Il lavoro fornisce un contributo alla letteratura sulla legittimazione delle iniziative imprenditoriali, offrendo un'analisi che si concentra sul settore deep tech e, in particolare, sul contesto europeo. L'analisi mette in risalto il ruolo del linguaggio come strumento di ricomposizione tra le aspettative interne ed esterne delle startup, e come mezzo per esprimere il ruolo della startup come attore di sostenibilità. Inoltre, il lavoro integra le tradizionali immagini retoriche con altre legate al contesto interno del team, al ruolo dell'imprenditore come leader e comunicatore e come agente di creazione di valore sostenibile nell'economia e nella società.

Il lavoro contribuisce alla letteratura sulla legittimazione delle iniziative imprenditoriali, mettendo in risalto il ruolo del linguaggio come strumento di ricomposizione tra le aspettative interne ed esterne e come mezzo per esprimere il ruolo della startup come attore di cambiamento. Inoltre, il lavoro integra le tradizionali immagini retoriche con altre legate al contesto interno del team, al ruolo dell'imprenditore come leader e comunicatore e alla sostenibilità.

Sotto il profilo manageriale, lo studio suggerisce parole chiave e contesti che disegnano il linguaggio e offrono quindi strumenti pratici agli startupper per costruire le proprie attività di comunicazione verso gli stakeholder in modo efficace. I risultati offrono agli imprenditori nascenti le chiavi interpretative per costruire una comunicazione efficace per investitori e potenziali clienti, nonché una guida per la costruzione di un linguaggio che alimenta una cultura dell'innovazione disruptive all'interno dell'impresa, attivando forze volte a proiettare la startup attraverso l'innovazione come agente di trasformazione non solo nell'economia, ma anche nella società.

I limiti dello studio. Lo studio presenta alcuni limiti che suggeriscono possibili linee di ricerca future. In particolare, l'analisi si è incentrati sui post pubblicati dagli innovatori su una sola fonte (LinkedIn). Ulteriori studi potrebbero tenere in considerazione altre risorse, come i comunicati stampa o ulteriori canali social. Inoltre, lo studio si è concentrato sul contesto europeo, ma sarebbe interessante condurre analisi comparative tra diversi contesti geografici per cogliere le differenze nel linguaggio degli innovatori.

Originalità del lavoro. Il lavoro analizza sotto una prospettiva nuova il processo di framing identitario delle startup, concentrandosi sul contesto degli innovatori deep tech a livello europeo. Inoltre lo studio si basa su un disegno di ricerca che fa uso di tecniche computazionali di analisi linguistica che mettono insieme significati, tono e simboli.

Finanziamento.

A double-edged sword: The ambivalent role of digitalization for Italian Inner Areas sustainable development

SIMONE LUONGO, FABIANA SEPE, GIOVANNA DEL GAUDIO, MARIO TANI, GIANPAOLO BASILE

Abstract. *Tourism is known to be an important driver of economic growth and territorial development. Nevertheless, its benefits are not distributed evenly across regions; some destinations are facing issues that are related to overtourism and environmental pressure, while most internal areas are experiencing the opposite phenomena. They have a good cultural heritage, ripe with natural landscapes and strong local identities, but they are even struggling to fully capitalize on their resource endowment to attract stable tourism flows. In this context, digital technologies have progressively become a fundamental element in the transformation of tourism dynamics; Online platforms, social media and digital communication tools can be seen as a "double-edged sword" as on one side they can enhance the visibility of lesser-known destinations, facilitating the interaction with visitors also creating new opportunities for community engagement. On the other side, the growing digital exposure of destinations may also generate new risks, particularly for territories with limited infrastructures or vulnerable local ecosystems. Moving beyond the pro-innovation bias in tourism management, this article looks into the effects of digital visibility on supporting tourism development in Italian internal areas. More specifically, it explores how local communities perceive both the opportunities and the potential threats associated with the use of digital technologies in tourism management and promotion.*

To this end, we adopt a comparative qualitative approach focusing on four Italian regions characterized by different tourism dynamics: Campania and Basilicata in Southern Italy, and Veneto and South Tyrol in Northern Italy. These regions provide an interesting comparison between territories experiencing relatively limited tourism flows and others already facing increasing tourism pressure. Specifically, we conducted semi-structured interviews with representatives of local Pro Loco associations. These organizations play a key role in promoting local initiatives and often act as intermediaries between residents, public institutions and visitors.

Preliminary findings suggest that digital technologies represent an ambivalent phenomenon for internal areas. On the one hand, digital platforms significantly improve the visibility of peripheral destinations and it supports local actors in promoting their place's cultural and environmental resources. On the other hand, increased online exposure can catalyze rapid growth creating systemic crises, as these areas often lack the adequate managerial expertise and the infrastructures needed to manage the added complexity coming out of sudden tourism development.

Overall, the paper contributes to the ongoing debate on tourism-led, community-based, development by highlighting the complex role played by digital technologies and by providing insights into how internal areas may strategically use digitalization to foster more sustainable and resilient tourism pathways.

Keywords: *inner areas; digital technologies; tourism development; rural tourism; local communities*

Framing of the research. Tourism has traditionally been recognized as a key sector capable of fostering economic growth, generating employment and supporting local development (Du et al., 2016). However, the effects of tourism expansion are far from uniform and positive across territories (Ursache, 2015) as while the dominant narrative in rural development emphasizes the 'digital bridge' (the idea that technology overcomes geographic isolation), recent management scholars (e.g., Rullani, 2022) suggest that digitalization can also exacerbate existing vulnerabilities. Even in the more successful and developed destinations, such as the metropolitan areas, a never-ending growth of tourism flows has led to big challenges such as overtourism (Chaney & Séraphin, 2023), environmental pressure and growing tensions between residents and tourists (Della Corte et al., 2025). As a consequence, an increasing debate within both academia and policy makers has spawned the need to rethink how tourism can be considered an active player in sustainable development processes for the local area (Basile et al., 2021; Buhalis et al., 2023).

A very different situation can be observed looking at rural and internal areas. These territories often possess valuable, under-utilized, cultural heritage and strong local traditions (Wu et al., 2022), and they frequently struggle to attract stable tourism flows (Guizzardi et al., 2022). Scholars have examined the potential of the tourism industry as a driver in developing local economies, revitalizing traditions and fostering community identity (Bramwell & Lane, 2011; Tabatabaei et al., 2025). Research on peripheral tourism emphasized its vulnerability, due to limited infrastructure, seasonality and restricted visibility in global markets (Bennike & Nielsen, 2024). In 2025, Kumar, Argawala and Kumar, in their systematic literature review, studying 277 publications (1990-2023), found that the need for a stronger integration of local community in tourism, helping a sustainable resource utilization (Basile & Tani, 2024), is advocated but only rarely implemented and that communities are marginal change actors.

The academic debate has increasingly highlighted tourism as a potential driver for the revitalization of peripheral regions (Splendiani et al., 2023; Hu et al, 2025). When appropriately managed, tourism can stimulate local economic activity, reinforce community identity and contribute to the preservation of cultural traditions and local knowledge. Nevertheless, tourism development in these contexts tends to remain fragile and strongly dependent on external factors,

including accessibility, market trends and broader regional development dynamics (Soták-Benedeková et al., 2025). Recently, digital-technologies have been found to be a relevant driver of tourism-led development (Pencarelli, 2020), even in rural areas (Brandano et al., 2023; Lapuz, 2023), but some found that, in order to get their benefits, the local areas should already have a some-what high level of technology-related education and skills (Salemink et al., 2017). Online platforms, booking systems and social media channels have significantly transformed the way destinations communicate with potential visitors, making it possible for small communities to reach audiences that were previously difficult to catch (Gursoy et al., 2024). Through digital tools, local actors can promote cultural events, natural attractions and territorial identities on a much broader scale. Yet the growing digitalization of tourism also introduces new challenges. Furthermore, they may help in strengthening the local area community participation (Sigala, 2018).
At the same time, in territories with limited infrastructure or fragile socio-environmental systems, such fluctuations may generate additional pressures that are difficult to manage and may effectively prove to be detrimental (Branduini & Carnelli, 2021), such as those related to the increased risk of massification they bring to the peripheral areas as well (Kamarulzaman et al., 2025). Moreover, increasing digital exposure may amplify existing territorial disparities, create reputational risks, and require acquiring new resources, and new capabilities, that small destinations may struggle to control (Guedes et al., 2023). Therefore, the present research investigates how digitalization interacts with tourism development processes in Italian inner areas. In particular, it explores how local communities and local actors perceive the opportunities, challenges and potential risks associated with the growing role of digital technologies in the tourism sector.

Purpose of the paper. The purpose of this paper is to investigate the conditions under which digital visibility transitions from a developmental asset to a 'double-edged sword,' specifically focusing on how different community stakeholders perceive these risks. Over the last decade, tourism sector has been deeply influenced by digitalization; digital technologies influence how destinations are promoted, how travelers plan and organize their experiences, and how local communities interact with visitors (Gursoy et al., 2024). These changes have been studied in several cases to understand how they happen in mature tourism destinations, but their implications for internal area, the less accessible and often rural areas in Italy, remain comparatively unresearched. This study investigates how digital tools impact on inner areas to increase their destination visibility, to encourage community participation, and to support sustainable development. Usually digital technologies, such as digital platforms, social media and other online communication channels, offer these destinations to reach wider audiences and to promote their cultural and environmental resources to a broader audience than otherwise (Luongo et al., 2024). At the same time, this increased digital visibility may also generate new challenges for these territories. A broad, sudden online exposure can trigger unexpected tourism demand, potentially creating pressure on local area's infrastructures, environmental resources and even the well-being of local communities (Rullani, 2022). Accordingly, it becomes important to look at the digital technologies without falling in the "pro-innovation bias" highlighting not only the positive effects, but also the potential risks that may arise when fragile destinations become more visible. In this study we adopt a comparative perspective focusing on four Italian regions characterized by different tourism development trajectories. Campania and Basilicata represent regions with plenty of valuable resources, but that experience difficulties in attracting stable tourism flows. By contrast, Veneto and South Tyrol are regions where tourism is already well established and where even peripheral destinations may experience increasing visitor pressure due to the overall attractiveness of the region. Comparing these different contexts let us examine how digital technologies interact with tourism development processes in areas characterized either by limited tourism demand or by increasing tourism intensity. Such a comparative perspective also helps to understand how local actors respond to digitalization depending on the maturity of the tourism system in which they operate.
More specifically, this research has beel developed to address the following questions:
RQ1: How do local actors in internal areas use digital technologies to promote tourism and enhance destination visibility?
RQ2: How do residents and local stakeholders perceive the opportunities and potential risks associated with increased digital exposure?
RQ3: To what extent can digitization promote sustainable tourism development in peripheral regions?

Methodology. To address the ambivalent role of digitalization, this study adopts a multiple case study research design, inspired by the principles of Grounded Theory, which allows theoretical insights to emerge inductively from the empirical material (Charmaz, 2014). This research design is particularly useful for exploring the perceptions and experiences of local stakeholders to capture the "how" and "why" in complex phenomena (Yin, 2017). Specifically, qualitative methods were considered particularly appropriate for capturing the perspectives of local actors and for gaining a deeper understanding of how tourism dynamics are experienced at the community level (Phillimore & Goodson, 2004).

We selected six Italian Inner Areas characterized by diverse tourism trajectories: Bisaccia (AV), Calitri (AV), Irsina (MT), Castelmezzano (PZ) in Southern Italy, and Cison di Valmarino (TV) and Commezzadura (TN) in Northern Italy. This selection allows for a comparative analysis between areas facing "under-tourism" challenges and those managing high-pressure tourism flows.

Data were collected through 18 semi-structured expert interviews in January and February 2026. To ensure that we were able to collect data from stakeholder with different perspectives and to help data triangulation, we implemented a purposive sampling strategy in each area, starting from the president of the local area Pro-Loco (to capture the official approach to the role of digital technologies in local area tourism development), some local tourism-entrepreneur (to

capture the more business-related factors), and some other actor (pointed out by the previous two in a snowballing sampling process) selected to capture engagement with territorial digital strategies. After the first interview, participants were recruited to enable a progressive identification of additional key informants suggested by initial interviewees as particularly knowledgeable about local tourism dynamics.

The interviews, all conducted via phone, lasted between 30 and 60 minutes by two researchers at the same time. These "focused expert interviews" were transcribed to ease the following analysis, and they were later supplemented by secondary data (web-sites of attractions and businesses in the area, social media profiles) to enhance their reliability.

After each round of interviews, the collected material was coded following Charmaz's (2014) approach: initial coding to stay close to the data and focused coding to synthesize large amounts of data into the four-core dimensions that emerged during the analysis:

- Visibility vs. Vitality (the gap between digital image and local services);
- Viral Spike vs. Structural Growth (the 'firework' vs. 'engine' development models);
- The Algorithm's Distortion (the homogenization of local heritage to fit digital aesthetics);
- The Housing and Labor Paradox (the displacement of residents and workers due to digital tourism pressure).

These dimensions were then cross-referenced with the territories' digital presence to identify how digital visibility interacts with local perceptions of seasonality and authenticity.

Preliminary results. The analysis of the 18 interviews across our selection of six Italian Inner Areas pointed out that digitalization cannot be considered a "strategy", but it is a complex factor that, interacts with territorial fragility, wil enable the local area to develop only when it is met with some other relevant factors. Our findings suggest that the "double-edged sword" effect is manifested through four distinct thematic patterns:

1. Visibility vs. Vitality
2. Viral Spike vs. Structural Growth
3. The Algorithm's Distortion
4. The Housing and Labor Paradox

The first primary pattern is linked to identify the difference between digital visibility and territorial vitality. In some cases, such as Irsina, digital platforms have successfully attracted some international interest, with the positive effect to sale properties to foreign buyers attracted via digital marketplaces, but, at the same time, respondents highlighted that this increased visibility was not able to stop the decline of essential services (healthcare, schools, transport) in the local area. This creates an "empty shell" effect: the territory becomes a scenic digital backdrop for temporary residents, but it is not able to create the needed "vitality" required for permanent local life to nurtur and develop.

Then we have the theme of the model of digital development for those local area succesfully using the digital technologies, and platforms, as a way to foster local area development. In some cases they are able to create some viral spike in attention, such as the one linked to the Sponz Festival in Calitri; we called it a "spike" as it is a sporadic and high-intensity burst of digital promotion, but it is linked to some specific events. These spikes have to potential to overwhelm the local area capacity without leaving a structural legacy if they are not managed as a way to "de-spike" the flows. On the other side, we have some completely different approach where the growth is more homogeneous during the year, as exemplified by Castelmezzano. This approach relies on some "territorial orchestrator" (in the case of Castelmezzano is a local cooperative in charge of managing the Angel's Flight). Here, digital tools are used as part of a coordinated governance strategy to ensure steady, manageable flows that support long-term economic stability while the local area gradually build a all-year-round offer that is able to deseasonalize the tourism, and economic, flows.

A third theme is the one comparing the homogenization and TikTok-ification linking to the algorithms. Especially in the Northern Italy cases (Commezzadura and Cison di Valmarino), we have found a mechanism of "algorithmic pressure". Local actors, particularly entrepreneurs, expressed a perceived need to adapt traditional architecture and heritage to fit the "Instagrammable" aesthetic dictated by global platform algorithms. The local area stakeholder saw the risks of transforming authentic territorial identity into a homogenized product that are not able to express the real local area identity. Respondents noted that this is related to the requests to new tourism flows that often prioritizes aesthetic appeal over the complex, sometimes reality of rural traditions.

Eventually, there is the theme of a potential systemic paradox. Digital visibility, while attracting tourists, often displaces the local labor and residential base. As found in high-pressure over-tourism areas like Commezzadura, the presence in the ever more diffused digital short-term rental platforms (e.g., Airbnb) has increased the housing prices that in some cases are so high that seasonal workers, and young residents as well, can no longer afford to live in the area. This creates a "digital gentrification", a paradox where the territory has the digital capacity to attract guests but, if left unmanaged, it will lack the "true-to-the-place" human and social capital needed to serve them, threatening the long-term sustainability of the tourism system.

Research limitations. While this study provides useful insights on the relationship between digitalization and tourism development in internal areas, it has some limitations to acknowledge. First of all, this research is based on a qualitative research design built on a small number of semi-structured interviews with local expert such as the presidents of local Pro Loco associations. These organizations play an important role in promoting tourism initiatives and often act as intermediaries between residents, institutions and visitors. Given the limited number of interviews in each area, the

findings should be interpreted as exploratory in nature and cannot be generalized to all internal areas or tourism destinations. Another aspect to consider concerns the range of stakeholders included in the analysis as the study focuses primarily on actors directly involved in tourism promotion, and that have been reached through the Pro Loco associations. Other relevant actors, such as local entrepreneurs, accommodation providers, public administrators or residents not directly engaged in tourism activities, may hold different perspectives regarding the opportunities and potential challenges associated with digital tourism development. Including a broader variety of stakeholders could therefore offer a more comprehensive understanding of the phenomenon. A further limitation relates to the geographical scope of the research. The empirical analysis focuses on four Italian regions (Campania, Basilicata, Veneto and South Tyrol), selected to represent different tourism development trajectories, but not really able to capture the whole set of diversity of the internal areas, usually characterized by diverse socio-economic, cultural and infrastructural. As a result, the findings of this research may not fully reflect the variety of tourism dynamics that can be observed in other peripheral territories. It is also important to understand the temporal dimension of the analysis as this study captures local perceptions regarding the role of digital technologies at a specific moment in time as both tourism dynamics and digital communication strategies are evolving rapidly. Further developing this research using a longitudinal research protocol could provide a deeper understanding.

Finally, our study relies only on the perceptions and experiences of the interviewed experts without trying to look at quantitative indicators used to measure the evolution over time of tourism flows, digital engagement and/or online visibility; combining qualitative insights with quantitative data, for instance website traffic, social media interaction metrics or visitor statistics, to strengthen the empirical basis of the analysis could be beneficial in getting a better understanding of the effect of digital technologies in these areas; accordingly, future studies could adopt mixed-method approaches, expand the number of case studies and develop comparative analyses across different national contexts. Such efforts would help further clarify how digitalization influences tourism development trajectories in peripheral territories.

Managerial implications. The findings of this study suggest that managing the digital transformation of inner areas requires a holistic approach that managers and policy makers should adopt. Looking at the results adopting the four identified themes, we have that, looking at the first dimension (Visibility vs. Vitality), the primary implication is the need to develop a preliminary "territorial audit" before proceeding to design a digital promotion strategy. In developing this audit, local area managers should move beyond traditional tourism metrics (e.g., bed-nights, social media reach), to consider some sort of "Vitality Metrics" to assess the health of the local social dimension, including elements such as primary healthcare accessibility, local supply chains stability, or even how is evolving the ratio of seasonal visitors to permanent residents. Managers should pace the digital visibility to the "offline" area vitality to avoid the risk of creating an unsustainable "empty shell" where the territory remain unlivable for residents. Managers could reduce the impacts of these issues targeting their communication to specific visitor segments more aligned with the territory's current carrying capacity. Furthermore, in destinations where digital success attracts significant foreign property investment, the managerial focus must transition from the "promote the area" to "engage the resident" mindset, using digital platforms to integrate the new owners into the local community and its activities. Ultimately, governance in this phase requires an integrated planning approach where the Destination Management Organization (DMO), and municipal planners, should justify and prioritize the physical service improvements, using digital demand data as a diagnostic tool.

Regarding the second dimension (i.e., Viral Spike vs. Structural Growth), results suggest practitioners to move beyond searching for viral content to look at structural development. Managers should audit the local event to identify the sporadic bursts of digital attention not able to create lasting benefits. One key strategy is to leverage an "Orchestrator" in charge of coordinating digital efforts and shifting the narrative to highlight off-peak assets (if any) trying to to "de-spike" tourism flows. Governance should focus on shared digital protocols and unified information systems encouraging a homogeneous distribution of visitors to deseasonalize the flows.

Looking at the results for the third dimension (Algorithm's Distortion), the primary implication for practitioners is to critically assess the destination's digital presence and if it is drifting towards aesthetic homogenization. Managers should evaluate if they are forcing local heritage into "instagrammable" archetypes prioritizing visual appeal over their real cultural depth. The resulting strategy should center on a "narrative leadership", asking the local area managers to proactively curate content highlighting the complex, and sometimes un-photogenic, reality of rural traditions, while training local entrepreneurs to communicate their authentic identity rather than merely "following the algorithm". From a governance perspective, this may involve creating digital guardrails (quality labels or narrative protocols) to safeguard the territory's unique character and to ensure that digital platforms are used as educational tools, rather than as mechanisms for producing standardized global tourism products.

Lastly - i.e., for the 4th dimension "Housing and Labor Paradox" - local area managers should focus on aligning digital strategies and social sustainability. Practitioners should implement a monitoring (e.g., leveraging data from Airbnb or Booking) to track the "displacement effect" in real-time, identifying early signs of "digital gentrification" that could undermine the destination's operational capacity. Local area strategy should integrate tourism development in residential welfare policies, implying that DMOs should collaborate with local authorities to create "worker-resident housing quotas" or to incentivize hospitality networks to provide affordable accommodation for the workforce (even in the off-season periods). From a governance perspective, this asks for an active regulation of short-term rental platforms through digital licensing and zoning laws to maintain a healthy balance between tourism profitability and community livability.

Originality of the paper. This study contributes to the literature on tourism management by offering a comparative perspective on tourism-led development in internal areas, that moved, if possible, beyond the typical "pro-innovation" bias. While existing research often treats digitalization, and the related platforms, only as an opportunity for the existing rural areas to foster a development process, the present analysis challenges the implicit optimism regarding the effects of digital visibility aligning with newer approaches such as the OCO theory (Oberländer et al., 2024). Our preliminary results show that a rural area needs both managerial expertise, community support, and infrastructure, to let digital exposure become a ripe fruit to collect, without these competences, and the related capabilities and resources, digital exposure risks to act as a "double-edged sword" potentially triggering systemic crises and volatile demand rather than stable growth.

Furthermore, the research goes beyond an homogeneous treatment of "local communities" common in existing literature (Salemink et al., 2017). By comparing territories in diverse regional context – ranging from the under-tourism in Basilicata and Campania to the high-pressure ones in Veneto and South Tyrol, the study provides some evidence on how digitalization may not only impact differently in different contexts, but it might have a different impact on different local actors as well (Fan et al., 2023; Li, et al., 2026b). Our preliminary results highlight that local area communities, even in the smaller and more engaged rural areas, are not monoliths; instead our results show that these areas face internal fragmentation, with different levels of digital readiness, and with a different perception of the related risks according to both an Area-effect and a Stakeholder-effect (Li et al., 2026a). In this sense, the analysis contributes to a more nuanced understanding of how digitalization interacts with different local area contexts to reconfigure the tourism development processes in territories that are often marginal within mainstream tourism circuits.

A Socio-Technical Perspective on Digital Transformation and Organizational Change. Empirical Evidence from C-level Executives

GIORGIA MASILI[1], FRANCESCA FALCITELLI[2], MARIO RISSO[3], DANIELE BINCI[4]

Abstract. *Digital transformation aims to reconfigure processes, structures, and relationships through digital technologies, with failure rates estimated at around 70%. Adopting a socio-technical perspective, this paper conceptualises DT as the co-evolution of different variables by examining how enabling conditions interact with technological infrastructures, organisational variables, and human factors. The study addresses three questions: (1) how the transition of the IT function from cost centre to strategic driver reshapes transformational leadership behaviours; (2) which leadership mechanisms most effectively reduce cultural resistance during IT strategic repositioning; and (3) which competencies are perceived as most critical for AI-enabled DT.*

We employ qualitative content analysis of interviews with nine C-level managers. Findings show that resistance is a physiological, multi-level phenomenon signalling socio-technical misalignment rather than mere conservatism; that IT is increasingly reframed as a strategic engine, with CIOs/CTOs reporting directly to CEOs and business intelligence supporting value creation; and that cognitive and hybrid skills, combined with transformational leadership, are considered decisive. Finally, we argue that DT effectiveness depends less on specific technologies than on the alignment of technical, cultural, and leadership enablers, and highlights the need for continuous reskilling and leadership development.

Keywords: *Digital transformation; Socio-technical systems; Enabling conditions; Leadership; Skill development*

Framing of the research. Digital transformation (DT) is a pervasive phenomenon that aims to radically reconfigure processes, structures, and relationships by integrating digital technologies (Zapata et al., 2022). However, a large portion of DT projects fail to deliver expected benefits because organisational and cultural factors are underestimated with a consistent focus on technology (Kane et al., 2019; Vial, 2019). According to socio-technical theory (Trist and Emery, 1978), DT is a multidimensional process that extends beyond mere technological implementation and encompasses the soft variables of changes (Vial, 2019; Govers and van Amelsvoort, 2023). At the technical level, advanced IT infrastructures facilitate information flows, but these alone are insufficient and require integration and balancing with social variables such as organisational culture, skills, and leadership (Vial, 2019). In terms of organisational culture, evidence shows that rigid and hierarchical cultures tend to implement digital technologies superficially, reproducing obsolete decision-making patterns, whereas flexible and adaptive cultures foster continuous learning, innovation, and experimentation, thereby enhancing the transformative potential of technology and supporting digital transformation (Kim and Yu, 2024; Trenerry et al., 2021). Such cultures are also associated with higher levels of organisational and digital agility, understood as the dynamic capability to quickly sense and respond to environmental changes by leveraging digital technologies (Zhang et al., 2024).

Investing in technical skills development to cope with technological issues undermines change, whereas structured reskilling and upskilling programmes help build adaptability and reduce resistance to digital initiatives (Trenerry et al., 2021; BCG, 2024). Furthermore, leaders are enablers of DT, as they manage socio-technical interactions, frame technology as an opportunity, cultivate psychological safety, and invest in people's development (Pretorius and Smit, 2025). Leadership depends on the quality of decision-making processes in response to environmental signals and enabling conditions, which are developed through iterative cycles of sensemaking, experimentation, and learning (Weick et al., 2005). Strategic vision is a critical dimension: transformational leaders articulate a compelling direction while granting autonomy to operational units, enabling them to translate that vision into locally appropriate action (Nasution, 2024).

According to the DT literature, technical innovations, such as process innovation, can be entirely frozen by a lack of cultural support or a rigid decision-making structure (Kim and Yu, 2024; Trenerry et al., 2021). Therefore, identifying the enablers of an initiative's overall success is fundamental, but not sufficient. Recognising these factors requires a holistic perspective, as they do not operate independently but rather through feedback loops that amplify or attenuate their effects. Indeed, when the technical, organisational, and social enablers are well aligned, strong configurations emerge, facilitating systemic transformation and co-evolution, avoiding passively undergoing change or rigidly seeking to control it. A setback to change is resistance, which reveals socio-technical gaps, such as insufficient engagement or threats to autonomy (Trenerry et al., 2021). Other causes include mismatches between technical and social elements, skills deficits,

and inconsistencies between leadership and culture. Other misalignments are reflected in the perceptual dissonance that often emerges between leaders who see digital transformation as an opportunity and employees, who may perceive it as a threat to job stability (Kane et al., 2019).

Purpose of the paper. This study aims to explore the complex interplay among technological strategy, organizational culture, leadership development, and skills development, which are crucial aspects for addressing digital transformation in contemporary organizations. Its overarching objective is to investigate the dynamics by which organizations can implement a strategic alignment between the IT function and business objectives, turning technology into a sustainable competitive advantage while overcoming resistance to change. The research questions guiding the study are the following: How does the transition of the IT function to a strategic driver reshape leadership behaviours? Which specific leadership mechanisms reduce cultural resistance? Which managerial competencies are perceived as most critical to implement AI-enabled digital transformation successfully?

Methodology. To develop the analysis, we interviewed nine C-level managers from the IT and HR departments of different Italian organisations. In more detail, we applied an iterative thematic analysis (Braun and Clarke, 2006) to present our results by reviewing all documents and identifying recurring concepts (i.e., resistance, the role of IT, skills, and leadership). Accordingly, we carefully reviewed the data by reading transcripts and forming initial ideas of recurring patterns and core themes. Next, we systematically generated initial descriptive codes inductively, such as “IT from cost to strategic driver”, “cognitive balance”, “culture of curiosity”, “cultural resistance”, “structural constraints”, “transformational leadership”, and “technical-leadership issues”. Then we grouped codes into broader sets, defining five final themes: “cultural and structural resistance”, “IT governance shift”, “Cognitive balance and hybrid skills”, “Data-driven decision-making”, and “Transformational leadership”. We presented them in narrative form, using quotations as supporting evidence.

Results. (Theme 1) Cultural and structural resistance. Interviewees consistently highlighted the physiological resistance to digital tools and structural barriers. Resistance to implementing digital tools represents a fundamental challenge in organizational transformation. Research demonstrates that resistance arises from multiple levels: individual psychological barriers, including age, fear, cultural inertia, technological complexity, and ethical considerations, which overwhelm users' cognitive capacity (Sumarlin, 2024). Employees perceive automation as a threat to their professional roles (Najari et al., 2025) and manifest fear in multiple forms, including fear of job loss due to automation and skills gap (Ramadhani, 2025). The uncertainty of change extends beyond technological issues to encompass organizational aspects, career prospects, and the legitimacy of professional roles.

Table 1 – Evidence theme 1

Evidence 1	*“(Resistance) is a physiological step in any transformation process: not everyone is able or willing to embrace change, but progress cannot be stopped. I often hear comments such as: ‘Our customers are too old to use digital tools.’ When someone says that, I reply with a personal example. When I was working in China, I had to go to a hospital for a check-up required for my visa. At the entrance, even elderly people were required to scan a QR code and enter their details online. No paper, no exceptions. I asked my colleague how older people managed to handle everything via smartphone. The answer was simple: ‘We taught them.”*
Evidence 2	*“Such resistance does not stem only from a conservative attitude, but also from structural and regulatory constraints that make it difficult to introduce radical innovations into management and operational processes”.*
Evidence 3	*“Digital transformation challenges the traditional narrative of career progression, generating pressure on staff to acquire advanced skills”.*

(Theme 2) IT governance shift. The IT department evolves from a cost centre to a strategic driver by highlighting a fundamental reconceptualization of technology's role in organisational value creation. The core of this transformation lies in the strategic role of technology, which requires deep integration into the company’s overall business strategy (Alami, 2026). This transition reflects a paradigm shift the reorganisation of managerial roles. The IT function (and its CIO/CTO roles) increasingly operates at CEO-reporting level within executive levels, with direct involvement in strategic, board-level decision-making (Deloitte, 2025). According to the literature, organisations in which CIOs possess business competence and demonstrate strategic thinking capabilities achieve superior organisational performance compared to those that treat IT as merely a technical function. This change reflects the recognition that technology strategy must be connected to business, customer, and organisational strategies (Surjana, 2025).

In addition, the literature also highlights that CIO engagement at the strategic level is particularly critical during organizational transformation initiatives. CIOs functioning as strategic partners help executive teams understand how

technology investments create new market opportunities, strengthen customer relationships, and enable business model innovation (Pham et al., 2025). This strategic involvement shifts IT from a cost-management to a value-creation focus, in which technology investments are evaluated using business-impact metrics rather than purely technical performance indicators.

Table 2 – Evidence theme 2

Evidence 1	*"The IT function has evolved from a predominantly operational function into an increasingly strategic role: today, a culture of curiosity is the most authentic form of innovation. It is not about training someone, but about building a context in which every person feels legitimised to experiment".*
Evidence 2	*"The role of IT has changed profoundly over the years. It used to be essentially a service department; today it is a department of strategy and vision, fundamental in both the short and the medium term".*
Evidence 3	*"IT has shifted from a mere cost centre to a true strategic engine. Business intelligence tools make it possible to transform immense volumes of operational data into actionable insights, demonstrating the enabling role of advanced technologies".*
Evidence 4	*"There has been a significant hierarchical shift, whereby the CIO/CTO has moved from reporting to the Finance function to reporting directly to the CEO. This change signals full awareness that technology is no longer just a cost to be minimised, but the enabling factor and driving force behind business development".*

(Theme 3) Data-driven decision-making. The integration of AI-driven BI capabilities represents a critical evolution in which organizations transition from reactive, historical data analysis to predictive, prescriptive analytics that inform real-time strategic decisions (Ramasamy, 2025). Research highlights that organizations that establish robust data governance, data quality management, and data democratization frameworks achieve substantially higher returns from BI and analytics investments. When BI systems are designed for strategic alignment, connecting data insights directly to organizational performance metrics and strategic objectives, they enable executives to shift from intuition-based to evidence-based strategic decision-making (Mamun, 2025). Organizations implementing advanced BI platforms can integrate data across diverse domains to create unified dashboards informing strategic decisions regarding portfolio optimization, geographic expansion, and investment prioritization.

Table 3 – Evidence theme 3

Evidence 1	*"To what extent will we improve customer experience, efficiency, and service quality?' This change of perspective enables us to clearly select those digital initiatives that create real value for both the customer and the company".*
Evidence 2	*"Technology can help improve data analysis, the drafting of communications, and the management of repetitive information, easing administrative work and making institutional communication more timely. However, in the political sphere, AI cannot and must not replace human thought. Ideals, vision, sensitivity, and the ability to interpret reality remain prerogatives of human beings".*

(Theme 4) Cognitive balance and hybrid skills. Organizations achieving competitive advantage in technology-enabled environments prioritize cognitive balance, curiosity, and hybrid skill development over narrow technical specialization. Cognitive balance, the integration of analytical thinking, creative insight, emotional intelligence, and ethical reasoning, emerges as a critical differentiator for organizational success in AI-dominated landscapes (King, 2025). Organizations fostering curiosity, experimentation, and continuous questioning achieve superior innovation outcomes, as psychological safety enables employees to voice ideas, take interpersonal risks, and learn from experimentation during technology adoption. Hybrid skills represent a fundamental reconceptualization in which effectiveness in AI-driven contexts depends on leaders' capacity to blend strategic vision, people-centred leadership, and technical understanding to ask informed questions (Mamun, 2025). AI deployment success relies on effective collaboration between technical developers and business strategists (Mamun, 2025).

Table 4 – Evidence theme 4

Evidence 1	*"The key competencies are not technical but cognitive: we need to balance the pursuit of maximum efficiency with the need to explore new opportunities and experiment with artificial intelligence. This requires a clear 'yes' to radical changes in training, with specific programmes provided by companies".*

Evidence 2	*"In the digital realm, true competitive advantage does not lie in the super IT expert, but in the manager who is able to steer technology with a clear business vision. Transformation projects fail when the business completely delegates to technicians, without defining concrete objectives and expected benefits. For this reason, future managers will need to combine digital literacy, critical thinking, and an innovative mindset, orienting every decision to the value generated for the customer".*

(Theme 5) Transformational leadership. It is an effective leadership approach for enabling successful digital transformation while mitigating resistance and uncertainty (Dwivedi et al., 2019). Transformational leadership operates through four core mechanisms: idealized influence (modelling commitment to vision), inspirational motivation (creating compelling future narratives), intellectual stimulation (encouraging innovation and problem-solving), and individualized consideration (attending to individual development needs) (Seltzer and Bass, 1990). The impact of transformational leadership extends particularly to psychological safety, the perception that one can take interpersonal risks within the organization without fear of punishment. Leaders who combine transformational approaches with emotional intelligence create psychologically safe environments in which employees feel secure in voicing concerns about technology implementation, admitting skill gaps, and requesting support (Budhwar et al., 2023). This psychological safety is essential in translating resistance into constructive feedback that informs better implementation strategies (Newman et al., 2017; Edmondson, 1999).

Table 5 – Evidence theme 5

Evidence 1	*"Leadership is precisely about destabilising the status quo: clearly explaining the direction, providing concrete tools, and demonstrating in practice that digitalisation is not a threat but a driver of growth, efficiency, and satisfaction for both customers and employees".*
Evidence 2	*"The introduction of more advanced digital tools or automation logics requires a gradual and shared approach. The main lever for "destabilising the status quo" is not so much the technology itself as transformational leadership, understood as the ability to communicate the vision and actively engage staff".*

Research limitations. This work-in-progress is not free of limitations. First, the findings are based on a limited number of qualitative interviews, and thus, the available evidence is purely exploratory. As a result, the interpretations advanced here require further empirical confirmation through an expanded sample and the inclusion of more diverse organizational contexts. Future research, grounded in a broader and more heterogeneous empirical foundation, is needed to validate, refine, or challenge the conceptual patterns that have emerged at this initial stage.

Managerial implications. Digitalization has progressively transformed organizational dynamics and the role of technology within firms, as IT shifts from an operational support tool to a central component of strategic decision-making and value creation (Hess et al., 2016; Gobble, 2018). Digital tools and data reshape strategic decision processes, redistributing information, power, and autonomy across organizational levels (D'Cruz, 2024). Moreover, leadership practices that promote psychological safety, curiosity, and experimentation enable employees to accept change, voice concerns, and turn resistance into learning, thereby supporting effective digital transformation (Edmondson, 1999). The interconnection of cognitive flexibility, growth mindset, and cultures of openness, supported by leaders who frame AI as a partner to human capabilities, emerges as a key driver of innovation when socio-technical systems are deliberately designed for human-AI collaboration rather than mere automation.

The first managerial implication concerns the transition of the IT function to the board level, with CIOs becoming part of the top management team and working as strategic partners rather than back-office service providers (Campana and Schott, 2025). Elevating CIOs to CEO-level reporting and aligning IT metrics with customer value, growth, productivity, and service quality reinforces technology as a value-creation lever rather than a cost centre (Arnitz et al., 2017). This change requires joint strategy processes in which business and IT leaders co-define priorities and embed analytics and technology into board-level decision-making rather than confining them to operational reporting (Luftman, 2000). Secondly, skills development must focus on hybrid competences: organisations should design continuous reskilling loops on data literacy, AI and change management, while rewarding openness, curiosity, experimentation, risk-taking and shifting from compliance-oriented training events to continuous learning ecosystems (BCG, 2024; McKinsey, 2020). Organisational cultures must legitimise experimentation and calculated risk-taking while maintaining ethical boundaries, especially in AI-enabled contexts. Strategic visions should clearly articulate how AI serves human development and organisational purpose, linking digital initiatives to long-term societal and stakeholder value (Gobble, 2018). Third, leadership programmes should explicitly cultivate transformational behaviours, vision framing, psychological safety, and individualised support, so that digitalisation is perceived as a credible path for growth rather than a threat (Edmondson, 1999). Organisations that successfully integrate these dimensions realise the transformative potential of AI while simultaneously developing human capabilities for ongoing innovation, demonstrating that

competitive advantage lies in their capacity to foster cognitive balance, curiosity-driven cultures, hybrid leadership, systematic experimentation, organisational vision, and continuous learning.

Originality of the paper. This study contributes to DT research from a socio-technical perspective. It conceptualizes technological strategy, culture, leadership, and skills as interdependent elements that co-evolve through feedback loops, and resistance as a signal of misalignment between technical and social systems. Overall, this work-in-progress proposes a unified interpretive framework that links shifts in IT governance, socio-technical alignment, leadership mechanisms, and competency evolution into a coherent explanation of sustainable digital transformation.

Anticipating Emerging Technologies: Innovation Trajectories and Technology Transfer in an AI-Based University Spin-Off. A Longitudinal Case Study

NICCOLÒ FIORINI[1], FAHEEM UDDIN SYED[2]

Abstract. *In recent years, Artificial Intelligence (AI) has increased its importance in innovation processes and digital transformation. However, the technology on which AI is based has deep roots and not limited to recent years. The innovative solutions much discussed and used in recent years are the result of research and innovation that began decades ago whose enhancement on the market could not be immediate. In this context, universities play a fundamental role in the development and dissemination of new technologies, even if not in the short term, also through the creation of academic spin-offs aimed at exploiting the results of basic and advanced research. This study analyses, over a twenty-year timespan, the evolution of a university spin-off operating in the field of AI aiming to understand how technologies developed in academic environments can progressively evolve into industrial applications. The research adopts a qualitative approach based on a longitudinal case study of a deep-tech company founded in 2007 and originating from university research activities in the fields of natural language processing and question answering systems. The study integrates different sources of information, official data, documents, interviews, and other documents and data collected over almost two decades, allowing the reconstruction of the organisation's evolutionary trajectory from the initial academic research phase to the development of artificial intelligence application platforms. The findings show how university spin-offs can contribute to the early development of emerging technologies by developing capabilities and technological solutions well before their large-scale industrial deployment.*
Keywords: *Technology Transfer; Innovation Management; Academic Entrepreneurship; University Spin-Offs; Artificial Intelligence.*

Framing of the research. In recent years, AI(AI) has become one of the main drivers of technological transformation and industrial innovation processes (Dwivedi et al., 2021). The evolution of machine learning techniques, natural language processing technologies and conversational platforms has fostered the spread of new digital applications in numerous economic sectors, helping to redefine business models, organizational processes and ways of interaction between companies and users (Plathottam et al., 2023; Gama and Magistretti, 2025).

Within this scenario, universities play an increasingly important role in contemporary innovation systems, contributing to technological development also through knowledge transfer activities and research-based entrepreneurial initiatives (Perkmann et al., 2013; Audretsch and Belitski, 2020; Makai and Rámháp, 2021). In addition to the production of scientific knowledge, many academic institutions actively participate in the development and dissemination of new technologies through technology transfer (TT) activities, collaborations with companies and the creation of new research-based business initiatives (Dabić et al., 2022; Scarrà and Piccaluga, 2022). In this context, university spin-offs represent one of the main tools through which the results of scientific research can be transformed into technological applications and market opportunities (Hayter et al., 2018; Cantner et al., 2024).

The literature on academic entrepreneurship has mainly focused on the factors that favour the creation of university spin-offs and on the role of these companies in innovation and regional development systems (Caputo et al., 2022). Less attention has been paid to the long-term evolutionary trajectories of these organizations and to the processes through which technologies developed in scientific research are progressively transformed into industrial solutions through different phases of technological and organizational development (Rasmussen et al., 2011). This aspect is particularly relevant in the field of emerging technologies, such as AI, where the transition from scientific research to industrial applications can require long times and complex processes of technological development, experimentation and adaptation to market contexts. However, the literature has devoted less attention to the processes through which deep-tech academic entrepreneurial initiatives are able to sustain technological trajectories in the long term that are still far from maturity and market interests. In particular, there is limited understanding of how university spin-offs can operate as intermediate structures capable of keeping alive, adapting and progressively reconfiguring technologies developed in scientific contexts and in times considered premature with respect to existing market demand.

In many cases, the technologies that today characterize the current phase of AI diffusion were developed and tested in academia many years before their large-scale industrial diffusion (Verspagen, 2006).

Understanding how these emerging technologies can be developed, adapted and progressively transformed into industrial applications is therefore a central theme for studies on innovation management, TTTT and technological entrepreneurship (Markman et al., 2008). In this perspective, the analysis of cases of companies born from academic

[2] Dipartimento di Studi Aziendali e Giuridici, Università degli Studi di Siena

research and developed over time offers the opportunity to observe in depth the processes through which scientific knowledge can evolve into technological innovations and application solutions.

Purpose of the paper. The aim of this work is to analyse the long-term evolution of a university spin-off operating in the field of AI in order to understand how technologies developed within academic contexts, often long before their widespread diffusion in firms and everyday applications, can progressively be transformed into successful industrial solutions through processes of technological entrepreneurship and TT (Perkmann et al., 2013).

This research analyses in detail a deep-tech company founded in 2007 as a spin-off of a medium-sized Italian university, specialized in the development of natural language processing technologies and question answering systems. The peculiarity of this case, which makes it decidedly interesting to analyse, is that the company began to develop solutions based on AI, or rather on technology that is now identified by the market as AI, well before the widespread use that many AI tools have had recently. This allows us to observe how academic basic research can contribute to the development of emerging technologies, through the emergence of entrepreneurial activity well before their large-scale diffusion in the markets. Adopting a longitudinal perspective, the study reconstructs the evolutionary trajectory of the company and identifies the main phases through which a technological project originating within a university environment may evolve into a research-based entrepreneurial initiative and subsequently into an applied technological platform (Rasmussen et al.,2011). The analysis highlights the processes through which scientific competences developed in the academic context are progressively translated into technological innovations through entrepreneurial initiatives, collaborations with universities and integration processes involving industrial actors. In addition to reconstructing the evolution of a single company, the study aims to explore how university spin-offs operating in deep-tech sectors can help sustain and shape technological trajectories during phases in which market demand is still limited or not yet clearly defined. In this perspective, the article interprets TT not as a linear transition from research to the market, but as a long-term process of technological adaptation, organizational reconfiguration and progressive alignment between scientific capabilities and emerging application contexts recognized as valuable by the market. This perspective allows the study to address the following research question: how can cutting-edge academic research developed in a phase that precedes market demand give rise to a TT process capable of generating a sustainable and successful entrepreneurial initiative over time?

From a broader perspective, the study contributes to the literature on innovation management, academic entrepreneurship and TT by highlighting the role that university spin-offs may play in the early development of new technological trajectories (Clarysse et al., 2011). In particular, the analysis of the case suggests that academic research can act as a forerunner in the development of technologies well before they are considered emerging from the market, but that it can still contribute to their maturation and subsequent diffusion within industrial systems.

Methodology. The research adopts a qualitative approach based on a longitudinal case study aimed at reconstructing the evolution of a university spin-off operating in the field of AI. The case study approach is particularly suitable for analysing complex processes of innovation and entrepreneurial development, in which organisational and technological phenomena evolve over time through non-linear dynamics (Eisenhardt, 1989).

The case analysed concerns a deep-tech company founded in 2007 as a spin-off of an Italian university and specialised in the development of natural language processing technologies and question answering systems. The longitudinal reconstruction of the case is based on the integration of different empirical sources collected between 2007 and 2025, including archival and institutional documentation relating to both the university of origin and the company, organizational and technological materials, as well as data collected as part of academic and TT activities. These sources also include three longitudinal semi-structured interviews conducted in 2023, 2024 and 2025 with company representatives. The interviews, lasting an average of about forty minutes, were recorded and transcribed. The combination of archival, documentary and interview-based sources has allowed the triangulation of empirical evidence and the reconstruction of the technological and organizational evolution of the company in the long term. For reasons of confidentiality, the name of the company and some contextual elements have been anonymised. The selection of the case is motivated by the availability of a particularly extensive information base that allows the reconstruction in detail of the technological and entrepreneurial development of the organisation over time. In addition, one of the authors observed the case longitudinally through academic and TT activities, maintaining an external position with respect to the operational and managerial activities of the company.

The analysis is based on the integration of different types of empirical sources collected over a period of approximately two decades. These include archival documents relating to the creation phase of the spin-off, institutional materials produced within the university context of origin, company documentation and information sources relating to the organisation's early technological development activities. These materials make it possible to reconstruct accurately the context in which the entrepreneurial initiative emerged and the early stages of the TT process. These sources are complemented by materials collected over time through direct interactions with the company and with the academic environment from which it originated. This information includes analyses developed in the context of research, teaching and collaboration with the organisation over several years, which have made it possible to observe the evolution of the technologies developed, the applications proposed and the business strategies adopted by the company.

The availability of information sources covering both the phase preceding the creation of the spin-off and the subsequent phases of the company's development makes it possible to adopt a longitudinal perspective on the evolution

of the case. This approach enables the reconstruction of the process through which scientific competences developed in academic environments are progressively transformed into technological applications and industrial solutions through research-based entrepreneurial initiatives. This methodological approach allows an in-depth understanding of the evolutionary dynamics that characterise research-based entrepreneurial initiatives in emerging technological domains. The empirical analysis was developed through a longitudinal interpretative approach and a thematic analysis of the main transformations observed over time. The four evolutionary phases identified have not been defined a priori but have emerged progressively from the analysis of the technological, organizational and market changes of the company and its relations with the university and industrial context. To limit possible risks of proximity bias, the analysis was based on the triangulation of independent empirical sources, including archival sources, institutional documentation and recorded and transcribed interviews.

Results. The longitudinal analysis of the case study allows us to reconstruct the evolution of a deep-tech company originating from academic research over a time span of almost two decades. The trajectory of the organization highlights how scientific knowledge developed in the university environment can be progressively transformed into application technologies through a process of entrepreneurial development characterized by different evolutionary phases. The evolution of the company can be interpreted as a sequence of four main phases that reflect the progressive transition from academic research to the development of AI application platforms.

The first phase is linked to the academic origins of the technologies developed. The initial activities are in fact rooted in a university research context in the field of natural language processing and question answering systems. In this phase, the activities are mainly oriented towards scientific research and the development of technological solutions based on semantic analysis techniques, information retrieval and automatic natural language processing.

The technologies developed in this context are aimed at the automatic understanding of queries formulated in natural language and at the search for information within structured and unstructured knowledge bases. These scientific skills constitute the technological basis that will make possible the subsequent creation of the company and represent the core of knowledge on which subsequent technological applications will be developed. It is important to underline that these research activities are developing in a period in which AI does not yet represent a widely used technological field at an industrial level. At this stage, many of the applications that characterize the AI landscape today is still mainly the subject of academic research and scientific experimentation. This element contributes to making the case analysed particularly interesting to understand how some entrepreneurial initiatives can anticipate the development of emerging technologies, developing skills and technological solutions at a very early stage with respect to their diffusion in the markets.

The second phase includes the creation of the university spin-off that represents a particularly pivotal moment in the evolutionary path of the organization coincides with. The formal establishment of the company, which took place in 2007, originates from the intention of the researchers/founders to test in a competitive and applicative environment some technologies previously developed within academic research activities. With this step, scientific knowledge gained in the university context started to shift towards an entrepreneurial perspective. Here the results of research move from an academic-confined environment towards possible operational applications, still maintaining their scientific standing.

The main objective of this TT activity was the industrial development of question answering systems. In fact, analysing the original business plan, it appears evident that these systems represent the core of the company's technological proposal. The solutions developed in the early stages are designed to interpret queries expressed in natural language and return relevant answers by combining information retrieval techniques and semantic analysis tools. These systems can be interpreted as one attempt to translate scientific knowledge produced in the academic field that was mainly use for theoretical purposes into something that could have been used within organizational contexts characterized by an intensive use of information. Furthermore, during the first years of activity, the organization's attention remained strongly focused on technological development, still highly science based. A significant share of the resources both of the university group and of the company’s employees were dedicated the improvement of the scientific knowledge that forms the basis of the solutions developed. At the same time, an activity of exploration of the possible areas of application of the technologies takes shape. This orientation is typical of deep-tech initiatives, in which the scientific dimension continues to play a central role even in the early entrepreneurial phases.

The third phase is the more market-oriented phase, with better structured interactions with potential users and concrete application contexts, came soon after: these contacts, made possible to better understand in which areas the technologies developed can generate value. Over time, technological development was accompanied by a progressive strengthening of the organizational dimension of the company. Internal expertise continues to deepen, particularly in the fields of natural language processing and semantic technologies, while the number of contexts in which such solutions are tested is increasing. A significant part of this evolution derives from the need to adapt technologies originally conceived within research environments to the operational needs of different organizational systems. In deep-tech initiatives, this process of reconfiguration is quite frequent: scientific knowledge must be progressively reworked so that it can function within complex industrial and organizational contexts. The period was characterized by a profound transformation oriented towards the progressive conversion of scientific skills and experimental technologies into solutions that can be concretely used in organizational and industrial contexts. Through the analysis of the context, it was possible to understand the different and varied uses of technology that have allowed its exploitation from a more commercial and industrial perspective. All while always maintaining a strong link with the university to which they belong. Collaboration with the

academic environment continues to fuel exchanges of knowledge between scientific research and application-oriented innovation. This continuity in relationships is one of the elements that most frequently characterize deep-tech companies born in university contexts. In this phase, TT does not take the form of a simple transfer of knowledge from the university to the market, but of an iterative process of adaptation and reinterpretation of scientific skills in relation to progressively more articulated application contexts. The expansion of the company's activities has also allowed the development of relationships with more structured industrial operators. This has allowed not only access to new resources, but also to acquire more specific managerial skills and wider commercial channels. These elements contribute to strengthening the organization's ability to operate in increasingly complex and competitive market environments. At the same time, the technological architecture of the solutions is also evolving. At this point, we are at fourth phase of evolution that describe the transition of a deep-tech company from its academic roots to a consolidated industrial platform. Systems initially focused on questions and natural language processing are progressively integrated into more articulated platforms, capable of supporting conversational interfaces and virtual assistants based on AI. From pure academic research, the company is arriving at products and services that are perfectly in line with market demands and the most advanced technological needs. This transformation highlights how the maturation of deep-tech technologies often requires long processes of realignment between scientific development, organizational capabilities and market conditions. This evolution is part of a broader transformation that has affected the field of AI in recent years. Conversational technologies and human-machine interaction systems have in fact acquired an increasingly important role in digital applications. Overall, the dynamics observed show how an entrepreneurial initiative born from academic research can develop through a continuous process of technological adaptation and organizational transformation. The case study also suggests that university spin-offs may represent particularly favourable contexts for the experimentation of emerging technologies. In such environments, scientific expertise and operational applications often tend to take shape before technologies reach large-scale industrial deployment. At the same time, the company's evolutionary path remains open. In fact, the organization continues to introduce new technological solutions and redefine its role within the innovation ecosystem in which it operates. Such a trajectory reflects the dynamic nature of many deep-tech initiatives in rapidly changing and ongoing technology environments. Overall, the four evolutionary stages identified show a progressive transition from pure academic research to the development of AI platforms that are more valued by the market and scalable. The first phase is characterized by the development of anticipatory scientific skills in the field of natural language processing and question answering systems, which constitute the technological basis of the entrepreneurial initiative in a phase in which the market was not yet ready to fully understand its application potential. The second phase coincides with the creation of the spin-off and with the first forms of entrepreneurial experimentation aimed at transforming scientific knowledge into concrete technological applications. The third phase, on the other hand, highlights a progressive process of adaptation and reconfiguration of the skills developed in the academic field through interaction with the market, the expansion of application contexts and the strengthening of the company's organizational capacities. Finally, the fourth phase shows the consolidation of more structured and industrially scalable AI platforms, also favoured by the continuity of relations with the university context and the integration with industrial partners. Taken together, the observed dynamics suggest that the evolution of deep-tech university spin-offs does not occur through linear transitions from research to market, but through cumulative processes of technological maturation, organizational adaptation and progressive alignment with emerging application contexts.

Research limitations. This study presents some limitations that are typical of research based on single case studies. In particular, the analysis focuses on the long-term evolution of a specific deep-tech company originating from academic research and operating in the field of AI. Consequently, the findings cannot be directly generalised to other organisational settings or technological sectors. A further limitation concerns the qualitative nature of the research design. Although the availability of multiple sources of information covering an extended time span makes it possible to reconstruct the company’s evolutionary trajectory in considerable detail, the interpretation of the observed dynamics inevitably remains linked to the specific characteristics of the case analysed. At the same time, the longitudinal perspective adopted also represents one of the main strengths of the study. The availability of archival materials and empirical evidence spanning different stages of the company’s development makes it possible to observe over time the technological and entrepreneurial processes that characterise deep-tech firms originating from academic research.

Future research could extend the analysis in several directions. Comparative studies involving multiple university spin-offs operating in similar technological domains could help to identify recurring patterns in the evolution of research-based ventures. In addition, quantitative analyses could contribute to a more systematic understanding of the developmental trajectories of deep-tech companies originating from academic contexts.

Theoretical and managerial implications. From a theoretical point of view, the case suggests that deep-tech university spin-offs do not only represent research commercialization tools, but also actors involved in the progressive construction and maturation of new technological trajectories. In this perspective, TT emerges as an iterative process of technological adaptation, organizational reconfiguration and progressive alignment with emerging application contexts, rather than as a simple linear transfer of knowledge from the university to the market.

The empirical results that emerged from this study allow us to identify some relevant implications for universities, public decision-makers and entrepreneurs involved in the development of entrepreneurial initiatives based on research and deep-tech technologies. The analysis of the case suggests that university spin-offs often tend to be located in the early

stages of the technological development path, when scientific knowledge is still the subject of technical refinement and application-oriented experimentation. In these circumstances, organizations born in the academic field can take on the role of intermediaries through which technologies that are still embryonic are progressively adapted and transformed into concretely usable solutions, before reaching a wider industrial diffusion. From this perspective, the strategic importance of supporting entrepreneurial initiatives originating from research activities clearly emerges for universities and TT offices, especially in sectors characterized by long and complex technological development cycles, such as in the case of AI. The case analysed also suggests that universities and TT offices should adopt support mechanisms capable of accompanying deep-tech initiatives even in the medium to long term, avoiding concentrating support exclusively in the initial stages of spin-off creation.

A further element highlighted concerns the continuity of the relationships between the academic context and entrepreneurial initiative along the different phases of organizational development. The relationship between university spin-offs and academic institutions does not necessarily end when research is transferred to the market. On the contrary, in many cases this relationship tends to continue over time, continuing to offer scientific stimuli, new research questions and further opportunities for technological exploration. The persistence of interactions between the company and the academic context seems to favour the circulation of highly specialized knowledge and, at the same time, contribute to maintaining a direct link between scientific activity and the development of application solutions. In this perspective, the link with the university does not only take on the role of the point of origin of the entrepreneurial initiative but can be transformed into a continuous source of knowledge and technological orientation. This dynamic also has significant implications for the public actors involved in the definition of innovation policies. For policy makers, the case highlights the need to develop support tools consistent with the long maturation times of deep-tech initiatives, avoiding evaluation logics exclusively oriented towards short-term results. If the interactions between academic research and entrepreneurial initiatives can be prolonged over time and generate mutual benefits, then it becomes significant to promote institutional arrangements that make it possible to build stable collaborations between research organizations and emerging companies. This is particularly important in technological sectors characterised by high scientific complexity and long and uncertain development processes. A further element concerns the organizational transformations that deep-tech initiatives tend to face as their technological and commercial activities begin to expand. Entrepreneurial projects originating within academic research are often initially focused on the scientific development of technologies. However, as these initiatives enter the markets as they enter the market, they are confronted with different organisational needs. The transition to a more structured industrial organization requires the gradual integration of managerial skills, financial capabilities and commercial infrastructures that are rarely available in the initial stages of academic initiatives. In this growth process, interaction with already established industrial players can play an important role. Collaborations with more structured companies allow access to additional resources and organizational skills that contribute to strengthening the company's technological capabilities. At the same time, such relationships can facilitate the scalability of solutions originally developed in research, making it possible to adapt them to broader application and industrial contexts.

Industrial partnerships or, in some cases, deeper forms of strategic integration can therefore represent a significant step in the path through which technologies originating in the academic context are able to reach broader market applications. Overall, the case analysis shows how the development of research-based entrepreneurial initiatives tends to be configured as a progressive process in which scientific skills, entrepreneurial experimentation and industrial collaboration gradually align over time. From an entrepreneurial perspective, the case also suggests the importance of maintaining a balance between continuity of original scientific skills and the ability to adapt to changes in application contexts and market needs. In this perspective, institutional actors interested in strengthening innovation ecosystems can benefit from policies capable of supporting these dynamics in the long term, allowing technologies derived from research to mature and transform into solid industrial applications within complex technological contexts.

Originality of the paper. The main contribution of this study consists in the longitudinal reconstruction of the development of a university spin-off active in the field of AI over a time span that extends for almost two decades. The availability of empirical material relating to such a wide period allows us to observe in greater depth how an entrepreneurial initiative born within academic research can evolve over time to become a technological organization capable of operating in structured industrial contexts. Much of the literature on academic entrepreneurship has focused on the conditions that favour the emergence of university spin-offs or on the very early stages of their development. The analysis proposed in this paper is instead placed on a longer temporal level and follows the subsequent evolution of a deep-tech company, observing how technological capabilities, organizational structures and market positioning gradually transform when the company goes beyond the initial phase strongly focused on research. This broader temporal perspective allows us to examine in greater detail the processes through which the scientific skills developed within universities are progressively translated into applied technologies and increasingly articulated technological platforms. The case analysis also allows us to observe the development of AI technologies in a historical phase prior to their large-scale industrial diffusion. A particularly important aspect concerns the historical moment in which the company started its first experimental activities. Solutions based on natural language processing and question answering systems were in fact developed at a time when many of the applications associated with AI today had not yet assumed a significant presence in industrial contexts and remained, to a large extent, confined within the perimeter of academic research. Placing the case within this scenario allows us to better grasp its scope, because it shows how some technological

trajectories began to take shape well before their subsequent affirmation on a larger scale. Precisely for this reason, following the evolution of the company over time allows us to focus on the contribution that entrepreneurial initiatives born in the university environment can offer in the initial phase of defining new technological paths. The point is not only that these companies transfer the knowledge produced in research to the outside world, but that, through experimentation, adaptation and the progressive implementation of solutions, they participate directly in the construction of the directions along which technological development will then tend to consolidate. In other words, organizations of this type can have a significant impact on the early configuration of areas that only later acquire a more extensive relevance within industrial innovation systems. From this point of view, the case suggests that companies originating from academic research should not be interpreted solely as vehicles for exploiting knowledge already available. Their function appears broader. In many cases, they contribute to creating an intermediate space in which scientific knowledge is reworked, tested and progressively oriented towards possible application developments, thus favouring the emergence of new solutions and, more generally, of new technological directions. It is precisely the longitudinal perspective that allows these processes to be read more precisely. By observing the trajectory of the company over time, it becomes possible to reconstruct the mechanisms through which university research can generate entrepreneurial initiatives capable not only of enhancing existing scientific skills, but also of accompanying their evolution, supporting the development of further technological solutions over time. In this key, these initiatives end up contributing, in a gradual but significant way, to the formation and consolidation of new technological areas.

Artificial Intelligence in Public Services: Reshaping the Conditions of Value Creation

BEATRICE BELLASSI[1], MARIA CRISTINA DARDANO[2], ANGELA CARIDÀ[3]

Abstract. *Artificial intelligence (AI) is increasingly embedded in digital public services, with implications for how citizens access and engage with public administration. Existing research has largely focused on governance, transparency and the ethical implications of AI, while comparatively less attention has been paid to how AI may reshape interaction practices within public services.*
This paper aims to examine how the adoption of AI in digital public services may reshape interaction practices between citizens and public administrations, and how these transformations may influence the conditions under which public value is co-created or co-destroyed.
Drawing on the Estonian digital government ecosystem, the study adopts an exploratory qualitative approach based on document analysis of selected AI-enabled public service examples. Preliminary findings suggest that AI-mediated interactions may support or hinder the alignment between institutionalised service templates and the enactment of service practices. Rather than exerting uniform effects, AI appears to be associated with different configurations through which such alignment is sustained or disrupted, pointing to its context-sensitive and potentially ambivalent role in shaping public value in digital public services.
Keywords: *Artificial Intelligence; Digital public services; Public value; Value co-creation; Value co-destruction*

Framing of the research. *The growing complexity of contemporary societal challenges - environmental, social, and democratic - has intensified debates on the role of organizations in generating value for society. Within public administration research, these discussions have been articulated through the concept of public value, which emphasizes the responsibility of public institutions to align public action with socially valued outcomes (Moore, 1995; Benington, 2011). From this perspective, public administration can no longer be understood merely as a bureaucratic apparatus dedicated to service provision, but increasingly as an institutional actor oriented toward the generation of public value.*

Originally formulated by Moore (1995) and further developed within public management scholarship (O'Flynn, 2007; Bryson et al., 2014), public value extends beyond organizational efficiency and administrative performance. It is co-created through interactions among institutions, citizens, and communities (Benington, 2011), in which heterogeneous resources and capabilities are integrated to achieve collectively valued outcomes (Mazzucato and Ryan-Collins, 2022). This view aligns with public service logic, which frames services as processes emerging from interactions among multiple actors within service systems (Sergianni et al., 2026).
Building on this perspective, public services can be conceptualized as bundles of interaction practices structured through the relationship between service templates and their situated performances (Skålén, 2022). Service templates refer to the institutionalized configurations through which services are designed and organised, such as procedures, rules, digital infrastructures and interfaces, while situated performances capture how these configurations are enacted in concrete interactions (Skålén and Trischler, 2024).

While templates are intended to enable value creation, their enactment in practice may lead to either value co-creation or value co-destruction depending on how actors mobilize resources and interpret their roles (Skålén and Trischler, 2024). Value co-creation occurs when enacted practices align with the expectations, roles and resources embedded in service templates, enabling actors to integrate their knowledge and capabilities in the delivery and improvement of services (Voorberg et al., 2015; Torfing et al., 2019; Cepiku et al., 2022). Conversely, value co-destruction may occur when enacted practices diverge from the expectations embedded in service templates, generating misalignments among actors' expectations, roles, resources and modes of interaction (Engen et al., 2021; Plé and Caceres, 2010; Echeverri and Skålén, 2011). The relationship between these dimensions is therefore critical, as value depends on the extent to which situated performances align with, or diverge from, service templates (Skålén, 2022).

Against this background, the growing adoption of AI in public administration is progressively reshaping the interaction architectures through which public value is generated. AI is increasingly embedded in digital public services, where it supports administrative processes, decision-making and citizen–government interactions through automation and data-driven analytics (van Noordt and Misuraca, 2022; Aldemir and Uçma Uysal, 2025). As AI becomes embedded in service encounters, it does not simply automate existing processes but actively reconfigures how service interactions are designed and performed (Hjaltalin and Sigurdarson, 2024).

This transformation creates both opportunities for more responsive and data-informed public services and tensions related to transparency, data bias and accountability (OECD, 2025), particularly when algorithmic mediation becomes

[3] University of Catanzaro "Magna Græcia", angela.carida@unicz.it

opaque to citizens and may undermine trust and the perceived legitimacy of service encounters (de Fine Licht and de Fine Licht, 2020). From this perspective, AI becomes analytically relevant not only for its technical capabilities or governance implications (Wirtz et al., 2019), but for how it may reshape how actors access, interpret and enact public services in practice, with implications for public value. Despite this growing body of research, existing studies on AI in the public sector remain predominantly focused on governance, ethics, and accountability issues related to algorithmic decision-making (Wirtz et al., 2019; OECD, 2025). While these perspectives are crucial, they tend to privilege an outcome- or system-level view of AI adoption, leaving underexplored how AI intervenes within the practices through which public services are enacted.

In particular, limited attention has been paid to how AI-mediated interactions reshape the alignment between institutionalized service templates and the situated performances of service practices. This matters because such alignment represents a central mechanism through which public value may be sustained or undermined within service interactions (Skålén and Trischler, 2024). By focusing on this dimension, the paper shifts attention from AI as a governance or decision-making tool (van Noordt and Misuraca, 2022) to AI as a mechanism that reconfigures interaction practices and, consequently, the conditions under which public value emerges in digital public services.

Purpose of the paper. *Building on these considerations, the paper aims to examine how the adoption of AI in digital public services reshapes interaction practices between citizens and public administrations, and how these transformations may influence the alignment between service templates and their situated performances, with implications for public value co-creation or co-destruction.*

Methodology. *This study adopts an exploratory qualitative research design based on document analysis (Bowen, 2009) to examine how AI-enabled services are embedded within digital public services and how they relate to citizen–government interaction practices. The study draws on secondary data, including official government websites, policy reports, institutional documents and prior studies describing the development of AI-enabled applications within Estonia's digital public service ecosystem.*

Estonia provides a particularly relevant empirical context because it represents one of the most advanced digital government ecosystems in Europe, characterised by highly integrated digital infrastructures and extensive online public service delivery (Lember et al., 2018; Margetts and Naumann, 2024; Salumaa-Lepik and Nisu, 2024). According to the State of the Digital Decade 2025, Estonia consistently ranks among the leading EU countries in digital public services and e-government development (European Commission, 2025).

The study examines AI-enabled public service applications, including initiatives in digital government assistance (Bürokratt), justice (Smart Court) and education (Marakratt). These empirical examples are used as analytically relevant cases to explore how AI-mediated interactions between citizens and public administrations are configured in practice, and how such configurations relate to conditions of alignment or misalignment between service templates and their situated performances. The analysis, therefore, focuses on conditions of alignment or misalignment, which prior research links to processes of value co-creation and value co-destruction (Echeverri and Skålén, 2011; Skålén and Trischler, 2024).

Empirical context: Estonia's digital public service ecosystem. *Estonia is widely recognised as one of the most advanced digital government systems in Europe (Lember et al., 2018; Margetts and Naumann, 2024; Salumaa-Lepik and Nisu, 2024). Since regaining independence in the early 1990s, the country has progressively developed a highly integrated digital governance ecosystem that supports interaction between citizens, businesses and public institutions through digital public services (Entreprise Estonia, 2025).*

The Estonian digital public service ecosystem relies on several interconnected infrastructures that enable secure identification, service access and data exchange across public institutions. Three components are particularly central to this ecosystem. The first is the national digital identity system (e-ID), which enables secure authentication and legally valid digital signatures. The second is the digital service layer, accessed through national platforms such as the national e-services portal eesti.ee, through which citizens interact with public services (with approximately 99% of public services available digitally). The third is the interoperability platform X-Road, which connects the country's distributed information systems and enables secure data exchange across public and private databases (Margetts and Naumann, 2024). An important feature of this ecosystem concerns transparency in data use. Citizens can verify which public authorities have accessed their personal data and for what purpose, as all data access and modifications are recorded through a comprehensive audit trail.

X-Road represents the core infrastructural layer enabling secure data exchange between institutions. Rather than centralising information, the platform allows hundreds of organisations across the public and private sectors to exchange data through a distributed architecture that ensures interoperability, integrity and security. Together with the national digital identity system, this infrastructure also supports the "once-only" principle, whereby citizens are not required to repeatedly provide the same information to different public authorities (e-Estonia, 2018; e-Estonia, 2023).

Building on this digitally mature public service ecosystem, Estonia has progressively expanded the adoption of artificial intelligence within public administration. Guided by the national AI strategy, approximately 80 AI-related projects had been initiated or implemented across the public sector by the end of 2020 (Ministry of Economic Affairs and Communications, 2021).

Results. *The following section presents empirically grounded examples from Estonia's digital public service ecosystem to examine how the introduction of artificial intelligence reshapes interaction practices between citizens and public administrations. The examples illustrate how AI-enabled services reconfigure key elements of public service templates and, in doing so, shape the conditions under which public value may emerge.*

Each example focuses on a particular service domain and is analysed through three analytical dimensions derived from the template–performance perspective on public service practices (Skålén and Trischler, 2024).

First, interaction configuration refers to how AI technologies reconfigure the structure of interaction between citizens and public institutions, for instance by introducing new digital interfaces or mediating communication processes.

Second, decision configuration captures how AI systems participate in decision-related processes within service interactions, including activities such as information provision, recommendation, or decision support.

Third, the analysis considers the potential alignment or misalignment of practices, referring to the extent to which AI-mediated interactions remain consistent with the expectations embedded in service templates, or instead generate divergences in how service interactions are enacted in practice.

***Example 1. Conversational AI for public services: Bürokratt**. Bürokratt is a government-wide conversational AI system used in Estonia to support citizen interaction with public services through a network of digital assistants deployed across government websites and service portals. The system allows citizens to submit questions in natural language and receive guidance on administrative procedures, services or required documentation across multiple public institutions (Ministry of Justice and Digital Affairs & Information System Authority, 2024a; Entreprise Estonia, 2025).*

***Interaction configuration.** The introduction of Bürokratt modifies the interaction configuration of digital public services by introducing conversational agents as an additional interaction interface between citizens and public administrations, thereby reshaping how service access takes place (Entreprise Estonia, 2025; Ministry of Justice and Digital Affairs & Information System Authority, 2024b). Instead of requiring citizens to navigate institutional websites and independently identify procedures and interpret service requirements, conversational agents mediate access to information across multiple public services.*

Some of the work traditionally carried out by citizens—such as locating relevant information, identifying the responsible institution or interpreting administrative guidance—is shifted to the AI system. For citizens, conversational interfaces can reduce the effort required to identify the appropriate service or procedure. For public administrations, they can centralise the management of routine information requests and reduce fragmentation across multiple institutional access points (Ministry of Justice and Digital Affairs & Information System Authority, 2024b).

From a practice perspective, the enactment of service interactions consequently shifts: rather than independently navigating administrative procedures, citizens increasingly rely on AI-mediated guidance to access and interpret public services. This influence occurs at the entry point of service practices, shaping how citizens engage with administrative procedures before interacting with formal decision processes.

***Decision configuration.** In the example of Bürokratt, AI does not perform administrative decision-making but intervenes in how access to decision processes is structured. The authority to determine eligibility, approve services or apply administrative rules remains fully under the responsibility of public institutions and existing legal procedures.*

The role of AI instead concerns how access to decision processes is structured. By mediating how citizens obtain information about procedures, documentation requirements and responsible institutions, conversational agents influence how individuals approach administrative decision points.

In this configuration, AI operates as a decision intermediary rather than a decision-maker, shaping how decision-relevant information is accessed and interpreted without altering institutional authority (Ministry of Justice and Digital Affairs & Information System Authority, 2024b).

From a practice perspective, decision-making remains institutionally controlled, while the informational pathway through which citizens reach administrative decisions becomes increasingly AI-mediated.

***Potential alignment or misalignment of practice.** Conditions of practice alignment may emerge when conversational interaction supports routine and information-based service requests. When citizens seek guidance on standard administrative procedures, documentation requirements or basic service information, conversational agents can simplify access to institutional knowledge and reduce the effort required to identify relevant services. In these situations, AI-mediated interaction can support interaction practices that are more likely to remain consistent with the accessibility and responsiveness objectives embedded in digital public service templates (Wirtz et al., 2019; van Noordt and Misuraca, 2022).*

At the same time, potential conditions of practice misalignment may arise when user requests involve more complex or context-specific situations that exceed the interpretative capabilities of conversational systems. When requests cannot be fully interpreted or when responses remain limited to predefined institutional knowledge sources, citizens may receive incomplete guidance and still need to navigate administrative procedures independently. In such situations, interaction practices may diverge from the expectations embedded in service templates, reducing the effective usability of the service (Ministry of Justice and Digital Affairs & Information System Authority, 2024b). This example illustrates how conversational AI may shape the conditions under which procedural forms of public value may emerge in digital public services. When conversational mediation effectively supports citizens in accessing and navigating services, interaction practices are more likely to remain aligned with service templates. Conversely, when this mediation fails to accommodate

more complex citizen needs, it may introduce conditions of misalignment that constrain how citizens engage with public services, potentially limiting the realisation of public value.

Example 2. E-Justice: digital infrastructures and "smart court" initiatives. *In Estonia, judicial services are accessed through a connected infrastructure that integrates case submission, information exchange and procedural communication within a single platform (Courts Data Solutions, 2024). Through the e-File system, citizens, legal professionals and courts interact within the same digital space, where procedural documents are submitted, case information is accessed and judicial exchanges are coordinated (European e-Justice Portal, 2025).*

This configuration does not simply digitise existing procedures; it reorganises how judicial processes are accessed and how information is handled across them. All procedural information enters the same digital environment, where it is stored, structured and made available for use across different stages of the process.

In practical terms, once documents are submitted into the system, they are automatically organised, indexed and made retrievable within the same environment, rather than being handled across separate files, offices or communication channels.

Within this setting, "smart court" initiatives introduce functionalities that operate in the background, supporting how procedural information is organised, retrieved and processed (Nafid and Joraiche, 2025). Rather than appearing as visible interfaces or autonomous decision-making systems, these functionalities shape how information flows within the system.

Interaction configuration. *Access to judicial services is organised around a single point of entry that structures how procedural information is submitted, retrieved and exchanged. Instead of navigating multiple institutional channels, users interact with judicial processes through a unified environment that coordinates interaction across actors and stages.*

The e-File platform enables this integration by bringing together document submission, communication and access to case-related information within one system. As a result, interaction becomes less dependent on users' ability to navigate institutional complexity and more shaped by how access to information is organised (e-Estonia, 2025)

From a practice perspective, interaction is not only simplified but also reoriented: the way information is submitted and enters the system influences how it can be used in subsequent stages of the judicial process.

In this configuration, interaction is mediated indirectly. Functionalities embedded in the system influence how information is filtered and made accessible, without operating as distinct interaction interfaces (Courts Data Solutions, 2024; European e-Justice Portal, 2025).

Decision configuration*. This reorganisation extends into the internal dynamics of judicial work. Decision configuration is shaped by how procedural information is processed and made usable within the system, rather than by changes in decision authority. In this configuration, the influence of system functionalities does not occur at the point of access, but within the ongoing processing of cases, shaping how judicial practices are internally carried out.*

Through electronic filing and integrated case management, case-related information is handled in digital form throughout judicial proceedings. Judges and court staff engage with case materials within a unified environment, rather than manually searching across dispersed documents, records or communication exchanges (Courts Data Solutions, 2024; European e-Justice Portal, 2025). From a practice perspective, the preparation of decisions depends on how information is transformed into actionable inputs. System functionalities support this transformation by enabling the classification of procedural documents, the retrieval of relevant materials and the rapid processing of large volumes of case data. These capabilities facilitate the identification of relevant elements and patterns within case materials, shaping how information is prioritised and interpreted in judicial workflows.

Decision authority remains unchanged, but the conditions under which judicial reasoning takes place are redefined. The influence of these functionalities is therefore indirect, operating through how information is processed and prioritised rather than through direct involvement in decision-making (e-Estonia, 2026a).

Potential alignment or misalignment of practices. *The integration of interaction and decision processes within a unified digital environment creates conditions that may support alignment between institutional expectations and enacted practices. By centralising procedural activities and structuring how information flows across different stages of judicial processes, the system facilitates coordination and continuity in how cases are handled (Nafid and Joraiche, 2025). In this sense, alignment emerges from the consistency between how procedural information is organised and how judicial work is carried out.*

At the same time, these conditions may also generate misalignment. Rather than arising primarily from access constraints, misalignment may emerge from how information is structured and processed within the system in relation to the practical requirements of judicial work. When procedural information is organised into predefined formats and categories, relevant elements of a case may be emphasised, simplified or overlooked depending on how they are represented within the system.

In practice, this may affect how case materials are navigated, how relevant information is retrieved and how attention is directed during the preparation of decisions. As a result, judicial actors may rely on system-structured representations of information that do not fully reflect the complexity or context of individual cases.

More critically, as information is processed and prioritised through embedded functionalities, the logic guiding these processes may not be fully visible to actors. This introduces tensions related to transparency and interpretability (Nafid and Joraiche, 2025), but also affects how judicial actors engage with and trust the organisation of case materials within

the system. In such situations, misalignment may emerge within the execution of practices, influencing how decisions are prepared, rather than from failures in access or interaction.

More broadly, the standardisation embedded in the system may not fully accommodate the variability and situated nature of judicial work, generating divergences between institutional templates and enacted practices (Skålén and Trischler, 2024).

From a public value perspective, this configuration suggests that digitally enabled judicial services may support value co-creation by enhancing coordination, consistency and efficiency in judicial processes, while also generating risks of value co-destruction when the structuring of information constrains how actors engage with case complexity in practice. Here, public value is thus contingent on the alignment between the informational structure embedded in the system and the ways in which judicial actors enact decision practices within it and engage with it in practice.

Example 3. AI in digital education: Marakratt. *Artificial intelligence has been introduced into Estonia's digital education ecosystem (e-Estonia, 2025a) through AI-enabled learning analytics and recommendation systems embedded in digital learning environments (Ministry of Justice and Digital Affairs & Information System Authority, 2024a).*

One example is the Marakratt project, which developed a proof-of-concept system designed to support personalised learning trajectories. Using machine learning techniques, the system analyses behavioural data generated through students' interactions with digital learning platforms and recommends educational materials aligned with students' learning needs, knowledge levels and interests (Ministry of Justice and Digital Affairs & Information System Authority, 2024a).

Interaction configuration. *The introduction of AI-enabled learning analytics modifies the interaction configuration of digital education services by embedding algorithmic analysis within students' engagement with digital learning environments. As students interact with learning platforms, their activities generate behavioural data that can be analysed to identify patterns of engagement, progress and potential learning difficulties (e-Estonia, 2025b).*

Within this configuration, part of the interaction work traditionally carried out by students and teachers, such as identifying relevant learning materials, monitoring progress or recognising emerging learning challenges, is partially delegated to AI-based analytical systems. Rather than relying solely on direct pedagogical guidance or independent navigation of learning resources, interaction with educational content increasingly unfolds through data-driven insights generated from students' activity within digital platforms (e-Estonia, 2026b).

From a practice perspective, the enactment of learning interaction shifts from primarily human-mediated pedagogical guidance towards a configuration in which learning activity is continuously interpreted through AI-generated analysis of behavioural data. These insights are generated as students engage with the platform, shaping interaction in real time rather than only at the point of access or after the learning activity.

Decision configuration. *In the Marakratt example AI-enabled learning analytics could contribute to the decision process by generating analytical insights derived from students' behavioural data. These systems detect patterns of engagement, progress and potential learning difficulties and can recommend learning resources aligned with individual learning trajectories.*

In this configuration, AI does not determine pedagogical decisions but influences how decision-relevant information is produced and interpreted. The system therefore contributes to the evidential basis through which educators assess learning progress and plan instructional responses, with this informational input being continuously updated as learning activities unfold (Ministry of Education and Research of Estonia, 2021).

From a practice perspective, pedagogical decisions remain educator-led, while the informational foundations on which these decisions rely become increasingly shaped by AI-generated learning analytics during the ongoing learning process.

Potential alignment or misalignment of practices. *In the Marakratt system, conditions of practice alignment may emerge when the analysis of behavioural data from digital learning platforms enables teachers to detect patterns of engagement that would otherwise remain difficult to observe. By aggregating traces of students' activity—such as time spent on learning materials, task completion patterns or repeated difficulties with specific exercises—the system makes aspects of learning interaction visible that would otherwise remain distributed across multiple digital activities.*

In such situations, learning analytics can support teachers in adjusting instructional activities or recommending alternative learning resources, thereby reinforcing the pedagogical objectives embedded in digital education services (Ministry of Justice and Digital Affairs & Information System Authority, 2024a).

At the same time, conditions of practice misalignment may arise when the recommendation mechanisms embedded in the system begin to structure how students navigate learning resources within the platform. If learning interaction increasingly follows system-generated recommendations, such as suggested materials or automatically prioritised exercises, students' engagement with educational content may become organised around algorithmically suggested pathways rather than teacher-guided exploration of learning activities.

In these situations, a tension may emerge between the pedagogical intentions embedded in the education service template and the learning practices enacted within the AI-mediated environment (Skålén and Trischler, 2024). While the Marakratt system is designed to support teachers' capacity to monitor and guide learning processes, the increasing reliance on automated analysis and recommendations may gradually shift how learning interaction is organised within the platform, potentially narrowing the range of learning activities that students encounter to those that can be captured,

analysed and prioritised by the system. From a public value perspective, when AI-supported insights expand teachers' ability to interpret and respond to student needs, this may enhance the responsiveness and adaptability of educational processes (OECD, 2025). However, when learning pathways become overly structured around what can be captured and prioritised by the system, misalignment may constrain how students engage with learning activities, with implications for the public value generated through education.

Table 1 synthesises the analytical dimensions emerging from the examples, illustrating how different configurations of AI-mediated interaction relate to distinct alignment dynamics and associated conditions for public value.

Table 1. Configurations of AI-mediated interaction and alignment dynamics in digital public services

Example	***AI / Digital feature***	***Interaction configuration***	***Decision configuration***	***Alignment dynamics***	***Implications for public value***
Bürokratt	*Network of conversational AI assistants integrated across public service portals*	*Interaction shifts from independent navigation of administrative procedures to AI-mediated conversational access to service information*	*AI does not perform decisions but mediates access to decision-relevant information, shaping how citizens approach administrative processes*	*Alignment emerges in routine and standardised requests; misalignment arises when user needs exceed the interpretative scope of predefined interaction logics*	*Potential for value co-creation through improved accessibility and navigation; risk of co-destruction when incomplete or misinterpreted guidance constrains effective service use*
E-justice (smart court initiatives)	*Integrated digital judicial infrastructures (e-File system, case management, data processing functionalities)*	*Interaction is reorganised within a unified digital environment where procedural information is submitted, accessed and exchanged across actors and stages*	*AI-enabled functionalities operate within the processing of case information, shaping how data is structured, retrieved and prioritised in judicial workflows*	*Alignment emerges through coordinated and consistent information flows; misalignment arises when standardised representations fail to capture case-specific complexity or remain opaque to users*	*Potential for value co-creation through enhanced efficiency and coordination; risk of co-destruction when information structuring constrains interpretability and limits engagement with case complexity*
Digital education (Marakratt)	*AI-enabled learning analytics and recommendation systems embedded in digital learning environments*	*Interaction is continuously mediated through the analysis of behavioural data, shaping how students engage with learning content over time*	*AI contributes to decision processes by generating real-time insights and recommendations that inform pedagogical decisions without replacing educator authority*	*Alignment emerges when AI-supported insights enhance teachers' capacity to interpret learning needs; misalignment arises when learning pathways become overly structured by system-generated recommendations*	*Potential for value co-creation through more tailored and responsive learning processes; risk of co-destruction when algorithmic structuring narrows learning trajectories and constrains student engagement*

Source: authors' elaboration.

Research limitations. *This study relies on secondary documentary sources describing AI-enabled applications within Estonia's digital public service ecosystem. While this approach enables a systematic examination of publicly documented initiatives, it does not capture the direct experiences of citizens, public officials or service professionals interacting with these systems. Future research could therefore complement documentary analysis with qualitative methods such as interviews or ethnographic observation to examine how AI-mediated interactions are enacted in everyday service encounters.*

A further limitation relates to the context-specific nature of the empirical setting. Estonia represents one of the most advanced digital governance environments in Europe, characterised by highly integrated digital infrastructures and widespread adoption of digital public services. While this context provides a particularly informative setting for examining emerging AI-enabled service configurations, the transferability of the findings to larger or more institutionally complex administrative systems remains an open empirical question. Future research could therefore explore whether similar dynamics emerge in countries characterised by different administrative traditions, levels of digital maturity or degrees of institutional trust.

Managerial implications. *The findings offer implications for public managers and policy makers involved in the implementation of AI-enabled digital public services. First, the introduction of AI systems reshapes how service interactions are organized (van Noordt and Misuraca, 2022) rather than simply automating existing procedures. As the examples show, AI technologies such as conversational agents or learning analytics systems alter how citizens access services, how interactions unfold during service encounters and how responsibilities are distributed between human and technological actors.*

Importantly, these effects are not uniform but depend on how AI is positioned within service processes. As illustrated by the examples, AI may operate at the point of access (e.g. conversational agents), within the infrastructural organisation of services (e.g. digital judicial systems), or during the ongoing enactment of service practices (e.g. learning analytics), thereby reshaping interaction in different ways.

Public managers should therefore approach AI implementation as a redesign of service interaction processes, ensuring that digital systems support rather than complicate citizen–government engagement. In this perspective, the effective design of AI-mediated interactions becomes a key condition for enabling the creation of public value through digital public services.

Second, the results highlight that AI systems in public services frequently operate as intermediaries in the production and interpretation of decision-relevant information. Rather than replacing institutional decision authority, AI technologies influence how information is gathered, structured and made visible to professionals and administrators.

This suggests that the role of AI in decision processes should be understood in relation to how it shapes the informational conditions under which decisions are prepared, rather than as a substitute for human judgement (Wirtz et al., 2019). In particular, as highlighted by the examples, AI may influence decision processes before decisions are formally enacted (e.g. by guiding access to procedures), within organisational processes (e.g. by structuring case-related information), or during ongoing activities (e.g. by continuously updating analytical insights).

For public sector leaders, this implies that the governance of AI should not focus exclusively on automated decision-making but also on the informational processes through which AI systems shape how decisions are informed (van Noordt and Misuraca, 2022).

Finally, the study suggests that the effective integration of AI in public services depends on the alignment between digitally enabled service templates and the practices through which services are enacted in everyday interactions. When AI systems support existing roles, capabilities and expectations, they may enhance the accessibility and responsiveness of public services. When such alignment is lacking, however, AI-mediated interactions may disrupt service encounters or create new barriers for users (OECD, 2025).

Across the examples, misalignment emerges in relation to forms of complexity that resist standardisation, although this operates at different stages of practice. In conversational systems, misalignment is more likely to arise at the point of interpretation, when user needs cannot be fully captured by predefined interaction logics. In infrastructural systems, misalignment emerges in the representation and processing of information, when standardised formats fail to reflect the contextual complexity of cases. In more dynamic settings, such as digital education, misalignment may arise when ongoing practices are increasingly shaped by system-generated pathways that prioritise what can be captured and analysed.

These findings suggest that AI may encounter limitations not with complexity per se, but with forms of complexity that resist standardisation, and that this depends on where AI intervenes within service practices.

Public managers should therefore pay close attention to how AI-enabled services are enacted in practice and ensure that technological innovation remains compatible with citizens' needs, professional routines and institutional objectives, as this alignment represents a key condition for sustaining public value within AI-enabled public service systems (Skålén, 2022).

Originality of the paper. *This study contributes to the emerging literature on artificial intelligence in the public sector by mobilising a practice-based perspective on AI-enabled public services. While existing research has primarily examined AI in relation to governance, transparency and algorithmic decision-making (Wirtz et al., 2019; van Noordt and Misuraca, 2022), this study focuses on how AI relates to the alignment between service templates and the enactment of service practices (Skålén, 2022; Skålén and Trischler, 2024).*

Preliminary findings suggest that AI may not simply influence service outcomes but may be associated with different mechanisms through which alignment between templates and practices is sustained or disrupted. These mechanisms appear to vary depending on where AI is embedded within service practices, such as at the point of access, within the structuring of information, or in the ongoing enactment of service activities.

By articulating these distinctions, the study extends practice-based approaches to public service research into the domain of AI-enabled services (Sergianni et al., 2026), offering a more fine-grained understanding of how AI relate to the conditions under which public value may emerge (Skålén and Trischler, 2024).

Digital transformation in Italian museums

LORENA MARIA D'AGOSTINO, GIOVANNI SIGNORELLO

Abstract. *As digital technologies are increasingly adopted by museums and are recognized as important to support the traditional multi-faced mission of cultural organizations, it is becoming relevant to understand the degree of diffusion and the underlying factors that explain the high heterogeneity in the adoption. The goal of this study is to identify which organizational characteristics and contextual factors are associated with adopting a wider range of digital technologies by combining descriptive evidence with preliminary regression analyses. Descriptive insights reveal significant heterogeneity: while some museums deploy multiple technologies, many others remain at an early stage of digital transformation. Preliminary regression models show consistent positive associations between technology adoption and several key factors. Among these, the degree of collection digitization emerges as a foundational enabler, supporting the idea that digital assets act as a platform for further innovation. Second, the presence of a digital strategy is strongly linked to broader adoption, underscoring the importance of intentional planning rather than isolated digital initiatives. Third, the number of KPIs tracked by museums correlates with higher adoption levels, suggesting that data-driven management practices help organizations evaluate needs, reduce uncertainty, and prioritize investments. In addition, access via payment, visitor volume, and city size emerge as relevant factors, indicating that financial resources, demand, and location economies can shape digital investment decisions. These findings contribute to cultural heritage literature through the lens of innovation management literature to explain digital transformation in cultural institutions. We show that internal capabilities, managerial practices, and local context support the adoption of digital technologies.*
Keywords: *digital technologies; technology adoption; museums*

Framing of the research. *Digital technologies are being increasingly adopted by museums, transforming the traditional ways of achieving their mission to preserve cultural heritage, educate the public, and contribute to social change* (Gombault et al. 2016). *Despite digital technologies are common in many museums, their diffusion and the level of quality seem to be unevenly distributed* (Leoni and Cristofaro 2021, 2022; Cavalieri et al. 2024). *This is because museums, as any organization adopting digital technologies, have to engage also in changes in several organizational dimensions (e.g. processes, values, managerial approaches)* (Hanelt et al. 2021). *These changes are challenging for any organization, and in particular for museums because of the lack of financial resources, strategic orientation, skilled human resources or low commitment of top management* (Lazzeretti et al. 2022; Nuccio and Bertacchini 2022).

Management scholars refer to the organizational changes induced by the adoption of digital technologies as digital transformation (DT) (Hanelt et al. 2021). *While in management literature DT has been widely discussed* (Hanelt et al. 2021; Verhoef et al. 2021) *and empirically investigated in industrial sectors* (Brynjolfsson and McElheran 2016; D'Agostino and Torrisi 2023), *it seems that there is more limited knowledge on how these transformations take place in museums* (Guccio et al. 2022; Taormina and Baraldi 2022). *This is partially due to museums being among the latest adopters of digital technologies* (Bertacchini and Morando 2013; Li et al. 2023). *However, DT may provide new opportunities for museums to better achieve their mission* (De Bernardi et al. 2019; Mazzamuto et al. 2024). *Therefore, it is crucial to better understand the state of adoption of digital technologies in museums and what concurrent factors explain the heterogeneity in the degree and types of technologies used.*

Purpose of the paper. *The purpose of this paper is to examine the adoption of digital technologies by Italian museums, drawing on the existing empirical evidence that highlights both the opportunities and persistent challenges facing cultural institutions. According to Rogers' theory of innovation diffusion* (Rogers 2003), *organizations adopt new technologies unevenly, depending on perceived attributes such as relative advantage, compatibility, complexity, trialability, and observability. These attributes determine different categories of adopters, from innovators to laggards. The diffusion of innovation is facilitated by mass media channels (e.g. the MiC national digitalization plan in the case of museums) and interpersonal linkages (e.g. peer network of museum directors), and it is shaped by the social system, including governance (e.g. state-owned or private museums) and geographical disparities (e.g. difference in digital infrastructures and institutional capacities across Italian regions). Since museums respond to different missions, technology adoption may be also strongly influenced by legitimacy in the eyes of funders, peers, and society* (Meyer and Rowan 1977; DiMaggio and Powell 1983). *In this sense, isomorphic processes may determine the position of the museum in the Rogers' categories of adopters.*

Recent studies show that Italian museums have increasingly invested in digital technologies (such as virtual tours, augmented reality applications, advanced collection management systems, and data-driven visitor analytics) (Leoni and Cristofaro 2021; Cavalieri et al. 2024) *to enhance accessibility, enrich the visitor experience, and strengthen engagement beyond physical boundaries. Empirical analyses conducted after the pandemic underscore how digital transformation has shifted from being a complementary activity to a strategic necessity, allowing museums to diversify audiences, experiment with new educational formats, and build resilience in the face of fluctuating in-person attendance* (Giannini and Bowen 2022; Godovykh et al. 2022). *However, the evidence also reveals significant heterogeneity across institutions:*

smaller museums often lack financial resources, digital skills, and organizational capabilities, while larger institutions tend to lead in adopting sophisticated technologies (Leoni and Cristofaro 2021, 2022; Antonucci et al. 2024; Cavalieri et al. 2024). *By tapping into this recent stream of studies, the paper aims to assess the underlying factors related to the adoption of digital technologies in the Italian museums through an original survey. In particular, this paper studies 1) the degree of adoption of digital technologies in museums and the types of technologies mostly used, both in terms of sophistication (common, intermediate and advanced) and in terms of the online-onsite dichotomy; 2) the contextual factors (e.g. organizational structures, size, ownership, location, type of museums) supporting the adoption of digital technologies.*

Methodology. *The data are based on a survey submitted to a sample of museums within the VALUE project*[1] *in the period from October 2022 to June 2023* (Mazzamuto et al. 2024). *The final sample consists of 305 museums located in Italy for which we have a completed questionnaire, out of a population of about 4500 institutions.*

The questionnaire investigated various aspects of digitalisation: i) the perceived reasons of the respondent for the adoption of new digital technologies worldwide; ii) the status of digitalization in the museum and future plans; iii) the characteristics of the museum, its visitors and the respondent.

Additional information has been collected from the census survey on Italian museums, and museum websites; in particular, this integration regarded: i) the variables related to the number of visitors, ii) whether the access to the museum is free or fee-based, and iii) alternative classification of the museums.

We firstly conduct a descriptive analysis of the main variables of interest. Secondly, we run an econometric analysis in which the adoption of digital technologies is estimated as a function of factors related to the organization and its strategy, and structural factors:

$$n.tech._i = \beta_0 + \beta_1 \boldsymbol{ORG} + \beta_3 \boldsymbol{STRU} + \varepsilon_i$$

where "n. tech.$_i$" is the number of technologies adopted by museum i. It is based on two questions related to digital services provided online and onsite. We explore different operationalization of this variable. Firstly, we use the total number of technologies, treated them as equally important. Secondly, we assign weights to each technology based on how common they are; in particular, we assign a weight of 1 to basic and common technologies, 2 to intermediate technologies, and 3 to advanced technologies. The resulting count variable is then disproportionally oriented towards more advanced technologies. These weights have been assigned on the basis of existing empirical studies and literature reviews on technological adoption in museums and cultural organizations. From these studies, it clearly emerge that some technologies are widely adopted, and are considered the first step of digital transformation in museums (e.g. websites, newsletters) (Fernandez-Lores et al. 2022), *others are common and indicate a more sophisticated level of interaction with audience (e.g. mobile apps, digital catalogue), and a third group implies high cost and complexity, and a more interactive way of addressing audience (e.g. VR, AR, gamification)* (Li et al. 2024). *Third, we use two different count variables, one for online technologies, and one for onsite technologies.*

ORG *is a set of variables related to organization and strategy. "Digitized collection" measures whether the institution i has or is about to digitalize its collections or exhibitions (dummy equals to 1 if yes, 0 if no); in line with national policies, digital cultural contents increase access and align to digital transformation of the society and the economy (PND, 2023). "Digital strategy" measures whether the institution i has a digital innovation plan (dummy equals to 1 if yes, 0 if no); indeed, strategic planning allows to better address the numerous challenges posed by the digital transformation, from technical issues to resources (both financial and human), from setting the objectives to implementing solutions* (Taormina and Baraldi 2022). *The variable "n. KPI" is built on three questions, and ranges from 0 to 3 on the bases of how many different types of data the museums collect (on visitors' satisfaction, on the pieces mostly observed, and on paths mostly visited); monitoring specific indicators suggests advanced decisions making processes, in line with data-driven approaches* (D'Agostino and Torrisi 2023). *"Digital skills" measures whether the museum possesses a high degree of skills in digital domains; indeed, skills is among the organizational dimension that support and facilitate digital transformation* (Zardini Lacedelli et al. 2019).

STRU *is a set of variables related to structural factors (internal and external) of museums: "Access via payment", "Public-owned" (Cavalieri et al 2023), "size", and dummies for nine categories ("Art", "History & Natural Science", "Science & Technology", "Ethnography & Anthropology", "Specialized", "Territory", "General", "Industrial & Business", "Others"). Finally, we control for the size of the city in which the museum is located to account for demand factor (measured in terms of population, in log); additional territorial controls are 20 dummies for Italian regions (at NUTS2 level).*

Preliminary results are presented and discussed below.

[1] The University of Catania, together with other private companies, funded from the European program PO FESR 2014/2020, has developed the system Visual Analysis for Location and Understanding of Environments (VALUE), which consists of wearable and/or mobile devices aimed at improving the visiting experience within museum spaces. To test the interest on the adoption of the system, a survey has been submitted to Italian and international museums; along with specific questions related to the VALUE system, the survey contained a set of questions related to the adoption of digital technologies.

Results. *Two questions of the survey are used to identify the digital technologies adopted by the museums, one is related to the online services[2] and the second is about onsite services[3]. Most institutions have adopted digital technologies such as websites (83.4%) and social media presence (78.2%), which are both online services. With regard to onsite services, only the Wi-Fi connection is offered by more than half the institutions (52.8%). The second most diffused in-situ service is the QR code, adopted by 48.5% of the museums.*

Table 1 shows that, on average, museums adopt 9.36 technologies, with a variance of 40.1, a minimum of 1 and maximum of 34, suggesting that the majority of museums adopt few technologies. No institution covers all the possible technologies. The coefficient of variation (CV), which indicates the dispersion around the mean, is quite hight, i.e. 68%. The distribution is asymmetric with a long tail on the right, with few museums adopting high number of services. About six online technologies are adopted on average, which is 2-times the average adoption of onsite services (i.e. 3.22). The CV allows to compare the two distributions that have different maximum number of choices; the CV of 102% for onsite is much higher than the CV of the online services, suggesting that institutions are more dissimilar in their offer of onsite services than online services. Possible reasons for that may be found in higher cost of onsite services, often based on physical devices (e.g. Wi-Fi coverage, computers or screens for interactive visits). On the contrary, the cost of many online services (e.g. the presence and use of social media, Wikipedia, etc) is significant lower. In addition, although some online services may have high cost, they play a fundamental role for attracting visitors (such as the websites, online ticketing, the use of intermediates such as travel agencies, etc), therefore the cost-benefit balance may be in favour of adoption. As expected, when counting technologies with weights for more advanced technologies, mean value is higher (14.97). The CV shows slightly higher dispersion of the distribution of total technologies, albeit less dispersed than onsite service.

Table 1 – Summary statistics of digital technologies

Variable	Mean	Median	SD	Variance	Skewness	Kurtosis	Min	Max	CV
Total technologies	9.36	8	6.33	40.10	0.99	3.66	1	34	68%
Total technologies, weighted	14.97	12	11.69	136.70	1.17	3.96	1	60	78%
Online technologies	6.13	5	4.21	17.76	0.93	3.32	1	20	69%
Onsite technologies	3.23	2	3.28	10.74	1.75	6.79	0	17	102%

By looking at the average of technology adoption by type of museums (not shown here), "Science and technologies" rank on top (i.e. 14.29 total technologies, although there are just 7 in the sample), as expected. Private-own museums (which are 31% of the total) prevail on the public-own (i.e. 10.39 vs 8.9 total technologies adopted), as the former may have higher resources and incentives to invest in digitalization. Along this line, size classes (based on the number of visitors in 2019 from ISTAT census) show that larger museums invest in a higher number of technologies.

Table 2 shows the results of count models[4], where the dependent variables are: the total number of adopted technologies (n. tech., model 1), the number of adopted technologies weighted (n. tech w, model 2), the number of adopted online technologies (n. online tech., model 3), and the number of adopted onsite technologies (n. onsite tech., model 4). The econometric results show that two of the organizational variables (i.e. digitalized collection and digital strategy) are positive and statistically significant for all the four models, which indicates that the general orientation of the institutions towards digitalization is correlated with a wider adoption of services. Instead, a more specific variable related to a data-driven organization, such as the use of data to monitor the performance (n. KPI) (Brynjolfsson and McElheran 2016) *is positive and statistically significant for total technologies (model 1 and 2), and for online services (model 3). This may be due to the fact that while digitalization of collection and digital plan are strongly supported by policies and therefore more widely spread, the use of KPI is a choice of the museum, often related to data-driven orientation and therefore is more likely to be found where the institution has a strong commitment to digitalization.*

With reference to structural variables, access via payment is positive and statistically significant in all four models; certainly, the provision of any additional service (being online or onsite) requires financial resources, and free museum may have more conservative budget. In addition, free museum may be simply more oriented to other aspects (e.g. accessibility, preservation), rather than on the adoption of technologies.

In terms of size, we observe that, in comparison to the benchmark class of less than 500 visitors, large institutions (i.e. higher than 10 thousand visitors) have positive and statistically coefficients for all model, except for onsite technologies. Larger museums have simply more resources to devote to technology adoption, but also have higher incentives to do so, e.g. to improve the organization (e.g. online tickets to avoid long queues) or increase revenue stream (e.g. through online advertising, use of tour operators, e-commerce etc), to engage in a long-term relationship with visitors (e.g. through presence on social media, blogs, Wikipedia etc), or to simply broaden services compatible to the

[2] The question is: "Which one of the following online digital services are offered to museum's visitors currently?"
[3] The question is: "Which additional digital services and tools does the museum offer to visitors in order to improve their cultural, physical, sensorial and cognitive experience of the visit onsite?"
[4] After proper testing, the assumption of overdispersion is not violated in model 1, 2, and 4; hence, negative poisson is chosen. Overdispersion is present in model 3, therefore negative binomial is preferred.

reputation of a large, well-known museum. When using the number of technologies weighted for how common it is a service, the significant level of large size is weaker (p<0.1), suggesting that probably the size is a less relevant factor for advanced technologies, and other factors may be relevant (e.g. the content of the collection, or digital readiness toward peculiar services). The relation with size is not found relevant for onsite technologies, for neither of the size classes. It may be due to the fact that the few onsite services used in the sample are more established technologies (e.g. auto guide for rent), or they may be part of a larger local infrastructure (e.g. city free Wi-Fi), therefore they are adopted with low relation to the size of the institutions.

Population of the city in which the museums is located is positive and statistically significant for total technologies (model 1 and 2), but it becomes less important for online and onsite technologies taken separately (with p<0.10 in model 3, and not significant in model 4).

Regarding the types of museums, several variables are positive and statistically significant in model 1 and 2, in comparison to the benchmark category which is Others. All these variables are statistically significant also for onsite technologies (model 4), but not for online technologies. There is a lot of diversity within the types of museums; therefore, further analyses are needed to investigate specific adoption patterns across types of institutions.

We insert the number of onsite technologies on estimation with online technologies as outcome variable (model 3), and vice versa we insert the number of online technologies on the estimation with onsite technologies as outcome variable (model 4). Both regressors turn out positive and significant, suggesting complementarity between the two types of technologies that are worthy further investigation.

Research limitations. *This study presents several limitations that should be acknowledged when interpreting its findings. First, the analysis relies primarily on descriptive statistics and preliminary regression models, which, while useful for highlighting relations, do not allow for causal inferences. Second, the cross-sectional nature of the data constrains the ability to capture the dynamic evolution of digital adoption over time or to disentangle potential reverse causality (e.g., whether digital technologies attract more visitors, or whether museums with more visitors invest more in technology). Third, measurement limitations may arise from self-reported variables, which could introduce bias or inconsistencies in how museums assess their digital maturity or strategic orientation. Additionally, the dataset may not fully account for organizational factors such as governance structures, skills, or top-management attitude that could influence digital investment decisions. Finally, the preliminary nature of the regression models implies that the findings should be viewed as exploratory and used to guide future investigation.*

Managerial implications. *Despite results being preliminary, the findings of this study offer several managerial implications for museum directors and policy makers seeking to accelerate digital transformation in the cultural sector. First, the positive effect of collection digitalization on the number of technologies adopted suggests that digitizing heritage assets is not merely an archival activity but a strategic enabler that unlocks further innovation. Managers should therefore prioritize structured digitization programs and allocate dedicated resources to build high-quality digital collections. Second, the strong role of a clear digital strategy indicates that technology adoption is most effective when guided by an overarching vision rather than by isolated, opportunistic initiatives, in line with management literature on digital transformation* (Hanelt et al. 2021). *Museums would benefit from defining goals, identifying target audiences, and aligning digital investments with their broader mission. Third, the association between the number of KPIs used and technology adoption highlights the importance of developing a data-driven managerial culture* (Nuccio and Bertacchini 2022). *Institutions that monitor performance systematically are better positioned to select technologies that enhance visitor engagement and operational efficiency. In addition, museums that rely on paid access, attract higher visitor flows, or are located in larger cities appear more likely to invest in digital tools, signaling the relevance of financial stability, demand, and territorial context. These insights call for tailored managerial approaches that consider resource constraints while fostering strategic, data-oriented innovation.*

Originality of the paper. *As digital transformation is increasingly embraced by cultural organizations, a stream of studies has focused on the adoption patterns, drivers and obstacles of technology adoption These studies have been focused on specific samples (e.g. small museums as in Leoni and Cristofaro, 2022, 2021), or specific technologies (e.g. Trunfio et al.* (2022) *about the effect of virtual reality and augmented reality on visitor experience). We advance existing knowledge on digital technology adoption in museums in three ways. First, by using an original survey on 305 Italian institutions. Secondly, by investigating a broad set of digital technologies and different adoption patterns. In addition to a standard count of the number of technologies, we advance existing studies firstly by assigning different weights depending how common they are, and secondly by considering separately online (e.g. website, presence on social media, online booking services, etc), and onsite services (e.g. free Wi-Fi, audio guides, presence of informative screens or computers). Although the online vs. onsite classification is not novel* (Leoni and Cristofaro 2021; Guccio et al. 2022)*, the list of technologies in this paper is more extended*[5]*. Thirdly, by conducting regression analysis in order to assess technology adoption and the relations with different factors simultaneously, we extend and complement existing evidence of the relation between technology adoption and concurrent factors in a multivariate setting.*

Disneyfication of places: Organizing smart cities for what- and for whom?

FILIPPO MARCHESANI[1], FEDERICA CECI[1], ANDREA PRENCIPE[2]

Abstract. *Over the past two decades, cities have increasingly embraced the smart city paradigm as a model for technological innovation, efficiency, and improved urban governance. While this transition promises enhanced services and data-driven decision-making, its broader societal implications remain underexplored. This study examines whether the advancement of smart city initiatives affects the social fabric of urban communities. Building on the concept of the disneyfication of places, we argue that the growing emphasis on technological capabilities and performance-oriented governance may unintentionally weaken the relational infrastructures that sustain civic participation and community ties.*

To investigate this relationship, we employ a dynamic panel data approach using the Generalized Method of Moments (GMM) on a longitudinal dataset of 38 Italian cities. Smart city advancement is operationalized through six indicators capturing organizational and relational dimensions of urban transformation, while social capital is measured through indicators of civic participation, volunteering, and associational activity.

Preliminary results reveal a negative association between the intensity of smart city initiatives and urban social capital. Cities that advance more rapidly along the smart city paradigm tend to experience stronger declines in civic participation and community engagement. These findings suggest a paradox of contemporary urban development: as cities become technologically smarter, they risk becoming socially thinner. The study contributes to the critical debate on smart cities by highlighting the need to rebalance technological innovation with the preservation of place-based social capital.

Keywords: *Smart cities; Social capital; Disneyfication; Urban governance; Digital Technology, Smartness*

Framing of the research. *Over the past two decades, cities have entered a profound organizational transition toward smart city models of governance and development. Defined by Bakici et al., (2012, p. 139) as a high-tech intensive and advanced city that connects people, information and city elements using new technologies in order to create a sustainable, greener city, competitive and innovative commerce, and an increased life quality, the concept of smart cities has progressively reshaped places and communities (Albino et al., 2015; Caragliu et al., 2011; Caragliu & Del Bo, 2019). In this transition, the notion of "smart" is intended to function in support of cities and their inhabitants, yet it simultaneously reconfigures interactions, institutional proximities, and broader urban dynamics (Shelton et al., 2015). Historically conceived as "polis", understood as political and social communities grounded in shared civic life, collective identity, and relational embeddedness, cities are increasingly reorganized as "urbs spectans", viewed as an urban system structured around continuous observation, data extraction, and performative governance (Gupta et al., 2020). In this configuration, smart cities operate as functional, sensor-laden, and platform-mediated environments in which digital infrastructures, real-time monitoring, and performance indicators are mobilized to optimize efficiency, connectivity, and innovation. In recent years, however, the smart city paradigm has increasingly become the subject of critical reflection. A growing body of scholarship highlights the emergence of several paradoxes associated with smart urban development, where technological advancement and data-driven governance coexist with new forms of social fragmentation, institutional distancing, and uneven urban benefits (Caragliu & Del Bo, 2022; Carlsen & Leknes, 2022; Datta, 2015; Marchesani & Kummitha, 2026; Marchesani & Masciarelli, 2026). Rather than producing universally inclusive and participatory urban environments, smart city initiatives may generate tensions between efficiency and inclusiveness, technological optimization and democratic participation, as well as between global models of urban innovation and locally embedded forms of community life (Taylor Buck & While, 2017; Fromhold-Eisebith & Eisebith, 2019).*

This transformation has deeply altered how cities define what it means to be "smart." Rather than asking for "whom" smartness is pursued, urban strategies increasingly emphasize what cities can do to be. As a result, smartness becomes a category defined by technical capabilities and advanced applications, rather than by social embeddedness or civic outcomes. In this line, a growing critical literature suggests that this process risks producing a form of urban depersonalization (Datta, 2015; Hollands, 2020; O'Reilly & Reed, 2011), that we conceptualize as the "disneyfication of place". Early critical accounts of disneyfication (Choi, 2012; Warren, 1994) describe how places are transformed into aseptic, standardized, and consumption-oriented environments, where complexity, conflict, and local specificity are progressively erased. In these accounts, urban spaces are redesigned to be efficient, attractive, and easily consumable, but increasingly detached from the lived experiences, identities, and social ties that historically constituted them. Contemporary smart cities, we suggest, represent a technologically updated manifestation of this logic that is not themed around entertainment, but around innovation, efficiency, and digital excellence. As a result, the city risks losing its relational and political core, replacing it with a standardized and instrumental vision of urban development (Grossi &

[1] Department of Management and Business Administration. University of "G. d'Annunzio" Chieti-Pescara
[2] LUISS University in Roma, Italy

Pianezzi, 2017). In this sense, smart cities may increasingly operate as curated and performative environments in which technological sophistication becomes a visible symbol of progress, while the social infrastructures that sustain civic life risk being progressively marginalized (Hollands, 2020; Yang, 2020).

In the Italian context, this shift is particularly visible. As anticipated by Vanolo (2014, p. 984), the rhetoric of smartness increasingly operates as a "non-critical consensus, sustained by celebratory narratives, media enthusiasm, and a lack of structured opposition". Smart city strategies are often presented as inherently desirable, progressive, and inevitable, leaving little space for reflexive debate about their social consequences (Kummitha & Crutzen, 2017; Pooley et al., 2005; Marchesani et al., 2026). Indeed, social consequences often directly reshape place-based communities by influencing patterns of civic participation, weakening proximity between citizens and urban institutions, and reconfiguring modes of interaction between residents and local authorities, while simultaneously marginalizing alternative visions of the city and obscuring questions of inclusion, exclusion, and collective meaning (Shelton et al., 2015). Smart cities are no longer primarily "polis" but increasingly function as the "smart" per-se, thereby disconnecting with citizens and communities.

This shift has important implications for social capital in places. Building on Putnam's (2001; 2000) seminal work, social capital refers to the networks, norms, and trust that enable coordination and cooperation for mutual benefit within a community. In Bowling Alone, Putnam (2000) documented the long-term erosion of social capital in American society, linking it to declining civic participation, weakened community ties, and reduced institutional trust. More recent organizational research echoes these concerns. Marquis et al. (2013), in Golfing Alone, show how organizational elites and corporations increasingly decouple from local communities, contributing to the hollowing out of community-based organizations and civic life . In this ongoing work, we argue that the disneyfication of place (through the smart city paradigm), represents a contemporary manifestation of this erosion. While the smart transformation of cities promises connectivity and efficiency, they may simultaneously weaken the relational infrastructures that sustain place-based communities. As cities become smarter in technical terms, they risk becoming thinner in social terms, less connected to residents' identities, practices, and collective life. Building on these insights, we posit the following research question:

RQ: As cities advance along the smart city paradigm, do they undermine social capital by prioritizing what cities can do over whom they are meant to serve?

To address this question, we empirically examine the relationship between the advancement of smart cities and changes in urban social capital. Recognizing that social capital typically evolves slowly over time (Ceci et al., 2019; Marino et al., 2025; McGraw, 2012), we investigate whether smart city transitions accelerate their erosion. In doing so, we assess how organizational smart-led transformations of cities reshape place-based social relations.

Purpose of the paper. *The purpose of this study is to investigate the societal consequences of the organizational transition toward smart city models of governance and development. While the smart city paradigm has been widely associated with technological progress, efficiency, and improved urban services, less attention has been devoted to its potential implications for the social fabric of cities. Building on the concept of "disneyfication of places," this paper examines whether the increasing prioritization of technological capabilities, performance indicators, and digital infrastructures may unintentionally weaken the relational infrastructures that historically sustain civic participation, trust, and community ties. Specifically, the study explores whether cities that advance more intensively along the smart city paradigm experience a progressive erosion of place-based social capital. By empirically analyzing the relationship between the development of smart city initiatives and changes in urban social capital, the paper aims to contribute to the debate on the organizational and societal implications of smart urban transformations. In doing so, the study contributes to the growing critical debate surrounding the smart city paradigm in recent literature (Caragliu & Del Bo, 2022; Kummitha, 2018; Marchesani & Kummitha, 2026; Vanolo, 2014), questioning whether contemporary smart city trajectories risk privileging what cities can technologically do over whom they are ultimately meant to serve .*

Methodology. *To empirically investigate the relationship between smart city advancement and social capital, we follow the approach proposed by Lee and Yu (2014) and employ a dynamic panel data model estimated through the Generalized Method of Moments (GMM). This approach is particularly suitable for capturing the dynamic evolution of social capital over time while addressing potential endogeneity issues. The analysis relies on a longitudinal dataset of 38 Italian cities observed over multiple years, selected through a probability-proportional-to-size sampling strategy (Levy & Lemeshow, 2008) to ensure representativeness across geographic areas, population size, and levels of economic development. Building on the smart city literature (Caragliu & Del Bo, 2019; Marchesani & Ceci, 2025; Marchesani & Kummitha, 2026), smart city initiatives are operationalized through six indicators capturing both organizational and relational dimensions of urban transformation: Public R&D Investments, Digital Public Services, Smart Practices (SEAP), Green Governance, Public Engagement, and Open Data Initiatives. While some of these dimensions reflect internal organizational restructuring and process reconfiguration within municipal administrations (Mora, 2023) others capture new forms of interaction between cities, users, and local communities enabled by digital infrastructures (Yeh, 2017).*

Social capital is measured following established approaches in the literature (Laursen et al., 2012; Laursen & Salter, 2006; Nakano & Washizu, 2021) through five indicators capturing civic participation and community engagement, namely Non-Profit Associations, Electoral Participation, Cultural Participation, Crime Rate, and Volunteering Activities. Finally, consistent with research on urban agglomeration and city-level dynamics (Glaeser, 2000; Glaeser & Gottlieb, 2009), the models include a comprehensive set of control variables capturing structural urban conditions, including city

size, economic development, migration flows, GDP, total firms, employment levels, airport presence, population, and education. These controls allow us to disentangle the effect of smart city advancement from broader demographic, economic, and infrastructural dynamics shaping urban communities.

Results. *Preliminary results indicate a negative association between the advancement of smart city initiatives and urban social capital. Cities exhibiting higher levels of smart city initiatives show a stronger decline in social capital, particularly in the upper quartiles of smart city initiatives intensity. This pattern is especially pronounced in larger and more economically developed cities, where the acceleration of smart initiatives coincides with sharper reductions in civic participation, volunteering activities, and associational density. These findings suggest that the rapid diffusion of smart city practices may unintentionally amplify existing structural trends of social disengagement rather than counteracting them. In particular, the growing emphasis on technological infrastructures, data-driven governance, and performance-oriented urban management appears to be associated with a gradual weakening of relational forms of civic life. Overall, the preliminary evidence supports our conceptual argument that as cities become smarter in functional and technological terms, they risk becoming socially thinner, increasingly detached from community-based practices, collective participation, and relational forms of urban life.*

Research limitations. *This study presents several limitations that open avenues for future research. First, the empirical analysis focuses on Italian cities, which may limit the generalizability of the findings to other national contexts characterized by different institutional arrangements, governance models, and levels of digital transformation. Comparative studies across countries or regions could provide a broader understanding of how smart city development interacts with local social structures. Second, while the study relies on multiple indicators to capture both smart city advancement and social capital, these constructs remain inherently complex and multidimensional. Future research could further refine the measurement of social capital by incorporating additional qualitative or perception-based indicators that capture citizens' sense of belonging, trust, and engagement with local institutions. Third, the analysis focuses on the macro-level relationship between smart city initiatives and urban social capital. Future research could explore the micro-level mechanisms through which digital infrastructures, platform governance, and data-driven urban management influence everyday forms of civic participation and community interaction. Such investigations may provide a deeper understanding of how smart-led transformations reshape the social fabric of cities over time. Fourth, the study adopts a quantitative longitudinal approach that captures structural trends over time but does not directly observe how citizens perceive or experience smart city transformations. Future research could complement these findings through qualitative methods, such as interviews, ethnographic observations, or participatory studies, to better understand how digital urban policies reshape everyday urban life and civic engagement. Finally, while the models account for a broad set of structural controls, smart city transformations are embedded within complex institutional and cultural environments that may shape their social consequences. Future research could further investigate the moderating role of local governance practices, participatory policies, and institutional trust in shaping the relationship between smart city initiatives and the evolution of urban social capital.*

Managerial implications. *The findings of this study carry implications for policymakers, urban planners, and public managers involved in the design and governance of smart city initiatives. While the smart city paradigm is often framed as a pathway toward efficiency, innovation, and improved urban services, our results suggest that the pursuit of technological advancement is not socially neutral. In particular, an excessive emphasis on digital infrastructures, performance indicators, and technology-driven governance may unintentionally weaken the relational infrastructures that sustain civic participation, trust, and community engagement within cities.*

For urban policymakers, these findings highlight the need to reconsider the balance between technological development and social embeddedness in smart city strategies. If cities prioritize technological capabilities without simultaneously reinforcing civic participation and community ties, smart initiatives risk contributing to a gradual erosion of social capital. In this sense, the emerging logic of the "disneyfication of places" suggests that cities may increasingly be organized as curated, standardized, and performance-oriented environments designed to optimize efficiency and visibility rather than to nurture community life and collective identity.

From a governance perspective, smart city policies should therefore move beyond a purely technology-centered approach and incorporate mechanisms that actively support civic engagement, local associations, and participatory governance. Strengthening community-based initiatives, fostering inclusive forms of digital participation, and maintaining strong connections between local institutions and citizens become essential components of sustainable urban transformation.

Ultimately, the results call for a broader redefinition of what it means for a city to be "smart." While the logic of urbs spectans may enhance efficiency, monitoring, and optimization, the long-term resilience and vitality of cities continue to depend on the logic of polis, where citizens, communities, and social relations remain at the center of urban development. Reintegrating this human-centered perspective into smart city strategies may help prevent the unintended social consequences associated with the disneyfication of contemporary urban environments.

Originality of the paper. *This study contributes to the emerging critical debate on smart cities by introducing the concept of the disneyfication of places as an organizing logic through which contemporary smart city transformations can be interpreted. While most smart city research emphasizes technological innovation, efficiency, and service improvement, this paper shifts the focus toward the societal consequences of these transformations. By linking the advancement of smart city initiatives to the erosion of urban social capital, the study bridges the literature on smart cities, organizational studies, and social capital. Empirically, it provides one of the first longitudinal analyses examining how smart city development relates to changes in civic participation and community engagement at the city level. In doing so, the paper offers a novel perspective on smart urban development, highlighting the potential paradox whereby cities may become technologically smarter while simultaneously becoming socially thinner.*

Education for sustainability as a pedagogical, psychological and sociological paradigm: A transdisciplinary survey between Italy, Tanzania and Spain

MARIO D'AVINO[1]

Abstract. *The ecological transition represents one of the greatest global challenges of the 21st century, requiring educational systems to assume a strategic role in forming the cognitive, ethical and socio-emotional competencies necessary to address socio-ecological crises. This paper explores sustainability as a pedagogical, psychological, sociological, and managerial paradigm, examining how schools in Italy, Tanzania, and Spain translate sustainability policies into daily practices and organizational innovation.*

Using a mixed-methods design (document analysis, ethnographic observation, 82 interviews, 1,245 questionnaires, and 3 case studies), the study highlights schools as sustainability ecosystems capable of organizational learning and community value creation. An Integrated Model of Pedagogical Sustainability (IMPS) is developed across three contribution levels—conceptual, empirical, and managerial.

Nevertheless, significant territorial diversities emerge, revealing barriers related to governance, cultural resistance and inequalities. The paper's originality lies in the development of an integrated model of pedagogical sustainability that connects curricular, psychological and sociological dimensions in a unified framework. This integration is motivated by the recognition that effective sustainability education requires not only innovative curricula, but also the psychological conditions that support agency and wellbeing, and the sociological structures that enable participation and school–territory cooperation.

Within this perspective, the study offers five specific contributions:

1. *it establishes a transdisciplinary link between pedagogy, sustainability psychology and environmental sociology;*
2. *it provides comparative empirical evidence from three different countries;*
3. *it proposes a replicable mixed-methods design applicable in diverse educational settings;*
4. *it advances a conceptual and operational model to guide educational innovation;*
5. *it introduces a framework for policy development and school–community integration.*

Overall, the study strengthens the bridge between theory and practice, showing how schools can become key drivers of sustainability through coordinated pedagogical, psychological and sociological action.

Keywords: *sustainability education; pedagogy; sustainability psychology; environmental sociology; mixed methods; international comparison*

Introduction and Background. Sustainability education represents a shift from environmental awareness to organizational transformation. Global frameworks such as the UN 2030 Agenda, UNESCO ESD Roadmap (2020-2030), and EU GreenComp (2022) have shaped curricula, teacher competencies, and institutional governance. However, three gaps persist:

1. Limited evidence of how schools implement sustainability frameworks.
2. Weak integration of pedagogical, psychological, and managerial perspectives.
3. Scarce international comparisons across diverse socio-economic contexts.

This study positions education for sustainability as a management innovation process, viewing schools as hybrid organizations that learn, adapt, and engage communities.

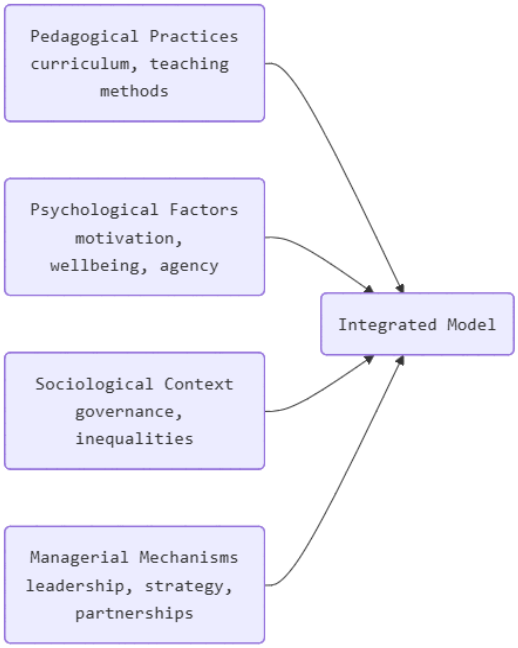
Framing of the research. *Over the last twenty years, sustainability has transformed from a sectorial theme into a comprehensive paradigm structuring global, European and national educational policies. Frameworks such as the 2030 Agenda, the UNESCO Education for Sustainable Development (ESD) programmes and, at the European level, the GreenComp Recommendation (2022) have imposed profound changes in curricula, teaching methodologies and the professional identities of educators. Schools are now explicitly called to promote systemic thinking, ecological awareness, civic participation and emotional competencies necessary to address climate change, social inequalities, biodiversity loss, demographic transitions and new risks.*

Within this landscape, the concept of pedagogical sustainability emerges as a complex and multidimensional category. Unlike mere environmental education, pedagogical sustainability integrates ecological, social, economic and cultural dimensions and focuses on the ability of educational systems to innovate, regenerate and orient themselves toward the future. It involves designing learning environments that cultivate agency, responsibility, cooperation and participatory citizenship.

In parallel, contributions from sustainability psychology—drawing on authors such as Goleman, Bandura, Lewin—

[1] Mercatorum University of Rome, dr.mariodavino@gmail.com

highlight the role of emotional literacy, motivation, collective efficacy, pro-environmental attitudes and behavioural regulation. Psychological factors are decisive in determining whether educational inputs translate into sustainable behaviours. Similarly, environmental sociology (Beck, Morin, Schnaiberg) underscores the importance of structural conditions, power relations, territorial inequalities and governance systems in shaping the capacity of institutions to act sustainably.
Despite this rich theoretical background, several gaps persist. First, empirical research still struggles to capture how schools concretely interpret and implement sustainability policies. Secondly, few studies connect pedagogical, psychological and sociological dimensions within a unified analytical framework. Thirdly, international comparisons remain limited, even though sustainability is profoundly influenced by cultural, socio-economic and territorial contexts. This research addresses these gaps by proposing a transdisciplinary investigation across three distinct contexts—Italy, Tanzania and Spain—aimed at understanding how sustainability is constructed, perceived and acted upon within educational ecosystems.



Purpose of the paper. *The paper has four main objectives:*

1. *Pedagogical objective:*
   Analyse how school curricula, extracurricular activities and organizational practices promote sustainability competencies, with particular attention to teaching methods, spaces, materials and partnerships.
2. *Psychological objective:*
   Investigate the effects of sustainability education on students' socio-emotional wellbeing, motivation, perceived efficacy and forms of ecological and social agency.
3. *Sociological objective;*
   Explore how schools interact with local communities, institutions and environmental actors, shaping participatory governance processes and contributing to territorial sustainability.
4. *Comparative objective:*
   Understand how different territorial, cultural and socio-economic conditions influence both the design and implementation of sustainability education and the acquisition of sustainable competencies. The final purpose is to build an integrated model of pedagogical sustainability able to guide teacher training, policy frameworks and school-territory collaboration.

Dimension	Theoretical Focus	Key Authors
Pedagogical	Learning design, agency, future orientation	Sterling, Morin, Tilbury
Psychological	Motivation, self-efficacy, emotional literacy	Bandura, Goleman
Sociological	Governance, inequality, reflexive modernity	Beck, Schnaiberg
Managerial	Organizational learning, leadership, networks	Senge, Fullan

These dimensions converge into the Integrated Model of Pedagogical Sustainability (IMPS), where management acts as the connector that enables learning, participation, and innovation.

Figure 1. Integrated Model of Pedagogical Sustainability (IMPS)

Methodology. *The research employs a Mixed Methods Approach, ensuring analytical depth and methodological triangulation.*

1. Document analysis
A systematic analysis was conducted on:
- *international frameworks (Agenda 2030, UNESCO ESD);*
- *European policies (GreenComp);*
- *national legislation (Italian Law 92/2019 on Civic Education);*
- *regional and local guidelines;*
- *strategic reports (WWF, ARPA, SNPA, ASviS).*

This phase provided the normative and conceptual structure necessary to interpret empirical data.

2. Ethnographic investigation
Ethnographic fieldwork involved visits to schools in Italy, Tanzania (particularly in the Kilolo district in collaboration with RUCU and Fondazione Tovini) and Spain. Observations focused on:
- *classroom practices and relational dynamics;*
- *school governance;*
- *collaborations with NGOs, local authorities and environmental bodies;*
- *routines related to waste, mobility, food, urban green and energy consumption.*

This approach enabled the identification of tacit and culturally embedded practices often not captured by formal documentation.
3. Semi-structured interviews
Interviews were conducted with:
- *teachers and school leaders;*
- *local and national administrators;*
- *representatives of institutions (Carabinieri Forestali, Navy);*
- *NGOs (WWF, local environmental associations);*
- *university experts and training officers.*

Topics addressed included visions, problems, barriers, opportunities and future trajectories.

4. Quantitative questionnaires
Surveys were administered to:
- *school students (primary to upper secondary);*
- *teachers;*
- *university students (future teachers).*

Variables investigated:
- *sustainability attitudes and representations;*
- *daily pro-environmental behaviours;*
- *sense of personal and collective efficacy;*
- *perceived impact of school projects;*
- *socio-emotional wellbeing indicators.*

5. Participant observation
Participation in public meetings, institutional consultations and territorial assemblies allowed the observation of participatory processes and governance dynamics related to sustainability.

6. Case studies
Three emblematic cases were studied:
- *WWF: environmental education projects and student engagement models.*
- *Carabinieri Forestali: biodiversity protection and legality education.*
- *Navy: marine education, civic responsibility and ecological awareness.*

These cases function as replicable models of school–territory integration.

7. International comparison
Cross-country comparison highlights cultural, structural and pedagogical differences, offering a global-local perspective on sustainability education.
A convergent mixed-methods approach combines qualitative and quantitative evidence to capture both systemic and perceptual dimensions.

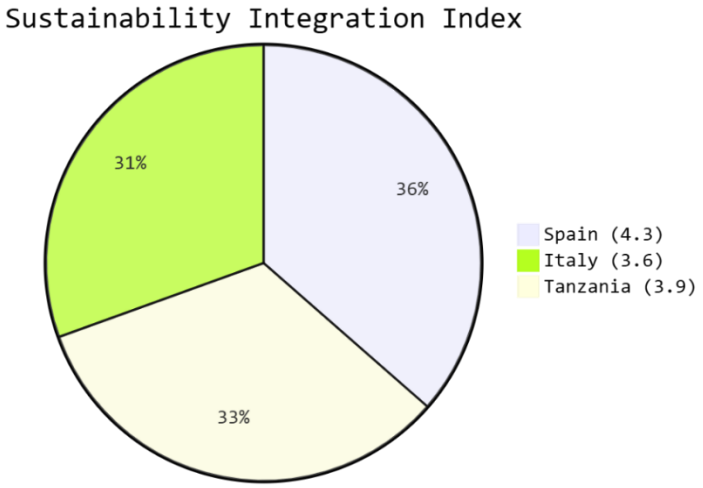
Method	Tool	Data Collected
Document Analysis	Policy and institutional texts	37 documents
Ethnography	Classroom and school observations	102 hours

Method	Tool	Data Collected
Interviews	Semi-structured, 45 min avg	82
Surveys	Online questionnaires	1,245 respondents
Participant Observation	Public meetings, assemblies	17 total
Case Studies	WWF, Carabinieri Forestali, Eco-Schools Spain	3 cases

Samples

- Schools: 38 (Italy = 15, Tanzania = 10, Spain = 13)
- Respondents: Students (70%), Teachers (25%), Administrators (5%)
- Sampling: Purposive stratified by region, school type, and governance model

Data Analysis Procedures



- *Qualitative*: NVivo 14 coding (thematic analysis, cross-country matrices)
- *Quantitative*: SPSS 28 (ANOVA, correlations, composite indices 0–5)
- *Integration*: Joint data displays for pattern convergence

Results.

Schools as Sustainability Ecosystems

Schools with distributed leadership and strong partnerships perform better in sustainability integration.

Figure 2. Sustainability Integration Index by Country

Spain shows systematic integration of policy and practice; Tanzania demonstrates contextual sustainability rooted in everyday survival practices; Italy presents strong policy frameworks but regional variability.

Competency Development

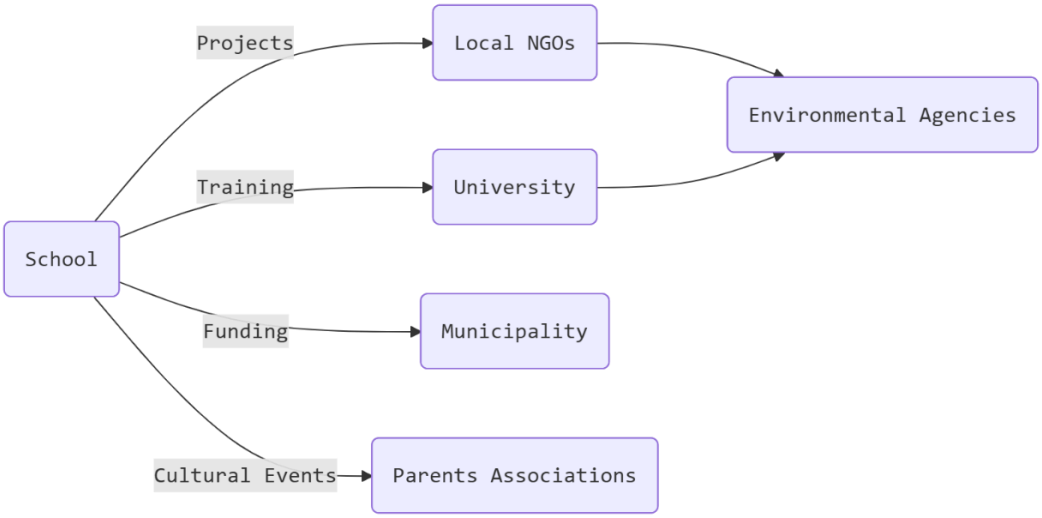


Figure 3. Heatmap – Growth in Core Student Competencies (%)

Competence	Italy	Tanzania	Spain
Systemic Thinking	72	77	78
Agency & Self-Efficacy	65	70	74
Emotional Regulation	58	67	65
Global Citizenship	68	73	79

Higher competency growth correlates with stronger participatory practices ($r = 0.64$, $p < .01$).

Comparative Governance Models

Figure 4. Network Diagram – School–Community Partnerships

The Spanish network shows densest connectivity; Tanzania's model is community-centric; Italy's is policy-driven but fragmented.

Cross-Country Comparative Matrix

Category	Italy	Tanzania	Spain
Policy Framework	Strong national law, uneven enforcement	Minimal policy, pragmatic actions	Regional plans, national coherence
Leadership Model	Individual, principal-centered	Communal and collective	Shared and institutionalized
Teacher Training	Fragmented, voluntary	Informal, NGO-based	Structured CPD programs
Governance	Top-down, variable	Local consensus	Network-based
Key Innovation	Curriculum projects	Food and water sustainability	Eco-school certification system

Discussion: Managerial Implications

Education for sustainability acts as a management innovation, reshaping schools as learning organizations and public value creators.

- Micro level: teachers as change agents using project and design-thinking methods;
- Meso level: schools as learning organizations with participatory governance;
- Macro level: systems promoting network governance and evidence-based decision-making.

Key conditions for impact:

1. Distributed leadership and reflective principals.
2. Teacher professional development aligned to GreenComp.
3. Institutionalized stakeholder partnerships.
4. Monitoring systems linking education outcomes to SDGs.

Policy Recommendations

Target Area	Key Recommendation
Teacher Education	Embed sustainability competencies into national frameworks
Leadership Training	Introduce strategic management and ESD modules
Governance	Develop regional Sustainability Networks with joint KPIs
Evaluation	Implement SDG-linked performance indicators
Financing	Promote public-private partnerships for sustainable infrastructure

Limitations and Future Research

- National heterogeneity limits direct comparability.
- Translation and cultural bias may affect data interpretation.
- Future phases will expand sampling, include longitudinal impact assessment, and explore digital sustainability competencies.

Managerial implications. *The study supports:*

- *the design of teacher training aligned with GreenComp;*
- *the creation of local sustainability networks;*
- *evidence-based school governance;*
- *cross-sectoral projects integrating NGOs, institutions and environmental bodies;*
- *development of territorial sustainability plans.*

Conclusions. Education for sustainability represents both a pedagogical transformation and a strategic managerial challenge. The IMPS framework offers an integrative model linking learning, wellbeing, governance, and leadership. Italy, Tanzania, and Spain illustrate distinct yet complementary trajectories—policy-driven, community-based, and system-integrated—demonstrating that sustainability thrives where educational innovation and managerial governance converge.

The research demonstrates that education for sustainability is both a pedagogical and managerial transformation process. Schools that adopt distributed leadership, organizational learning and community partnerships generate measurable gains in student wellbeing, agency and civic participation.

The Integrated Model of Pedagogical Sustainability (IMPS) thus offers a practical and theoretical contribution for managers, educators and policymakers—turning schools into laboratories of sustainable innovation.

The findings of this study reaffirm that education for sustainability (EfS) must be understood not solely as a pedagogical innovation but as a comprehensive organizational and managerial transformation. Schools are no longer confined to their traditional instructional role; they operate as complex adaptive systems, where learning, governance, psychological wellbeing, and community engagement intersect in the pursuit of the Sustainable Development Goals (SDGs).

Across the three research contexts—Italy, Tanzania, and Spain—common structural and cultural patterns emerge, yet their trajectories reveal the intricate interplay between global frameworks and local enactments.

In Italy, the normative apparatus for civic and environmental education provides a solid conceptual foundation; however, implementation depends on local leadership and the capacity of schools to navigate fragmented governance. Tanzania illustrates a different paradigm—sustainability as a lived, community-embedded necessity, where schools act as anchor institutions fostering resilience and social cohesion in contexts of resource scarcity. Spain, in contrast, demonstrates a mature and systemic approach: regional environmental plans, participatory governance, and consistent teacher training have consolidated a networked model of educational sustainability.

From a managerial perspective, these findings contribute to the understanding of schools as learning organizations (Senge, 1990) and public value institutions. The capacity to mainstream sustainability depends on the presence of distributed leadership, collaborative cultures, and continuous professional learning communities. Leadership is not restricted to formal authority but emerges as collective competence, nourished by relational capital and reflective practices. The evidence suggests that effective sustainability governance in education systems is shaped by a triadic equilibrium among policy coherence, organizational learning, and stakeholder participation.

At a more theoretical level, the Integrated Model of Pedagogical Sustainability (IMPS) articulates the nexus between pedagogy, psychology, sociology, and management. The model sees sustainability education as a *transdisciplinary ecosystem of value creation*, where cognitive, emotional, and structural resources co-evolve.

- The pedagogical dimension ensures curricular innovation and experiential learning.
- The psychological dimension sustains motivation, wellbeing, and agency.
- The sociological dimension embeds equity, governance and participation.
- The managerial dimension orchestrates these components into an adaptable and accountable system.

This integrative approach expands existing ESD research by anchoring it in organizational theory and management studies—fields that provide the analytical tools to understand how change is institutionalized and how sustainability becomes organizational routine rather than isolated pedagogical initiatives.

Empirically, the study demonstrates that students exposed to integrated sustainability curricula develop higher levels of complex thinking, emotional regulation, and civic engagement. Such competencies translate into enhanced wellbeing and a stronger sense of agency—the psychological prerequisites for sustainable behavior. These outcomes reinforce the argument that sustainability education simultaneously cultivates individual competences and collective capabilities, bridging micro-level learning with macro-level governance.

Moreover, this research underscores the importance of multilevel governance in education management. Nations and regions that institutionalize horizontal collaboration—connecting ministries, municipalities, NGOs, and academic institutions—generate more coherent ecosystems of sustainability. The Spanish experience illustrates a governance model in which schools, municipalities, and civil actors co-design educational strategies, resulting in improved alignment between policies, resources, and outcomes.

From a policy standpoint, EfS should thus be regarded as a domain of strategic management for public institutions, requiring structured investment, evaluation mechanisms, and transparent accountability. Integrating GreenComp competencies into national curricula, accrediting sustainability in teacher education, and defining measurable sustainability indicators are no longer optional reforms—they are imperatives for systemic transformation.

Future research should pursue longitudinal studies of how sustainability becomes embedded in institutional culture and how it transforms leadership identities. Expanding the comparative design to include non-European and Global South contexts will further illuminate the social and cultural variability of sustainable education as a management paradigm.

Ultimately, this paper contributes to the emerging vision of the school as a sustainability ecosystem—a microcosm of the sustainable society it seeks to build. As the evidence suggests, schools that learn to manage complexity, foster wellbeing, and mobilize collective agency are not only educating for sustainability—they are practicing it. The pedagogical, psychological, sociological, and managerial dimensions thus converge into an operational reality where education ceases to be preparation for the future and becomes, instead, a living practice of sustainable transformation in the present.

E-Government Service Quality as a Driver of Digital Inclusion

GIUSEPPE BONGIORNO[1], MARIA COLURCIO[2], OLIMPIA MEGLIO[3]

Abstract. *This paper examines how the quality of e-government service delivery shapes digital inclusion in citizens' interactions with public administrations. Grounded in a public service perspective, the study conceptualizes the quality of digital public services as a feature of the service environment that can influence not only the overall use of online public services, but also the distribution of access across social groups. The analysis focuses on different dimensions of digital inclusion: interaction with Public Authorities, perceived barriers to digital interaction and the educational gap in the use of digital public services. Using a panel dataset covering 36 European countries over the period 2012–2022, the study employs a Two-Way Fixed Effects model to assess the relationship between e-government service quality and inclusion outcomes. The findings indicate that higher lagged quality of e-government service delivery is associated with a reduction in the educational gap in digital service use. This equalizing effect is more pronounced in countries characterized by greater fragility in digital skills. These results suggest that improvements in the design and enabling conditions of digital public services can support a more inclusive pattern of digital transformation. The paper contributes to research on public value, digital inclusion, and e-government by showing that the benefits of digitalization depend not only on citizens' individual capabilities, but also on the quality of the public digital service ecosystem in which interactions take place.*
Keywords: *Digital public services; Digital inclusion; Service quality; Public service Logic.*

Framing of the research. The digital transformation of public administration is increasingly reshaping how public organizations design, deliver, and manage services (Mergel et al., 2019). Digital public services can be interpreted as value propositions embedded in broader service ecosystems, whose design characteristics shape citizens' opportunities to access and benefit from services (Petrescu, 2019; Eriksson et al., 2020). This broader perspective is important because it shifts analytical attention from technology adoption alone to the conditions under which digital public services create value for citizens (Yang et al., 2024). Building on this perspective, Public Service Logic (PSL) offers a useful framework for addressing this issue by arguing that value is not produced unilaterally by public organizations (Osborne, 2018; Osborne et al., 2021). Applied to digital government, this implies that online public services should be understood not merely as technological tools or administrative channels, but as service environments whose design can facilitate or constrain citizens' capacity to benefit from public services. These strands of literature provide a coherent foundation for understanding how the design and delivery of digital public services influence not only their uptake, but also their inclusiveness (Morte-Nadal and Esteban-Navarro, 2025). This perspective becomes especially relevant when considered alongside the literature on digital inclusion. Rather, it encompasses a wider set of organizational and institutional changes that affect administrative processes, service delivery models, and the nature of citizen government interactions (Haug et al., 2024). In this context, PSL emerges as a particularly suitable analytical lens to grasp these dynamics. PSL conceptualizes public services as processes through which value emerges through interactions between public organizations, citizens, and other actors operating within service systems (Osborne, 2018; Osborne et al., 2021). From this perspective, public organizations are not seen as direct creators of value. Instead, they offer value propositions that enable citizens to generate value through their engagement with public services in everyday life contexts (Osborne et al., 2021, 2022). Furthermore, PSL highlights that value creation unfolds within broader public service ecosystems, where multiple actors integrate resources in order to achieve desired outcomes (Petrescu, 2019; Eriksson et al., 2020).

At the same time, the literature on the digital divide has extensively documented how disparities in access to technology, levels of digital skills, and broader socio-economic resources shape individuals' ability to participate effectively in digital environments (Mesa, 2023). These inequalities do not only affect whether individuals can access digital services, but also influence how they experience and use them. In this regard, existing research has also emphasized that the design of administrative procedures and service interfaces may generate administrative burdens, which can take the form of learning, compliance, and psychological costs that discourage citizens from accessing public services (Moynihan et al., 2015). In digital contexts, such barriers may lead individuals to rely on intermediaries or other people to complete online administrative procedures, thereby limiting their autonomy in interacting with public administrations. Within digital government settings, the quality of service provision becomes a crucial factor in shaping these dynamics. It encompasses multiple dimensions, including usability, accessibility, and the interoperability of systems, as well as the availability of enabling infrastructures such as digital identification systems and secure data exchange mechanisms (European Commission, 2025). These elements play a central role in influencing citizens' perceptions of convenience, ease of use, and trust when engaging with digital public services (Scott et al., 2016; Campmas et al., 2022). Despite the relevance of these aspects, much of the existing literature has primarily focused on explaining patterns of digital service

adoption, while comparatively fewer studies have examined whether improvements in the quality of digital supply also contribute to reducing barriers to access or to narrowing inequalities between different social groups (Liu et al., 2025).

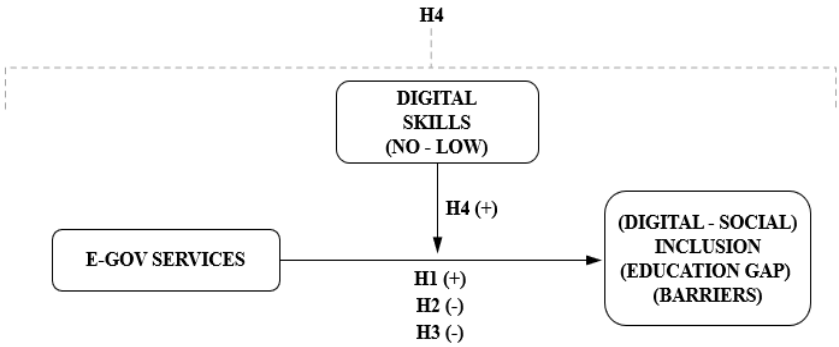
Purpose of the paper. The purpose of this paper is to examine whether improvements in the quality of digital public service provision are associated with more inclusive patterns of interaction between citizens and public authorities. In particular, the study investigates the extent to which higher quality in eGovernment service delivery may influence not only the overall use of digital services, but also the degree to which such use is distributed more evenly across different social groups.

In line with a Public Service Logic perspective, we conceptualise digital public service quality as a value proposition that may facilitate citizens' ability to access and use services. From this standpoint, the quality of digital provision is not simply a technical attribute, but a key enabling condition that can shape how citizens engage with public services and generate value through their interactions.

This developmental paper assesses whether eGovernment supply quality is associated with digital inclusion through two complementary channels, namely an intensive margin, understood as higher average usage, and an equalising margin, reflected in lower perceived barriers and a smaller educational gap. This focus aligns with perspectives that evaluate digital transformation not only by efficiency gains but also by its contribution to public value and socially inclusive outcomes (Moore, 1995; Hartley et al., 2017). It also speaks to digital divide research emphasising that inclusion depends on both individual capabilities and the conditions that shape effective access, including barriers to use (van Dijk, 2020; Lythreatis et al., 2022), and to inclusive innovation arguments that link innovation to "no one left behind" objectives (Osborne et al., 2016; Bovaird and Löffler, 2012).

Building on the European Commission's eGovernment Benchmark framework, we incorporate gap measures to capture the distributional dimension of inclusion and test the following hypotheses:

H1: Higher e-government supply quality is associated with greater online citizen–public authority interaction.



H2: Higher e-government supply quality is associated with a reduction in barriers to use.

H3: Higher e-government supply quality is associated with a reduction in the education divide in online interaction with public authorities.

H4: The negative association between supply and the education divide is stronger in contexts with a higher share of the population with no or low digital skills.

The conceptual model (Figure 1) links eGov supply quality to digital inclusion through two complementary channels. The intensive margin concerns the intensity of online use/interaction with public authorities (D1). The equalising margin concerns constraints and inequalities in access, captured by perceived barriers (D4) and by the education gap in interaction (LogGap). We further posit that the equalising margin is contingent on digital skills fragility: the effect of supply on LogGap is moderated by the share of citizens with low or no digital skills.

Figure 1 – Conceptual model

Source: Authors' elaboration

Methodology. This study employs a longitudinal panel dataset encompassing 36 European countries over the period 2012 to 2022. Data on the quality of e-government service provision are drawn from the European Commission's eGovernment Benchmark, which we combine with Eurostat measures of citizens' online interaction with public authorities, perceived barriers to autonomous digital use, and educational inequalities in digital participation. The analytical strategy is based on Two-Way Fixed Effects models, allowing us to exploit both cross-country and temporal variation in these indicators (Wooldridge, 2025).

Empirically, the dataset includes 36 countries across 11 years, resulting in a total of 377 potential country-year observations. The actual number of observations varies depending on the specification and outcome due to missing data, primarily arising from Eurostat series on digital skills prior to 2015. The models are estimated using R-Studio, incorporating country and year fixed effects along with robust standard errors, clustered by country or, in more conservative specifications, two-way clustered by both country and year (Croissant and Millo, 2019).

To assess the quality of digital public service provision in the context of eGovernment, we rely on two main dimensions—User Centricity and Key Enablers—operationalized through their average values (M_UC and M_KEY).

The former captures the overall quality of the user experience, referring to how far information and services are accessible online, supported through digital channels, and compatible with different devices, while the latter reflects the availability of the core infrastructures that enable digital delivery, such as eID, eDocuments, authentic sources, digital mail, and security systems.

To provide a more comprehensive measure, we also construct a composite indicator of eGovernment supply, obtained as the average of these two dimensions. Inclusion is then examined from two complementary perspectives: on the one hand, we consider actual usage through the indicator Interaction (Interaction PA12), which measures the share of individuals who have interacted online with public authorities over the past 12 months; on the other hand, we account for structural constraints through Barriers_people, capturing the extent to which individuals rely on intermediaries to access digital services. Building on this, we further explore inclusion by introducing an inclusion gap aimed at identifying inequalities between individuals with different educational levels. More specifically, we focus on the educational gap in online interactions with public authorities, derived from Interaction PA12: values approaching zero indicate a more inclusive system, as they signal similar levels of use across groups, whereas positive values reveal that individuals with higher education levels make greater use of digital services, pointing to lower distributive inclusion; conversely, a reduction in this value suggests a narrowing of the gap and a more even distribution of access.

From this perspective, the analysis goes beyond the mere observation of usage rates by explicitly considering whether digital services effectively reach more disadvantaged groups. Digital skills (Digital skills – no-low) are included as a moderating factor and, given data constraints, are defined as the country-level average share of individuals with no or low digital skills, a choice that captures a more structural dimension of digital vulnerability while also limiting issues related to missing data in annual series. Finally, the model controls for two relevant contextual factors—the logarithm of GDP per capita (log(GDP)) and broadband coverage above 30 Mbps (broadband >30)—in order to account for differences in economic development and in the availability of digital infrastructure, both of which are likely to influence the use of online public services. All details regarding the variables used are provided in the "Websites" section.

Results. The analysis reveals that higher quality in digital public service provision is linked to both lower barriers to autonomous digital interaction and narrower educational inequalities in citizens' engagement with public authorities. These equalising effects are particularly pronounced in contexts characterised by greater digital skills fragility.

To gain a deeper understanding of these patterns, we first examine citizens' interactions with public authorities over the previous twelve months and subsequently explore the barriers to use, focusing particularly on cases where a citizen does not manage digital interactions directly and relies on intermediaries. Across various model specifications, the evidence appears more consistent for the equalising margin than for the intensive margin. Moreover, the moderation patterns suggest that the association between supply quality and inclusion strengthens as digital fragility increases. Interpreted cautiously, the results align with the idea that improvements in enabling conditions may reduce frictions that disproportionately constrain lower-capability groups, thereby promoting a more equitable distribution of access (van Dijk, 2020; Lythreatis et al., 2022). Given the observational nature of the study, these findings are treated as developmental evidence rather than causal estimates.

The findings indicate that the societal significance of high-quality digital public services lies in their potential to reshape both the distribution of access and citizens' autonomy in service use. Focusing more closely on the empirical patterns, higher levels of supply quality are associated with reduced reliance on intermediaries and a smaller educational gap in digital interactions, particularly in contexts characterised by heightened digital skills fragility. Rather than concentrating solely on measures of uptake or transaction volumes, the evidence emphasizes the importance of understanding how digital service systems influence citizens' capacity to engage with public administration independently and on their own terms.

From this perspective, digital public services can be interpreted as institutional arrangements that determine not only access to administrative transactions but also the conditions under which citizens experience inclusion or exclusion in service encounters. Accordingly, improvements in digital service quality may effectively alleviate structural frictions in citizens' interactions with public administration, contributing to more equitable patterns of participation within digitally mediated public service systems. Taken together, the results highlight meaningful structural relationships between the quality of digital service systems and outcomes of inclusion. Table 1 summarizes the results.

Table 1 - Integrated Summary of TWFE Results on E-Government Service Quality, Online Interaction, and Digital Inclusion

Supply measure	*Specification*	*β supply (SE)*	*γ interaction (SE)*	*Marginal effects*	*N*	*Model notes*
		A. *Online interaction with public authorities (D1)*

Note. TWFE estimates with country and year fixed effects in all specifications. For sections A and B, coefficients refer to a +10-point increase in contemporaneous supply quality and no time-varying controls are included. For section C, supply is lagged by one period (t−1) and moderated with digital skills fragility. β denotes the supply coefficient, γ the interaction term, and ME the marginal effect of supply at the first, second, and third quartiles of the moderator. Controls include log GDP per capita and broadband coverage above 30 Mbps. Robust standard errors are reported in parentheses. Significance levels: *** p < 0.01, ** p < 0.05, * p < 0.10.
Source: Authors' elaboration.

Coefficients for M_UC and M_KEY are positive but do not reach conventional levels of statistical significance in these baseline specifications without controls, remaining directionally consistent with H1. The coefficient for the composite index is positive and statistically significant: a 10-point increase in the composite supply measure is associated with an average increase of 0.97 percentage points in online interaction. Net of fixed effects, temporal variation in supply explains a limited share of within-country variation in use, consistent with strong country-specific inertia. The User Centricity coefficient is negative and statistically significant in the baseline specification: a 10-point increase in User Centricity is associated with about 0.5 percentage points fewer citizens reporting dependency-related barriers. Results support H3 and the moderation pattern in H4: lagged supply quality is associated with a lower InclusionGap, and the equalising effect strengthens as digital skills fragility increases. For Key Enablers (t−1), the main supply coefficient is negative and significant in all specifications with controls. At the mean value of the moderator, a 10-point increase in lagged Key Enablers is associated with a reduction in InclusionGap of about 0.030 units. The interaction term γ is negative and consistently significant, indicating that the equalising effect is stronger in countries with a higher share of citizens with low digital skills. This trend is also reflected in the marginal effects by quartile shown in Table 1.

Research limitations. Future research could further investigate how specific features of digital service design shape inclusive value creation across diverse public service contexts. Three main limitations of the current study suggest directions for a structured research agenda. First, although we employ country-level panel estimates, unobserved time-varying factors and potential reverse causality may still influence the results. Second, indicators related to dependency or intermediation do not capture the full range of obstacles that shape inclusion (van Dijk, 2020; Lythreatis et al., 2022). Third, missing data in certain series, particularly digital skills prior to 2015, reduces the effective sample size in some models and underscores the preliminary nature of the evidence.

Building on these limitations, future studies should expand the analysis by incorporating alternative measures of inequality alongside the educational gap and by further testing the robustness of the findings (van Dijk, 2020; Lythreatis et al., 2022). Research could also disentangle the specific contributions of user-centredness and key enabling factors, drawing on insights from both the digital divide and inclusive innovation literature (van Dijk, 2020; Osborne et al., 2016). In addition, quasi-experimental and mixed-method approaches may help clarify whether improvements in supply-side

digital government measures translate into more equitable access and engagement with public services (Moore, 1995; Hartley et al., 2017).

Managerial implications. The findings of this study carry several practical and social implications for public managers and policymakers engaged in digital transformation initiatives. Practically, the results highlight the importance of prioritising usability, accessibility, and user-centred design in the development of digital public services. From a societal perspective, the evidence that higher-quality digital public services are associated with narrower inequalities in access and use underscores the critical role of service system design in promoting more inclusive digital transitions.

First, the societal value of investments in digital government should extend beyond merely increasing the availability of services to enhancing the quality of service interactions from the user's perspective (Van Deursen and Van Dijk, 2019). In this regard, initiatives that improve usability, clarify procedures, and ensure interoperability across digital systems can play a key role in enabling citizens to engage more autonomously with public administration. Second, the stronger link between high-quality digital services and reductions in educational inequalities highlights the necessity of adopting an inclusion-oriented approach to service design. Digitalisation alone does not automatically ensure equitable access; public organisations must deliberately consider how service interfaces, procedural requirements, and support mechanisms influence citizens' ability to participate in digitally mediated service encounters. This approach aligns closely with Public Service Logic perspectives, which view public organisations as facilitators of value creation within service systems (Osborne, 2018; Osborne et al., 2021).

Third, the moderating role of digital skills fragility indicates that improvements in digital public service quality may yield the greatest benefits in contexts where structural barriers to digital participation are more pronounced (Scheerder et al., 2017). This underscores the importance of integrated policy strategies that combine investments in service design, digital infrastructure, and citizens' digital capabilities. Enhancing the usability, accessibility, and navigability of digital services may therefore be particularly critical for reducing inequalities in effective service use. These insights are consistent with emerging policy orientations that emphasise user-centred and inclusive design principles as core elements of digital public service development in the digital era (OECD, 2022). Rather than treating inclusion as a downstream effect of technological innovation, public organisations should embed considerations of accessibility and autonomy of use directly into the architecture of digital service systems. From a Public Service Logic perspective, this entails recognising digital public services as enabling environments that shape citizens' opportunities to generate value in their interactions with public administration (Osborne, 2018; Osborne et al., 2021; Sergianni et al., 2026).

Originality of the paper. This paper contributes to research on service systems, digital government, and digital inclusion by conceptualising the quality of digital public services as an enabling condition that shapes citizens' opportunities for value creation in their interactions with public organisations. The novelty of the contribution is particularly evident in the integration of the digital skills–inclusion gap model, which highlights how structural digital vulnerabilities interact with service quality to influence patterns of access. Furthermore, the study contributes to the literature on digital inclusion by shifting attention from determinants at the individual level toward the characteristics of public service provision itself, underscoring the central role of service design and enabling conditions in fostering more equitable digital participation. In addition, this paper provides empirical evidence within the Public Service Logic literature, demonstrating that the quality of digital public service provision, understood as a public value proposition, can directly influence citizens' ability to access and effectively engage with public services. Furthermore, this study underscores the importance of considering structural and institutional factors, emphasizing that inclusive access to digital services depends as much on how public services are designed and delivered as on the skills and resources of the users themselves. Finally, we contribute to the literature on digital inclusion by shifting attention from individual level determinants of technology use to the role of public service provision itself, thereby emphasizing the importance of structural and institutional factors in shaping inclusive access to digital services.

Exploring the interplay between dynamic capabilities and contextual factors for circular innovation ecosystem emergence: An agent-based modeling approach

ANDREA ANCONA, VALENTINA LAZZAROTTI, LETIZIA MORTARA

Abstract. *The emergence of Circular Innovation Ecosystems (CIEs) is increasingly recognized as crucial for enabling circular economy transitions, yet the mechanisms driving their formation remain under-theorized. This paper develops a theoretical framework explaining CIE emergence as the result of the interplay between macro-level contextual conditions and micro-level organizational capabilities. Specifically, it integrates insights from the literature on Sustainable Entrepreneurial Ecosystems and Dynamic Capability theory within a multi-level perspective. To explore these dynamics, the study adopts an Agent-Based Modeling approach that simulates interactions among heterogeneous actors and opportunities embedded in a sustainability-oriented ecosystem context. CIE emergence is operationalized through network-based metrics capturing ecosystem structure and circular interaction patterns. The study contributes to ecosystem research by proposing a computational approach to theory building and by identifying mechanisms linking firm-level capabilities with system-level circular innovation outcomes.*
Keywords: *Dynamic capabilities; Circular innovation ecosystem; Sustainable entrepreneurial ecosystem; Agent-based modeling; Multi-level perspective; Complex systems.*

Framing of the research. The ecosystem concept, originally developed in biological and natural sciences, has progressively been adopted in business and economic research, particularly in debates on innovation and entrepreneurship (Granstrand & Holgersson, 2020; Stam & Van de Ven, 2021). This conceptual shift reflects the growing recognition of the complexity and interdependence among heterogeneous actors and elements involved in the generation and diffusion of innovation. Within this perspective, innovation processes are increasingly understood as collective and systemic phenomena, emerging from interactions among firms, institutions, and other stakeholders (Roundy et al., 2018; Russell & Smorodinskaya, 2018).

At the same time, the focus of entrepreneurship and innovation research - both in academia and in practice - has gradually expanded beyond purely economic objectives toward the creation of social and environmental value (Dean & McMullen, 2007). This shift has contributed to the emergence of concepts such as sustainable entrepreneurship (Cohen & Winn, 2007) and sustainable innovation (Bos-Brouwers, 2010). Ventures operating under these logics differ from conventional firms in both their business models and performance metrics, as they incorporate the "triple bottom line" of economic, social, and environmental outcomes and often adopt circular rather than linear production and consumption models (Urbinati et al., 2017).

The convergence of these two streams of research has led to the notion of circular ecosystems, defined as communities of heterogeneous and interdependent actors that collectively generate system-level sustainable outcomes characterized by circular processes such as recycling, reuse, and resource reduction (Aarikka-Stenroos et al., 2021). Within the innovation literature, this perspective has further evolved into the concept of Circular Innovation Ecosystems (CIEs). Building on the broader notion of innovation ecosystems - defined as evolving configurations of actors, activities, artifacts, institutions, and relationships shaping the innovative performance of individual actors or populations of actors (Granstrand & Holgersson, 2020) - CIEs explicitly integrate circular economy principles into collaborative innovation processes (Thakur & Wildon, 2024).

Given their roots in biological and ecological domains, as well as complex systems theory, ecosystem emergence and evolution are typically understood as the result of dynamic and multi-level interactions among diverse actors and structural conditions (Holland, 1997). However, in the case of CIEs, the processes through which such systems emerge and develop over time remain relatively under-theorized. Similar to innovation ecosystems, CIEs arise from the interaction between macro-level contextual conditions and micro-level characteristics of ecosystem actors. At the organizational level, for instance, SMEs' degree of sustainability orientation in innovation practices is often shaped by these multi-level influences as reflected in the different SME typologies proposed by Klewitz & Hansen (2014). Resistant SMEs largely disregard sustainability-related pressures, whereas reactive SMEs respond adaptively to regulatory or stakeholder demands. Anticipatory SMEs adopt forward-looking strategies that anticipate emerging opportunities related to sustainability. Innovation-based SMEs integrate environmental and social considerations into the design of new products and services, while sustainability-rooted SMEs embed the triple bottom line directly into their business models, explicitly addressing environmental, social, and economic challenges. These heterogeneous orientations influence the ability of firms to engage in ecosystem-level sustainability transitions.

At the macro level, the broader institutional and market environment plays a crucial role in shaping the emergence of sustainable innovation activity. Sustainable ventures often operate under more challenging conditions, facing higher financial and institutional barriers than conventional firms, even though their propensity for risk-taking remains

comparable (Hoogendoorn et al., 2019). Market imperfections - such as negative externalities, inefficient pricing mechanisms, and information asymmetries - have historically contributed to environmental degradation but have also created opportunities for new entrepreneurial models based on radical innovation and alternative business approaches (Muñoz & Cohen, 2018). Empirical evidence further highlights the importance of contextual conditions in shaping sustainable entrepreneurship and innovation. For example, examining the foundations of sustainable entrepreneurship in Canada, Tunisia, and Cameroon, Spence et al. (2011) show that while entrepreneurs' commitment to sustainability is strongly influenced by individual values and entrepreneurial intent, cultural and normative frameworks significantly shape how sustainability is interpreted and enacted. Similarly, Sunny & Shu (2019) find that in the U.S. clean-technology sector regulatory policies positively influence the emergence of sustainable ventures, whereas financial incentives alone do not produce a significant effect. In addition, spatial proximity to industrial clusters appears to facilitate venture creation through knowledge spillovers, human capital mobility, and access to specialized services. Building on these insights, recent research has identified four categories of barriers that may hinder the emergence of CIEs. These include contextual barriers linked to regulatory and institutional conditions; economic barriers related to the cost and financial feasibility of circular initiatives; cultural barriers associated with societal attitudes toward sustainability; and technical barriers concerning knowledge, skills, and technological capabilities (Dorrego-Viera et al., 2025). Addressing these barriers typically requires coordinated action among multiple ecosystem actors, including public institutions, universities, firms, and civil society organizations.

Alongside these contextual dynamics, a growing body of literature emphasizes the importance of micro-level factors such as orchestration capabilities in circular ecosystem development (Aryee et al., 2025). Ecosystem orchestration refers to the ability of central actors to integrate and coordinate resources, activities, and relationships within the ecosystem in order to adapt to changing environmental conditions (Kanda et al., 2025). In the context of circular ecosystems, orchestration involves managing circular consumer offerings, coordinating circular supply-chain activities, and developing effective partnership strategies (Sandberg, 2023). Because of the complexity and interdependence characterizing circular value creation, no single firm can achieve the transition toward a circular economy independently; instead, ecosystem-wide orchestration mechanisms - such as standardization, nurturing, and negotiation - are necessary to facilitate collective transformation (Parida et al., 2019). Complementing this perspective, Block et al. (2026) adopt an organizational capability-based approach, highlighting the role of dynamic capabilities in the development of circular business models. Authors show that dynamic capabilities influence circular value propositions both directly and indirectly, with the strength of these effects depending on the level of stakeholder pressure faced by firms. Their findings also suggest that changes in operational capabilities are necessary to support broader transformations toward circular business models.

Building on these strands of literature, this paper aims to integrate ecosystem-level and organization-level perspectives in order to develop a conceptual framework explaining how the interplay between contextual conditions and organizational capabilities can lead to the emergence of CIEs.

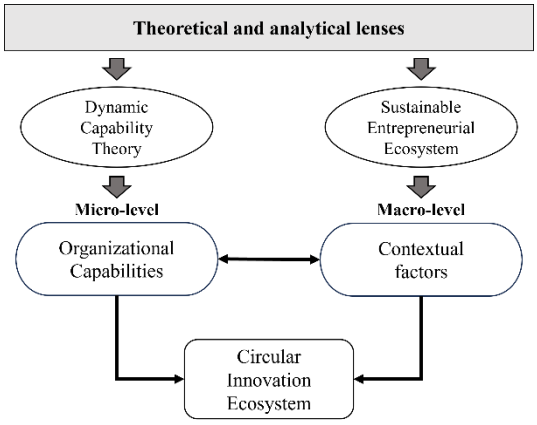
Purpose of the paper. The main purpose of this paper is to develop hypotheses for theory-building on the emergence of CIEs. Specifically, the study addresses the following research question: "How does the interplay between contextual (macro-level) factors and organizational (micro-level) capabilities influence the emergence and development of CIEs?".

To address this question, we first develop a theoretical framework that integrates two complementary perspectives for mapping contextual conditions and organizational capabilities. This approach aligns with the Multi-Level Perspective framework in sustainability transitions research (Geels 2011), which emphasizes how systemic transformations emerge from the interaction of processes operating at different analytical levels.

With regard to contextual conditions, the paper builds on the concept of Sustainable Entrepreneurial Ecosystems (SEEs). According to Cohen (2006), SEEs can be defined as "an interconnected group of actors in a local geographic community committed to sustainable development through the support and facilitation of new sustainable ventures" (p. 3). Within this perspective, the development of sustainable ventures is seen as a key mechanism not only for generating economic growth and employment but also for improving environmental quality, public health, and social welfare. Building on the broader concept of entrepreneurial ecosystem stemming from strategic management and regional development research (Acs et al., 2017), SEEs emphasize the role of localized economic, institutional, and social conditions in enabling sustainability-oriented entrepreneurial activity. As highlighted in a recent comprehensive review by Joel et al. (2026), at least four distinct streams of research have emerged within the SEE literature. This paper draws on the stream that conceptualizes SEEs as an evolutionary extension of entrepreneurial ecosystems toward a sustainability orientation. Based on this view, the development of an ecosystem-level sustainability orientation is seen as a key driver of ecosystem evolution. Ecosystem governance and sustainability orientation can therefore be interpreted as elements of the regime level in the multi-level perspective, encompassing cultural, institutional, and socio-technical structures that shape how embedded actors align their practices and coordinate collective action. In this sense, sustainability orientation functions as a form of meta-coordination that both reflects and reshapes prevailing regime rules. It operates through governance structures, stakeholder interactions, sustainability-oriented ecosystem dimensions, feedback mechanisms between ecosystem outcomes and orientation, and the role of sub-ecosystems in reinforcing the sustainability trajectory of the broader ecosystem (Joel et al., 2026).

Strong structural and cognitive dimensions within ecosystems facilitate resource generation, reinforce relational ties, and build trust among ecosystem members (Theodoraki et al., 2018). These dynamics foster shared values and collective

visions, enabling SEEs to evolve as learning systems that continuously identify and exploit sustainable opportunities (O'Shea et al., 2021). Recent empirical studies have further examined the factors influencing the sustainability orientation of ventures operating within SEEs. For instance, Khatami et al. (2021) show that ecosystem pillars such as policy, finance, and institutional support positively affect the development of sustainable entrepreneurial innovations, whereas cultural and human capital factors may exert weaker or even negative effects. Similarly, Bischoff (2021) highlights the role of regional entrepreneurial and collaborative networks in promoting sustainable innovation and entrepreneurship. Consistent with these findings, the orientation of ecosystem actors - particularly their ability to recognize sustainability-oriented opportunities, collaborate for sustainable innovation, and develop or access markets for sustainable products - emerges as a key determinant of SEE performance (DiVito & Ingen-Housz, 2021). Within this context, successful firms adopting sustainable business models can play a particularly important role. These firms, described by Tiba et al. (2020) as "lighthouses", help other actors identify and exploit sustainability-oriented entrepreneurial opportunities.



Taken together, these insights suggest that policy, cultural, social, and technological dimensions of SEEs both shape and are shaped by the actions of ecosystem actors, influencing their sustainability orientation and their capacity to engage in multi-stakeholder innovation processes. Under these conditions, SEEs may provide a fertile context for the emergence of CIEs. This perspective is consistent with recent research suggesting that different ecosystem types - such as SEEs and CIEs - while analytically distinct, are not mutually exclusive. Rather, they often coexist and interact within broader configurations characterized by nested ecosystem structures, where multiple ecosystem logics overlap and reinforce one another (Ceci et al., 2026).

In relation to organizational capabilities, this paper adopts Dynamic Capability (DC) Theory as a primary analytical lens (Teece et al., 1997; Teece, 2007). DCs are defined as an organization's higher-level ability to sense, seize, and transform internal resources and external opportunities in order to create and sustain competitive advantage (Teece et al., 1997). An emerging and growing body of literature has begun to connect sustainability and DCs (Buzzao & Rizzi, 2021; Inigo et al., 2017). In the context of sustainability, it is not sufficient for firms to develop only technical or operational capabilities to implement Environmental, Social, and Governance (ESG)-related activities (Dzhengiz & Niesten, 2020). Equally important are DCs that enable firms to strategically integrate sustainability considerations into their core activities, rather than treating them merely as compliance requirements (Liang et al., 2022). Building on this perspective, Block et al. (2026) argue that both innovation management and sustainability research highlight the central role of organizational capabilities. In particular, capabilities are seen both as a key ingredient for business model innovation (Hock-Doepgen et al., 2025) and as a critical driver of firms' ability to transform their business models toward circularity (Bocken & Geradts, 2020). Conversely, the lack of relevant capabilities has been identified as one of the main barriers to the adoption of circular economy practices at the firm level (García-Quevedo et al., 2020).

Despite these advances, the relationship between DCs and sustainability has been predominantly examined at the organizational (micro) level. This study contributes to extending this perspective to the ecosystem level. In doing so, it aligns with recent work by Spilotro et al. (2026), which highlights the role of DCs in navigating the complex interplay between digital transformation, AI integration, and organizational adaptation within innovation ecosystems.

Figure 1 illustrates the research design connecting these two strands of research to address our research question.

Figure 1: Research design.

Methodology. In order to develop hypotheses for theory-building on the emergence of CIEs, this study adopts an Agent-Based Modeling (ABM) approach. ABM represents a simulated system composed of autonomous and interacting agents, where each agent typically represents an individual entity that acts according to a set of theoretically defined behavioral rules, interacting with both other agents and the simulated environment over time (Macal & North, 2005). This approach enables researchers to observe the large-scale consequences of theoretical assumptions about agent behavior when iterated dynamically over extended periods of time. Such characteristics make ABM particularly suitable for investigating complex phenomena characterized by distributed agency and dynamic interactions, such as ecosystem emergence.

The use of autonomous agents has indeed increasingly become an analytical lens for theorizing about emergence, agency, and the organization of complex systems (Kauffman & Clayton, 2006). Recent applications can also be found in the field of entrepreneurial and innovation ecosystems. For instance, Carayannis et al. (2016) employ ABM simulations to examine the regional effects of institutions and knowledge acquisition on new venture formation within entrepreneurial ecosystems, while Engler & Kusiak (2011) use ABM to represent inter-organizational dynamics in innovation ecosystems and explore their implications for the global economy.

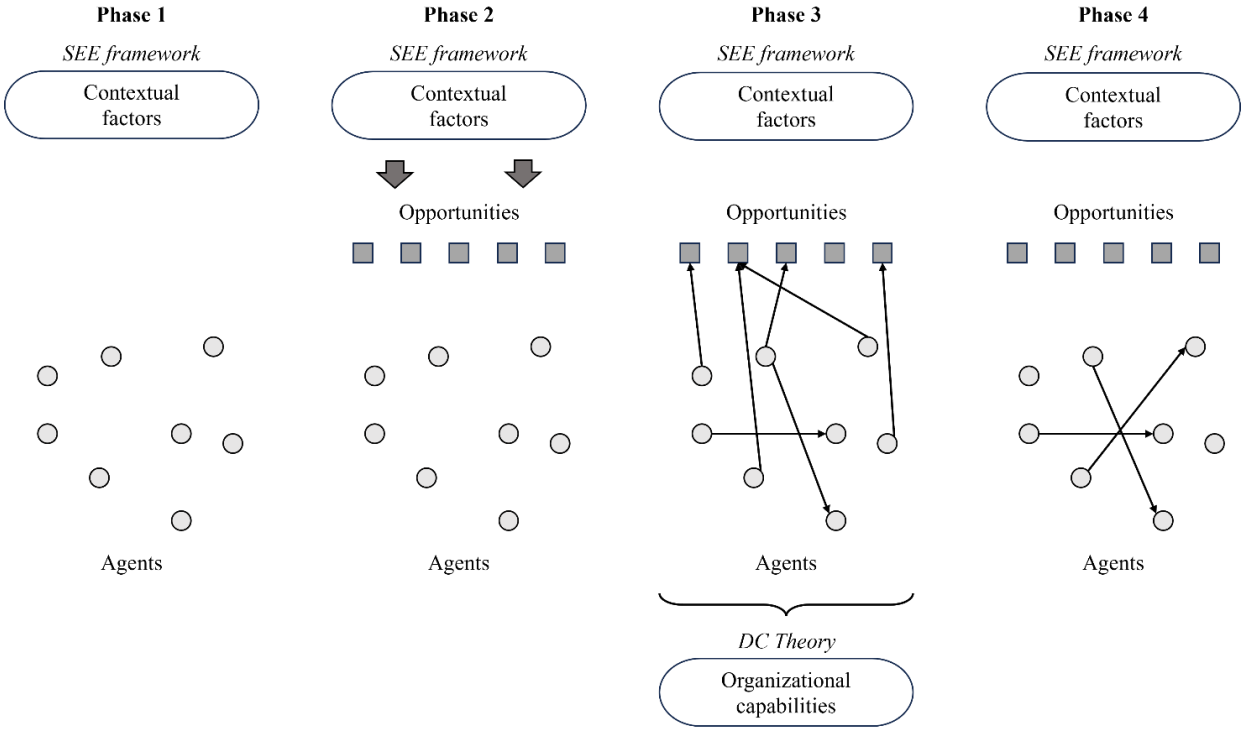
ABM is particularly suited to the purpose of this study given the central role of agency in CIEs. As highlighted by Aarikka-Stenroos et al. (2021), the actions of ecosystem actors are not solely contingent on actor-level outcomes. Instead, they are shaped by the specific roles that actors occupy within the ecosystem. Actors' agency varies according to their position and role within the ecosystem. Because roles are interdependent, some actors exert greater influence on ecosystem dynamics, while others perform more supportive functions.

Using ABM for theory-building represents a relatively novel approach in management and organizational studies, although it has already been shown to generate important insights into complex organizational phenomena and contribute to theory development (Gómez-Cruz et al., 2017). The approach builds on earlier sociological and psychological research, where ABM has been used to capture and theorize complex, dynamic, and interactive processes in social systems, including studies on group dynamics and organizational behavior (Smith & Conrey, 2007; Smaldino et al., 2015). In the context of this study, the adoption of an ABM approach provides a novel way to develop theoretically grounded hypotheses linking bodies of literature that have not yet been systematically integrated in empirical research.

Specifically, we consider a set of agents $V_I = \{1, \dots, n\}$, representing different types of actors typically forming innovation ecosystems (e.g., private companies, public organizations, universities and research centers, civil society organizations, and intermediary actors). Each agent i is associated with a vector of attributes $\overrightarrow{a_i} = (a_{i,1}, \dots, a_{i,h})$. In addition, we define a set of opportunities $V_J = \{1, \dots, m\}$, where each opportunity j is characterized by a vector of attributes $\overrightarrow{b_j} = (b_{j,1}, \dots, b_{j,k})$, and by a saturation level representing the maximum number of agents that can interact with that specific opportunity. In the proposed design, the agents' behavior depends on both their attributes and their DCs, while the opportunity space is determined by the characteristics of the SEE in which the actors are embedded. In this way, the simulations explicitly model the multi-level interplay between organizational capabilities (framed through DC Theory) and contextual conditions (captured through the SEE framework).

At each time step, a set of opportunities enters the system. Agents interact with these opportunities and with other agents according to the functional rules governing their behavior. Links between two actors at time t can arise either through first-order interactions, when two actors directly interact based on their attributes and DCs, or through second-order interactions, when two actors become connected because they have interacted with the same opportunity.

The monitoring of CIE emergence is based on system-level network metrics computed at the end of each iteration. These metrics assess both (i) the ecosystem nature of the system and (ii) its circularity. The set of metrics for the first dimension draws on previous work by Ancona et al. (2023) and includes indicators such as network density, assortativity, and small-worldness. The second set of metrics aims to capture the cyclicity of relationships within the network and includes measures such as the number of cliques and the clustering coefficient. The simulation therefore evaluates how the dynamic interplay between contextual conditions and organizational capabilities progressively leads to the emergence of CIE structures under different configurations of outcome metrics.



The model requires several parameters to be specified and varied across simulation runs, including the number of agents, the frequency of opportunities (i.e., the number of opportunities generated at each iteration), the maximum size of the opportunity space, and the number of iterations.

Finally, the simulation design will be initialized and calibrated using empirical evidence where available and grounded in existing theoretical insights. In particular, the behavioral rules governing agent interactions will be defined through the computational operationalization of the DC framework proposed by Shang et al. (2020), covering the three dimensions of sensing, seizing, and reconfiguring.

For clarity, the main phases of the model within each iteration are illustrated in Figure 2.

Expected results. The simulation is expected to show how the emergence of CIEs depends on the dynamic interplay between contextual ecosystem conditions and the DCs of individual actors. In particular, the model is expected to demonstrate that favorable contextual configurations within SEEs - such as supportive policy environments, strong collaborative networks, and sustainability-oriented institutional frameworks - expand the opportunity space for circular innovation. At the same time, actors endowed with stronger DCs (i.e., sensing, seizing, and reconfiguring) are expected to be more effective in identifying and exploiting these opportunities and in forming collaborative relationships. As these interactions exhibit over time, the system is expected to evolve toward increasingly dense and clustered network structures, signaling the emergence of CIEs. Overall, the simulation should illustrate how micro-level organizational capabilities and macro-level contextual factors jointly shape the emergence and structural configuration of CIEs, contributing to the development of new theoretical frameworks and hypotheses.

Figure 2: Main phases of the model within each iteration.

Research limitations. The proposed model relies on an agent-based simulation approach, which necessarily simplifies real-world dynamics by representing actors and interactions through stylized behavioral rules. Although these rules are grounded in established theoretical frameworks, the results obtained are contingent on the model's specifications and underlying assumptions. Moreover, the behavior of the agents and the representation of the entire system may not fully capture the complexity and heterogeneity of real ecosystem actors and institutional environments. However, this is inherent to the research design of the study, which adopts a theoretical and exploratory perspective aimed at generating hypotheses on a topic that connects bodies of literature not yet systematically integrated in empirical research. Further studies could therefore combine simulation approaches with empirical data on ecosystem actors and circular innovation initiatives to refine the model and assess its external validity.

Managerial implications. The findings of this study are expected to offer several implications for managers, ecosystem orchestrators, and policymakers seeking to promote circular innovation. First, the study highlights the importance of developing DCs that enable organizations to sense sustainability-related opportunities, mobilize resources, and reconfigure existing processes to support circular business models. Firms exhibiting these capabilities are more likely to participate in collaborative circular innovation initiatives. Second, the study suggests that the emergence of CIEs cannot be achieved solely through initiatives at the organizational level but requires supportive ecosystem conditions. Policymakers and ecosystem intermediaries should therefore foster institutional environments that encourage collaboration, facilitate knowledge exchange, and reduce barriers to sustainability-oriented innovation. Finally, the model highlights the importance of multi-actor coordination in enabling circular transitions. Ecosystem leaders and orchestrators may play a critical role in connecting actors, aligning incentives, and facilitating collective experimentation around circular opportunities, thereby accelerating the emergence of CIEs.

Originality of the paper. This paper contributes to the literature by integrating two research streams that have so far remained largely disconnected, namely SEEs and DC theory. By combining these perspectives within a multi-level analytical framework, the study advances the understanding of how contextual ecosystem conditions and organizational capabilities jointly influence the emergence of CIEs. In doing so, it extends prior contributions in innovation and entrepreneurship research that have adopted a DC perspective to investigate pre-incubation practices in entrepreneurial ecosystems (Nana et al., 2026) and the relationship between DCs and open innovation environments for university-industry collaborations (Crupi & Mortara, 2025). A second key contribution lies in the methodological approach. The paper adopts an ABM framework to explore the emergence of ecosystem structures from the interactions of heterogeneous actors, providing a computational approach to theory building in ecosystem research. This allows the study to model the complex and dynamic interactions between actors, opportunities, and contextual conditions that characterize circular innovation processes. Finally, the study contributes to the growing literature on circular ecosystems by proposing a network-based operationalization of ecosystem emergence and by identifying potential mechanisms linking individual capabilities with system-level outcomes.

Integrating Digitalisation and Sustainability in sport business: An Institutional Analysis in Professional Football

ALESSANDRA DELL'AQUILA, SILVIA BLASI, BARBARA GAUDENZI

Abstract. *Professional football is increasingly exposed to institutional pressures encouraging the simultaneous advancement of sustainability and digitalisation agendas, often referred to as the "twin transition". While governing bodies and policy frameworks promote the alignment of green and digital objectives, little is known about how football clubs interpret and operationalise these expectations in practice.*
Drawing on Institutional Theory, this study examines how professional football clubs interpret and implement sustainability and digitalisation under institutional pressures.
The research adopts a qualitative design based on semi-structured interviews with professionals responsible for sustainability-related activities within clubs competing in four major European leagues: the English Premier League, the German Bundesliga, the Italian Serie A and the Spanish LaLiga. While data collection and analysis are still ongoing, preliminary findings suggest that sustainability engagement within football clubs is strongly shaped by regulatory requirements and sectoral governance frameworks. At the same time, organisational-level factors such as governance capacity, internal coordination, resource availability and digital maturity appear to mediate how clubs respond to these pressures. Early evidence indicates that sustainability–digital integration within professional football tends to emerge through differentiated and incremental organisational responses rather than through uniform or transformative change.
Keywords: *Institutional Theory; Twin Transition; ESG; Football; Sport; Gioia Method*

Framing of the research. The sustainability transition has become a central strategic and governance challenge for organisations across industries (Chatzistamoulou, 2023; Mäkitie et al., 2023). In this context, sustainability is increasingly understood as a process requiring structural reconfiguration of organisational routines, capabilities, and inter-organisational relationships (Lazaretti et al., 2020).

Professional sport, and European football in particular, represents a relevant empirical setting for examining these dynamics, as clubs operate under conditions of high institutional visibility, legitimacy pressure, and stakeholder complexity that increasingly characterise organisations facing ESG-related transformation across multiple industries. These characteristics make professional football particularly useful for examining how organisations respond to sustainability pressures in contexts where legitimacy, stakeholder expectations and governance complexity strongly interact. Football clubs operate within a highly institutionalised environment characterised by strong regulatory oversight, intense public visibility, and persistent commercial pressures (De Bock et al., 2023; Relvas et al., 2010; Todaro et al., 2025). Professional football constitutes an institutionalised field shaped by governing bodies (UEFA, leagues and federations), commercial partners, fan communities, and broader society (Lozano & Barreiro-Gen, 2023). At the European level, professional football is governed through a multi-actor system in which authority and responsibility are distributed across a broad stakeholder ecosystem (Geeraert et al., 2013; Viglia et al., 2023). The central role of UEFA has gradually expanded from competition organisation to the development of regulatory frameworks, strategic programmes, and sectoral policies (de Witte & Zglinski, 2022; Dimitropoulos et al., 2016). European Football Clubs (EFC, formerly the European Club Association – ECA), European Leagues, FIFPRO, and national governing bodies further contribute to the institutional complexity of European football governance, generating overlapping and sometimes competing demands that clubs must interpret and prioritise at the organisational level.

Within this institutional environment, football organisations have increasingly been exposed to a growing set of expectations related to environmental, social and governance (ESG) issues, reflecting broader societal pressures toward sustainability and responsible organisational behaviour. While governing bodies and international organisations increasingly promote sustainability agendas aligned with the United Nations Sustainable Development Goals (SDGs) and the European Union's Green Deal, empirical research consistently shows that sustainability engagement across sport organisations remains fragmented and often weakly embedded in core organisational processes (Cury et al., 2023; McCullough, 2023). Sustainability therefore represents one of the domains in which the configuration of multiple actors and institutional expectations becomes particularly visible, as concerns related to social responsibility, governance and long-term organisational viability increasingly intersect with sporting and commercial objectives (Trendafilova & Ziakas, 2025; Walker & Parent, 2010). In this sense, professional football offers a useful setting for examining how organisations navigate competing institutional demands under conditions of strong public scrutiny and governance complexity. Accordingly, the evolution of sustainability in professional football can be interpreted as a process of institutionalisation rather than a simple diffusion of voluntary organisational practices (Anagnostopoulos et al., 2014).

Within this institutional setting, sustainability has progressively evolved from a set of discretionary and philanthropic initiatives towards a more formalised and multidimensional agenda. Early engagement with sustainability was predominantly rooted in community engagement, social inclusion, and charitable activities (Breitbarth & Harris, 2008; Fernández-Villarino, 2021). UEFA has played a central role in this process by progressively embedding sustainability

within its policy architecture, moving from awareness-raising initiatives towards more structured forms of coordination, monitoring and accountability (Dimitropoulos et al., 2016; Konstantopoulos et al., 2024). The introduction of binding regulatory mechanisms, most notably Financial Fair Play and its subsequent evolution into the Club Licensing and Financial Sustainability Regulations, marked a significant shift towards the formal regulation of financial sustainability (Martín-Magdalena et al., 2024). This led to a broader reconfiguration of sustainability in football, extending beyond social responsibility initiatives towards a more comprehensive governance agenda encompassing ESG dimensions (Lozano & Barreiro-Gen, 2023).

By contrast, the digital transformation of professional football has followed a more fragmented and functionally oriented trajectory. Sport has a long-standing tradition of using technology to support athletic performance and tactical decision-making, with digital technologies quickly expanding across multiple dimensions, including fan engagement, media ecosystems, data analytics and operational management (Miah, 2017; Ströbel et al., 2021). Existing research suggests that the adoption of digital technologies is mainly driven by functional, performance-related or administrative needs, rather than embedded within a coherent governance or sustainability-oriented framework (Ehnold et al., 2021). As a result, digitalisation has often developed as a set of domain-specific solutions addressing discrete organisational challenges, with limited integration into broader sustainability strategies (Nylén & Holmström, 2015; Robertson et al., 2012). In organisational contexts such as professional football clubs, these innovations often take the form of monitoring, optimisation or decision-support tools, which may generate indirect sustainability-related benefits, such as reducing resource waste or improving risk management, while primarily reinforcing existing organisational trajectories rather than enabling substantive change (Holopainen et al., 2024).

Studies on digitalisation and sustainability highlight a persistent "implementation gap" between the potential of digital tools to enable sustainability transitions and their actual use in practice (Guandalini, 2022). This tension is particularly evident in the European Union's policy discourse on the "Twin Transition", which conceptualises digital and green transformations as mutually reinforcing processes (Kovacic et al., 2024; Tabares et al., 2025). Within this framework, digital technologies are expected to enable sustainability-oriented change by improving monitoring, transparency, coordination, and performance measurement. However, empirical studies advocate in-depth investigation on the implementation of these synergies (Diodato et al., 2023; Mäkitie et al., 2023). In particular, further research is needed to understand how sustainability and digitalisation become integrated within organisational practices and governance structures.

Institutional Theory provides a robust lens for addressing this gap. Building on the foundational work of Meyer & Rowan (1977) and DiMaggio and Powell (1983), Institutional Theory explains how organisations conform to rules, norms and expectations in order to secure legitimacy within highly institutionalised organisational fields. As Scott (2008) notes, organisations often align their structures and practices with institutional expectations to gain legitimacy, while Oliver (1992) highlights how organisations acquire social acceptability and endorsement through conformity to institutional norms. Legitimacy can be as critical for organisational survival as efficiency, especially in highly institutionalized fields (DiMaggio & Powell, 1983; Meyer & Rowan, 1977). These pressures are commonly distinguished as coercive, stemming from formal regulations and external mandates such as UEFA rules or non-financial reporting requirements (Daddi et al., 2021; Posadas et al., 2023); mimetic, arising under conditions of uncertainty when organisations model their practices on peers perceived as successful or legitimate (Hernández-Hernández et al., 2023; Krell et al., 2016; Yang & Kang, 2020); and normative, associated with professionalisation processes and the diffusion of shared standards, norms and expertise within organisational fields (Daddi et al., 2021; Krell et al., 2016). Organisations exposed to similar pressures may nevertheless respond differently depending on internal capacities, governance arrangements and organisational interpretation processes (Dowling et al., 2024; Greenwood et al., 2014), giving rise to heterogeneous and often incremental organisational responses.

Within the European policy context, the interaction between sustainability and digitalisation has increasingly been articulated through the concept of the Twin Transition, which refers to the deliberate coupling of green and digital transformations in order to accelerate structural change and enable broader societal and organisational transformation (Montresor & Vezzani, 2023; Tabares et al., 2025). Digital technologies are framed as key enablers of sustainability-oriented change by enhancing monitoring, transparency, coordination and performance measurement (Diodato et al., 2023), while sustainability objectives provide the normative orientation guiding the development and use of digital technologies (Christmann et al., 2024). From an institutional perspective, this concept offers a useful framework to examine how sustainability and digital innovation are shaped by field-level pressures and legitimacy concerns. In highly institutionalised fields such as professional football, coercive, mimetic, and normative pressures influence not only whether clubs engage with such initiatives, but also how sustainability and digitalisation become organisationally coupled, often giving rise to incremental and uneven forms of implementation oriented toward optimisation, legitimacy, and compliance rather than transformative change.

Institutional Theory therefore helps explain variation in how clubs configure sustainability–digital integration under shared pressures. Despite the growing policy emphasis on integrating sustainability and digitalisation, empirical evidence on how this interaction is interpreted and enacted within professional football clubs remains limited (Guandalini, 2022; Rith & Spinelli, 2024). This study addresses this gap by exploring how clubs translate institutional sustainability and digitalisation pressures into organisational responses within a highly institutionalised field.

Purpose of the paper. Building on the institutional perspective outlined above, this study aims to investigate how professional football clubs engage with sustainability and to what extent digitalisation is substantively integrated into their ESG strategies under institutional pressures. Accordingly, the study addresses the following research question: How do professional football clubs interpret and implement sustainability and digitalisation under institutional pressures?

To address this question, the study investigates clubs competing across four European football contexts (England, Germany, Italy and Spain) through a qualitative research design based on semi-structured interviews with sustainability managers, and other key informants. By analysing clubs' organisational structures, governance arrangements, sustainability, and digital strategies through the lens of Institutional Theory, the paper provides an empirically grounded investigation of how sustainability and digitalisation are jointly enacted at the organisational level within professional football clubs.

At the time of writing, data collection is still ongoing, particularly with regard to clubs competing in the English and German leagues, as the research seeks to develop a balanced comparative sample across the four national contexts.

Methodology. The study adopts a qualitative research design to examine how sustainability and digitalisation are interpreted and institutionally embedded as interrelated ("twin") processes within professional football clubs. A qualitative approach is particularly suited to capturing complex organisational dynamics and context-dependent interpretations in highly institutionalised and value-laden environments such as professional sport (Yin, 1981, 2009, 2018). It also enables the exploration of how organisational actors interpret sustainability and digital technologies while navigating tensions between economic imperatives, operational constraints and legitimacy demands (Eisenhardt, 1989; Greenwood et al., 2011).

The empirical setting of the study consists of professional football clubs competing across four major domestic championships: English Premier League, Bundesliga, Serie A and LaLiga. These leagues belong to the group of the so-called "Big-Five" European competitions and represent highly visible institutional environments where sustainability expectations are increasingly formalised and publicly debated (Ludvigsen & Petersen-Wagner, 2023). Clubs across these leagues operate within a shared European institutional framework shaped by UEFA regulations and broader sustainability agendas, providing analytically informative settings for examining club responses under shared European institutional conditions and supporting analytical transferability (Kiselakova et al., 2020). At the same time, the four contexts also present relevant institutional and governance differences, providing a valuable comparative setting for examining how clubs interpret and implement sustainability and digital transformation under institutional pressures.

The study targets the full population of clubs competing in the above-mentioned leagues. Clubs are being contacted using publicly available information, professional networks and direct outreach via email, LinkedIn and telephone. Interviews are conducted with organisational actors holding roles formally or informally associated with sustainability; where no dedicated sustainability position exists, interviews are conducted with staff identified by the club as responsible for sustainability-related activities. At the time of writing, the dataset includes an initial set of 14 interviews conducted with clubs competing in Serie A and LaLiga, evenly distributed across the two leagues, covering organisations with different ownership structures, governance arrangements and sustainability positioning. Additional interviews with clubs, leagues and federations in Germany, France and England are currently being incorporated as part of the ongoing comparative extension of the project. Respondents include sustainability and CSR managers, operations and facilities managers, public affairs staff, and other senior organisational actors involved in sustainability-related activities.

Preparatory work was undertaken to refine the research focus and develop an interview guide consistent with the study's institutional perspective on the twin transition. This phase combined a review of academic literature, practitioner documents (e.g., club reports, federation strategies and league publications), and exploratory interviews with key informants. This documentary analysis helped identify key governance frameworks, institutional priorities and areas of convergence or ambiguity in the way sustainability and digital transformation are articulated within the sector. Exploratory discussions with experts provided preliminary insights into how sustainability and digitalisation are interpreted within the football ecosystem and contributed to refining the structure of the interview guide. This covers core thematic areas including sustainability governance and organisational arrangements, perceived institutional pressures, implementation challenges, and the role of digital and technological tools.

Building on this preparatory phase, semi-structured interviews are being conducted as the primary data collection method, allowing participants to articulate their experiences and perspectives in their own terms, while enabling the researcher to probe organisational practices and interpretations related to the twin transition (Patton, 2002). Interviews are conducted primarily via Microsoft Teams, and generally last between 30 and 60 minutes. Participants are asked in advance for permission to record and transcribe the interviews, which is granted in most cases. Transcripts are checked for accuracy prior to analysis.

Data analysis focuses on an iterative coding process following the Gioia methodology, proceeding in multiple, iterative stages, moving from informant-centric to more abstract theoretical categories (Gioia et al., 2013). In a first stage, interview material is coded using in vivo, first-order codes that preserve participants' own language and interpretations of sustainability, digitalisation and related organisational practices. In a second stage, first-order codes are progressively grouped into second-order themes, with Institutional Theory used as an interpretive lens to support abstraction and theorisation. The coding framework is iteratively refined as additional interviews are incorporated into the dataset. In a final stage, second-order themes will be consolidated into aggregate dimensions capturing recurring patterns in how clubs

interpret and enact sustainability–digital integration under institutional pressures, while allowing for variation across organisational contexts.

Results. Preliminary analysis of the interview material provides initial insights into how professional football clubs interpret and enact sustainability and digitalisation within their organisational practices. Although the data collection and coding process are still ongoing, the analysis conducted so far suggests several recurring patterns concerning how clubs respond to sustainability-related institutional pressures and how digital technologies are incorporated into these processes, giving rise to differentiated and predominantly incremental organisational responses.

Overall, emerging evidence indicates that sustainability engagement within professional football clubs is strongly influenced by a combination of institutional pressures originating from sport governing bodies as well as broader regulatory frameworks operating at European and national level. These include licensing requirements and governance standards imposed by football authorities, alongside emerging corporate sustainability regulations and reporting obligations – such as the European Corporate Sustainability Reporting Directive (CSRD) – which increasingly apply to organisations across sectors and are progressively shaping expectations around transparency and ESG accountability.

Sustainability initiatives are frequently described by interviewees as responses to formal requirements linked to licensing systems, reporting obligations and compliance with evolving governance standards. In this context, sustainability often appears to be framed primarily as a condition for organisational legitimacy and participation in professional competitions rather than as a fully integrated strategic priority. Clubs commonly describe sustainability-related activities in procedural terms, particularly in relation to environmental reporting, certification and regulatory compliance. At the same time, regulatory requirements may also function as internal leverage mechanisms, enabling sustainability managers or responsible staff to mobilise organisational support and justify new initiatives within the club.

Beyond coercive regulatory pressures, preliminary findings also point to the importance of mimetic and normative dynamics within the football ecosystem. In situations characterised by uncertainty regarding sustainability expectations or implementation pathways, clubs appear to rely on observation and informal benchmarking of peer organisations. Sustainability practices also appear to be shaped through processes of field learning, whereby clubs monitor initiatives undertaken by other clubs and selectively adapt them to their own organisational context. Such dynamics may contribute to the gradual diffusion of shared practices and expectations across the field, reinforcing normative understandings of what constitutes appropriate sustainability engagement in professional football. However, these processes rarely translate into radical experimentation or disruptive innovation. Instead, they tend to support incremental adjustments aligned with practices already perceived as legitimate within the sector, reinforcing convergence around institutionally accepted approaches to sustainability.

Preliminary findings also highlight the importance of internal governance capacity and organisational coordination in shaping how sustainability initiatives are implemented. While many clubs have introduced formal sustainability or CSR roles, the organisational positioning and strategic influence of these roles vary considerably. In several cases, sustainability responsibilities remain weakly embedded within the organisational structure, often combined with other administrative or operational functions. This configuration may reflect forms of symbolic organisational arrangements, whereby sustainability roles are formally established but only partially integrated into decision-making processes. Limited governance capacity may also constrain the development of cross-departmental coordination mechanisms necessary to translate sustainability commitments into concrete actions. At the same time, some clubs appear to experiment with coordination practices aimed at aligning sustainability-related activities across organisational units, suggesting early attempts to strengthen governance arrangements and institutionalise sustainability more systematically within the organisation.

A further recurring pattern concerns the way sustainability is interpreted through the historical social role of football clubs and their long-standing CSR traditions. Many organisations continue to associate sustainability primarily with social engagement, community initiatives and educational programmes, particularly those linked to youth academies and grassroots activities. In these contexts, sustainability is frequently framed in value- and identity-based terms, emphasising football's social influence and responsibility toward local communities and supporters. While such initiatives contribute to generating symbolic legitimacy and positive stakeholder engagement, they may also reinforce a path dependency in which sustainability remains largely associated with philanthropic or community-oriented activities rather than being fully integrated into transversal ESG governance and strategic decision-making processes.

Resource availability and infrastructural constraints further shape how sustainability initiatives are enacted in practice. Preliminary interview evidence suggests that clubs often prioritise initiatives that are economically feasible and capable of delivering organisational benefits, particularly in terms of efficiency improvements or cost reductions. In this context, sustainability-related decisions are frequently filtered through a business-case logic that emphasises financial viability and operational feasibility. Environmental benefits may therefore emerge as indirect outcomes of efficiency-oriented investments rather than as the result of explicitly sustainability-driven strategies. In addition, structural constraints such as ageing facilities, infrastructure limitations or restricted control over stadium ownership may limit the scope of environmental initiatives, reinforcing incremental rather than comprehensive sustainability pathways.

Finally, the relationship between digitalisation and sustainability appears to be characterised by a significant degree of organisational decoupling. While digital technologies are widely used across football organisations in areas such as performance analysis, fan engagement or operational management, their integration into sustainability strategies remains uneven and often indirect. Preliminary findings suggest that sustainability-related data are frequently fragmented across

organisational units and collected through manual processes, limiting the development of integrated digital infrastructures capable of supporting systematic ESG management. At the same time, some clubs report the adoption of specific digital tools – such as monitoring systems or energy-efficiency technologies – that contribute to environmental performance improvements primarily through operational optimisation. In these cases, digitalisation contributes to sustainability outcomes indirectly through operational optimisation rather than being embedded within intentional sustainability-oriented digital strategies. Clubs also appear to adopt certain digital solutions that are relatively easy to implement and capable of generating visible social benefits, particularly in areas related to accessibility and fan inclusion.

Taken together, these emerging patterns suggest that, under institutional pressures, sustainability and digitalisation are predominantly integrated through incremental organisational adjustments rather than through radical transformation. Sustainability and digital technologies are often incorporated into existing organisational structures and operational routines in ways that allow clubs to respond to institutional expectations while preserving organisational stability. At the same time, preliminary evidence indicates that governance capacity, organisational resources and internal coordination mechanisms mediate the extent to which clubs ~~are able to~~ move beyond compliance-oriented and functionally driven approaches toward more integrated sustainability–digital configurations.

Preliminary observations from the comparative analysis across the four national contexts suggest that institutional environments may shape how clubs interpret sustainability pressures and digital transformation. Differences in governance traditions, regulatory frameworks and organisational models across European football leagues may therefore influence the conditions under which sustainability and digitalisation are implemented. Further analysis will explore these dynamics in greater depth as additional interview data are incorporated into the study.

Research limitations. This study should be interpreted in light of several limitations. First, the research is currently ongoing and the empirical analysis presented in this paper is based on preliminary evidence. Data collection is still in progress; consequently, the patterns discussed in the results section should be interpreted as emerging tendencies rather than definitive findings.

Second, the study is based on an in-depth qualitative analysis of a limited number of professional football clubs operating within top-tier leagues. While this approach allows for rich, contextualised insights into organisational processes and institutional mediation, it necessarily constrains the generalisability of the findings. Future research could extend this analysis to a broader range of clubs, including lower-tier organisations or clubs operating in different national and regulatory contexts, to assess the extent to which the patterns identified here hold across varying institutional environments.

Third, the study focuses on professional football as a specific organisational field characterised by strong performance pressures, regulatory oversight and resource asymmetries. These features may shape the predominance of incremental innovation observed. Comparative studies across sports or industries could clarify whether the configurations identified are field-specific or reflect broader patterns of sustainability–digital integration.

Fourth, the analysis relies primarily on interview data, which captures managerial perceptions, interpretations and narratives rather than direct observations of practices or performance outcomes. Although this is consistent with the study's interest in institutional interpretation and organisational mediation, future research could complement qualitative insights with longitudinal or mixed methods designs. Such approaches may enable a more systematic examination of how sustainability–digital configurations evolve over time and whether incremental forms of twin transition progressively develop into more coordinated arrangements under changing institutional or organisational conditions.

Managerial implications. The findings of this study offer several implications for managers and decision-makers operating within professional football organisations, as well as for governing bodies and institutional actors seeking to foster sustainability and digital transformation across the sector. First, the analysis suggests that institutional pressure alone is insufficient to generate meaningful sustainability–digital integration. Regulatory requirements, licensing criteria and reporting obligations play an important role in legitimising sustainability and triggering initial organisational responses. However, when such pressures are not accompanied by adequate governance capacity and internal coordination, sustainability initiatives are likely to remain symbolic or procedurally driven. Compliance should therefore be treated as a starting point rather than an end point. Investing in basic governance structures can enhance clubs' ability to translate external demands into more integrated operational practices.

Second, the findings highlight the importance of organisational mediation as a managerial lever. Clubs facing similar institutional environments may display markedly different outcomes depending on how sustainability and digitalisation are internally organised. Managers can actively shape these outcomes by strengthening coordination across functional silos, particularly between sustainability, operations, facilities, marketing and data-related functions. Even modest interventions, such as interdepartmental meetings or shared ESG data responsibilities, can support more integrative arrangements.

Third, preliminary findings from the ongoing study highlight the need for managers to reframe digitalisation as a potential enabler of sustainability governance, rather than as a purely technical or performance-oriented domain. Extending experimental approaches used in performance analytics to sustainability challenges, particularly data integration and monitoring, may strengthen digital–ESG alignment.

Finally, the findings also carry implications for governing bodies and football institutions. While regulatory frameworks and licensing requirements play an important role in legitimising sustainability and stimulating initial organisational engagement, the preliminary results suggest that compliance-based approaches alone are unlikely to generate deeper sustainability–digital integration. Policy frameworks may therefore benefit from complementing regulatory pressure with initiatives that support organisational learning, coordination and capacity development across clubs. In particular, leagues and governing bodies may play a key role in facilitating knowledge exchange, promoting shared practices and supporting collective learning processes across the field. Such coordination mechanisms may be especially valuable in areas such as ESG data collection, monitoring and reporting, where digital solutions could support sustainability objectives but often remain fragmented across organisations.

Originality of the paper. This ongoing study contributes to Institutional Theory and to the emerging literature on the twin transition by challenging the assumption of a direct and deterministic relationship between institutional pressures and sustainability–digital transformation outcomes. While prior research often implies that stronger coercive, normative or mimetic pressures should lead organisations towards more integrated or transformative sustainability–digital configurations, the preliminary findings of this study suggest that such a relationship is mediated by organisational-level mechanisms, including governance capacity, internal coordination, resource availability and digital maturity.

By highlighting the mediating role of organisational processes, the study aims to advance institutional perspectives on sustainability in sport, providing empirical insights into how sustainability and digitalisation interact within a highly institutionalised and performance-driven organisational field. In doing so, it also extends twin transition scholarship into the context of professional sport, a domain that remains relatively underexplored in the literature. Preliminary evidence suggests that sustainability–digital integration within professional football tends to emerge through differentiated and incremental organisational responses rather than through uniform or transformative change.

By foregrounding organisational mediation, the study refines institutional accounts of sustainability in sport by explaining why similar pressures may generate different patterns of sustainability–digital configurations within the same field.

Managing uncertainty and irreversibility in quantum computing adoption: a systematic literature review

ORLANDO TROISI[1], MARA GRIMALDI[2], CORRADO DE CRISTOFARO[3]

Abstract. *This study analyses how technological, organizational, and environmental factors influence the strategic timing of quantum computing (QC) adoption in business settings. To fill the scarce systematization of the literature on the transition of QC from experimental object to integrated managerial capacity, the work adopts a systematic literature review conducted according to the PRISMA protocol and using the Technology–Organization–Environment framework with the Real Options Theory for content analysis in an integrated way.*
The results show that the adoption of QC is not a binary choice, but a progressive commitment process in which management modulates the timing, intensity and depth of the investment according to uncertainty and irreversibility. Alignment between use cases and quantum capabilities, interoperability with legacy systems, centralized governance, economic and financial flexibility, internal capabilities, regulatory framework and ecosystem partnerships emerge as key determinants of option value.
The study thus contributes to the managerial literature by showing that the competitive advantage does not depend on early adoption in itself, but on the ability to build selective, reversible and scalable experimental trajectories.
Keywords: *Quantum computing; Quantum technologies; TOE; Real Option; Systematic literature review*

1. Introduction. The emergence of quantum computing (QC) as a technology with high computational capacity is fueling significant expectations about the reconfiguration of decision-making processes and enterprise information architectures. The physical properties that characterize QC make it potentially suitable for addressing optimization and simulation problems with greater efficiency than classical paradigms, with direct implications for business management (Ajagekar & You, 2019; Phillipson, 2024). In this context, the literature points to a particularly relevant application potential in areas such as finance, healthcare, logistics and the pharmaceutical industry (Egger et al., 2020; Zinner et al., 2021; Jeyaraman et al., 2024; Shamsuddoha et al., 2025). Furthermore, some contributions frame QC as a potential technological response to regulatory issues related to the green transition, hypothesizing benefits for efficiency and, consequently, opportunities for competitive differentiation in ESG performance (Maraveas et al., 2024; Lo & Shih, 2021; Chatterjee et al., 2023). Attention to these prospects is also reflected in public policies: governments and institutions support quantum innovation through dedicated programs, aiming to accelerate its development trajectory and industrialization (Sood & Chauhan, 2023; Ansere et al., 2023).

Despite the theoretical benefits attributed to quantum technologies (QT), their development remains at a relatively early stage. This condition is attributable to an interrelated set of risks that condition investment decisions, slow technological maturation, and, consequently, limit the diffusion of its applications; at the same time, companies that monitor QTs with a view to industrial implementation are also confronted with interdependent complexity factors that tend to hinder or postpone their adoption. Nguyen (2025) highlights the multidimensional nature of these risks: uncertainty about the timing of technology maturation translates into market uncertainty, especially in relation to the predictability of revenues, and, cumulatively, into a high financial risk due to the low predictability of returns on investment. On the industrial adoption side, further constraints derive from the high development costs, the complexity of integration with legacy infrastructures and systems, the lack of specialized skills and the absence of a sufficiently mature and stable legislative-regulatory framework (Egger et al., 2020; Shamsuddoha et al., 2025). The latter element amplifies the risk of conversion and adaptation costs should future regulatory adjustments become necessary, contributing to the slowdown in the large-scale adoption of QT in the industrial sector. These elements impact with varying degrees of intensity on the uncertainty and irreversibility of the investments that companies are required to plan regarding the implementation of QC in the corporate environment.

The evidence that clarifies how QC is transformed from an experimental object to a computational engine permanently integrated into managerial processes is still poorly systematized. In particular, the limitation of the literature concerns not only the identification of the factors that influence the adoption of QC, but also the understanding of how these factors orient the strategic timing of adoption. Hence the following research question:

RQ: How do technological, organizational and environmental factors influence the strategic timing of the adoption of QC in business contexts?

To fill this gap, the present study integrates the lens of Technology, Organization, Environment (TOE) (Tornatzky et al., 1983), a well-established framework for the analysis of the adoption of digital innovations at the organizational level

(Nguyen et al., 2022) and widely used in different technological contexts (Bany Mohammad et al., 2022; Schwaeke et al., 2025), with the lens offered by Real Options Theory. This integration makes it possible to interpret the adoption of emerging technologies not as a binary decision, but as a sequence of commitments functional to the adoption of QC with reference to which management may or may not assume wait-and-see attitudes depending on the degrees of uncertainty and irreversibility that characterize the commitments themselves. In this perspective, TOE factors operate as determinants of option value as they influence the degree of uncertainty and irreversibility of QC investments; the combined effect of uncertainty and irreversibility of QC investments allows the strategic timing of adoption to be derived.

2. Technology–Organization–Environment (TOE) model and integration in Real Options key. To interpret the adoption of QC as an organizational phenomenon, and therefore as a set of strategic choices involving infrastructures, data, skills and ecosystem assets, the present study adopts the TOE framework (Tornatzky et al., 1983), one of the most accredited theoretical frameworks for the analysis of the adoption of digital innovations at the enterprise level (Nguyen et al., 2022). The TOE allows to conceptualize the adoption and implementation of emerging technologies as a joint outcome of three sets of conditions: (i) technological, related to operational compatibility, complexity, as well as availability and operational characteristics of technical infrastructures; (ii) organisational, related to the availability of financial and human resources, centralised governance mechanisms and a corporate culture open to innovative processes; (iii) environmental, attributable to competitive pressures, regulation, supply chain dynamics, availability of partners willing to collaborate synergistically (Baker J., 2011). The robustness of the model lies in its holistic framework, which makes it possible to make evidence from different contexts comparable and, at the same time, to adapt the specific factors to the different technological domains while preserving a stable analytical structure (Baker J., 2011; Bany Mohammad et al., 2022; Schwaeke et al., 2025). Consistently, previous studies have validated its usefulness in heterogeneous digital environments: Schwaeke et al. (2025) use it to analyze the adoption of Artificial Intelligence in SMEs; Bany Mohammad et al. (2022) for Business Intelligence Technologies in the Banking Industry; Zhu et al. (2002) to map enabling and limiting factors for e-business. The choice of TOE is further motivated by its greater relevance compared to models centered on the single user, such as the Technology Acceptance Model (TAM**)** and UTAUT, which are less suitable for capturing the dimension of strategic commitment, the allocation of resources and the infrastructural reconfiguration typical of organizational adoption decisions. Similarly, the TOE appears preferable to the Task-Technology Fit (TTF), which is more oriented towards explaining the impacts of technology on performance (Goodhue & Thompson, 1995).

However, in the case of QC, it is not enough to identify or "list" the factors that influence adoption: what remains unclear is how these factors guide managerial commitment and, above all, how they affect the strategic timing of QC adoption. Hence the need to integrate the TOE with the logic of Real Options Theory (McGrath, 1997), which makes it possible to interpret the adoption of technologies characterized by high uncertainty not as a binary choice, but as a sequence of progressive commitments within which management can decide to adopt a more or less interventionist approach depending on the degrees of uncertainty and irreversibility that affect the investment itself (fig. 1). In operational terms, the logic of real options makes it possible to treat TOE factors as determinants of option value, guiding managerial commitment and the time trajectory related to the adoption of QC.

Source: authors' elaboration

3. Methodology. In order to achieve the research objective, a systematic literature review (SLR) was conducted, an approach that allows to accurately and rigorous exploration of the accumulated knowledge on an emerging phenomenon and to synthesize it into robust conceptual categories (Troisi et al., 2024; Polese et al., 2017). In the case at hand, the SLR has made possible a critical reconstruction of the state of the art on the adoption of QC in business contexts, as well as the systematization of the evidence in an explicitly managerial decision-oriented perspective. To ensure transparency and quality of reporting, the review was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) protocol.

The bibliographic search was carried out using a combination of keywords designed to ensure adequate coverage of the topics under investigation. The string adopted is as follows: *("quantum comput" OR "quantum algorithm*" OR "quantum technolog*") AND (Management OR "business management" OR "firm management" OR governance OR Strateg**). To ensure completeness and robustness of the analysis, the research was conducted jointly on the Web of

Science and Scopus databases; the presence of keywords was checked in the title, abstract, and keywords sections (Schwaeke et al., 2024).

In line with the aims of the review and the need to ensure rigor of the results, studies that comply with the following criteria were included: (i) peer-reviewed contributions in English published in scientific journals or conference proceedings in the 2020–2025 time frame; (ii) works that analyze QC in relation to adoption, implementation, readiness and investment decisions, with a focus attributable to at least one of the Technology, Organization or Environment dimensions; (iii) contributions of a predominantly technical-engineering or physical-mathematical nature have been included as long as they have implications consistent with the domains of the TOE framework and with the interpretative logic of Real Option. Papers without managerial implications and studies in which QC was treated without adequate treatment of determinants or adoption/implementation processes such as to allow a coherent coding with respect to the TOE dimensions and the Real Option Theory were excluded. Inclusion and exclusion criteria were systematically applied throughout the screening process. Screening was conducted by multiple reviewers autonomously, with conflict resolution through consensus. In procedural terms, the selection took place in two phases: a first scan based on title and abstract, followed, for the documents deemed suitable, by a second screening phase by full-text (Pedrini & Ferri, 2019).

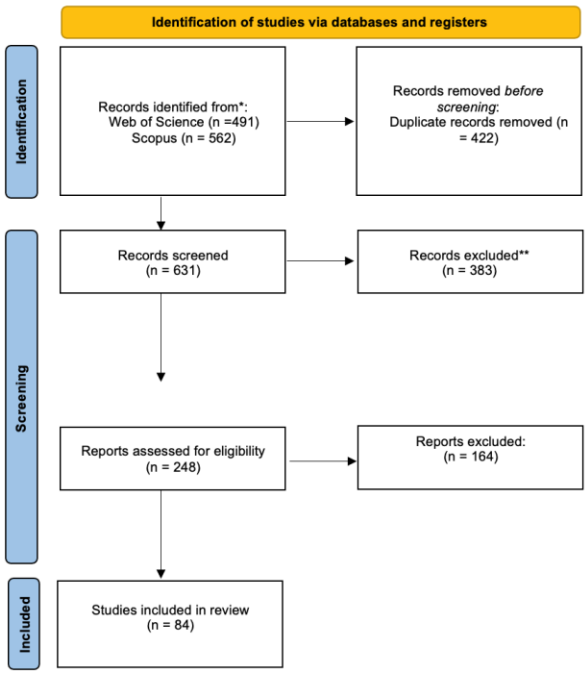
The included contributions have been subjected to a two-level content analysis and coherently designed with an integrated use of the theoretical lenses of the TOE and the Real Option Theory. First, based on the TOE framework, an initial coding scheme was built divided into the three dimensions technology, organization and environment. In this phase, each contribution was codified along the three dimensions of the model and, within each of them, the recurring themes were identified and progressively consolidated, to obtain an interpretative taxonomy consistent with the literature on the adoption of innovations. Secondly, the themes that emerged from the TOE analysis have been recoded in line with the Real Option Theory, in order to transform the descriptive taxonomy into a reading oriented towards the strategic timing of the adoption of the aforementioned technology. In particular, the integration with the perspective of real options has made it possible to reinterpret technological, organizational and environmental factors as determinants of the breadth and configuration of the decision-making range, making it possible to link the evidence of the literature not only to the presence of barriers and enablers, but also to the conditions that make it rational to anticipate, postpone, modulate or interrupt the commitment in the adoption process.

4. Results. The bibliographic search produced 1053 documents; of these, only 84 were included in the analysis (Fig.2). The 84 articles included in the review outline a constellation of elements that companies are called upon to monitor and, where necessary, actively govern to support the implementation of QC in organizational contexts. In line with the TOE framework, the evidence has been systematized along the technological, organizational and environmental dimensions. In line with the Real Options analysis, the work is not limited to tracing these factors back to mere "determinants of adoption": for each TOE element, empirical and conceptual evidence has been extracted and interpreted that allows it to be read as a determinant of option value*,* i.e. as a variable capable of affecting the uncertainty, the irreversibility of the implementation trajectories. The joint action of these channels makes the strategic timing of QC adoption intelligible, highlighting when it is rational to enter early, when it is preferable to wait, when it is appropriate to scale progressively or abandon the investment.

RQ 1: How do technological, organizational and environmental factors influence the strategic timing of the adoption of QC in business contexts?

Effective adoption of QC depends on the alignment between the business problem and the quantum platform available (Liu et al., 2025). When the structure of the problem, operational flows and performance objectives are consistent with the capabilities of the quantum ecosystem that can be governed by the company, the benefits are more plausible and, above all, assessable ex ante (De Stefano et al., 2024; Serrano et al., 2024; Liu et al., 2025), these circumstances also produce effects of mitigation of dependence on technology providers and mitigate the stop-and-go dynamic (Bozejko et al., 2024). In this perspective, the alignment between problem and technology reduces the technical uncertainty of QC, increasing the predictability of the application value and limiting exposure to investments in unsuitable applications (De Stefano et al., 2024; Serrano et al., 2024; Liu et al., 2025). It follows that a preliminary evaluation of the quantum-suitable use cases has a direct impact on the strategic timing of the adoption of the aforementioned technology, allowing the transition from wait-and-see or exploratory logics to interventionist logics.

The implementation of QC in the company requires an assessment of the ability to integrate with existing information and operational systems: reliable outputs and reduction of bottlenecks require data logistics that ensure information in the "right format" and at the "right time" (Egger et al., 2020; Zhou, 2025; Chen et al., 2025). The presence of interoperability reduces technical and operational uncertainty, making integration times and complexities more predictable and allowing management to avoid costly interventions on architectures and processes, which are difficult to recover in the event of a negative outcome (Aljaafari & Alotaibi, 2023; Zhou, 2025).



Finally, noise and decoherence impair effective performance and make many current systems suitable only for relatively simple tasks or otherwise dependent on error mitigation strategies (Liu et al., 2025; Chen et al., 2025). It follows that adoption decisions are driven less by "peak power" and more by the ability to ensure acceptable and replicable performance in support of complex operations (Egger et al., 2020; Zhou, 2025). Limited operational reliability increases technical uncertainty and makes investments related to deep QC integration riskier; For this reason, companies are faced

with the need to adopt an exploratory or wait-and-see approach in order to avoid incurring high risks and at the same time accumulate knowledge thanks to the first exploratory applications.

The effective adoption of QC also depends on management's ability to integrate quantum solutions into information and operational systems, translating technological complexity into coherent organizational choices (Cranganore et al., 2024; Coccia, 2024). This requires centralized governance mechanisms of quantum resources, hybrid workflows and response times (Cheng et al., 2025); along this path, some capabilities are decisive, including thermal management (Brahmbhatt et al., 2024; Salmangoli et al., 2024) and the design of efficient architectures in light of high energy demand, with attention to costs and emissions (Gill et al., 2024). The literature also recalls possible side effects and the need for responsible practices, including the construction of ethical and transparent databases (Carbajal-Pina & Acur, 2024; Li, 2025). In this framework, centralized QC governance tends to reduce organizational uncertainty by directing the prioritization of use cases, defining shared criteria for evaluating pilot projects and assigning clear responsibilities, with effects of mitigating ambiguity in use and internal conflicts and greater predictability of the adoption path (Cranganore et al., 2024; Coccia, 2024; Bozejko et al., 2024; Cheng et al., 2025). Therefore, the need emerges for management to preliminarily define the organizational governance of the QC, avoiding proceeding in a fragmented way, with misaligned pilot projects and ambiguous responsibilities, which would fuel situations of chaos and uncertainty; in this sense, the centralized governance of the QC indirectly makes it possible to reduce the risk of irreversible resources being used in disorderly or premature way. In essence, centralized government avoids adding to technical uncertainty further internal uncertainty, produced by decision-making.

On this basis of governance there is a second critical dimension, related to the economic and financial sustainability of the implementation of QC, as this involves a complex cost structure, determined by hardware and licenses, staff training, thermal infrastructure, R&D and maintenance, which requires careful planning and strict control of resources to mitigate the associated economic uncertainty (Zheng et al., 2023; Aljaafari & Alotaibi, 2023; Liu et al., 2025; Chen et al., 2025). To mitigate exposure and risk, access to quantum capabilities through "as-a-service" models and cloud solutions is frequent, reducing CAPEX and preserving economic, financial and organizational flexibility (Wilkens & Moorhouse, 2023).

Fig. 2: Flow chart PISMA 2020

Source: authors' elaboration

Finally, the feasibility of adoption is closely linked to the human resources and skills available: the literature highlights a marked scarcity of adequately trained personnel (Shahid & Hassan, 2023; Khan et al., 2025; Malinverno & Blasco Alberto, 2025) and the need for multidisciplinary teams capable of integrating quantum skills with business objectives and constraints (Cheng et al., 2025). In response, many companies launch training programs and capability building initiatives in contexts where skills remain limited and geographically concentrated (Hilkamo et al., 2021; Zhai et al., 2024; Gill et al., 2024; Paglieri et al., 2025); however, conservative cultures and internal resistance can slow adoption even in the presence of favorable technical and financial conditions (Chen et al., 2025). At the same time, robust expertise reduces the technical uncertainty associated with QC, allowing more accurate assessments of strategic alternatives and reducing the risk of premature choices along particularly complex trajectories characterized by high degrees of irreversibility (Cheng et al., 2025).

Incentives and institutional constraints influence the timing, application areas and intensity of investments in QC (Baiutulmal & Adem, 2023; Alubaidi, 2023; Joshi, 2024; Zhou, 2025; Zafar, 2025). Regulatory fragmentation generates pacing problems and hinders experimentation (Carbajal-Pina & Acur, 2024), favoring waiting strategies aimed at avoiding conversion costs (Carbajal-Pina & Acur, 2024; Zafar, 2025) and opening up spaces for regulatory arbitrage (Joshi, 2024; Baitulmal & Adem, 2023). In highly regulated sectors, moreover, validation and audit processes tend to slow down experimentation (Zhou, 2025; Zafar, 2025). It follows that an uncertain or fragmented regulatory framework increases institutional uncertainty and potential irreversibility, as it increases the cost of error; at the same time, regulation can be enabling when QC strengthens security and compliance (Gupta et al., 2023).Alongside the institutional dimension, sustainability is another aspect to consider quantum capabilities are sometimes interpreted as levers to optimize the use of resources and reduce emissions (Maraveas et al., 2024; Chatterjee et al., 2023), as well as a basis for possible competitive differentiation in ESG (Lo & Shih, 2021; Chatterjee et al., 2023). Such promises, however, need to be evaluated considering the energy consumption associated with quantum systems (Leclerc et al., 2023; Gill et al., 2024; Li, 2025), introducing uncertainty about the net balance between environmental benefits and energy costs, especially in the presence of infrastructure and energy decisions that are difficult to reverse.

In this context, the ability to manage uncertainty and complexity also depends on the configuration of the ecosystem: companies develop collaboration networks to govern the costs and complexity of quantum innovation (Zafar, 2025; Chen et al., 2025; Coccia & Roshani, 2024). Universities play a central role in both developing evidence-based practices and exploring new use cases (Lebrun-Gallagher et al., 2022; Zhao et. al, 2023; De Stefano et al., 2024; Khan et al., 2025), contributing to the dissemination of knowledge and the reduction of technical uncertainty (Ansere et al., 2023; Brahmbhatt et al., 2024). In parallel, venture capital supports hardware, industrial use cases, and start-ups (Lebrun-Gallagher et al., 2022; Zhao et al., 2023; Kshetri, 2024). Since quantum infrastructures require a joint public-private effort (Sood & Chauhan, 2023), insufficient public investment in applied research can be a bottleneck for industrial scalability (Malinverno & Blasco Alberto, 2025). Overall, partnerships reduce uncertainty through access to expertise and shared experimentation and can mitigate financial irreversibility through pooling of resources; however, it is necessary to oversee the risk of degeneration in forms of relational lock-in.

5. Discussion and implications. The results of the review show that the adoption of QC cannot be interpreted as a binary decision between adoption and non-adoption, but rather as a process of progressive commitment, in which management modulates the timing, intensity and depth of the investment according to how technological, organizational and environmental factors affect the uncertainty and irreversibility of company commitments (Table 1). In this work, the joint use of the TOE framework with Real option analysis allows to overcome the predominantly classificatory approach of the first model and to define an analytical device capable of explaining when the company is rationally induced to anticipate entry, postpone the investment, proceed in phases or interrupt the implementation process of the QC. More precisely, TOE factors emerge as determinants of option value, as they simultaneously affect the uncertainty and irreversibility of adoption trajectories. It follows that the timing of the adoption of the QC does not depend only on the perceived technological attractiveness, but on the possibility, for the company, to build margins of decision-making reversibility in a context still characterized by technological immaturity, regulatory instability and scarcity of skills.

The results show that the technological dimension orients strategic timing mainly through three mechanisms: the degree of consistency between use cases and quantum capabilities available, interoperability with legacy systems and processes, and the computational reliability of the solutions that can be adopted (De Stefano et al., 2024; Serrano et al., 2024; Liu et al., 2025; Egger et al., 2020). When these conditions are favourable, uncertainty is reduced and it becomes more rational to initiate forms of early adoption; otherwise, the value of waiting increases and makes a more prudent and gradual adoption strategy more justifiable, which is also functional to favor an initial positioning of the company and capability building. This suggests that the potential competitive advantage of QC does not lie, at least in this evolutionary phase, in the early adoption itself, but in the ability to accurately select the application domains in which the technology presents a favorable relationship between experimentability, integration cost and expected value.

The organizational dimension shows, in turn, that the adoption of QC depends less on the mere availability of resources and more on the ability of the firm to transform technical complexity into manageable decision-making architectures (Cheng et al., 2025; Aljaafari & Alotaibi, 2023). The presence of centralized coordination mechanisms, multidisciplinary skills, integration capabilities and economically flexible solutions, such as cloud or "as-a-service" access, reduces the irreversibility of commitment and makes disciplined experimentation possible. In this perspective, internal governance is not only an enabling condition for adoption, but a real mechanism for regulating the timing of the investment: organizations with robust skills and shared criteria for evaluating pilot projects can learn more quickly, correct the path and decide more accurately when to increase or reduce exposure. On the contrary, cultural resistance, scarcity of talent and infrastructural rigidity increase the risk of premature errors, transforming QC into a resource-intensive and low-recoverability investment.

The environmental dimension is also decisive in defining the strategic timing of the adoption of QC. The results show that regulatory framework, institutional pressure, ecosystem configuration, and ESG policies operate not as simple context variables, but as forces that redefine the relative convenience between anticipation and expectation in QC implementation (Baiutulmal & Adem, 2023; Alubaidi, 2023). In particular, regulatory fragmentation and validation processes typical of highly regulated sectors increase the cost of error and, therefore, the value of the referral option; conversely, the presence

of partnerships with universities, investors and public actors mitigates uncertainty, makes risk shareable and expands the range of trajectories that can be tested. Also relevant is the fact that sustainability emerges as an ambivalent driver: on the one hand, QC is associated with promises of efficiency and competitive differentiation in an ESG key; on the other hand, high energy demand and uncertainty about the net environmental balance prevent the technology from automatically assuming the "green" superiority. This result is particularly important because it shows that, in emerging technologies, institutional and environmental legitimacy does not necessarily coincide with an immediate convenience to adoption but requires progressive and contextualized verification processes.

Tab. 1: Summary of the results

TOE dimension	*Category*	*Evidence*	*Determinant of the option value*	*Implication on strategic timing*
Technology	**Technology alignment**	The effectiveness of adoption depends on the alignment between the business problem and the capabilities of the quantum platform. High alignment uses cases reduce technical uncertainty related to QC deployment and make application value clearer.	A high level of technology alignment reduces technical uncertainty and increases clarity of the potential value of the investment.	Management tends to anticipate adoption in cases of high technological alignment, while adopting a wait-and-see or exploratory logic when such alignment is low.
Technology	**Interoperability with legacy systems**	QC must integrate with existing information systems to operate as an additional and permanently integrated computational engine in the company. This requires data management that is consistent with the peculiarities of quantum systems and legacy systems.	Interoperability with legacy systems reduces the technical and operational uncertainty associated with implementing QC.	When interoperability is high, management can adopt QC more quickly, limiting integration risks and avoiding costly interventions on architectures and processes.
Technology	**Operational reliability**	Noise and de-consistency limit QC performance, making it useful especially for simple tasks and accompanied by error mitigation strategies.	Limited operational reliability increases technical uncertainty and makes investments related to deep QC integration riskier.	Management tends to adopt it prudently, focused on limited applications, until signs of greater stability emerge. This approach also allows you to accumulate experience in the use of QC.
Organization	**Centralized government**	Successful adoption of QC depends on management's ability to graft the technology into existing systems, managing resources, hybrid workflows, and response times.	Centralized government reduces organizational uncertainty by defining a common trajectory and mitigating the risk of adoption being driven by isolated or opportunistic initiatives.	The timing of adoption depends on how this reduction in organizational uncertainty combines with technological and external uncertainties. In the presence of high technological risks, it is advisable to proceed in phases; otherwise, a direct strategic investment is possible. In the presence of strong external uncertainty, a wait-and-see logic prevails.
Organization	**CAPEX/OPEX management**	QC involves a complex cost structure due to hardware, licenses, qualified personnel, infrastructure, R&D, therefore requires rigorous planning. This plurality of items makes it difficult to estimate ex ante the actual cost of adoption and its sustainability over time.	A CAPEX-intensive cost structure increases the irreversibility of investments and increases their risk in conditions of uncertainty. In contrast, *as-a-service* models reduce irreversibility and make costs more observable and distinguishable over time.	If irreversibility is low, even in the presence of high uncertainty, the company can invest early to position itself, since the exit is less expensive. On the other hand, when irreversibility is high, the timing must be more prudent and depends on the nature of the uncertainty.
Organization	**Capability**	Implementing QC requires addressing a marked shortage of skills and knowledge: multidisciplinary teams and dedicated training programs are needed, while cultural resistance can slow adoption.	The development of knowledge and skills in QC directly reduces uncertainty, because it improves the company's ability to understand, evaluate and govern complex strategic alternatives. While not eliminating irreversibility, it reduces its inefficient exposure, limiting the risk of premature commitments on technological and organizational trajectories that are difficult to reverse. At the same time, capability building involves a specific and partially irreversible investment share, which nevertheless serves as a risk-reducing mechanism for more challenging future decisions.	Capability building reduces technical uncertainty and increases the company's ability to govern irreversible investments; consequently, it tends to favour early but sequential adoption and, only when it makes the results sufficiently predictable, opens the way to a direct commitment.
Environment	**Regulatory framework**	Regulatory fragmentation and uncertainty affect the timing, scope and intensity of QC adoption, hampering transnational experimentation.	The legislative and regulatory framework affects uncertainty, as it makes the conditions, times and areas of adoption of the QC predictable. It also affects irreversibility because, when it is unstable or fragmented, it increases the risk that investments already made will have to be reconverted or adapted, transforming part of the costs into sunk costs.	An uncertain and fragmented regulatory framework fuels external uncertainty and increases the risk of repurposing investments already made; this pushes management to take a wait-and-see attitude towards the implementation of QC.
Environment	**Relationships-partnerships from an ecosystem perspective**	Networks with universities and technological and financial partners foster experimentation, management practices and the dissemination of knowledge.	Strategic relationships and partnerships reduce uncertainty through access to expertise, shared validation, and collective learning; they also reduce irreversibility, as they allow costs and resources to be distributed, limiting the company's direct commitment.	The development of strategic partnerships tends to favour an early and gradual entry, thanks to the reduction of uncertainty and the mitigation of the degree of irreversibility.

Source: Authors' elaboration

On a theoretical level, the study offers at least three implications. Firstly, it extends the TOE framework by introducing a temporal and decision-making dimension that usually remains implicit: technological, organizational and environmental factors explain not only the probability of adoption, but also the sequence with which the company builds its commitment. Secondly, the integration with Real Options Theory makes it possible to overcome static readings of the adoption of emerging technologies, showing that, in view of the current level of technological development, the strategic value of QC depends on the possibility of preserving flexibility, progressively learning and limiting the irreversibility of investments. Thirdly, the work contributes to the literature on innovation management by highlighting that, in the presence of radical and immature technologies, competition is not played exclusively on the speed of adoption, but on the ability to govern uncertainty through organizational architectures, collaborative ecosystems and temporally calibrated entry choices. In this sense, the research proposes a reading of the adoption of QC as a process of strategic orchestration of uncertainty, rather than as a simple technical implementation.

From a managerial point of view, evidence suggests that companies should avoid both indiscriminate wait-and-see approaches and excessively rigid advance commitments. An investment logic by options appears more appropriate, articulated in limited pilot projects, rigorous selection of use cases, development of quantum suitability metrics, access to flexible infrastructures and progressive construction of internal capabilities functional to a profitable use of QC. It follows that management should oversee at least five levers: the choice of use cases with high technological coherence; the preparation of a central governance capable of coordinating experimentation and learning; the containment of economic irreversibility through cloud or as-a-service models; the development of interdisciplinary teams that integrate technical and business skills; and the construction of external partnerships useful for sharing knowledge, costs and risk. At the same time, policy makers are called upon to reduce institutional uncertainty through standards, guidelines and programs to support applied experimentation, to prevent regulatory fragmentation from slowing down the transformation of QC from a technological promise to a truly scalable industrial capacity.

6. Conclusions. In conclusion, this study shows that the adoption of QC does *not* represent a dichotomous choice, but a process of progressive commitment, whose strategic timing depends on the interaction between technological, organizational and environmental factors. The integration between the TOE framework and Real Options Theory makes it possible to highlight how these factors not only influence the probability of adoption, but also the convenience of anticipating, postponing or modulating the investment. In particular, the alignment between *use cases* and quantum capabilities, interoperability with legacy systems, the availability of internal expertise, economic and financial flexibility, centralized governance and the quality of the institutional ecosystem emerge as decisive conditions to reduce uncertainty and irreversibility. It follows that, in the current phase of QC maturation, the competitive advantage does not lie in early adoption per se, but in the managerial ability to build reversible, selective and scalable experimental trajectories. The contribution of the work consists, therefore, in having shown that the real strategic issue, for companies, is not whether to adopt the QC, but when and under what conditions to do it rationally and effectively.

Network Structures in Homogeneous Open Innovation Ecosystems: Evidence from Heterogeneous Accelerator Context

ALICE GUZZETTI[1], VALERIA BELVEDERE[2]

Abstract. This extended abstract explores the application of network theory to compare structural dynamics and differences of heterogenous startup accelerators within open innovation ecosystems. The literature reveals gaps in the application of network theory to startup accelerators and innovation ecosystems, with limited use of formal network metrics such as centrality degree, clustering, or betweenness centrality. Instead, qualitative evidence dominates, and direct comparisons of local versus global accelerators within the same industry-tech ecosystem lack. Drawing on social network theory, orchestration resource theory and entrepreneurial ecosystem framing, the study investigates how accelerator maturity influences network architecture, clustering, brokerage roles and technology diffusion. Using a mixed-methods approach with network mapping from 3000 international startups operating in the fashion technology ecosystem in Italy, the research aims to demonstrate how distinct network structures shape innovation flows and startup scalability. More specifically, we hypothesize that mature accelerators exhibit higher degree of centrality and betweenness, positioning startups as brokers across diverse technological clusters. Conversely, younger local accelerators function as concentrators: while their geographically bounded networks offer high cohesion and protection, they may constrain a global vision. Consequently, while mature programs leverage diversification for resiliency, local ones rely on intra-supply chain density. Having a geographically limited network, its value will be to close ranks around the startup, protecting it, but potentially limiting its diffusion.

These findings will provide actionable insights for startups, venture capitalists, investors, and institutional stakeholders focused on regional development and knowledge transfer. The theoretical framework positions the study at the intersection of entrepreneurship, innovation management, and social network analysis, contributing to the ecosystem startup research. By focusing on Italy's dual accelerator landscape, it illuminates pathways for ecosystem orchestration, aligning with UN Sustainable Development Goal 9.

Keywords: startup accelerators; network theory; innovation ecosystem; open innovation; resource orchestration; entrepeneurship ecosystems.

Framing of the research. In an era defined by rapid technological advancements and interconnected global markets, open innovation has emerged as a pivotal paradigm for fostering innovation and competitiveness, particularly in large companies but also within startup ecosystems (Yulianto & Supriono, 2023). Unlike traditional closed models that rely solely on internal R&D, open innovation emphasizes the bidirectional flow of knowledge—sourcing external ideas and commercializing internal innovations through external pathways—to accelerate value creation (Enkel et al., 2009). Studies of innovation management focus on how corporations rely on ecosystem resources to generate innovation (Cukier & Kon, 2018). This approach is especially relevant for startups, where resource constraints amplify the need for collaborative networks to bridge knowledge gaps, access complementary assets, validate products, and scale operations (Bogers & West, 2012).

In the context of open innovation, the startup ecosystem has witnessed an exponential growth, driving increasing interest in accelerators programs. Startup accelerators have emerged as critical engines within innovation ecosystems, providing early-stage ventures with mentorship, funding, and a network, to facilitate rapid scaling and survival. Accelerators are positioned as facilitators of social capital, spillovers, and inter-organizational ties shaping innovation (Fehder, 2019; Dumont, 2018). In these contexts, open innovation manifests through orchestrated ecosystems where participants co-create value via inter-organizational ties (Isabelle, 2013).

Defined as fixed-term, cohort-based programs providing mentorship, funding and networking, accelerator programs connect startups with investors, peers and potential stakeholders. They operate as dynamic social structures where actors – including founders, mentors and corporations – interact to generate value through knowledge flows and opportunity recognition. Yet, accelerators vary significantly not much on sector-specific innovations, but on scope: nascent local programs often focus on community building and problem-specific support, while mature global-wide editions leverage on an established network for startup cross-border scalability.

Nevertheless, the stage of maturity of an accelerator raises questions about structural differences of these programs affect startups, and in turn, the innovation ecosystems. Yet their efficacy relays on underlying network dynamics, for example the strength of ties, patterns of brokerage, and flows of information that support the social capital.

Network Theory provides a lens for framing this research. Originating from sociology (Granovetter, 1973) and extended to entrepreneurship (Aldrich & Zimmer, 1986), it posits that innovation emerges not in isolation but through relational ties that facilitate knowledge diffusion, resource access, and opportunity recognition (Burt, 2004). In startup

[2] Università Cattolica del Sacro Cuore, Milan, Italy, Faculty of Economics. Mail: valeria.belvedere@unicatt.it

contexts, accelerators act as network orchestrators, creating ego-networks where startups (ego) connect to alters (mentor, investors, institutions, peers), via ties of varying strength (Carnovale, 2014; Carnovale & Yeniyurt, 2015). Despite accelerators proliferation, the application of network theory to dissect their structure remains underdeveloped (Baraldi et al., 2019; Ancona et al., 2023). Nevertheless, social network theory offers powerful lenses to map how accelerators embed within broader ecosystems of universities, institutions and investors.

Recent literature underscores the relevance of the intersection among social network theory, resource orchestration theory and entrepreneurial ecosystem framing (Neumeyer & McKenna, 2016; Theodoraki & Catanzaro, 2022; Spigel & Harrison, 2018). Resource Orchestration Theory (ROT) posits that firms actively manage resources through structuring (acquiring/redeploying), bundling (integrating), and leveraging (exploiting) processes to generate value (Sirmon et al., 2011). In accelerators, this manifests as orchestrating network ties: local programs structure regional resources (Marcone, 2018), while global ones bundle different "alters" for leveraging opportunities (Fehder, 2019). Complementing ROT, Entrepreneurial Ecosystem (EE) theory (Stam, 2015) situates accelerators within systemic interactions—networks, institutions, and culture—that enable or constrain innovation.

Studies on US accelerators show that network density correlates with funding success (Hallen et al., 2020), while European-based analysis reveals regional disparities in tie formation (Borgatti et al. 2013). In Italy, fashion tech accelerators exemplify the Italian localized networks, emphasizing district-based supply chain collaborations (Marcone, 2018). However, these studies remain descriptive, rarely applying formal metrics like degree centrality (number of ties), betweenness centrality (brokerage positions), or clustering coefficients (subgroup cohesion) to compare accelerator maturities (Stone, 2018). A meta-review of 150 accelerator studies found that only 15% employ network analysis, with most focusing on outcomes (e.g., survival rates) rather than structural antecedents and maturity effects on network resilience (Drover et al., 2017).

The literature reveals a clear research gap in applying network theory to analyze innovation startup ecosystems beyond just fashion tech, particularly in comparative studies of heterogeneous accelerators with different maturity stage (Hausberg & Korreck, 2020). While past studies investigated startup innovation, open innovation in SMEs or in corporate accelerators, and general startup ecosystems, none systematically use network metrics (centrality, clustering, tie strength) to quantify how accelerator maturity shapes ecosystem structure, knowledge flows, and startup success across different markets and regional disparities. Moreover, no comprehensive studies apply network theory to dissect how open innovation ecosystems form around tech accelerators in manufacturing districts, comparing local versus global scopes and different operational maturities, in a context characterized by medium-sized firms, funding disparities, and sustainability transitions, like Italian ones.

Past studies predominantly employed qualitative case analyses, with few quantitative approaches and comparative analysis (Del Sarto et al., 2020). No studies analyzed accelerator characteristics (local nascent, global mature), startup ecosystem roles specific to fashion tech, accelerator heterogeneity, or network structures using metrics like centrality or clusters. Also, past evidence provides results overlapping with incubators and calls for systemic work beyond corporate accelerators (Pauwels et al., 2016; Leitão et al., 2022).

Purpose of the Paper. Accelerators, as ecosystem epycenters, adopt open innovation approaches to facilitate external knowledge flows, exchange of resources, partnerships and collaborations. The Italian fashion manufacturing system is affected by fragmentation and the production geographically dislocated in districts shape a diffused entrepreneurship difficult to track and potentially yielding divergent network configurations and innovation outputs. Moreover, innovation development and technology adoption may vary according to accelerator maturity and ecosystem context, raising questions about how network configurations mediate open innovation outcomes (Dumont, 2018).

This research addresses a critical gap in applying network theory to open innovation accelerators, within the context of the fashion technology ecosystem in Italy, where evidence draws from contexts of medium-sized firms, regional supply chains, international entrepreneurship, and targeted accelerators.

In Italy, the startup landscape is particularly dynamic, especially within the fashion value chain. Italy's fashion industry stands as a global cornerstone, renewed for its creative heritage and manufacturing excellence, yet it faces significant pressures from technological rapid advancements, sustainability demand, increasing due diligence regulations, supply chain disruptions, and competitive globalization (Di Maria et al., 2023). Fashion technology — encompassing digital innovation, blockchain for supply chains, circular business models, and digital platforms — represents a pivotal evolution in startup ecosystems, where agile ventures integrate technology to offer redefinen production systems, design, consumption, and reprocessing business models. Empirical research on network tie formation within Italian high-end fashion ventures highlights how new ventures pursue open innovation in this context (Butticè et al., 2023). Moreover, the Italian entrepreneurial ecosystem remains characterized by a fragmented regional structure and a predominance of family-owned small and medium-sized enterprises (SMEs), which affect innovation and networking patterns (OECD, 2019; Ghinoi, 2021). Studies on innovation-driven SMEs show that networking abilities and dynamic capabilities are critical for competitive performance, reinforcing the importance of collaborative ties in traditional ecosystems (Vrontis et al., 2020).

The primary purpose of this paper is to apply network theory to comparatively analyze the structural configurations of nascent local versus mature global accelerators in the Italian startup ecosystem, elucidating how maturity influences network properties and, consequently, open innovation outcomes for startups and the broader ecosystem.

While accelerators are recognized as key actors for networking (Del Sarto et al., 2020), empirical evidence on structural differences by maturity and outreach is scant. For instance, Stone (2018) calls for social network theory applications to accelerators, yet few studies compare local-global variables (Fehder, 2019; Hausberg & Korreck, 2020).

Drawing on network structures orchestrated within EEs, our study seeks to address the following research question: "How do network structures differ between heterogeneous startup accelerators in shaping an open innovation ecosystem?"

Specifically, the study pursues the following objectives:

1. Map and quantify ego-network structures (centrality, density, tie strength) in heterogeneous accelerators operating in a homogeneous environment.
2. Examine how these structures facilitate knowledge flows, brokerage opportunities, and scalability, addressing gaps in maturity-comparative analyses.
3. Derive implications for accelerator design and policy, particularly in regional contexts like Italy, where the ecosystem fragmentation limits growth.
4. Investigate how ROT processes (e.g., tie bundling) and EE elements (e.g., policy support) moderate network-outcome links.

Methodology. This study employs a mixed-methods design, combining quantitative Social Network Analysis (SNA) with qualitative insights, and compare two Italian accelerators operating in the fashion technology ecosystem: a nascent local program (year-1, regional focus) and a mature global edition (6th cohort, international partnerships, cross-industry scope). Purposive sampling targets about 3000 startups mapped and scouted via the accelerators from 2019 to 2025.

Primary data were collected from digital trace sources (e.g. CRM tools) and accelerator databases documenting startup participation in each cohort. Social network analysis methods provide the quantitative tools necessary to examine these relationships (Borgatti et al, 2013; Ozman et al., 2018; Hallen et al., 2020). Startups reported their ties to alters — including mentors, peers, and investors — along multiple dimensions, such as existence, strength, and type. This allowed the measurement of network metrics like degree centrality, betweenness centrality, and clustering coefficients. In this study, we observed the following metrics:

- Degree Centrality: Number of direct ties per ego.
- Betweenness Centrality or brokerage: Brokerage positions bridging clusters.
- Clustering Coefficient: Subgroup cohesion.
- Density: Overall tie proportion (comparing local vs. global ecosystems).
- Structural holes: Identifying where connections between universities and the market are lacking is essential for suggesting intervention policies.
- Small-World Properties: Path length and clustering ratio.

Following SNA, comparative case studies complement statistical elaborations. In-depth interviews selected for representativeness (n=20; 10 per accelerator, including founders, mentors) explore tie formation processes, using thematic analysis (Braun & Clarke, 2006) in NVivo, informed by open innovation frameworks (Chesbrough, 2020).

Expected Results. Based on theoretical propositions and preliminary data from two Italian accelerators operating in the fashion-tech ecosystem, the study anticipates distinct network structures by maturity and heterogeneity, with implications for innovation dynamics and network relationships.

Specifically, preliminary results revealed structural differences in terms of degree of centrality and brokerage. Mature global accelerators exhibit higher average degree of centrality driven by international mentors and alumni. We expect a higher degree of betweenness in global programs, positioning accelerated startups as brokers in diverse technological clusters. Thanks to its maturity, the global program has bridges to reach different markets, thus startups are not constrained in terms of end users of their technological solutions. On the contrary, the local-young accelerator will act as a concentrator. Having a geographically limited network, its value will be to close ranks around the startup, protecting it, but potentially limiting its global scope and reach.

We also expect differences in terms of clustering and density. Local- young program shows lower clustering due to nascent ties, but higher homophily (sector-specific, e.g., fashion knitwear). Global density is higher, fostering efficiency. In terms of tie strength, weak ties dominate global networks, enhancing exploration, while local emphasizes strong ties for trust-building among stakeholders. On resiliency, while mature accelerator leverage on diversification, young-local leverage on cohesion and intra-supply chain relationships.

Regarding innovation outcomes, we expect that maturity operates as an amplifier. Global programs accelerate open innovation via brokerage (e.g., international funding links), while locals foster incremental gains in regional supply chains. If a key investor leaves, the network is extremely fragile, unless the accelerator allows it to quickly pivot to new funding models. Nevertheless, EE integration reveals local programs' strength in cultural cohesion but vulnerability to institutional gaps (e.g., funding access).

Research limitations. While the Social Network Analysis (SNA) methodology provides rigor, we recognize several limitations linked to the unit of analysis and the generalizability of results. The focus on two Italian accelerators limits extrapolation to non-European contexts or non-tech sectors. Also, Italy's regional fragmentation may overstate local challenges. Future studies could expand to firms or comparative US or Asian cases.

In terms of methodological constraints, SNA's static snapshots overlook temporal dynamics (e.g., tie evolution over cohorts). Qualitative interviews provide depth, but self-reported ties risk recall bias, potentially inflating strong ties in local networks (Krishnan & Krishna, 2024).

Originality: Accelerators are pivotal in fostering startup scaling, regional venture spillovers, and ecosystem vitality, yet understanding their network driven dynamics is essential for optimizing innovation support. This extended abstract proposes a novel network theory application to Italian accelerator ecosystems, promising structural insights into maturity's role in open innovation. By addressing gaps through mixed methods, the research advances theory and practice, equipping stakeholders to forge scalable networks amid global challenges.

This paper's originality stems from its comparative application of network theory to accelerator maturity in homogeneous context, filling a methodological and empirical gap. Unlike descriptive studies which predominates EE literature (Pauwels et al., 2016; Guijarro-García et al, 2019; Hausberg & Korreck, 2020), it integrates SNA metrics. Moreover, the maturity lens addresses call for structural comparisons, examining how accelerator networks evolve across local and global contexts and maturity (Blair et al., 2020; Hallen et al., 2020). Recent studies applying advanced network metrics demonstrate how tie strength and structural holes interact to influence radical innovation (Liu et al., 2025; Zhang et al., 2025), highlighting the continuing relevance of structural network theories beyond classical formulations (Burt, 2004).

We contribute to theoretical advancement in the ecosystem maturity model in startup ecosystems by quantifying tie-mediated flows and hypothesizing maturity as a moderator, but with a novel focus on accelerators as units of analysis rather than purposively selected startups.

Managerial Implications. The findings offer actionable implications for accelerator managers, startup founders, policymakers, and investors in Italy and beyond, emphasizing network optimization for innovation and scaling.

For example, to accelerator managers, we suggest to nascent local programs to prioritize strong-tie building (e.g., regional SME partnerships) to boost clustering. Conversely, mature global editions must leverage brokerage and increasing centrality by involving alumni and mentors via investment in digital platforms.

Startup founders should prioritize strategic tie selection. Those participating in local programs should focus on strong ties for validation and benefitting mostly from emulating supply chain openness to build networks, targeting supplier ties for rapid capability gains under resource constraints. In global accelerators, startups can cultivate weak ties for funding. Founders should aim for brokerage roles, diversifying sectors to exploit structural holes and potentially doubling partnerships.

These implications highlighting Italy's EE potential for hybrid models in developing and promoting open innovation, according to cultural cohesions and regional technology development. Also, findings will illuminate patterns in network formation, innovation facilitation, and comparative insights, laying groundwork for targeted ecosystem enhancement.

Perceptions of Electronic Health Record within digital health services ecosystem and the role of Artificial Intelligence

RICCARDO POLLIFRONI[1], GABRIELE CIULLI[2]

Abstract. *This ongoing work investigates how citizens engage with digital health services and how these tools support the management of prevention, diagnosis, treatment and monitoring. The study explores the role of the Italian Electronic Health Record (EHR) within this evolving ecosystem, comparing its perceived value with privately offered digital health platforms. A qualitative exploratory approach based on focus groups was adopted to identify expectations, barriers and drivers influencing adoption. The analysis generated preliminary thematic categories and highlighted areas that require further empirical testing. Emerging insights suggest patterns of perceived utility, usability gaps, trust dynamics and differing attitudes toward AI-enabled functionalities. Although digital services are appreciated for their functional usefulness, the quest for informational autonomy frequently induces uncertainty and cognitive burden. This ongoing study aims at contributing to a deeper understanding of patient–technology interaction in digital healthcare ecosystems, providing the conceptual groundwork for future quantitative investigations and for the development of user-centred digital health strategies.*
Keywords: *digital health, electronic health record, artificial intelligence, patient-centered care, service delivery, focus group*

Framing of the research. *The increasing digitalization of health services (eHealth), combined with the progressive introduction of Artificial Intelligence (AI) based systems, is reshaping the healthcare ecosystem by redefining roles, processes and ways of interaction between patients and healthcare professionals. Osei-Frimpong et al. (2018) show that access to online health information prior to the consultation with their doctor can be associated with more active patient engagement during the clinical encounter, supporting interaction and participation in shared decision-making processes (Tursunbayeva and Renkema 2023). In this way, patients take an increasingly active role in their care pathway by using digital tools to obtain information, monitor their health status and communicate with professionals across different touchpoints. However, McColl-Kennedy et al. (2025) highlight that the introduction of a digital touchpoint alone is not sufficient to automatically generate effects on patient engagement. The literature on patient journey also highlights that the experience is never linear but is characterized by different expectations, emotions and needs (Lemon and Verhoef 2016; Davies et al. 2023). In fact, the way in which the eHealth ecosystem is designed and the context in which it is delivered can affect the methods of use, the degree of integration and the perceived usefulness of users (Swan et al. 2024; McColl-Kennedy et al. 2025).*

The entry into force of the European Health Data Space (EHDS) aims to promote the creation of public infrastructures that improve access to health information and strengthen the role of citizens in managing their own data. In Italy, the EHR represents the main institutional access point to the healthcare system, designed to collect and make available the patient's documentation. It also includes a personal notebook that allows citizens to independently record information related to their health, following the logic of co-participation in service delivery and co-production of data. The EHR represents one of the new digital touchpoints that can contribute to reconfiguring the interaction between patients and healthcare professionals, including the way the clinical encounter with the doctor is prepared and experienced. Despite the strategic role attributed to the EHR, usage data collected in Italy between April and June 2025 and available on the website of the Ministry of Health show low levels of adoption, with significant variations across regional macro-areas (north-west 29%, north-east 56%, centre 11%, south 11% and islands 9%). Only 26% of Italian citizens have consulted their EHR at least once. These access levels suggest a perceived gap between the institutional role attributed to the platform and its actual use by citizens (Cascini 2025).

Literature on technology acceptance suggests that perceived usefulness and perceived ease of use are central dimensions in adoption decisions. In the present study we want to preliminarily investigate whether these constructs emerge as meaningful areas to be explored in the narratives of the participants (Davis 1989; Venkatesh et al. 2003). Similarly, literature on the servicescape (Bitner 1992; Gallan et al. 2013) demonstrates how the integration of physical and digital elements can affect patient perceptions and behaviors, helping to support greater trust and satisfaction. Moreover, studies on patient portals show that the mere availability of a platform does not necessarily coincide with its actual use (Hoogenbosch et al. 2018; Portz et al. 2019). Understanding the ways in which citizens compare the EHR with other digital services already used, assessing whether it is perceived mainly as complementary or substitutive, helps to describe the behavior of users according to the role attributed to the tool in relation to the eHealth ecosystem.

Finally, a further dimension to consider is the role of AI. European data indicate that its diffusion in the healthcare context is mainly focused on clinical diagnostic tools rather than conversational or patient support chatbots (WHO 2025),

[1] University of Pisa, Italy, e-mail: riccardo.pollifroni@phd.unipi.it
[2] University of Pisa, Italy, e-mail: gabriele.ciulli@phd.unipi.it

highlighting an imbalance towards back-office interventions compared to its implementation within more relationship-oriented touchpoints. This asymmetry is consistent with the literature showing that many applications are still linked to favoring efficiency dynamics aimed at optimizing workflows and simplifying decision support processes (Eke and Shuib 2025). Literature suggests that the explainability of AI systems can increase trust and improve acceptance. In addition, patient engagement literature emphasizes that the perception of control and trust is critical for activation and informed participation. However, it is still necessary to investigate whether perceptions of the role of AI may change in relation to the role attributed to different digital tools (Hibbard et al. 2004; Osei-Frimpong et al. 2018; Hou et al. 2024).

Purpose of the paper. *The study conducts an exploratory analysis of perceptions of EHR in relation to the broader ecosystem of digital health services (eHealth ecosystem) in supporting the management of personal healthcare pathway. The aim is to describe the role attributed to the various eHealth tools used and known to participants, with a view to understanding whether the prevailing consensus regards the FSE as a complementary platform or as a tool with alternative functionalities within the ecosystem. Subsequently, the study focuses on the reasons given by participants when describing their choice to use private solutions rather than the public tool. Finally, we explore perceptions regarding the integration of AI into the eHealth ecosystem to observe whether positive or negative attitudes towards AI are consistent with the role attributed to the tool. To pursue these objectives, the study is structured around the following three main research questions:*

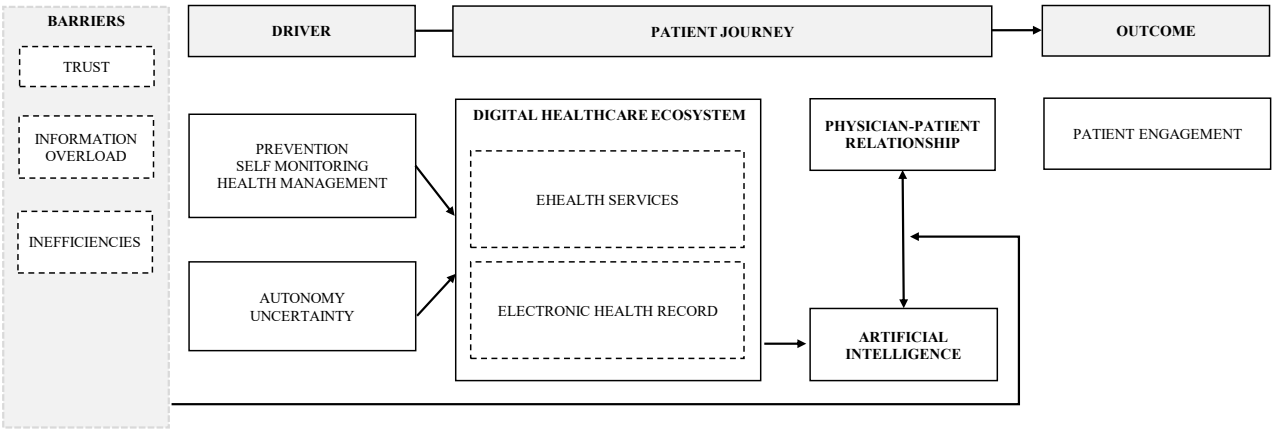
RQ1. How do citizens describe the role of the eHealth services ecosystem within their care pathway?
RQ2. What role do participants attribute to the EHR and how does it compare with the other eHealth services used?
RQ3. How is the perceived AI role within eHealth ecosystem?

Methodology. *The research adopts a qualitative exploratory approach, taking a realist-interpretative perspective, to investigate the perceptions reported by participants as an expression of concrete experiences rooted in their daily lives. This orientation is in line with the definition of experiential approach proposed by Braun and Clarke (2006). Consistent with this perspective, in the present study the Technology Acceptance Model (TAM) has not been used as a priori deductive framework but only recalled in the interpretative phase (Davis 1989).*
Data collection took place through online focus groups, preceded by a screening questionnaire. The survey was distributed using various online platforms, with Prolific being specifically chosen for its ability to provide a reliable, diverse and highly profiled panel of respondents. This feature was essential for carrying out targeted and rigorous sampling, enabling us to select the most suitable profiles and enhancing the heterogeneity of the focus groups (Brachten et al. 2021; Tomaino et al. 2023). All participants provided informed consent before starting the questionnaire. Confidentiality and voluntary participation were guaranteed throughout the process.

The pre-screening questionnaire focused on the measurement of digital literacy, use of eHealth services, knowledge and use of the EHR, perceptions and difficulties related to digital services and the hourly availability for participation in the focus group. The inclusion criteria established a priori and consistent with the objectives of the study, required that participants: (i) used or had used eHealth services, (ii) knew but not necessarily had used the EHR, (iii) had provided availability for at least one of the time slots provided by the focus group. Furthermore, in line with Berger (2015), it was decided not to include health professionals in the focus group, as this could have introduced an asymmetry capable of influencing the responses of the participants.

Overall, the pre-screening questionnaire collected a total of 31 responses. The average level of digital literacy, measured on a 7-point Likert scale, was in the upper-middle range (mean: 5.76). The application of the exclusion criteria identified 13 eligible participants. Table 1 presents the frequency percentages of the socio-demographic variables of the overall sample in a structured format. Values indicated as 'N/A' correspond to respondents for whom it was not possible to collect socio-demographic information, as they were excluded at the preliminary stage for failing to meet the inclusion criteria relating to the use of digital services or knowledge of the EHR (n=7 for criterion i; n=5 for criterion ii), or because they did not provide consent to the processing of personal data (n=2). However, the frequencies do include respondents who did not meet only the criteria relating to time availability (criterion iii; n=3), for whom the questionnaire had still recorded the necessary socio-demographic information. Consequently, the specific demographic metrics described below refer to the group of 17 respondents. Within this group, the average age is 39 years (median: 32; range: 20–65 years). The gender distribution is balanced, with an equal percentage of males and females (47.06%) and a minimal share of participants who selected "I prefer not to answer".

Two focus groups were organized between February and March 2026, consisting of six participants each and lasting about 90 minutes. The meetings took place via the Microsoft Teams platform. The choice of online format is consistent with Stewart and Shamdasani (2017), which recognizes how these methods guarantee quality compatible with face-to-face meetings, offering logistical flexibility. The focus groups were moderated by one of the members of the research team, with a background in marketing. The discussion was conducted following a protocol that defined the themes and guiding questions for the focus group. The meetings were recorded with the consent of the participants and transcribed separately by the two researchers, to reduce the risk of omissions and allow a comparison between the transcripts.



Tab. 1: General profile of the sample collected in the pre-screening phase

General sample profile (n=31)			
Gender	**Freq. % (n)**	**Education**	**Freq. % (n)**
N/A	46.67% (14)	N/A	45.16% (14)
Female	25.81% (8)	Master's degree (or single-cycle specialist degree)	35.48% (11)
Male	25.81% (8)	Postgraduate diploma	9.68% (3)
I prefer not to answer	3.23% (1)	High school diploma or equivalent	6.45% (2)
Age	**Years (n)**	Bachelor's degree	3.23% (1)
Mean	39.00 (17)	**Employment**	**Freq. % (n)**
Median	32.00 (17)	N/A	45.16% (14)
Consent	**Freq. % (n)**	Self-employed	12.90% (4)
Yes	93.55% (29)	Employee in private company	12.90% (4)
No	6.45% (2)	Student	9.68% (3)
Willingness to participate	**Freq. % (n)**	Employee in a public company	9.68% (3)
N/A	45.16% (14)	Not employed, looking for employment	6.45% (2)
Yes	45.16% (14)	Retired	3.33% (1)
No	9.68% (3)	**Residence**	**Freq. % (n)**
Use of eHealth services	**Freq. % (n)**	N/A	45.16% (14)
N/A	6.45% (2)	North-Eastern Italy	25.81% (8)
Yes	70.97% (22)	Central Italy	16.13% (5)

Data were analyzed by Thematic Analysis (TA) following the six steps described by Braun and Clarke (2006). This method was chosen for its theoretical flexibility and for its adequacy in identifying recurring patterns within a qualitative dataset. The coding was mainly conducted inductively and semantically, privileging the explicit meaning of the participants' statements, in line with a realist perspective and following the principles of Gioia et al. (2013) methodology. The relevance of the topics was evaluated in relation to its ability to contribute to the understanding of research questions. In line with Berger (2015), the researchers explained their theoretical backgrounds and their positions, which were monitored through moments of cross-review of the codes and critical discussion to avoid overinterpretations consistent with their initial theoretical expectations. Following Finlay (2002), reflexivity was understood as a continuous practice during the analysis phases. Coding decisions were discussed to verify that the interpretations were indeed rooted in the participants' accounts and not the result of overinterpretations driven by the researchers' backgrounds.

Results. *The analysis of the extracts and codes identified from the two focus groups made it possible to identify a series of recurring themes relating to the ways in which patients relate to digital health services and the Electronic Health Record. Two main drivers were identified in the discussions that motivate patients to use digital tools for managing their health. At the same time, participants highlighted structural features and barriers of the system that could influence its adoption. The concepts that emerged are summarized in the interpretative framework presented in Figure 1.*

Fig. 1: Interpretative framework (Source: authors' own elaboration)

Participants' journey through digital healthcare generally begins with a desire for greater control over information. Internet and digital platforms represent a parallel access point to understand symptoms or which clinical path to follow, in support of the doctor's consultation:

> *"If I find myself in a situation where I need medical advice, maybe first I rely on a doctor, but the second opinion, if we can call it like that, I go and find it online. I try maybe to ask for information from artificial intelligence or forums, things like that." (P10)*
>
> *"I feel safer, because the research I am going to do is a side search." (P08)*

However, this information autonomy generates a strong sense of uncertainty. The assortment of authoritative information sources creates confusion and cognitive overload. Participants seek online confirmation to manage anxiety but often end up increasing their disorientation:

> *"I look for everything, even the specific, even the most complex things. However, I try to understand them, I try to check what other people's experiences have been" (P09)*
>
> *"Very often we are also uninformed when we go to find information online, because in the end anyone can potentially pass themselves off as an expert, professor." (P10)*

A second driver for the adoption of digital health tools that emerged from the analysis of user experiences concerns self-monitoring. Attention to this aspect is not limited to moments of illness but is integrated into daily habits:

> *"Prevention becomes fundamental [...] can [referring to digital health tools] guide me in prevention quite precisely." (P01)*
>
> *"There is also the diet: what I eat. However, I try to eat healthily, so foods such as vegetables and fruit, avoiding foods that are too processed." (P02)*

The tendency to monitor one's parameters can become more systematic with advancing age or with the increase in personal awareness:

> *"I'm not saying that attention to my health is an obsession, but certainly in recent months I have greatly expanded everything, that is the monitoring of my health conditions in many respects [...] In my case, the monitoring was not constant, as I have already said. In the sense that it was absent until a few years ago. I have imposed it on myself in recent years." (P03)*
>
> *"I became interested in health only in the last period I began to think about the consequences of some of my addictions [show cigarettes] [...] I have been aware of this for some time now and I am trying to eliminate this type of addiction" (P04)*

Citizens attribute eHealth services to a predominantly functional role in responding to these needs. The eHealth ecosystem is evaluated positively when it guarantees convenience and simplification. Digital services have a positive value when they reduce waiting times, streamline bureaucracy and allow immediate and shareable management of clinical information:

> *"Now they have implemented the function whereby you can book directly from the online counter without going to the physical counter. This is very convenient because it speeds up so many processes." (P10)*
>
> *"Digital Experience is mainly limited to downloading the results of the analyses, then the reports that are online using your credentials." (P01)*

Within this ecosystem, the EHR plays a different role. The data confirms that the EHR is mainly used from a passive perspective. Participants consider it a simple archive dedicated to the preservation of reports and describe a limited use in time:

> *"My use is a very marginal and episodic use [referring to EHR]. So, at the moment there is no systematic use of the tool." (P03)*
>
> *"In addition, I found the possibility of having the vaccination record updated very convenient. [referring to EHR]" (P11)*

The experience also focuses on consultation. The current system configuration does not facilitate the continuous integration of data and limits its systemic role within a proactive care pathway. The digital experience of users is hindered by structural limitations of the national health system. The regional fragmentation of different platforms, functionalities and the complexity of interfaces generate frustration. The demand for autonomy imposed by digital services often turns into a burden that disorients the user:

> *"Autonomy, that is, being totally abandoned, allows me the term, having to juggle alone, perhaps even in areas where one does not know." (P08)*
>
> *"The regional platform [referring to EHR] that manages the whole booking discourse does not work." (P03)*
>
> *"If a person does not trust the health system, they will hardly be motivated to download an application that allows them to manage or view their health data. […] There is a certain prejudice against Italian healthcare, which is often described as very inefficient." (P06)*

The digital divide itself as a problem related to skills and age:

> *"[referring to EHR] there could also be a problem, in quotes, related to a large portion of the population, i.e. older people. In my opinion, it is difficult to ask, for example, an eighty-year-old person to use an application of this type." (P06)*
>
> *"If, as P06 said, some of us have reported difficulties in using these tools [referring to EHR], despite the fact that I spend practically the whole day using technologies of this type, let alone the people P06 referred to. So,*

in addition to making these tools work well, you also need to understand if they are really within everyone's reach or not." (P03)

The lack of knowledge regarding advanced functionalities of the EHR highlights a lack of institutional communication. The patient notebook is only one of many clear examples of this inefficiency making it perceived as impractical:

"Honestly, I didn't know the notebook. In fact, even when you mentioned it earlier, it seemed interesting to me and I immediately went to look for some information." (P04)

Perceptions of AI in digital healthcare services are twofold. Users recognize technology's potential but express concerns regarding privacy protection. AI is seen as a useful solution for simplifying navigation within portals:

"If by artificial intelligence we mean, for example, a chatbot that helps me better understand the tool I have available, then I embrace it without problems." (P04)

"I think it could support general practitioners, who often have a very large number of patients. Support of this type could speed up diagnoses and also help in reading reports." (P05)

Concerns arise in relation to decision-making autonomy and sensitive data. Users require the maintenance of strict human oversight over the diagnosis processes:

"In my opinion, it must be reiterated that artificial intelligence is not completely objective." (P06)

"As for the current use of data through artificial intelligence, I would be in favor of this taking place on input from the doctor or patient and not through massive use of data." (P03)

Excessive digitization risks isolating the user. This dichotomy highlights the limits of purely technological autonomy and the danger of distancing oneself from the care system:

"More autonomy for sure, because everything is much easier. […] [referring to digital health services] perhaps disconnects us from what is the human side and that interaction that we would have with the doctor and therefore could lead to distrust. In my opinion, this is the step." (P10)

Finally, citizens are asking for technology to facilitate the therapeutic relationship without ever interrupting it. When digital tools cause overload or distance, their perceived value inevitably collapses:

"That is, bookings, the online electronic file, all these now digital tools, rather than being substitute tools for our doctor, in my opinion they should be a bridge of communication." (P08)

In summary, the results of the thematic analysis highlight an ecosystem of digital health services in which new forms of autonomy and health management coexist with structural limits and barriers of use, helping to configure hybrid interaction between patients, digital technologies and health professionals.

Research limitations. *This study has some limitations. Firstly, the research is based on a small qualitative sample, so the results cannot be considered representative of the general population. The exploratory nature of the paper is aimed at generating initial evidence that can be deepened in subsequent works. Secondly, data collection took place through online focus groups, an approach that may limit the observation of non-verbal cues present in face-to-face interactions (Stewart and Shamdasani 2017). In addition, the study focuses on the Italian context and perceptions related to the EHR. Therefore, the results should be further explored in different contexts and through complementary research methods. Finally, as explained in Finlay (2002) and in Braun and Clarke (2006), although cross-checking and critical discussion were employed, the processes of coding and identifying themes reflect, to some extent, the researchers' interpretative choices.*

Managerial implications. *The eHealth ecosystem must be designed with a view to facilitating and not replacing human contact. Users want to manage their health independently but need constant guidance so as not to feel abandoned. When developing a new digital channel, policymakers must structure the way in which information is presented to citizens in a manner consistent with other channels and appropriately modulated, to avoid cognitive overload for the patient. Currently, individual healthcare platforms are more effective than the Electronic Health Record as they address specific needs and offer features that are easily understandable.*

It is necessary to carry out targeted institutional communication efforts to redefine the role of the Electronic Health Record. Although the system was originally designed to compile a patient's medical history and actively support them, it is now perceived merely as an archive and is therefore used solely in a passive way. Furthermore, the fragmentation of the various regional platforms prevents the adoption of a common language and interface capable of integrating notification systems, reminders and functions for collecting data from wearable devices. The development of a shared national platform is necessary to effectively guide patients.

Finally, Artificial Intelligence is primarily seen as an opportunity, but it triggers resistance linked to privacy and the delegation of decision-making. Healthcare managers must direct investment towards optimizing administrative procedures, providing proper patient guidance via virtual assistants and utilizing alert systems to flag clinical anomalies. Decision-makers must avoid proposing systems designed to provide clinical advice or to replace the doctor. This approach is perceived by patients as ineffective and triggers strong resistance. Acceptance of such automated tools occurs only in extreme cases, namely when the patient's pre-existing distrust of medical staff outweighs their concerns regarding the protection of their personal data.

Originality of the paper. *The originality of this study lies in its qualitative exploration of the Italian digital healthcare ecosystem through the combined lens of technological acceptance models and the patient journey. It investigates not only*

how the tool is used, but also the relational, emotional and cognitive dynamics underlying its adoption. The research introduces the "paradox of autonomy" concept, demonstrating how excessive and poorly implemented digitalization can isolate the patient, generating mistrust towards the entire healthcare system.

Preparing the Competitive Ground: Overlap in Knowledge Activities and Technological Entry

PAOLA GIURI[1] GABRIEL FRANCESCHINI[2] CLAUDIO GIACHETTI[3] MARCO CORSINO[4]

Abstract. *Technological competition increasingly unfolds in the knowledge arena, where firms position themselves through patenting rather than direct market confrontation. In this context, technological entry serves as a central mechanism of exploratory search. Building on research that extends multimarket competition to knowledge-based rivalry, we conceptualize multi-country overlap in knowledge activities, defined as the extent to which a focal firm and its rivals patent in the same national jurisdictions, as a form of multipoint contact in technological competition, and we examine how it shapes firms' technological entry decisions. We distinguish between entry into technological domains that are new to the focal firm but already established by rivals and entry into unexplored domains that are new to both the focal firm and its rivals. Drawing on the logic underlying the mutual forbearance hypothesis, we examine whether repeated contact with the same rivals across national patent jurisdictions restrains technological entry when competition unfolds through anticipatory knowledge positioning rather than product market competition. Using an original panel of 1,619 firm-year observations from the woodworking machinery industry, we find that greater multi-country overlap is associated with higher entry intensity along both dimensions, with a stronger effect for entry into unexplored domains. These findings show that, in technological competition, multipoint contact can stimulate both technological convergence and differentiation, providing support for the mutual forbearance hypothesis when the competitive battlefield is the technological arena.*
Keywords: *Technological Competition; Multimarket Competition; Mutual-Forbearance Hypothesis; Technological Entry; Exploratory Search*

Framing of the research. In today's highly dynamic and competitive environments, an increasing share of rivalry has shifted to the technological arena, where firms compete by shaping, defending, and expanding their technological positions across overlapping domains (Arts et al., 2023; Yan et al., 2020; Xia et al., 2025). In this context, patenting has become a central strategic instrument through which firms engage in technological competition (Leten et al., 2016). The logic of rivalry in this arena differs from that of product markets, where competitive actions are typically conceived as direct attacks on rivals' positions (Bloom et al., 2013; Smith et al., 2005). Instead, patenting represents a strategic commitment to technological trajectories that allows firms to stake claims, preserve freedom to operate, and position themselves for potential future confrontation (Clarkson & Toh, 2010; Mihm et al., 2015). Patenting decisions shape the technological landscape on which future rivalry may play out by influencing technological positions and subsequent competitive options (Hong, 2024). Through patenting, firms expand the option set for subsequent product launches and secure bargaining power in anticipation of rivalry that materialize later in downstream markets (Cappelli et al., 2023; Gaessler et al., 2025).

Within this setting, technological exploration—the search for novel technological opportunities—is central to firms' ability to adapt and renew their knowledge bases under competitive pressure (Cattani, 2005; Rosenkopf & Nerkar, 2001). A key mechanism of such exploration is technological entry, defined as the firm's entry into a technological domain in which it has not previously been active (Malerba & Orsenigo, 1999). Technological entry enables firms to reposition their technological portfolios and respond to evolving competitive conditions. Understanding how firms organize technological entry in response to rivalry is therefore critical. We conceptualize this phenomenon as "setting the stage for the battle" in the technological arena—that is, firms configuring their technological search before direct market confrontation unfolds. Despite its importance, the analysis of the antecedents of technological entry (Candiani et al., 2022; Chuang et al., 2023; Stagni et al., 2021) remains a fertile area for further research, particularly under conditions of overlapping knowledge activities among competitors.

Prior research has proposed several approaches to understand how rivalry under technological competition shapes firms' exploration through entry decisions (Anand et al., 2009; Hsu & Cohen, 2022). A prominent line of work focuses on multimarket competition, conceptualizing rivalry as repeated interactions with the same competitors across multiple arenas (Yu & Cannella, 2013). The mutual forbearance hypothesis has been the dominant explanation in this literature, suggesting that firms sharing multiple competitive footholds tend to moderate aggressive behavior because actions in one arena may trigger retaliation in others (Giachetti et al., 2024; Korn & Baum, 1999). While mutual forbearance has been shown to explain a variety of market outcomes (Baum & Korn, 1996; Fuentelsaz & Gomez, 2006; Young et al., 2000), empirical evidence is mixed, and its applicability appears contingent on the type of competitive action and contextual

conditions (Giachetti et al., 2025; Theeke & Lee, 2017; Ryu et al., 2020). The implications of the mutual forbearance hypothesis when rivalry takes place fully through technological competition remain an open space for further inquiry. This study addresses this gap.

Purpose of the paper. Building on recent work that extends the notion of multipoint contact to competition for knowledge-based resources (Berry, 2020; Berry & Donnelly, 2025), we conceptualize multi-country overlap in knowledge activities, captured by shared patent jurisdictions, as a key mechanism of competitive interdependence in technological competition. Because firms' decisions about where to protect and enforce intellectual property reflect strategic considerations about current and anticipated rivalry, shared patenting locations provide a meaningful indicator of overlapping competitive exposure (An et al., 2025; Lanjouw et al., 1998). Against this background, we examine whether the logic underlying the mutual forbearance hypothesis extends to rivalry that unfolds primarily within the technological arena and how cross-domain rivalry shapes firms' technological entry decisions. We therefore formalize the following research question: How does a firm's multi-country overlap in knowledge activities with its rivals relate to the type and intensity of technological entry?

Technological entry represents a central competitive response in knowledge-based rivalry. When expanding their technological assets, firms choose whether to enter technological domains already developed and protected by rivals but in which the focal firm has not been active yet, or to explore domains that are new to both the focal firm and its competitors, as reflected in their patenting activities. Drawing on Rosenkopf and Nerkar's (2001) typology of exploratory search, we distinguish between entry into rivals' domains and entry into unexplored domains. The former involves convergence toward technological areas where the focal firm has not been active, but rivals are already established, whereas the latter reflects exploration beyond existing organizational and industry trajectories (Cattani, 2005; Lee et al., 2024). We argue that greater multi-country overlap intensifies both forms of technological entry, with a stronger effect for entry into unexplored domains.

Methodology. The final sample comprises 1,619 firm-year observations in an unbalanced longitudinal panel covering 118 companies and more than 10,000 inventions across more than 400 technological areas and 50 patent jurisdictions from 2005 to 2022, resulting in an original dataset that combines organizational patent data, financial, and bibliographic information. Given the longitudinal structure of the data and the count nature of both dependent variables, with a large mass at zero and substantial firm-level heterogeneity over time, we estimate random effects Negative Binomial models. This choice follows two considerations. First, the distributions of the outcomes are inconsistent with the equidispersion implied by Poisson models: variance to mean ratios are well above one, Poisson goodness of fit tests reject the implied variance restriction, and unexplored entry is characterized by a prevalence of zeros. A Poisson specification would therefore impose an overly restrictive variance structure and mechanically understate uncertainty. We accordingly adopt the Negative Binomial formulation. Second, repeated observations within firms likely share persistent, time-invariant unobservables that shape entry intensity. A random effects structure captures firm-specific heterogeneity while retaining the ability to estimate time-invariant characteristics and to exploit both within-firm and between-firm variation. The comparison against a pooled alternative supports non-negligible panel-level heterogeneity. Because coefficients from nonlinear count models are not directly interpretable as changes in expected counts, we summarize results using Average Marginal Effects (AMEs), which express magnitudes on a relevant scale and facilitate comparisons across specifications and across the two dependent variables (Long & Mustillo, 2018). To align inference with this scale of interpretation and account for within-firm dependence, we computed bootstrap standard errors and confidence intervals for the sample AMEs using a firm-clustered bootstrap with 1,000 replications.

To test whether the focal effect differs in magnitude across the two entry outcomes, we estimate a stacked Negative Binomial regression that pools the two outcomes within a single model and allows the effect of Multi Country Overlap in Knowledge Activities to vary across outcomes. This approach is necessary because it keeps the conditioning set, timing, and distributional assumptions identical across outcomes, produces outcome-specific sample AMEs from the same estimated model, and enables a direct formal test of whether the two marginal effects differ rather than relying on informal comparisons across separate regressions.

Results. Our study examines whether the mutual forbearance hypothesis holds when rivalry occurs in the technological arena. We conceptualize multi-country overlap in knowledge activities as firms' repeated encounters across patent jurisdictions, and we link this form of competitive interdependence to technological entry, distinguishing between entry into domains that are new to the focal firm but already established by rivals and entry into domains that are unexplored. In our longitudinal analysis in the woodworking machinery industry, multi-country overlap in patent jurisdictions systematically coincides with higher entry intensity along both exploratory paths. Altogether, the main and additional analyses, as well as the robustness checks, provide strong support for the main findings that not only technological search targeted at rivals' technological domains is associated with higher subsequent entry, but also entry directed toward pristine technological trajectories. Moreover, the latter appears particularly responsive, with a systematically larger magnitude when competition across the same patenting countries intensifies, supporting the mutual forbearance hypothesis as a benchmark mechanism in technological competition. This implies that, when competitive stakes are shaped by anticipatory knowledge positioning rather than immediate product market attacks, multipoint contact does not translate into a broad restraint on technological search. Instead, overlap is associated with heightened exploratory activity: firms

both move toward rivals' established technological domains and expand into previously unexplored domains. Importantly, the relationship is systematically stronger for entry into domains that are new to both sides, making the connection to mutual forbearance explicit: repeated encounters across jurisdictions may increase firms' awareness of their mutual exposure and of the risk of costly retaliation through patent opposition, enforcement, or litigation, thereby encouraging exploratory expansion into less contested technological space rather than concentrating entry primarily in rivals' established areas.

Research limitations. The analysis focuses on a single industry, the woodworking machinery sector. While this setting is original and well-suited for observing patent-based rivalry, it is also a mature context with distinctive competitive and industry life-cycle features that may shape how firms strategize and respond to rivals. Accordingly, the theoretical and managerial implications should be treated with caution in terms of generalizability. We encourage future work to replicate our arguments in settings with different technological regimes and appropriability conditions.

Second, our evidence relies on a long longitudinal panel, which inevitably raises issues of data availability and completeness, which are mirrored in modelling choices such as the inclusion of time invariant controls. We are working to expand the dataset and further improve completeness by integrating additional sources.

Third, our framework isolates rivalry in the technological arena, yet firms often coordinate upstream knowledge positioning with downstream product market competition (Xia et al., 2025). A fuller account would connect multi-country overlap and technological entry to market entry, product launches, and enforcement actions within a unified framework.

Finally, we acknowledge potential endogeneity concerns, as several constructs are derived from the patent record and may co-evolve with unobserved firm attributes. We mitigate this risk through lag structure, panel modeling, alternative empirical specifications, and timing and falsification tests. However, future versions of the work could strengthen identification by exploiting exogenous shocks to jurisdiction attractiveness or enforcement intensity.

Managerial implications. On the managerial side, our analysis highlights the importance of considering two strategically interrelated aspects of patent-based competition. The technological dimension captures where firms are building capabilities and which trajectories they are signalling and committing to, while the jurisdictional dimension captures where those efforts are being secured, monitored, and potentially contested (An et al., 2025; Hötte, 2023). Managing patent-based rivalry therefore requires aligning where the firm explores with where it seeks protection, because overlap across jurisdictions can both expand the information available from rivals and alter the intensity of competitive exposure, shaping whether exploration is more likely to converge on rivals' domains, differentiate into less contested spaces, or do both in parallel.

Originality of the paper. Our work advances several theoretical contributions at the intersection of competitive dynamics, with particular attention to the multipoint contact literature, and organizational search strategy, with a focus on exploratory technological search. Primarily, by reconnecting with a recent and emerging line of research that extends multipoint contact beyond product markets, we advance a knowledge-based account of multipoint rivalry centered on patent jurisdictions as arenas of interfirm rivalry (Berry, 2020; Berry and Connelly, 2025). Prior work has bridged multimarket contact and innovation-related outcomes and has begun to theorize multipoint rivalry in knowledge and technology settings (Hsu and Cohen, 2022; Ryan Charleton and Galavan, 2024; Ryu et al., 2020), yet, to the best of our knowledge, we are the first to develop and test a framework in which both the competitive stimulus and the focal response are technology based. By doing so, we show how a classic prediction such as the mutual forbearance hypothesis can translate, in the technological arena, into a relative restraint from head-to-head entry into rivals' established domains as rivalry unfolds across shared patent jurisdictions.

Second, we extend the discussion on exploratory search by theorizing and distinguishing two directions of technological entry that have typically been treated in an aggregated form. Although prior research has generated rich insights into exploratory search, it left room to further clarify how competitive interdependence relates to qualitatively distinct directions of technological entry and to the intensity with which firms pursue them (Stagni et al., 2021).

Finally, we propose a framework for technological competition in which rivalry is structured not only by overlap in technological domains but also by overlap across patent jurisdictions as distinct footholds where firms make costly commitments to protect and monitor knowledge. This line of inquiry increasingly recognizes that competition can shift upstream into knowledge activities, and it also invites further theorizing on how predictions about restraint and escalation translate when rivalry is not centered on product markets (Chuang et al., 2023). By moving the unit of overlap from product markets to patent jurisdictions and linking it to technological entry, we show how cross country interdependence shapes exploratory search in ways that differ from classic market-based rivalry, and we open a platform for future work to connect knowledge-based competition to other strategic responses in patent strategies, including enforcement, opposition, and litigation, as well as to downstream market outcomes.

Sustainability Reporting as a Governance Template for Public Value Co-Creation Practices in Public Service Ecosystems

STEFANIA MANETTI, MARA GRIMALDI, ORLANDO TROISI

Abstract. *Public administrations are increasingly required to address complex societal challenges—including sustainability transitions, digital transformation, and social inclusion—that extend beyond the boundaries of single organizations. Addressing such challenges requires governance approaches capable of coordinating heterogeneous actors and integrating diverse resources within complex public service ecosystems. In this context, sustainability reporting has progressively gained relevance as a mechanism through which public organizations communicate their environmental, social, and economic impacts. However, research has mainly conceptualized sustainability reporting as an instrument of transparency, accountability, stakeholder communication, and organizational learning (Adams & Larrinaga, 2019), while paying limited attention to how reporting frameworks interact with the governance practices through which public value is generated in public service ecosystems. Drawing on a practice-based perspective on public value creation, this paper conceptualizes sustainability reporting as an institutionalized template that interacts with public value co-creation practices within public service ecosystems. Building on the framework of public value co-creation practices (PVCPs) proposed by Skålén and Trischler (2025), public services are interpreted as bundles of practices composed of templates—intended configurations embedded in governance arrangements—and performances, representing the situated enactments of those configurations by actors within specific contexts. The study adopts a qualitative exploratory design based on semi-structured interviews with municipal actors managing sustainability reporting initiatives, focusing on two Italian cases selected to capture contrasting reporting orientations: the Sustainability Report of the Municipality of Udine and the "Bilancio POP" initiative of the Municipality of Messina. Documentary materials, including sustainability reports and institutional documents, are used as contextual sources to support the interpretation of interview evidence. The findings suggest that sustainability reporting operates not only as a disclosure instrument but also as a governance template that interacts with the practices through which sustainability initiatives are coordinated within public administrations. At the same time, the performance of reporting templates varies depending on the municipality's institutional context and governance orientation.*

By bridging sustainability reporting research with practice-based approaches to public value creation, the study contributes to the literature by examining how sustainability reporting templates interact with public value co-creation practices through their situated enactment. The results show that reporting templates may reinforce governance arrangements or be reinterpreted by public actors to address local governance priorities, highlighting the context-dependent relationship between institutionalized reporting frameworks and the practices through which sustainability governance is enacted within public service ecosystems.

Keywords: *sustainability reporting; public value; public service ecosystems; co-creation practices; governance innovation*

Framing of the research. Public administrations increasingly operate within complex socio-institutional environments characterized by interconnected societal challenges such as climate change, social inequality, and sustainable economic development. Addressing these challenges requires governance approaches capable of mobilizing diverse actors and coordinating collective action across institutional boundaries. In recent years, sustainability has progressively emerged as a central strategic orientation guiding the transformation of public organizations and their governance practices (Aleixo et al., 2018; Fissi et al., 2021; Lima et al., 2023).

In this context, sustainability reporting has gained growing relevance within the public sector. Traditionally, such reporting practices have been interpreted primarily as instruments of transparency and accountability aimed at communicating the environmental, social, and economic impacts of public organizations to stakeholders. Public administrations increasingly adopt structured reporting frameworks—such as the Global Reporting Initiative (GRI)—to disclose sustainability strategies, performance indicators, and policy outcomes. However, more recent debates in sustainability accounting and public management suggest that reporting processes may also perform internal and relational governance functions, supporting strategic alignment, organizational learning, performance improvement, and stakeholder engagement (Adams & Larrinaga, 2019; Osborne et al., 2022). This implies a shift from viewing sustainability reporting only as an external disclosure mechanism toward understanding it as a governance infrastructure that may shape how sustainability priorities are interpreted, coordinated, and enacted within public organizations. These developments reflect a broader transformation in public management scholarship from organization-centered perspectives toward more relational and ecosystem-oriented approaches to value creation. Recent theoretical developments emphasize that public value emerges through interactions among multiple actors—including public organizations, citizens, private firms, and civil society organizations—operating within interconnected governance systems (Benington & Moore, 2011; Osborne et al., 2022). Within this perspective, public administrations increasingly assume roles as facilitators, coordinators, and

orchestrators of collaborative processes that mobilize the knowledge, capabilities, and resources of diverse actors operating within complex governance networks (Benington & Moore, 2011; Osborne et al., 2022).

Within this shift, the concept of public service ecosystems (PSE) has gained increasing attention as a framework for understanding how value is generated through processes of resource integration across heterogeneous actors and institutional levels (Vargo & Lusch, 2016; Trischler & Charles, 2019). In such ecosystems, public organizations increasingly act as orchestrators that facilitate coordination among actors contributing to the generation of collective outcomes. Recent developments in service research further extend this perspective by introducing a practice-theoretical understanding of public services. According to Skålén and Trischler (2025), public services can be understood as bundles of public value co-creation practices (PVCPs). In this paper, public value co-creation practices are understood as relational configurations through which actors collectively define, negotiate, and enact sustainability-related value within the public service ecosystem. From this perspective, practices do not simply refer to internal organizational routines or administrative procedures, but to socially situated configurations of meanings, rules, resources, and actions through which public value is produced, negotiated, and sometimes contested.

These practices consist of two key components: templates, which represent the intended configurations of practices embedded in institutional arrangements, governance structures, and organizational routines; and performances, which correspond to the situated enactments of these configurations by actors in everyday governance processes. Importantly, it is through such performances that value outcomes ultimately emerge, potentially generating both value co-creation and value co-destruction depending on how actors interpret and enact the practices involved (Echeverri & Skålén, 2021). From this perspective, sustainability reporting can be interpreted not merely as a managerial tool but as an institutionalized template that interacts with public value co-creation practices within public service ecosystems. Reporting frameworks may therefore operate as templates that define intended governance arrangements—through sustainability priorities, indicators, and reporting structures—while their actual effects depend on how they are enacted through the situated performances of public actors.

Despite the growing relevance of practice-based perspectives in public service research, the role of sustainability reporting within these dynamics remains relatively underexplored. Most studies continue to focus on disclosure standards, reporting quality, and accountability mechanisms, leaving open the question of how reporting infrastructures interact with the practices through which public value is generated within governance ecosystems. In particular, limited attention has been paid to how sustainability reporting templates are translated into situated governance performances and how such performances may reinforce, adapt, or transform public value co-creation practices in specific local contexts. Investigating how sustainability reporting templates are interpreted and enacted through situated performances may therefore provide valuable insights into the mechanisms through which sustainability-oriented public value is co-created, negotiated, and occasionally co-destroyed within contemporary public service ecosystems. This represents the central theoretical gap addressed by the paper: while sustainability reporting and public value co-creation have been widely discussed as separate streams of research, their interaction within public service ecosystems remains insufficiently theorized.

Purpose of the paper. Building on these theoretical developments and on the research gap outlined above, this paper examines the interaction between sustainability reporting templates and public value co-creation practices within public service ecosystems, adopting a practice-based perspective on public value creation. Specifically, the study conceptualizes sustainability reporting as an institutionalized governance template interacting with public value co-creation practices within governance processes. Rather than merely documenting organizational outcomes, reporting systems may contribute to structuring governance processes by defining strategic priorities, codifying indicators, and articulating shared understandings of sustainability objectives. However, consistent with a practice-based perspective, the study does not assume a deterministic influence of reporting frameworks on governance practices. Instead, sustainability reporting is examined as a template that interacts with existing public value co-creation practices through their situated enactment within specific institutional contexts.

The purpose of the study is, therefore, to explore how sustainability reporting templates are interpreted, adapted, and performed within public service ecosystems. In particular, the study investigates how reporting frameworks and governance practices mutually shape one another through their everyday performances, potentially reinforcing, transforming, or leaving unchanged existing sustainability-oriented governance arrangements. The paper addresses the following research question: How do sustainability reporting templates interact with public value co-creation practices within public service ecosystems through their situated performances? To address this question, the study adopts a comparative case study approach focusing on two sustainability reporting initiatives implemented by Italian municipalities: the Sustainability Report of the Municipality of Udine and the "Bilancio POP" initiative of the Municipality of Messina. These cases provide an empirical setting for examining how contrasting reporting orientations—managerial monitoring and citizen-oriented communication—are enacted and how public actors interpret, adapt, or incorporate these templates into existing sustainability-related governance practices.

More specifically, the study aims to contribute to the emerging debate on governance infrastructures that support sustainability-oriented transformations within public administrations. While sustainability reporting has traditionally been examined primarily as an accountability and disclosure mechanism, its interaction with public value co-creation practices within public service ecosystems remains underexplored (Adams & Larrinaga, 2019; Osborne et al., 2022). By adopting a practice-based perspective, this study shifts the analytical focus from reporting outputs to the interactions between reporting frameworks and the practices through which sustainability governance is enacted. By conceptualizing reporting

systems as templates that shape how sustainability priorities are articulated and operationalized within public organizations, this study seeks to provide a new perspective on the managerial and governance functions of sustainability reporting within public service ecosystems. Furthermore, the paper aims to advance current discussions on public value creation by examining how governance instruments influence the practices through which public value is collectively generated. In this context, sustainability reporting is analysed not only as a managerial device but as a governance arrangement whose effects depend on its situated performance within local public service ecosystems.

Methodology. This study adopts a qualitative research design aimed at exploring the interaction between sustainability reporting templates and public value co-creation practices within public service ecosystems. A comparative case study approach was selected as it enables the investigation of complex governance phenomena within their real-life contexts (Yin, 2018).

Two cases of sustainability-oriented reporting initiatives implemented by Italian municipalities were selected through purposive sampling. The cases were identified through a preliminary screening of publicly available municipal sustainability reporting initiatives and selected because they represented two contrasting reporting orientations. The Municipality of Udine represents a structured approach to sustainability reporting aligned with international standards such as the Global Reporting Initiative (GRI), while the Municipality of Messina developed the "Bilancio POP" as an innovative and simplified reporting format aimed at improving accessibility and citizen engagement. The selection of these cases follows a theoretical sampling logic aimed at capturing variation in the ways sustainability reporting is designed and implemented within local public administrations. While both municipalities share a commitment to sustainability-oriented governance, they differ in terms of reporting format, institutional objectives, and stakeholder engagement strategies. This variation provides a suitable empirical setting for examining how different sustainability reporting templates interact with existing public value co-creation practices and how such interactions are enacted through situated performances within local public service ecosystems. The Italian municipal context offers a particularly relevant setting for this investigation, as local governments play a key role in implementing sustainability policies and translating broader sustainability agendas into concrete territorial initiatives.

Data collection was primarily based on semi-structured interviews with actors involved in the preparation and communication of sustainability reporting initiatives within the two municipalities. Overall, twenty interviews were conducted between November 2024 and December 2025 with municipal officials, administrative staff, and actors directly involved in sustainability-related reporting activities. Respondents were selected because of their direct knowledge of the design, implementation, or communication of the reporting initiatives. Interviews were conducted with municipal officials and administrative staff engaged in sustainability-related activities in order to capture their perspectives on the objectives, functions, and practical use of sustainability reporting within the administration. Data collection continued until the interviews provided sufficient thematic convergence around the main analytical categories, although the exploratory nature of the study and the limited number of cases are acknowledged.

The interviews explored how sustainability reporting processes are organized, how sustainability priorities and indicators are interpreted by public actors, and how reporting frameworks are incorporated into the practices through which sustainability initiatives are coordinated across departments and communicated to stakeholders. Particular attention was devoted to understanding how actors perceive and enact the relationship between sustainability reporting templates and the public value co-creation practices through which sustainability governance is implemented within the local public service ecosystem. All interviewees were informed about the purpose of the study, and confidentiality was ensured through anonymization of individual quotations and institutional roles where necessary.

Documentary sources—including sustainability reports, institutional documents, and publicly available materials produced by the municipalities—were used as contextual material to support the interpretation of the interview evidence and to provide background information on the institutional setting in which reporting practices are developed and communicated. The empirical material was analysed through qualitative content analysis, an interpretive analytical approach widely used in qualitative social science research to systematically examine patterns of meaning within textual data (Krippendorff, 2018; Schreier, 2012). Qualitative content analysis allows researchers to identify recurring themes and interpret how actors construct and make sense of organizational practices within specific institutional contexts (Mayring, 2014; Hsieh & Shannon, 2005). In line with this approach, interview transcripts were analysed iteratively in order to identify patterns in how sustainability reporting templates are interpreted and incorporated into governance practices. The five dimensions reported in Table 1 were derived through a combined deductive and inductive process: the distinction between templates and performances was informed by the PVCP framework, while the specific dimensions emerged from cross-case coding of interviews and documents. The analysis focused on examining how reporting frameworks define sustainability priorities, indicators, and communication formats, and how these elements influence the practices through which public actors coordinate sustainability initiatives within the municipalities. This analytical process enabled the identification of situations in which sustainability reporting templates reinforce existing governance practices, are reinterpreted by actors within the local context, or contribute to reshaping sustainability-oriented governance arrangements through their situated performances.

Results. The analysis indicates that sustainability reporting can be interpreted as an institutionalized template that interacts with public value co-creation practices within public service ecosystems. In both cases examined, reporting systems articulate intended configurations of sustainability practices by defining strategic priorities, codifying indicators,

and structuring interactions among actors. However, rather than deterministically structuring governance practices, the empirical evidence shows that these templates interact with existing public value co-creation practices and are interpreted and enacted differently across institutional contexts.

The findings are primarily derived from the qualitative analysis of semi-structured interviews conducted with municipal actors involved in sustainability-related activities and reporting processes. Documentary materials—including sustainability reports and institutional documents—were used to contextualize the reporting initiatives implemented by the municipalities and to support the interpretation of interview evidence. The analysis focused on how public actors interpret the role of sustainability reporting within governance processes and how reporting frameworks interact with the public value co-creation practices through which sustainability initiatives are coordinated and communicated within the municipal administration. Across both cases, sustainability reporting functions as a reference infrastructure that interacts with sustainability-oriented public value co-creation practices. Sustainability reports typically articulate thematic policy areas—such as environmental protection, social inclusion, and sustainable urban development—supported by performance indicators that allow administrations to monitor progress toward sustainability objectives. Interview evidence suggests that these reporting frameworks often provide a shared interpretive structure through which municipal actors coordinate sustainability-related activities across departments. As one municipal officer involved in the preparation of the sustainability report in Udine explained: "The report helps us connect activities across departments. Sustainability is not only an environmental issue—it involves mobility, social policies, urban planning. The report provides a structure that allows us to see how these initiatives relate to each other."

This evidence indicates that reporting templates provide shared interpretive resources through which actors coordinate sustainability-related practices and align departmental activities with broader sustainability objectives. However, the performance of reporting templates differs significantly between the two municipalities. In the Municipality of Udine, sustainability reporting primarily performs a managerial coordination and monitoring function. The reporting framework is aligned with internationally recognized standards such as the Global Reporting Initiative (GRI) and emphasizes the systematic monitoring of sustainability indicators across policy domains. These indicators support internal coordination by enabling administrative units to track policy implementation and evaluate sustainability initiatives over time. As one administrative officer noted: "The indicators are useful because they allow us to see where we are improving and where we still need to intervene."

Interview evidence indicates that, in this context, reporting templates are largely incorporated into existing administrative routines that support internal monitoring and policy evaluation. Sustainability reporting therefore reinforces established governance practices by strengthening performance monitoring mechanisms and facilitating coordination among administrative units engaged in sustainability-oriented initiatives. In contrast, the "Bilancio POP" initiative implemented by the Municipality of Messina reflects a different interpretation of sustainability reporting. Rather than prioritizing performance monitoring, the reporting framework emphasizes accessibility and citizen-oriented communication. The Bilancio POP presents municipal activities through simplified narratives and visual representations designed to make sustainability initiatives more understandable to citizens. As one official involved in the initiative explained: "Traditional reports are often too technical. The idea of Bilancio POP was to create a document that citizens could actually read and understand."

Interview data suggest that, in this case, reporting practices are interpreted primarily as instruments for improving transparency and strengthening communication between the municipality and citizens. Rather than functioning mainly as an internal monitoring tool, the reporting framework becomes a communicative device through which municipal actors explain policy initiatives and their societal relevance.

In this context, actors reinterpret the reporting template by adapting it to the communicative needs of the local governance environment, thereby reshaping how sustainability-related public value co-creation practices are enacted.

The comparative analysis, therefore, suggests that sustainability reporting templates generate different governance performances depending on how they are interpreted and enacted by public actors. While both municipalities adopt reporting frameworks that articulate sustainability objectives and policy initiatives, their practical roles differ across contexts. Table 1 summarizes how the sustainability reporting template is interpreted and performed differently across the two municipalities. The dimensions included in the table reflect the main analytical categories emerging from the cross-case analysis and connect the empirical evidence to the distinction between templates and performances.

Taken together, the findings suggest that sustainability reporting functions as a governance template that interacts with public value co-creation practices rather than determining them unilaterally. In some instances, reporting templates reinforce existing governance arrangements; in others, actors reinterpret and adapt reporting frameworks to align them with local governance priorities and stakeholder expectations. Thus, the contribution of sustainability reporting to public value co-creation depends on the fit between the formal reporting template and the situated governance practices through which it is performed. Overall, the findings point to an ongoing process of adjustment between reporting templates and governance practices, suggesting a possible co-evolution between institutionalized reporting frameworks and the public value co-creation practices through which sustainability governance is enacted.

Table 1. Sustainability Reporting Templates and Performances in Public Service Ecosystems.

Dimension	Sustainability Reporting Template (Intended configuration)	Performance – Municipality of Udine	Performance – Municipality of Messina
Strategic orientation	Reporting frameworks define sustainability priorities and policy areas	Supports internal alignment of municipal departments around sustainability objectives	Frames sustainability initiatives through narratives aimed at explaining municipal actions to citizens
Role of indicators	Sustainability indicators provide structured reference points for monitoring initiatives	Indicators are used extensively for internal monitoring and evaluation of policy outcomes	Indicators play a limited role and are complemented by simplified explanations of municipal initiatives
Governance coordination	Reporting templates structure how sustainability initiatives are organized and communicated	Reporting reinforces coordination across administrative units and policy domains	Reporting supports communication between the municipality and citizens
Stakeholder engagement	Reporting frameworks identify relevant stakeholders and communication channels	Engagement primarily occurs within the municipal administration	Strong emphasis on accessibility and citizen-oriented communication
Governance function	Reporting templates guide how sustainability-related practices are organized within the administration	Sustainability reporting strengthens managerial monitoring and policy evaluation	Sustainability reporting operates as a transparency and public communication tool

Research limitations. This study presents several limitations. First, the analysis focuses on two municipal cases within the Italian public administration context, which limits the generalizability of the findings. Second, the research relies primarily on qualitative interview data supported by documentary materials, which may not fully capture the lived experiences of actors involved in the enactment of reporting practices. In particular, the qualitative evidence may only partially reflect the situated dynamics through which sustainability reporting templates interact with public value co-creation practices within local governance ecosystems. Future research could expand the analysis by examining additional cases across different institutional contexts and by incorporating broader qualitative data collection strategies involving a larger number of interviews and organizational actors.

A further limitation concerns the institutional specificity of the two case studies analysed. Both municipalities operate within the Italian administrative and regulatory framework, which shapes how sustainability reporting practices are designed, implemented, and interpreted within local governments. As a result, the findings should be interpreted with caution when considering their transferability to public administrations operating within different governance systems or regulatory environments. Different institutional environments may generate alternative configurations of interaction between sustainability reporting templates and the public value co-creation practices through which sustainability governance is enacted.

Additionally, the empirical material is based on a limited number of interviews with actors involved in sustainability reporting initiatives, which may restrict the diversity of perspectives captured in the analysis. While the interview data provide valuable insights into how public actors interpret and incorporate reporting frameworks into governance practices, a larger number of interviews across different organizational levels and stakeholder groups could provide a more comprehensive understanding of how sustainability reporting templates are interpreted and enacted within public service ecosystems. Future studies should also include the perspective of intended beneficiaries, particularly citizens, to examine how citizen-oriented reporting initiatives are perceived, used, and evaluated.

Future research could therefore extend this investigation by adopting longitudinal and multi-case research designs that examine how sustainability reporting practices evolve over time across different institutional contexts. Comparative studies involving municipalities from different countries or governance systems may also provide valuable insights into how institutional environments influence the design and performances of sustainability reporting templates within public service ecosystems. Longitudinal analyses may be particularly valuable for examining how sustainability reporting templates and public value co-creation practices gradually adjust to one another, shedding further light on the possible co-evolution between governance templates and the practices through which sustainability-oriented public value is enacted.

Managerial implications. The findings offer several implications for public managers and policymakers involved in sustainability governance. First, sustainability reporting should not be treated solely as a compliance mechanism but rather as an institutionalized governance practice that interacts with existing public value co-creation practices within public service ecosystems. Second, public managers should recognize that reporting templates may be interpreted and enacted differently by actors within the ecosystem. Designing reporting systems that foster stakeholder engagement and shared understanding may help reduce misalignments between templates and performances. From a practice perspective, the

effectiveness of sustainability reporting depends not only on its formal design but also on how actors incorporate reporting templates into the everyday practices through which sustainability initiatives are negotiated and coordinated. Finally, sustainability reporting can be interpreted as an innovation infrastructure for public governance, enabling coordination, knowledge sharing, and organizational learning within public service ecosystems.

The findings of the two case studies highlight how different interpretations of sustainability reporting can lead to distinct governance practices within public administrations. In the Municipality of Udine, the reporting framework primarily supports internal coordination and performance monitoring, enabling administrative departments to align their activities with sustainability objectives through standardized indicators. In contrast, the Bilancio POP initiative implemented by the Municipality of Messina demonstrates how reporting systems can also function as tools for strengthening transparency and citizen engagement. These different performances illustrate that the managerial value of sustainability reporting depends not only on the reporting framework itself, but also on how public actors interpret and enact the reporting template within their governance context. Monitoring-oriented approaches may therefore be more suitable for internal coordination, whereas citizen-oriented approaches may be more effective when accessibility and public communication are strategic priorities.

For public managers, this suggests the importance of approaching sustainability reporting not merely as a technical exercise of data collection and disclosure, but as a strategic governance instrument capable of shaping organizational practices. The design of reporting frameworks should therefore consider not only the technical requirements associated with sustainability indicators but also the broader organizational and relational dynamics through which sustainability initiatives are coordinated across departments and communicated to stakeholders. In particular, fostering collaboration among administrative units and creating opportunities for dialogue with external stakeholders may enhance the capacity of reporting systems to support public value creation processes. Encouraging reflexive use of reporting frameworks within organizations may also enable public actors to adapt reporting templates to evolving governance challenges, thereby strengthening the alignment between sustainability reporting and public value co-creation practices.

More broadly, sustainability reporting can function as a platform for organizational learning within public administrations. By encouraging systematic reflection on sustainability priorities, reporting processes can help public organizations identify policy gaps, evaluate the effectiveness of sustainability initiatives, and support continuous improvement in governance practices. Through these learning dynamics, sustainability reporting may gradually evolve together with the governance practices in which it is embedded, fostering ongoing adjustment between reporting templates and the practices through which sustainability-oriented public value is enacted.

Originality of the paper. This study contributes to the literature by integrating research on sustainability reporting with practice-based perspectives on public value creation. First, it conceptualizes sustainability reporting as an institutionalized template that interacts with public value co-creation practices within public service ecosystems. Rather than treating reporting systems as external managerial instruments, the study interprets sustainability reporting as part of the broader set of practices through which sustainability governance is organized and negotiated within public administrations.

Second, the study advances the understanding of sustainability reporting as a governance infrastructure capable of shaping how actors coordinate sustainability initiatives in complex institutional environments. By interpreting sustainability reporting through the lens of public value co-creation practices, the study shifts the analytical focus from reporting outputs to the governance practices through which sustainability initiatives are enacted. While previous research has primarily examined sustainability reporting as a tool for transparency and accountability, the findings suggest that reporting systems may also operate as institutional templates embedded within the practices through which actors interpret sustainability priorities and coordinate collective action within public service ecosystems.

Furthermore, the study contributes to practice-based approaches to public management by empirically illustrating how governance instruments influence the performances of public actors within institutional contexts. The comparative analysis of the two municipal cases demonstrates that sustainability reporting templates may generate different governance outcomes depending on how they are enacted in practice. More specifically, the findings show that reporting templates may reinforce existing governance practices, be reinterpreted to accommodate local priorities, or contribute to reshaping sustainability-oriented practices through their situated enactment.

In this sense, the paper highlights the importance of distinguishing between the formal design of governance instruments and their situated performances within organizational settings. This distinction allows the study to move beyond a deterministic view of governance instruments and conceptualize the relationship between reporting frameworks and governance practices as dynamic and context-dependent. Finally, by bridging sustainability reporting research with the literature on public service ecosystems and public value co-creation practices, the study expands the theoretical understanding of how governance infrastructures support sustainability-oriented transformations in the public sector. The findings point toward mutual adjustment between sustainability reporting templates and public value co-creation practices, suggesting the possible co-evolution of institutionalized reporting frameworks and governance practices within public service ecosystems.

The Influence of Virtual Tours in the Tourism Industry: An Investigation into Consumer Perceptions and Behavior

GIULIANO MASTROGIOVANNI[1], M. IRENE PRETE[2], DIEGO GABRIELE COPPOLA[3], ANTONIO MILETI[4]

Abstract. *This study analyzes the impact of virtual tours (VTs) on consumer behavior in the hospitality and tourism sector, comparing the effectiveness of these immersive tools with traditional visualization methods based on static images. The research adopts a theoretical perspective grounded in the Stimulus–Organism–Response (S-O-R) model, examining how the technological properties of interactivity and virtuality influence users' cognitive and emotional states. From a methodological standpoint, the study employs a quantitative experimental approach based on an A/B test conducted with a sample of 198 participants. The collected data were analyzed using the Partial Least Squares Structural Equation Modeling (PLS-SEM) method and the Van Westendorp Price Sensitivity Meter (PSM) to measure willingness to pay (WTP). The empirical results show that the integration of virtual tours generates higher levels of hedonic gratification, utilitarian value, and perceived information. A particularly relevant finding concerns willingness to pay. Contrary to expectations, the group exposed to static images showed a higher optimal price point (€65 compared to €55). This result can be interpreted considering the greater informational transparency provided by virtual tours, thereby limiting the so-called "risk factor" that consumers tend to implicitly incorporate into evaluations based on less comprehensive static images. The study contributes to the literature on digital management and tourism marketing by offering managerial implications for the development of communication and pricing strategies based on value perception and informational transparency.*
Keywords: *Virtual Reality, Virtual Tour, Consumer Behavior, Willingness to Pay, S-O-R Model, Tourism Management, PLS-SEM.*

Framing of the research. Virtual Reality (VR) represents a widely debated conceptual construct in the literature, whose use is sometimes heterogeneous and not univocal. The term is used to describe both technological systems capable of generating synthetic experiences and the experience itself, up to being assimilated into a form of communication comparable to language. The association of VR with specific hardware configurations is problematic due to rapid technological evolution and the heterogeneity of systems included under the same label (Beck et al., 2019). On the theoretical level, VR has been interpreted as an expression of the human desire for escape and exploration of alternative worlds. It is defined as a computer-simulated environment that allows the user to experience a sense of presence in a space different from the physical one (Desai et al., 2014). Beyond the escapist dimension, VR is characterized by multisensory stimulation and the interaction opportunities offered to the user (Guttentag, 2010). Virtual reality differs from other modal forms in terms of immersion and presence (Beck et al., 2019). Immersion constitutes an objective dimension, linked to the technological characteristics of the system, while presence is a subjective dimension, referring to the perception of "being there" in the virtual environment (Mel Slater and Wilbur, 1997). Immersion depends on four determinants: inclusion (exclusion of physical reality), surrounding environment (panoramic vision), sensory extent, and intensity (resolution and fidelity). The goal of VR is to maximize these dimensions to increase perceived presence. Empirical evidence shows that more advanced technologies favor higher levels of immersion and engagement, positively affecting the overall experience (Beck et al., 2019). In the tourism sector, VR presents significant transformative potential. Its applications range from planning to management, from marketing to education, and even to heritage conservation and accessibility (Beck et al., 2019). VR allows virtual visits to remote, dangerous, or inaccessible locations, reducing physical and cognitive barriers. However, questions remain regarding the authenticity of virtual experiences and their ability to fully replace traditional tourism. VR is generally considered a complementary or enriching tool for real experience.

From a technological standpoint, virtual environments can be generated through three-dimensional synthetic content or via 360-degree panoramic images and videos (Marasco et al., 2018). The latter, while offering limited interaction possibilities compared to fully computer-generated environments, are particularly suitable for representing large spaces and accommodation facilities, ensuring a high degree of verisimilitude. The literature distinguishes three main categories of systems based on their level of immersion. Non-immersive virtual reality (niVR) involves the use of traditional screens, such as in desktop VR, where interaction is mediated through devices like a mouse and keyboard (Beck et al., 2019). Semi-immersive virtual reality (siVR), on the other hand, relies on large screens or projection-based environments, such as CAVE systems, and is often designed for multi-user experiences (Cruz et al., 1992). Finally, fully immersive virtual reality (fiVR) makes use of head-mounted displays (HMDs), which isolate the user from the real world and provide a fully immersive experience (Slater and Sanchez-Vives, 2016). The classification is based on the degree of exclusion of

physical reality: the greater the perceptual isolation, the higher the level of immersion. Fully immersive technologies allow dynamic updating of the visual field based on the user's movements and favor high-intensity individual sensory experiences. Numerous studies have analyzed the impact of VR on travel intentions and attitudes toward destinations. Flow theory (Huang et al., 2012) highlights how interactivity, perceived skills, and presence mediate the relationship between interest and behavioral intentions. Similarly, the Technology Acceptance Model (TAM) shows that perceived usefulness, ease of use, emotional engagement, and enjoyment influence the intention to use a particular VR technology (Davis, 1989; Disztinger et al., 2017). In fully immersive VR, spatial presence and social presence are determinants for attitude change and visit intention (Jung et al., 2016; Tussyadiah et al., 2018). Immersive experiences generate higher levels of physiological engagement compared to non-immersive systems and can improve the affective image of the destination. However, promotional effectiveness depends on the aesthetic quality of the content and its consistency with the target audience. Integration between VR and traditional marketing tools is also recommended (Jung et al., 2016; Tussyadiah et al., 2018).

Among emerging critical issues is the so-called "simulator sickness," associated with low-quality devices or inadequately designed content, a phenomenon that requires further investigation. Moreover, the growing diffusion of immersive technologies has sparked interest among tourism operators and destination management organizations. Virtual tours act as strategic communication tools on online booking platforms, accommodation websites, and territorial promotion campaigns. The possibility of offering an experiential preview of spaces allows potential visitors to develop a more concrete perception of the tourist offer.

From a consumer behavior perspective, the use of virtual environments can reduce the informational uncertainty that characterizes many tourism decisions. Virtual tours contribute to strengthening the expectation formation process and improving the perceived quality of online information. Some studies also highlight that immersive technologies can influence how tourists mentally construct the image of a destination (Beck et al., 2019; Hyun and O'Keefe, 2012). Virtual exploration of environments allows the perception of spatial and atmospheric elements that are difficult to communicate through static images or textual descriptions. This aspect contributes to increasing the user's emotional and cognitive engagement during the search and planning phase of the trip.

The research is anchored in the Stimulus–Organism–Response (S-O-R) model (Jacoby, 2002), where the properties of the medium (interactivity and virtuality) act as Stimuli influencing the internal state of the user (Organism), determining a behavioral Response. This framework is integrated with the Technology Acceptance Model (TAM) (Disztinger et al., 2017), focused on usefulness (UTIL) and ease of use (EOUSE). The model also includes Flow Theory (Huang et al., 2012), which describes the state of optimal engagement during virtual exploration. The integration of these three theoretical approaches allows for a more comprehensive interpretation of consumer behavior in the context of immersive technologies applied to tourism. The Stimulus–Organism–Response model indeed allows analyzing how the technological characteristics of digital tools influence users' perceptions and internal evaluations. At the same time, the Technology Acceptance Model provides a consolidated perspective to understand the mechanisms determining the adoption of new technologies by consumers (Jacoby, 2002; Loureiro et al., 2019; Mehrabian & Russell, 1974).

Finally, Flow Theory (Huang et al., 2012) introduces the ideal engagement state that a user experiences during exploration of a virtual environment. According to this theory, flow is triggered when the user perceives a balance between their navigation skills and the opportunities offered by the virtual environment, allowing a state of intense engagement to develop, which encourages prolonged interaction with digital content. This state of cognitive and emotional immersion can help strengthen the attitude toward the tourist product and increase the likelihood of favorable behaviors. Willingness to Pay (WTP) is defined as the maximum reservation price a consumer is willing to pay based on perceived utility (Kalish et al., 1991). The present study favors Van Westendorp's Price Sensitivity Meter (PSM) (Van Westendorp, 1976). This method allows identifying the acceptable price range through the intersection of four perceptual thresholds: Cheap, Expensive, Too Cheap, and Too Expensive.

Purpose of the paper. The main objective of the research is to comparatively analyze the effectiveness of virtual tours versus traditional static photographs within the communication and advertising of tourist accommodations. Specifically, the study aims to investigate whether the superior informational richness offered by virtual reality influences the attitude and behavior of potential consumers, translating into a higher booking intention. In addition, the paper aims to empirically assess the monetary value attributed to technological innovation, evaluating whether potential customers are willing to accept a higher price positioning (Willingness to Pay) for accommodation.

Methodology. The core of the empirical investigation is based on the implementation of an A/B test, a technique widely used in marketing and web design to compare two variants of the same digital environment (Kumar, S., 2021). The A/B test allowed the sample of participants to be divided into two distinct groups: one group was exposed to the "experimental variant" (Ad A), characterized by the exclusive presence of a virtual tour. The other group viewed the "control variant" (Ad B), which presented the same accommodation illustrated solely through a gallery of traditional static photographs. This clear separation ensures that any differences in responses can be attributed exclusively to the technological difference of the advertisement. To guarantee a random and balanced distribution of online traffic between the two scenarios, the study used the software allocate.monster (Fergusson, A., 2016). Data were collected through the administration of a structured questionnaire. In social sciences, the questionnaire is the preferred tool for extracting standardized information that can subsequently be translated into matrices suitable for statistical processing. For this study, questionnaires were

administered via Google Forms. The questionnaire items were developed based on measurement scales that had already been validated in the academic literature on consumer behavior and immersive technologies. Participants were asked to evaluate a series of statements related to the constructs under investigation using a 7-point Likert scale, where 1 corresponded to "strongly disagree" and 7 to "strongly agree." The study explored multiple latent constructs within the S-O-R (Stimulus–Organism–Response) theoretical framework (Jacoby, 2002). In particular, interactivity (INTER) (Wu, 2005) and virtuality (VIR) (Babin and Burns, 1998) were considered technological stimuli. Empathy (EMPATIA) was also included as a relevant psychological dimension (Abreu et al., 2021). Furthermore, several variables were examined as cognitive and emotional reactions of the organism, namely ease of use (EOUSE) (Gefen et al., 2003), utilitarian gratification (UTIL) (Rese et al., 2017), information (INFORMAT) (Hausman and Siekpe, 2009), and hedonic gratification (HEDONIC) (Rese et al., 2017).

Finally, the study analyzed attitudes (ATT), behavioral intention (BI), and purchase or booking intention (INT) as outcome responses within the framework (Qin et al., 2021), along with participants' perception of and sensitivity to accommodation price (PRICE) (Chhabra, 2015). Before disseminating the questionnaire, a pilot test was conducted involving a group of university professors and students. A total of 198 usable questionnaires were collected, of which 92 were assigned to the virtual tour variant and 106 to the photographic variant. In the virtual tour variant, participants were shown a virtual tour of a hotel room, allowing interactive exploration of the environment. In the photographic variant, participants were presented with a series of photographs of the same accommodation, without the possibility of navigating the space virtually. To limit the risk of Common Method Bias (CMB) associated with self-administered questionnaires, the collected data were subjected to Harman's single-factor test using the statistical software IBM SPSS. The total variance level of 48.3% was below the critical threshold of 50%. Therefore, Common Method Bias did not pose a threatening issue (Vishwanath, 2017).

Descriptive statistics were calculated using the Gretl software. For each of the two samples, means, medians, min-max values, and standard deviations were computed. The analysis showed that the mean responses for the virtual tour advertisement were generally higher, except for the price variable. At the same time, a correlation matrix was created to study the direction and intensity (from -1 to +1) of preliminary linear relationships between variables. In this study, several hypotheses were tested to understand the relationships between the variables under investigation (Qin et al., 2021):

H1: The perception of the virtuality of the viewing experience positively influences the internal states of the consumer, particularly hedonic gratification, perceived informativeness, and ease of use.

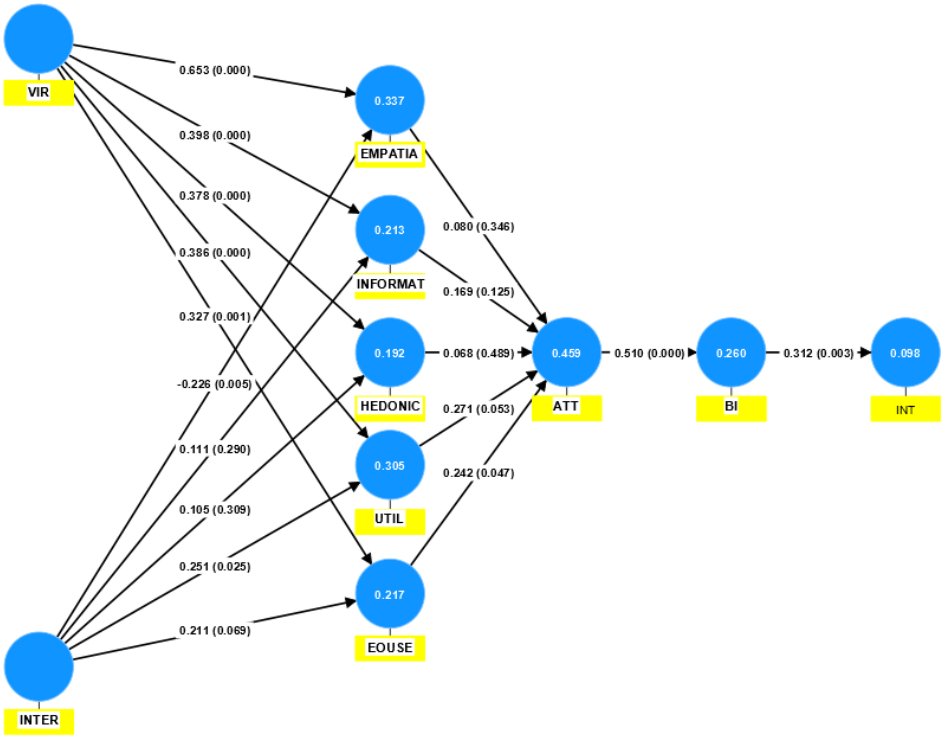
H2: Consumers' internal states positively influence attitudes toward the use of virtual tours (vs static photos).

H3: A positive attitude toward the use of virtual tours increases the behavioral intention to use this technology in the booking process.

H4: A higher behavioral intention to use virtual tours increases the intention to book the accommodation.

H5: The use of virtual tours (vs static photos) negatively influences the Willingness to Pay (WTP) for accommodation.

These hypotheses were tested using Structural Equation Models (SEM) and analyzed with SmartPLS4 software. The choice of the PLS (Partial Least Squares) approach, a "soft" modeling technique, is justified by the relatively modest sample size, the primary objective of predictive accuracy rather than strict validation of a prior theory, and the absence of stringent normality requirements for the data (Benitez et al., 2020; Wong, 2013). Within the PLS-SEM environment, the analysis processed two logical dimensions: the "outer model" (which assesses the reliability and validity of relationships between latent constructs and their specific questionnaire items) and the "inner model" (which illustrates causal paths and the direct impacts between independent exogenous variables and dependent endogenous variables). The results produced by SmartPLS4 provided standardized regression coefficients (path coefficients, to determine the strength and direction of causal effects) combined with the explained variance values to define the rejection or acceptance of the individual theoretical assumptions.



Van Westendorp Method: Testing the final hypothesis (H5) required a different and separate tool from SEM. Measuring consumers' exact reservation price is complex; to circumvent distortions from hypothetical bias inherent in classic "contingent valuation" (Backhaus et al., 2005; Wertenbroch and Skiera, 2002) and the restrictions of the complex BDM lottery mechanism (Becker–DeGroot–Marschak). The study applied Van Westendorp's Price Sensitivity Meter (PSM). Van Westendorp's PSM is an exploratory questioning methodology that considers four cognitive thresholds: the price at which the accommodation begins to be considered "cheap" but reassuring, "expensive" but bearable, "too expensive," and finally "too cheap" (threshold at which doubts about the actual quality of the property arise). The data obtained on these four monetary dimensions, segmented between virtual tour users and static photo users, were tabulated and processed using Microsoft Excel. By processing and graphically superimposing the cumulative frequency curves, it was possible to define a rigorous "acceptable price range" between the Marginal Cheapness Point (PMC) and the Marginal Expensiveness Point (PME). Excel intersections revealed the fundamental Optimal Price Point (OPP) for the two scenarios, i.e., the mathematical point where the sensations of "too expensive" and "too cheap" exactly balance, providing an indisputable economic comparison to measure the actual monetary value generated by the two different accommodation presentations.

Data were collected in 2023 through an online survey administered as part of an A/B testing procedure: 92 participants were exposed to an advertisement featuring a virtual tour, while 106 evaluated an advertisement consisting exclusively of photographic images. The analysis of the collected data made it possible to outline a detailed sociodemographic profile of the sample. With regard to gender, a slight female predominance emerges, with 115 women

and 82 men. From an age perspective, the population is predominantly young: the most represented age group is between 18 and 33 years (106 participants), followed by a gradual decline in the subsequent age categories, with only a marginal presence of individuals over 65. In terms of educational attainment, the majority of participants hold a high school diploma (118), while a significant proportion have obtained a university degree (54). Fewer individuals report lower secondary education (19) or postgraduate qualifications, such as a master's degree or PhD (6), indicating an overall medium-to-high level of education within the sample. The analysis of occupational status reveals a heterogeneous composition, with a notable presence of students (77) and employees (61), followed by self-employed professionals (21) and, to a lesser extent, other categories such as manual workers, homemakers, shopkeepers, and retirees. Regarding marital status, most respondents are single (133), while 64 are married. Consistently, the distribution of the number of children shows a predominance of individuals without children (127), followed by those with one or two children (57), whereas larger families are only minimally represented. Finally, the analysis of annual income indicates a concentration in the lower-to-middle income brackets: a substantial portion of the sample reports an income below €20,000, while only a very limited number of participants report incomes above €50,000.

Results. The descriptive analysis reveals significant differences between accommodation presentation via virtual tour (VT) and via static photographs. In particular, mean scores for perceived informativeness (INFORMAT: *M*_VT = 24.6 vs. *M*_Photos = 20.6) and ease of use (EOUSE: *M*_VT = 25.1 vs. *M*_Photos = 22.7) are higher in the virtual tour group. Similarly, hedonic gratification (HEDONIC: *M*_VT = 24.4 vs. *M*_Photos = 20.3) and perceived empathy (*M*_VT = 27.4 vs. *M*_Photos = 21.3) also exhibit higher mean values in the experimental group. Harman's single-factor test for common method bias (Podsakoff et al., 2003) returned a value of 48.43%, below the conventional 50% threshold, thus suggesting the absence of systematic bias in the collected data. The structural model was then estimated using PLS-SEM, specified according to the Stimulus–Organism–Response (S-O-R) paradigm, to test the research hypotheses. The results of the structural model estimation are graphically summarized in Figures 1 and 2.

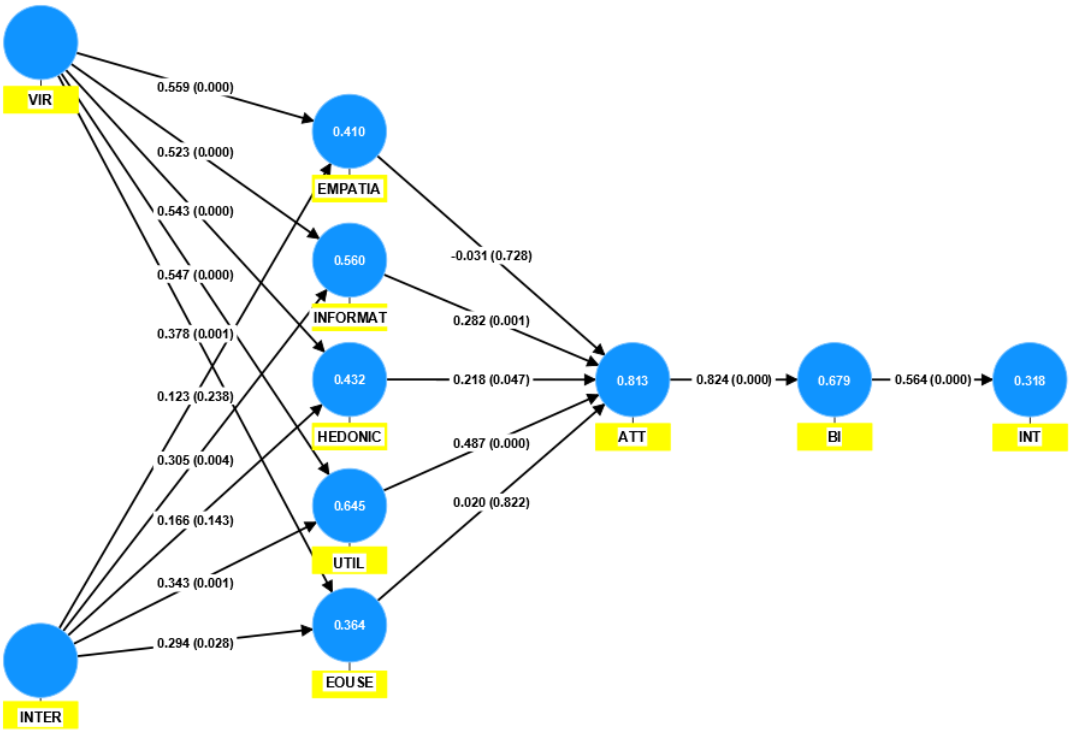


Figure 1. PLS-SEM results for static photos

The results support H1, indicating that the perceived virtuality of the viewing experience positively influences consumer internal states, specifically hedonic gratification, perceived informativeness, and ease of use. H2 is also supported, as consumers' internal states positively influence attitudes toward the use of virtual tours relative to static photographs: informativeness and hedonic gratification exert a significant positive effect on attitude (ATT), with a higher path coefficient in the VT group (β = 0.578) compared to the photo group (β = 0.493). The results further confirm H3, showing that a more favorable attitude toward virtual tours increases behavioral intention to adopt this technology in the accommodation evaluation process. In turn, behavioral intention is positively associated with booking intention, thereby confirming H4: the path coefficient for behavioral intention (BI) reaches a notable value in the VT group (β = 0.417), suggesting that virtual experience contributes to strengthening the consumer's behavioral response. Finally, the analysis of willingness to pay (WTP), conducted using the Van Westendorp Price Sensitivity Meter, supports H5. The results indicate that WTP is lower for accommodation presented via virtual tour than via static photographs. Specifically, the

estimated optimal price point (OPP) for accommodation viewed through a virtual tour is €55, compared to €65 for presentation via static photos.
This finding suggests that the virtual tour may function as a tool of enhanced informational transparency. While static photographs allow for a degree of idealization of the offering, the virtual tour presents the environment more completely and realistically, thereby reducing informational asymmetry. However, this increased transparency may also constrain the formation of overly positive expectations not fully warranted by the experience. In the sample analyzed, composed predominantly of young individuals with relatively modest income levels, this effect appears to operate as a price-moderating mechanism rather than as a driver of price premium.

Figure 2. PLS-SEM results for virtual tour

Research limitations. The study is limited by the small sample size and the hypothetical bias inherent in the Van Westendorp method (absence of real transactions). Moreover, the concentration of participants in the "Millennial/Gen Z" age group with lower incomes limits the generalizability of the results to luxury or corporate market segments.

Managerial Implications. The results of this study offer twofold implications for tourism marketing professionals and hospitality managers.

First, the virtual tour emerges as a powerful conversion and experiential marketing tool. Integrating virtual reality systems, even non-immersive, web-based ones, into accommodation listings represents a significant competitive advantage for capturing potential customers' interest. By enhancing perceived informativeness, ease of use, and hedonic gratification, virtual tours can effectively translate favorable attitudes into actual booking intentions. Managers should therefore adopt these technologies not as mere aesthetic additions to their websites, but as strategic instruments to reduce perceived risk during the travel planning phase, thereby substantially improving the pre-stay user experience.

Second, careful attention to pricing strategy is warranted. The findings related to H5 deliver a crucial insight: managers should not assume that the availability of a virtual tour alone justifies higher room prices. The results indicate that a listing supported by high-quality traditional static photography can anchor consumers' optimal price point at a higher level (OPP = €65) compared to a virtual tour presentation (OPP = €55). The strategic implication, therefore, points toward a hybrid approach. Virtual tours should be leveraged to increase conversion rates by making the property more attractive and transparent to potential guests. At the same time, for positioning in premium and luxury segments, meticulous high-quality static photography remains essential to sustain a higher willingness to pay. In this sense, the two presentation formats should be conceived as complementary rather than substitutive, each serving a distinct function within the overall communication and pricing strategy.

Originality of the paper. The distinctive value of this research lies in the rigorous integration of the S-O-R framework (analyzed via PLS-SEM) with the Van Westendorp metric. The paper empirically documents the discrepancy between

the excellence of the technological user experience and the contraction of monetary willingness to pay, providing an original contribution to the understanding of the value of digital transparency in tourism.

Twin transition in Italian firms: the role of supply chains

LORENA MARIA D'AGOSTINO, CLAUDIA GHISETTI, ERICA SANTINI

Abstract. *The twin transition, combining digital transformation and environmental sustainability, has become a central priority of European industrial policy. While existing research has examined how digital technologies enable environmental sustainability at the firm level, less attention has been devoted to the role of supply chains in shaping firms' sustainability investments. This study investigates whether and how firms' participation in supply chains influences environmental sustainability investments within a digital-for-green twin transition framework. Using firm-level data, we analyse the effect of participation in multiple supply chains and the role of specific supply chain contexts, namely circular economy and ICT-related supply chains. The results show that participation in supply chains positively affects sustainability investments, but the relationship is non-linear: while moderate exposure to multiple supply chains increases the likelihood of environmental investments, excessive exposure generates coordination costs that reduce these benefits. Moreover, participation in circular economy and ICT supply chains further supports sustainability investments. The findings highlight the role of supply chains as key mechanisms through which firms access knowledge, technologies and capabilities supporting the twin transition.*
Keywords: *green; digital; twin transition; supply chains; AI; circular economy*

Framing of the research. The European policy agenda has supported digital investments and environmental sustainability as part of an integrated "twin" transition (TT) aimed at fostering a competitive, fair and sustainable future (EU, 2022). A growing body of research emerged exploring dynamics, drivers, and effects of the TT along two main lines (Antonietti et al. 2026): I) "Digital for green" (e.g. Montresor & Vezzani, 2023; Biggi et al., 2025), and ii) "Greener digital" (e.g. Al Kez et al, 2022). Both digital (Ciffolilli & Muscio, 2018; Martinelli et al., 2021) and green (Truffer & Coenen, 2012) technologies are highly spatially embedded, being their development dependent on the local presence of related and enabling technologies, actors, and capabilities (e.g. Cicerone et al., 2023).

Firms therefore operate within territorially embedded innovation systems, interacting with proximate partners such as suppliers, customers and knowledge institutions. At the same time, firms are embedded in supply chains (SCs) that connect geographically dispersed actors across multiple stages of production. Understanding how firms coordinate these local and global relationships is therefore central to explaining how technological and sustainability transitions unfold within production systems (Di Maria et al., 2022; Del Giudice et al. 2021). The operations and supply chain management literature increasingly recognises that sustainability challenges cannot be addressed by individual firms alone but require coordination across supply chain partners. Supply chain operations play a pivotal role in achieving sustainability objectives by coordinating material, information and financial flows across production networks (Jia et al., 2025). In particular, SC collaborations enable firms to access complementary resources, knowledge and capabilities that support environmental innovation and sustainability-oriented practices (Bowen et al. 2001; Vachon & Klassen, 2008; Di Maria et al. 2022; Cainelli et al., 2015).

Recent contributions have studied the role of SC in fostering sustainability, while accounting for digitalisation. For instance, Jia et al. (2025) show that the degree of supply chain concentration affects firms' sustainability performance in a non-linear way, with excessive dependence on a limited number of partners initially constraining sustainability outcomes but potentially enabling stronger sustainability performance once deeper collaborative relationships are established. These findings suggest that the structure of supply chain relationships may significantly influence firms' ability to implement sustainability strategies. At the same time, knowledge and information exchanges across supply chain partners are crucial for enabling innovation and organisational learning. The knowledge management literature highlights how external knowledge acquisition and inter-organisational knowledge networks enhance firms' innovation capabilities and support the development of new technological solutions (Jimenez-Jimenez et al., 2019).

Moreover, Di Maria et al. (2022) assess the impact on circular economy of different types of Industry 4.0 technologies where SC integration acts as a mediator; in particular, the mediator effect is found only for smart manufacturing technologies, and not for data processing. Del Giudice et al. (2020) assess the impact of circular economy practices on firm performance for a circular supply chain, where big-data-driven supply chain acts as moderator. Not surprisingly, the majority of studies in SC management literature have focused on circular economy, which is widely recognized as a path towards environmental sustainability (Aarikka-Stenroos et al., 2022). However, the evidence on the role of SC within a general digital-for-green TT setting is less explored. Indeed, relations within SC may enable not only closed loops of materials and resources that may reduce waste and pollution, but they may provide a wide array of inputs that are correlated also to other sustainability investments by firms (e.g. pollution and CO_2 monitoring, use of renewable energy, transportation efficiency, green finance, certification, staff training, etc). In addition, the SC management literature has identified the difficulties to manage multiple partners (i.e. "tiers", including indirect, upstream, and sub-suppliers) (Sarkis et al., 2019); however, as far as we know, SC management literature has said little about the possible the nonlinear relation between multiple SCs and sustainability investments (an exception is e.g. Jia et al. 2025).

Purpose of the paper. Taking the perspective of digital-for-green TT, this work aims at understanding the role of firms' participation in supply chains in shaping environmental sustainability investments. In particular, we address whether the number of SCs in which the firm participate may affect the probability of investing in environmental sustainability, since multiple SCs can amplify the source of information related to products, processes, practices related to sustainability, as well as to stimulate compliance to environmental regulation and standards. However, the benefits of supply chain participation may not increase linearly. While exposure to multiple supply chain networks can expand firms' access to information and complementary capabilities, excessive exposure may also generate coordination costs, governance complexity and redundant knowledge flows. Managing relationships across multiple supply networks may therefore become increasingly demanding, potentially reducing firms' ability to effectively absorb and integrate sustainability-related knowledge. Building on this reasoning, we posit that participation in multiple supply chains may exhibit a non-linear relationship with sustainability investments, whereby the benefits associated with knowledge access and capability development may eventually be offset by coordination costs and diminishing informational returns. This argument resonates with recent evidence showing that supply chain structures may influence sustainability outcomes in non-linear ways, as firms balance the benefits of collaboration with the costs of managing complex supply networks (Jia et al., 2025).

Along with exposure to multiple SCs, sustainability investments may benefit from the participation of the firm in a green SC, such as the circular economy (Wong et al. 2018). Circular economy is widely recognized as a path towards environmental sustainability in SC management literature because of the necessity to coordinate with suppliers upstream and downstream to "close the loop" of material and resources flows, to innovate products and processes, to educate clients and respond to stakeholders' requests (Aarikka-Stenroos et al., 2022).

In addition to the specific circular economy supply chain, also ICT plays a pivotal role. Within the digital-for-green TT, digital technologies are considered enablers of the green transition (e.g. Biggi et al. 2025). Digital investments may improve efficiency and reduce emissions (e.g. through smart energy management), optimize resource use (e.g. through digital twins, and AI-driven optimization of materials use or logistics), and support circularity across sectors (e.g. through better traceability and transparency). We posit that participation in the ICT supply chain provides fastest access to key technologies that are used to facilitate the green transition.

Methodology. Data are drawn from the Permanent Census of Italian firms, conducted between November 2002 and March 2023 by the Italian Institute of Statistics (ISTAT, 2023). The dataset includes about 170 thousand firms with at least 2.5 employees. Smaller firms are sampled, while firms with more than 19.5 represent the total population. The sectors of activities are manufacturing, trade, and services. Agriculture, public administration, and associations are excluded (i.e. Ateco 01, 02, 03, 84, and 94). We estimate a model where the outcome binary variable is the investment in environmental sustainability ("Green"), as function of digital investments "AI-digital" (i.e. whether the firm has used AI for processes, goods and services innovation), the number of supply chains in which the firm is involved ("SC") and its squared term to assess non-linearity, and a set of controls (size, R&D investments, human capital, collaboration, governance, formal and informal agreements, and provincial and sectoral fixed effects). In addition, a second model qualifies the type of supply chains in which the firm is involved by inserting two binary variables for the participation in circular economy supply chain (SC_EC), and the supply chain related to infrastructure and telecommunication services (SC_IT), respectively.

We run econometric analysis (logit) for two models described above:

[1] $Green_i = f(AI\text{-}digital_i, SC_i, SC\text{^}2_i, \mathbf{X_i})$

[2] $Green_i = f(AI\text{-}digital_i, SC_CE_i, SC_IT_i, \mathbf{X_i})$

Preliminary results are presented and discussed below.

Results. Table 1 shows the summary statistics for the variables used in the models. In line with other studies (Montresor & Vezzani, 2003), the sustainability investments are carried out by a minority of firms (38%). The use of AI for innovation is declared only by 4% of the firms. In terms of number of supply chains, all firms contribute to at least 1 supply chain, up to 28, and the average is quite low, i.e. 1.56. The most common supply chains are related to the traditional specialization of the Italian economy, e.g. agri-food (18%), construction (18%), vehicles (12%), tourism and leisure (10%), clothing (9%), furniture (8%), machinery (8%). The two supply chains (Circular Economy, and ICT) are chosen by 4% and 3% of the firms, respectively, and are among the least diffused. By looking at the frequency of firms by sector and by supply chains, it is evidence that the majority of firms tend to contribute to the supply strictly related to its sector, and the participation to multiple supply chains is a rather rare event. For example, 85% of firms in "Food production" sector (NACE 10) declared to participate to the Agri-food supply chain [1].

[1] This is SC n. 1, defined as "Plant and animal production for human or animal consumption as food, beverages, and tobacco. Includes machinery and equipment dedicated to the supply chain, and pesticides."

Table 1 – Summary statistics, n. obs. 174,534

Variables	*Mean*	*SD*	*Min.*	*Max*
Green	0.38	0.38	0	1
AI-digital	0.04	0.04	0	1
SC	1.56	156	1	28
SC_EC	0.04	0.04	0	1
SC_IT	0.03	0.03	0	1
R&D investments	0.05	0.05	0	1
HK	0.62	0.62	0	1
Collaboration	0.52	0.52	0	1
Agreements	0.18	0.27	0	1
Governance	0.27	0.72	0	1
n. employees	47.99	515.11	2.5	120,215.9

Pair-wise correlations among selected variable in table 2 show that "Green" is related to all four regressors discussed before. As for the digital variable ("AI-Digital"), the positive and statistical significance of the correlation coefficient (0.140) recall the role of digital investments (and AI, specifically) as enabler of the sustainability transition (Montressor and Vezzani, 2023, Findik et al., 2023; Sjödin et al., 2023). As for the variables related to supply chains, the number ("SC") is positively correlated to sustainability, as pointed out in the SC management literature (Vachon and Klassen, 2008). AI use and the number of SC are positively correlated, although with a low coefficient (0.09), in line with the emerging literature on how AI may contribute to operation management (e.g. Mithas et al, 2022). The two specific supply chains (CE and IT) are positively correlated to sustainability, with different levels of strength. As expected, the contribution of the firm to circular economy supply chain is somewhat important for sustainability investments; also here the coefficient is not very high (0.106), probably due to the general low diffusion of CE supply chain in the sample. However, the firms that contribute to this supply chain are more engaged in sustainability. The contribution of the ICT supply chains is less strong for sustainability (0.038). Looking at the correlation for AI use, as expected, the correlation coefficient with "SC_EC" is even lower than for the number of SC, suggesting that the firms more engaged in the use of AI are not necessarily the ones that participate in the circular economy supply chain. Instead, such firms are more likely to contribute to ICT supply chain, as the correlation coefficient between AI-Digital and SC_IT is 0.08.

Table 2 – Selected pair-wise correlations

	Green	*AI-Digital*	*SC*	*SC_EC*	*SC_IT*
Green	*1*				
AI-Digital	*0.140***	*1*			
SC	*0.131***	*0.093***	*1*		
SC_EC	*0.106***	*0.029***	*0.318***	*1*	
SC_IT	*0.038***	*0.084***	*0.293***	*0.078***	*1*

*p-value<0.10 *; <0.05 **; <0.01 ****

Regression analyses of equations [1] and [2] allow to deepen such relations in a multivariate setting, as well as to assess the non-linearity of "SC". Table 3 shows the results of logit models for selected variables. The controls not shown are all positive and statistically significant, with the exception of "governance" that is never significant.

Model 1 in table 3 shows the results of estimating [1]. "AI-digital" is positive and significant, confirming the digital-for-green TT. The positive sign of "SC", and the negative sign of its squared term "SC^2" point to an inverse U-shaped relation with "Green". In line with our expectation, the exposure of the firm to multiple supply chains amplifies information sharing that can be used to improve product, process, and expertise related to sustainability. This multiple exposure can also entail compliance with environmental regulation of different supply chains, that ultimately stimulate investments in sustainability. At higher level of the number of supply chains to which the firms participate, the beneficial effects diminish and the effects of "SC" turns to negative, pointing to the difficulties of managing multiple SCs (Sarkis et al., 2019). Possible reasons for diminishing returns may be that the participation in many SCs brings higher coordination costs which may render information flows less present or less effective. In addition, additional SCs may also convey repetitive knowledge already accessed in other SCs. Finally, some regulations may be common to multiple SCs, therefore after a certain number of SCs the inducement-effect of law compliance may vanish.

Model 2 in table 3 shows the results of estimating [2]. "AI-digital" is positive and significant also in this setting. The two variables "SC_EC" and "SC_IT" are both positive and statistically significant. For the circular economy partners, this result points to the important role of green SC to foster sustainability, as highlighted by SC management literature (Aarikka-Stenroos et al., 2022). In particular, increased circularity requires the redesigning of technologies, products, services, operations, and business models. We also find that participation in the ICT supply can boost green transition. Digital technologies within supply chains are important enablers of sustainability investments (Schilling and Seuring,

2024). As observed in the pair-wise correlations, the effect of participation in circular economy supply chain is larger than the ICT supply chain, suggesting that, although present also for ICT SC, the linkage between CE SC and green investments is stronger.

Research limitations. The analysis provides valuable insights on how participating in supply chains is related to green transition, when also the digital transition is accounted for. However, some limitations apply. First, the cross-sectional data prevents us from providing any evidence of a causal relation. Second, endogeneity issues may arise, for example in the form of reverse causality: firms more engaged in green investments are more likely to participate in multiple supply chains to search for diverse inputs for their environmental activities, and specifically to engage with suppliers already operating within circular economy; similarly, the "greener" firms may be willing to search for IT inputs to sustain their activities, in line with the digital-for-green twin transition. Third, we discuss different mechanisms that explain why participation in multiple supply chains should increases the likelihood of sustainability investments, treating each supply chain as equal; however, supply chains differ in their greenness, hence the participation in specific supply chains may be more impactful than simple a higher number of supply chains. Unfortunately, we are not able to measure the environmental sustainability of the supply chains. Fourth, firms may participate in supply chains with different degree of integration, that may affect the amount and type of inputs they receive; yet, we are not able to measure how deep the firm is involved in the supply chain.

Managerial implications. The results suggest that participation in supply chains can be a powerful mechanism for accessing sustainability-related knowledge, technologies and practices, but that the benefits of such participation are not unlimited. Managers should therefore view supply chains not merely as transactional arrangements but as strategic environments for capability development, where collaboration with partners can facilitate the diffusion of environmental practices and digital solutions. At the same time, firms should be aware that excessive participation in multiple supply chains may generate coordination costs, managerial complexity and redundant knowledge flows that can hinder effective sustainability investments. Managers should therefore carefully balance the breadth of their supply chain relationships, prioritizing those partnerships that provide the most relevant technological and sustainability-related knowledge. Moreover, the study underscores the critical role of digital supply chains and ICT-related partnerships in supporting environmental sustainability. Participation in ICT supply chains can facilitate access to digital technologies that enable greener operations, such as smart energy management systems, digital twins, and AI-based optimization tools. Managers should therefore consider digital partnerships not only as drivers of operational efficiency but also as key enablers of environmental sustainability, supporting data transparency, emissions monitoring and resource optimization across supply networks. Finally, the findings suggest that successfully navigating the twin transition requires firms to strategically orchestrate both digital and environmental capabilities across their supply networks. Managers should therefore develop governance mechanisms that facilitate knowledge sharing, coordination and joint problem-solving with supply chain partners. In doing so, supply chains can evolve from simple coordination structures into platforms for collective capability building, enabling firms to respond more effectively to the technological and environmental challenges associated with the twin transition.

Originality of the paper. The study builds on firm-level literature on TT, and in particular, on the stream of literature that has looked at the digital-for-green relation (Montresor & Vezzani, 2003; Biggi et al. 2025). We extend this model by looking at the role of participation in supply chains. The literature on supply chain management has addressed the relation between supply chain and environmental performance (Bowen et al. 2001; Vachon & Klassen, 2008; Di Maria et al. 2022), since supply chain partners contribute to the development and adoption of new environmental practices, products/services, and provide complementary resources and capabilities (e.g. Cainelli et al., 2015; Kesidou & Demirel, 2012; Aarikka-Stenroos et al., 2022). Recent contributions have studied the role of SC in fostering sustainability, while accounting for digitalisation (Di Maria et al. 2022). However, the evidence on the role of supply chains in a twin transition context is less explored (an exception is e.g. Jia et al. 2025 for Chinese listed companies). This study advances the existing empirical evidence by showing that supply chains are important inputs for sustainability investments because of the

exposure to multiple sources of knowledge, practices, regulations etc. In addition to providing such evidence, the study addresses the issue of the non-linearity of this relation: the contribution of supply chain exposure diminishes at higher level, suggesting that the participation in supply chains entails also costs (e.g. coordination cost of diverse supplies/clients, risk of redundant knowledge, compliance cost for too many regulations). As third element of originality, this study addresses two specific supply chains that may affect green sustainability, the EC and the IT.

Agentic Commerce and the Future of FMCG Marketing: Managerial Perspectives from Emerging AI-Mediated Marketplaces

ALESSANDRO IUFFMANN GHEZZI[1], SEBASTIANO GRANDI[2], MARIO BENCIVINNI[3]

Abstract. *The emergence of generative artificial intelligence and autonomous software agents is giving rise to an "agentic economy" in which AI systems increasingly act on behalf of consumers by interpreting preferences, navigating digital marketplaces, and executing transactions. By reducing communication frictions between consumers and firms, agentic technologies have the potential to fundamentally reshape market interactions and commercial ecosystems. This transformation is particularly relevant for the fast-moving consumer goods (FMCG) sector, where marketing strategies have traditionally relied on brand visibility and consumer engagement to influence purchase decisions. In an agent-mediated marketplace, however, AI agents may prioritize functional attributes such as price, ratings, availability, and delivery speed over traditional brand cues. This work-in-progress study explores the strategic implications of agentic commerce for FMCG marketing through qualitative interviews with senior managers from leading consumer goods companies across food and non-food categories. The study aims to identify emerging opportunities and challenges for FMCG firms as consumer decision processes increasingly become mediated by AI systems.*
Keywords: *agentic commerce; agentic economy; FMCG marketing strategy; AI-mediated consumer decision-making; AI in Marketing; Algorithmic Marketplaces.*

Framing of the research. Recent advances in generative artificial intelligence are enabling the emergence of what has been described as an "agentic economy", in which autonomous AI agents are increasingly capable of interpreting human intent, interacting with digital infrastructures, and executing complex tasks on behalf of users (Rothschild et al., 2025). In such an environment, consumers may rely on personal AI assistants to communicate preferences, search for information, evaluate alternatives, and interact with firms through automated digital systems. This shift has the potential to reduce communication frictions between consumers and businesses and to reorganize how market interactions occur (McKinsey, 2026). The growing diffusion of these technologies is giving rise to "agentic commerce", a new paradigm in which AI systems actively participate, or even autonomously conduct, key stages of the purchasing process (BCG, 2025). Rather than manually navigating digital interfaces, consumers may increasingly delegate activities such as product discovery, comparison, negotiation, and transaction execution to AI agents capable of scanning multiple platforms and identifying optimal choices based on user preferences and contextual information. In this sense, AI agents may become a primary interface between consumers and digital markets, potentially transforming how demand is expressed and how firms compete for visibility (Davenport et al., 2020).

Industry analyses suggest that the implications of this shift may extend beyond incremental improvements in digital commerce (McKinsey, 2025). AI agents embedded in consumer devices and digital ecosystems could fundamentally reshape how products and services are discovered, evaluated, and purchased, automating many of the activities traditionally performed by human consumers (McKinsey, 2026). As a result, purchasing processes may become increasingly mediated by algorithmic systems capable of continuously learning from user data and optimizing decisions across a wide range of alternatives. These developments raise important questions for marketing scholars and practitioners. In particular, when AI agents act as intermediaries between consumers and firms, the mechanisms through which brands attract attention and influence purchase decisions may change significantly. For instance, algorithmic systems may prioritize structured product attributes (such as price competitiveness, product ratings, delivery speed, and inventory availability) over traditional branding cues that typically influence human consumers (Alecsiou et al., 2025). Consequently, firms may need to rethink how marketing strategies, product information, and digital infrastructures are designed in order to remain visible and competitive in AI-mediated marketplaces.

These questions are particularly relevant in the fast-moving consumer goods (FMCG) sector, where purchasing decisions have historically been influenced by brand equity, packaging design, retail shelf visibility, and promotional activities. FMCG markets are characterized by frequent purchases, relatively low consumer involvement, and intense competition among brands operating in categories such as food, home care, and personal care. In such environments, brand recognition, retailer presence, and competition between national brands and private labels have traditionally played a crucial role in shaping consumer choice and category dynamics (Ailawadi & Keller, 2004; Dhar & Hoch, 1997).

However, if product discovery and evaluation are increasingly conducted by AI agents rather than human consumers, the sources of competitive advantage in FMCG markets may evolve. In agent-mediated marketplaces, product visibility may depend less on traditional communication strategies and more on how effectively firms structure and communicate product information to algorithmic systems (Alecsiou et al., 2025). At the same time, firms may need to develop new

technological capabilities and digital infrastructures capable of interacting with AI-driven commerce ecosystems. Despite the growing relevance of these developments, academic research on the marketing implications of agentic commerce remains limited, particularly within the context of consumer goods industries. While existing studies have examined the use of artificial intelligence in marketing analytics (Davenport et al., 2020), personalization (Huang and Rust, 2021), and operational decision-making (Huang and Rust, 2021), less attention has been devoted to how autonomous AI agents may reshape consumer decision processes and competitive dynamics in consumer markets.

Against this background, this study explores how firms operating in FMCG markets perceive and interpret the emergence of agentic commerce and how they may adapt their marketing strategies in response to AI-mediated purchasing processes. By examining managerial perspectives from multinational consumer goods companies operating in food and non-food categories, the research aims to identify early strategic interpretations and emerging responses to a transformation that may significantly reshape the future of marketing management.

Purpose of the paper. Building on the emerging discussion on the agentic economy and AI-mediated marketplaces, the purpose of this study is to explore the strategic implications of agentic commerce for fast-moving consumer goods (FMCG) firms. While the growing diffusion of AI agents is expected to reshape how consumers search for, evaluate, and purchase products online, the consequences of this transformation for marketing management remain largely underexplored, particularly in industries characterized by frequent purchases, strong brand competition, and complex retail ecosystems. The FMCG sector provides a particularly relevant empirical context for investigating these dynamics. Traditionally, firms operating in categories such as food, home care, and personal care have relied heavily on brand equity, packaging design, retail visibility, and promotional strategies to influence consumer choice (Keller, 1993; Dhar & Hoch, 1997; Chandon et al., 2009). However, as product discovery and evaluation increasingly occur through AI-mediated systems, the mechanisms through which brands gain visibility and competitive advantage may evolve (Davenport et al., 2020; Huang and Rust, 2021). When AI agents act as intermediaries between consumers and firms, purchasing decisions may increasingly depend on how algorithmic systems interpret and compare product attributes such as price, ratings, availability, and delivery conditions.

Against this background, this work-in-progress study investigates how FMCG companies perceive and interpret the rise of agentic commerce and how they may adapt their marketing strategies in response to AI-mediated purchasing processes. In particular, the study focuses on managerial perspectives from multinational consumer goods firms operating across food and non-food categories, with the aim of capturing early strategic interpretations and emerging responses to this technological transformation.

More specifically, the research addresses the following questions:

- ***(RQ1)*** *How do FMCG managers interpret the emergence of agentic commerce and its potential implications for consumer purchasing processes?*
- ***(RQ2)*** *How might AI agents reshape traditional mechanisms of brand visibility and differentiation in AI-mediated marketplaces?*
- ***(RQ3)*** *What strategic and organizational responses are FMCG firms considering in order to adapt to agent-mediated commerce ecosystems?*

By addressing these questions, the study aims to generate early empirical insights into how marketing strategies, brand management practices, and digital infrastructures may evolve as AI agents become increasingly involved in consumer decision processes and digital commerce environments.

Methodology. Given the exploratory nature of the research and the limited academic literature on agentic commerce in FMCG markets, this study adopts a qualitative research design aimed at capturing managerial interpretations and emerging strategic responses to AI-mediated commerce.

The empirical investigation is based on semi-structured interviews with senior managers operating in the fast-moving consumer goods (FMCG) sector, covering both food and non-food categories. Interview participants are selected using a convenience sampling approach, leveraging the researchers' access to industry professionals working in multinational consumer goods companies. The current sample includes four top managers from global firms operating in food and nutrition markets (e.g., Nestlé and Mars) as well as companies active in home and personal care categories. Additional interviews with executives from leading FMCG companies are planned in the next phase of the research in order to further expand the empirical base and deepen the analysis. The four informants currently included in the sample hold senior-level positions (director or head level) in functions directly relevant to the research questions — namely marketing, digital transformation, and innovation — across firms operating in food and nutrition and home and personal care categories, ensuring strategic visibility on both consumer-facing activities and the digital infrastructures underpinning them. To preserve confidentiality, firms and informants are anonymized in the presentation of findings.

The interview protocol focuses on three main areas:

(1) managerial perceptions of the emergence of AI agents and agentic commerce,
(2) expected implications for consumer purchasing processes and brand visibility, and
(3) strategic responses that firms may adopt to remain competitive in AI-mediated marketplaces.

Interviews are conducted with managers involved in functions such as marketing, digital transformation, and innovation, allowing the study to capture different organizational perspectives on the role of AI in shaping future commerce ecosystems. The collected data will be analyzed through thematic analysis, following an inductive coding

approach aimed at identifying recurring themes, emerging strategic patterns, and managerial interpretations of agentic commerce within the FMCG sector. As this research is currently work in progress, the empirical material will continue to be expanded through additional interviews with industry managers in order to refine the emerging insights and develop a richer understanding of how FMCG firms are preparing for AI-mediated consumer markets. The three thematic blocks of the protocol map directly onto the three research questions: managerial perceptions of agentic commerce address RQ1, the expected implications for consumer purchasing processes and brand visibility correspond to RQ2, and the strategic responses considered by firms relate to RQ3. Within each block, open-ended questions invited informants to elaborate on their interpretations, supported by follow-up probes to deepen relevant themes as they emerged. Interviews are recorded, transcribed, and complemented with secondary industry sources discussing the diffusion of agentic commerce and AI-driven marketplaces in order to contextualize and triangulate the empirical insights. Data analysis follows the Gioia methodology for qualitative research (Gioia et al., 2013), which allows researchers to build theoretical insights grounded in informant perspectives while progressively developing higher-order interpretations through the iterative identification of first-order concepts, second-order themes, and aggregate dimensions.

Results. The thematic analysis surfaced three aggregate dimensions through which managers interpret the strategic implications of agentic commerce in FMCG markets. These dimensions, summarized in Table 1, are developed below as distinct analytical themes.

Consumer Disintermediation. A first dimension emerging from the interviews concerns the progressive insertion of AI agents between consumers and brands, which managers interpret as a structural shift in how demand is expressed. Informants describe a near future in which routine purchasing — particularly grocery replenishment and recurring household consumption — is increasingly delegated to AI assistants that interpret preferences, organize shopping, and execute transactions on behalf of users. As one informant observes, "consumers may increasingly rely on AI assistants to organize their shopping and evaluate alternatives," while another notes that "the interaction with the brand could happen through the AI assistant rather than through the consumer interface." This dynamic is read by managers as the convergence of two trends: the maturation of autonomous agents on the supply side, and the consolidation of convenience-driven consumption on the demand side. The implication is that the locus of consumer–brand interaction shifts away from the traditional consumer interface and toward an algorithmic intermediary — disintermediating not the retailer, as in earlier waves of digital commerce, but the consumer herself as the active decision-maker.

Algorithmic Re-encoding of Brand Value. A second dimension captures how managers expect competitive mechanisms to change when product evaluation is performed by algorithmic intermediaries rather than by human consumers. Informants consistently describe a transition from symbolic and affective brand cues — packaging, shelf prominence, promotional visibility — toward structured, machine-readable attributes. As one manager from the home and personal care category puts it, "an AI agent will compare products differently from a human consumer: price, ratings, delivery time," adding that "the traditional shelf advantage may not exist in algorithmic environments." Managers interpret this not as the disappearance of brand value, but as its translation into a different code: trust signals, certifications, structured nutritional or performance data, and aggregated consumer feedback become the new currency of competition. Brand equity, in this reading, is re-encoded into attributes that algorithmic systems can parse, rank, and compare, with consequences for how differentiation is achieved and sustained.

Agent-Readiness as Strategic Capability. A third dimension concerns the organizational and technological transformations that managers consider necessary to operate in AI-mediated marketplaces. Informants describe agent-readiness as a composite capability spanning data architecture, digital infrastructure, and cross-functional coordination. One manager emphasizes the need to "build a consumer-responsive system that anticipates demand and uses data to guide decisions," while another stresses that "brands will need structured product information that digital systems and AI can interpret." Managers interpret these requirements as going beyond incremental digitalization: they imply integrating marketing strategy with product data systems, interoperable APIs, and digital catalog architectures, while developing new competencies at the intersection of marketing, IT, and data functions. In this view, agent-readiness emerges as a strategic capability in its own right — a precondition for visibility and competitiveness in commerce ecosystems where algorithmic intermediaries, rather than human consumers, increasingly determine which products are surfaced and selected.

Table 1 - Preliminary Data Structure (in progress)

First-order evidence	***Second-order themes***	***Aggregate dimensions***
"Consumers may increasingly rely on AI assistants to organize their shopping and evaluate alternatives." (Nestlé manager)	*Delegation of shopping tasks to AI agents*	*Consumer Disintermediation*
"The interaction with the brand could happen through the AI assistant rather than through the consumer interface." (Nestlé manager)	*AI as intermediary in consumer–brand relationships*	*Consumer Disintermediation*
"Food purchasing is increasingly driven by convenience and speed. AI agents	*Automation of routine purchase decisions*	*Consumer Disintermediation*

could easily optimize these decisions." (Mars manager)		
"Consumers' lives are busier than ever and increasingly demand convenience and efficiency in food choices." (Mars manager)	*Acceleration of convenience-driven consumption*	*Consumer Disintermediation*
"An AI agent will compare products differently from a human consumer: price, ratings, delivery time." (Home & Personal Care manager)	*Algorithmic evaluation of product attributes*	*Algorithmic Re-encoding of Brand Value*
"The traditional shelf advantage may not exist in algorithmic environments." (Home & Personal Care manager)	*Reduced role of traditional visibility cues*	*Algorithmic Re-encoding of Brand Value*
"We need to build a consumer-responsive system that anticipates demand and uses data to guide decisions." (Danone manager)	*Data-driven responsiveness to consumer demand*	*Agent-Readiness as Strategic Capability*
"Brands will need structured product information that digital systems and AI can interpret." (Danone manager)	*Structured product data for AI systems*	*Agent-Readiness as Strategic Capability*

As the research is currently work in progress, additional interviews with managers from multinational FMCG firms will be conducted in the next phase of the study to further refine the emerging themes, strengthen the empirical evidence, and deepen the understanding of how companies across different FMCG categories are preparing for the transition toward AI-mediated commerce ecosystems.

Research limitations. This study presents several limitations that should be acknowledged. First, the research adopts a qualitative and exploratory design, which aims to generate early insights rather than provide generalizable findings. While this approach is appropriate given the novelty of agentic commerce, the results should be interpreted as indicative rather than conclusive.

Second, the empirical material relies on a convenience sampling strategy, based on the researchers' access to managers in multinational FMCG firms. Although the sample includes experienced professionals from leading companies operating in food (e.g., Nestlé and Mars) and non-food categories, it may not fully capture the diversity of perspectives across the broader FMCG ecosystem, including smaller firms, retailers, or digital platform providers.

Third, the study focuses on managerial perceptions and expectations regarding agentic commerce rather than on fully developed or widely implemented practices. As highlighted by recent industry reports, many organizations are still in the experimentation or pilot phases of adopting AI agents, with large-scale deployment remaining relatively limited. Consequently, the findings reflect how managers interpret an emerging technological transformation rather than how agentic commerce is currently shaping consumer behavior in practice.

Finally, the research concentrates on the FMCG sector, which may limit the transferability of insights to other industries characterized by different purchasing dynamics, product involvement, or decision-making processes. Future research could extend the analysis to other sectors and incorporate additional empirical evidence, including consumer-side perspectives and longitudinal data, to better understand how agentic commerce evolves over time.

Managerial implications. The emergence of agentic commerce raises profound implications for managers operating in consumer goods industries. As AI agents increasingly act as intermediaries between consumers and firms, the mechanisms through which products are discovered, evaluated, and purchased may fundamentally change. In the emerging agentic economy, interactions between consumers and businesses are expected to increasingly occur through autonomous digital agents capable of interpreting preferences, exchanging information, and completing transactions on behalf of users. This transformation suggests that market interfaces may progressively shift from consumer-facing digital environments toward AI-mediated ecosystems in which algorithmic agents play a growing role in organizing demand and mediating commercial interactions.

For FMCG managers, this transformation implies a shift from consumer-facing marketing to agent-facing marketing strategies. In traditional digital commerce environments, firms design marketing activities to capture the attention of human consumers across multiple touchpoints, including advertising, packaging, brand storytelling, and retail visibility. In contrast, in agent-mediated marketplaces, AI systems may increasingly influence or execute purchasing decisions by prioritizing structured product attributes such as price, ratings, availability, nutritional information, or delivery speed. Product visibility and competitiveness may therefore depend less on persuasive communication and more on how effectively brands structure and communicate machine-readable information to algorithmic intermediaries capable of scanning, comparing, and selecting products on behalf of consumers.

Second, the rise of agentic commerce requires FMCG firms to rethink the digital infrastructure of marketing and commerce systems. Industry analyses suggest that companies will increasingly need to develop "agent-ready" digital

ecosystems, including structured product data architectures, interoperable APIs, and commerce interfaces capable of interacting directly with AI agents. In such environments, product data quality, metadata completeness, and digital catalog structures may become key determinants of algorithmic visibility. For firms operating in highly competitive categories such as food, home care, and personal care, ensuring that product information can be accurately interpreted and compared by AI systems may therefore become a critical capability for maintaining market presence.

Third, agentic commerce may also alter the strategic role of brand management. While strong brands have traditionally relied on emotional engagement, symbolic meaning, and consumer recognition, algorithmic intermediaries may evaluate products according to more functional and comparable criteria. However, this does not necessarily imply the decline of branding. Rather, brand equity may evolve into a signal of trust, reliability, and credibility within AI-mediated decision environments. In contexts where AI agents increasingly filter and recommend products, trusted brands may still play a key role in shaping algorithmic recommendations, particularly when agents rely on indicators such as brand reputation, product reliability, or consumer feedback as signals of quality.

Finally, the findings suggest that managers must develop new organizational capabilities to operate in AI-mediated markets. Many companies are already experimenting with AI across supply chains, consumer analytics, and operations in order to build more responsive and data-driven organizations. However, the transition toward agentic commerce may require deeper organizational transformations, including closer collaboration between marketing, IT, and data teams and the development of new competencies related to algorithmic visibility, AI governance, and digital ecosystem management. In particular, firms may need to integrate marketing strategy with data architecture and digital infrastructure design in order to ensure that product information and brand signals remain visible and interpretable within AI-driven commerce systems.

While the aggregate implications of agentic commerce apply broadly across FMCG markets, the empirical insights suggest that their managerial relevance may vary across product categories. For example, in food markets, AI agents may increasingly support routine grocery purchasing decisions and optimize recurring consumption patterns, while in home and personal care categories algorithmic systems may place greater emphasis on functional product attributes such as performance indicators, product ratings, and comparative evaluations. Building on the aggregate dimensions emerging from the Gioia analysis, Table 2 summarizes below the main managerial implications of agentic commerce for FMCG firms and highlights key priorities for managers operating in food and non-food categories.

Table 2 - Managerial Implications of Agentic Commerce for FMCG Firms

Aggregate dimension (from Gioia analysis)	***Implications for FMCG marketing***	***Category-specific considerations***	***Managerial priorities***
Consumer Disintermediation	*Consumer journeys may increasingly be mediated by AI assistants that search, compare, and purchase products on behalf of users. Brand interactions may therefore occur through algorithmic intermediaries rather than directly with consumers.*	***Food**: AI agents may optimize recurring purchases such as grocery replenishment, where convenience and routine consumption are central (Mars, Nestlé insights).* ***Home & Personal Care**: agents may facilitate comparison of functional attributes such as product performance, sustainability, and price.*	*Structure product information for machine interpretation and improve digital product metadata to increase visibility in AI-mediated marketplaces.*
Algorithmic Re-encoding of Brand Value	*AI agents may evaluate products using structured attributes such as price, ratings, delivery speed, nutritional information, or performance indicators rather than traditional branding cues such as packaging or shelf visibility.*	***Food**: attributes such as ingredients, nutritional values, or dietary compatibility may become increasingly relevant in algorithmic comparisons (Danone insights).* ***Home & Personal Care**: product reviews and functional performance indicators may play a greater role in AI-driven recommendations.*	*Strengthen structured product data, ensure transparency of key product attributes, and optimize digital discoverability across commerce platforms.*
Agent-Readiness as Strategic Capability	*Competing in AI-mediated marketplaces requires infrastructures that allow AI systems to access and interpret product information*	***Food**: integration of demand forecasting, personalized nutrition data, and digital retail systems.* ***Home & Personal Care**:*	*Develop agent-ready infrastructures (APIs, digital catalogs, product data systems) and foster cross-functional collaboration*

	and interact with digital commerce ecosystems.	*product data standardization and interoperability with digital retail platforms.*	*between marketing, IT, and data teams.*

Taken together, these implications suggest that the rise of agentic commerce represents not only a technological shift but also a managerial transformation, requiring FMCG firms to rethink the foundations of marketing strategy in markets increasingly mediated by intelligent agents.

Originality of the paper. This study contributes to the emerging debate on AI and marketing in the context of the agentic economy by examining the implications of agentic commerce within the fast-moving consumer goods (FMCG) sector. While recent research has highlighted how autonomous AI agents may transform digital commerce by acting on behalf of consumers and reducing communication frictions between consumers and businesses, the marketing implications of this transformation remain underexplored in academic literature.

The originality of this research lies in bringing the concept of agentic commerce into the domain of FMCG marketing, a context in which purchasing decisions have historically been influenced by brand equity, packaging, retail visibility, and consumer engagement. Existing industry analyses suggest that AI agents may increasingly mediate product discovery and purchase decisions by prioritizing functional attributes such as price, ratings, and product availability. However, little research has examined how these dynamics may affect branding strategies and competitive positioning in consumer goods markets. Furthermore, the study adopts a managerial perspective grounded in qualitative insights from industry practitioners, including managers from multinational FMCG firms operating across food and home and personal care categories. By capturing how managers interpret and prepare for the rise of agentic commerce, the research provides early empirical insights into a phenomenon that is still emerging in practice.

In doing so, the paper responds to the growing call for research exploring the intersection between artificial intelligence and marketing strategy, particularly from a managerial perspective. By investigating how FMCG firms may need to rethink brand visibility, digital infrastructures, and strategic capabilities in AI-mediated marketplaces, the study contributes to understanding how marketing management may evolve in the era of agentic commerce.

Algorithmic Recommendations and Consumer Decision-Making: Experimental Evidence from a Food Product Study

RAFFAELE CAMPO[1], PIERPAOLO DI BITONTO[2], PIERFELICE ROSATO[3], SAVINO SANTOVITO[4]

Abstract. *Recommender systems have become a key component of digital marketing strategies, enabling firms to personalize consumer experiences and influence purchasing decisions. This study examines whether similarity-based recommendation mechanisms can affect consumer perceptions and substitution intentions. An experimental design was implemented in the food sector using biscuit products as a controlled consumption context. Participants evaluated four biscuits based on nine sensory attributes, including sweetness, chocolate intensity, crunchiness, and texture. A similarity analysis based on Euclidean distance was conducted to identify the product most comparable to a newly introduced biscuit, simulating the logic of a content-based recommender system. The results show that the recommended product was perceived as highly similar and that most participants were willing to accept the suggested substitution. These findings provide empirical evidence on the behavioral relevance of attribute-based recommendation mechanisms.*
Keywords: *recommender systems; algorithm; sensory; food; consumers; digital environment*

Framing of the research. *Recommender systems have become a central component of digital marketing strategies, significantly influencing consumer behavior and online purchasing decisions. As highlighted by Djakasaputra et al. (2021), digital marketing tools are increasingly used to enhance consumer engagement, increase sales, reduce costs, and strengthen brand image. Within this technological landscape, recommender systems represent one of the most impactful applications of artificial intelligence, as they enable firms to personalize interactions and influence purchasing decisions. Bachri et al. (2023) emphasize that digital marketing technologies affect customer satisfaction through their influence on purchase decisions, particularly when personalization mechanisms are effectively implemented.*

Personalization is widely recognized as a strategic advantage in electronic commerce. Wind and Rangaswamy (2001) introduced the concept of "customerization" arguing that digital environments allow firms to move from mass communication to individualized offerings. Postma and Brokke (2002) further explain that personalization improves performance by delivering immediate and relevant information to consumers, thereby increasing the likelihood of additional sales. Similarly, Srinivasan, Anderson, and Ponnavolu (2002) demonstrate that personalized online experiences strengthen customer loyalty and long-term engagement. In this context, recommender systems operationalize personalization by suggesting products based on user preferences, browsing history, or behavioral patterns. According to the e-Tailing Group (2003), the ability to provide tailored recommendations is one of the most promising tools for improving online retail performance. Recommendations may derive from user-generated content or algorithmic systems; West et al. (1999) note that both peer reviews and system-generated suggestions shape consumer perceptions and influence decision-making.

A foundational definition of recommender systems was proposed by Resnick and Varian (1997), who described them as systems that aggregate user input and deliver recommendations to potentially interested individuals. Their work highlighted the importance of collective intelligence in digital environments. Burke (2002) later expanded this definition, including a broader range of systems that suggest items regardless of the specific algorithmic mechanism employed. This evolution reflects the growing sophistication of recommendation technologies, which now rely on advanced data processing and predictive modeling techniques.

The literature identifies several typologies of recommender systems. Content-based filtering recommends items similar to those previously preferred by the user, relying on product attributes and individual interaction history. While this approach ensures high levels of personalization, it may limit exposure to diverse alternatives. Collaborative filtering, in contrast, is based on similarities among users, assuming that individuals with comparable behaviors will share preferences. Although highly effective in large datasets, collaborative filtering faces the "cold start" problem when limited data are available. To address these limitations, hybrid systems combine multiple techniques to enhance predictive accuracy and recommendation diversity. Additional models include knowledge-based systems, demographic-based systems, and utility-based systems, each designed to adapt recommendations to specific contexts and decision environments.

Beyond their technical functioning, recommender systems exert a significant influence on consumer behavior across the customer journey. Liu et al. (2022) underline how digital environments facilitate the sharing of reviews and opinions, which directly affect purchase intentions. Adam et al. (2022) further highlight the role of digital platforms in shaping brand image through interactive engagement. Recommender systems contribute to awareness by introducing new products, enhance engagement by increasing interaction time, and facilitate conversion by reducing uncertainty and

perceived risk. Continuous personalization also reinforces loyalty by encouraging repeat purchases and long-term relationships with the brand.

From a psychological perspective, recommender systems reduce cognitive effort and simplify decision-making processes. By presenting curated options, they mitigate information overload and increase confidence in purchase decisions. At the same time, repeated exposure to specific products may influence the formation of preferences, suggesting that algorithms not only reflect but also shape consumer tastes. This dynamic reinforces their strategic relevance within digital marketing.

However, the literature also highlights important ethical and social implications. The extensive collection and processing of personal data raise concerns about privacy and trust. If consumers perceive data practices as intrusive or opaque, their confidence in the platform may decline. Furthermore, the lack of transparency in algorithmic processes—often described as "black box" systems—can affect perceptions of fairness and autonomy. Another concern relates to the potential creation of filter bubbles, where users are repeatedly exposed to similar products, limiting diversity and exploration. Algorithmic bias represents an additional structural risk, as systems trained on biased data may reproduce or amplify existing inequalities.

Overall, the literature demonstrates that recommender systems are powerful strategic tools capable of enhancing personalization, increasing customer satisfaction, and improving firm performance. Drawing on the foundational contributions of Resnick and Varian (1997) and Burke (2002), as well as the broader digital marketing framework discussed by Wind and Rangaswamy (2001), Postma and Brokke (2002), Srinivasan et al. (2002), Djakasaputra et al. (2021), Liu et al. (2022), Adam et al. (2022), and Bachri et al. (2023), it becomes evident that recommendation technologies play a crucial role in shaping modern consumption experiences. At the same time, their effectiveness must be balanced with ethical responsibility, transparency, and careful data management to ensure sustainable and trust-based relationships between firms and consumers. In terms of gaps: while recommender systems have been widely studied in online retail environments, less research has explored how attribute-based similarity recommendations influence consumer substitution behavior in offline experimental settings.

Purpose of the paper. *The primary objective of this study is to analyze the role and impact of recommender systems within digital marketing, with particular emphasis on their influence on consumer behavior and purchasing decisions. As digital environments become increasingly data-driven and personalized, understanding how algorithmic recommendation mechanisms shape consumer perceptions, preferences, and choices has become both academically relevant and strategically important for firms.*

This research aims to bridge the theoretical discussion on recommender systems with empirical evidence by examining how personalized suggestions affect consumers in a controlled experimental context. Specifically, the study seeks to investigate whether algorithm-based recommendations can meaningfully influence product evaluation, perceived similarity, and substitution intentions. By focusing on a practical application within the food sector, the research moves beyond abstract theoretical models and explores how recommendation logic operates in a real consumption setting.

Another key objective is to assess the feasibility and effectiveness of a simplified recommender system built on product similarity analysis. Through the evaluation of specific product attributes—such as sweetness, crunchiness, and texture—the study examines whether consumers are willing to substitute a new product with a recommended alternative that shares similar characteristics. This approach allows for a deeper understanding of how attribute-based filtering mechanisms may guide consumer decisions.

Ultimately, the study aims to contribute to the broader academic debate on the behavioral impact of digital personalization tools. By combining theoretical insights with experimental findings, the research seeks to evaluate not only the technical applicability of recommender systems but also their practical implications for consumer autonomy, decision-making processes, and marketing strategy development.

Methodology. *This study adopts an experimental research design to evaluate the impact and feasibility of a simplified recommender system based on product similarity. The research focuses on the food sector, specifically on different types of biscuits, in order to simulate a realistic consumer choice context while maintaining control over product attributes.*

The experimental approach is based on the collection of primary data through a structured questionnaire. Participants were asked to evaluate four different biscuit products: three well-known products (Gocciole, Gocciolotti, and Frollini) and a new product (Grottoli). The objective was to analyze perceived similarity between the new product and the existing ones, simulating the logic of a content-based recommender system.

The evaluation was conducted using nine analytical variables representing key sensory and product characteristics: sweetness, chocolate intensity, crunchiness, butteriness, hardness, compactness, texture consistency, dryness, and saltiness. Respondents expressed their assessments using a rating scale, allowing for quantitative comparison across products. These attributes were selected to reflect measurable and comparable product features, enabling the construction of a similarity analysis based on aggregated consumer perceptions.

Following data collection, a similarity analysis was performed to determine which of the three existing products was most comparable to the new product (Grottoli). The similarity comparison was conducted by analyzing the average ratings assigned to each attribute and measuring the distance between products across the nine variables. The product with the smallest overall difference in attribute ratings was identified as the most similar alternative.

Based on these results, a simplified recommender system logic was simulated: if Grottoli were unavailable, the system would recommend the product with the highest similarity score. To evaluate the practical applicability of this mechanism, participants were asked whether they would consider substituting Grottoli with the recommended product. This step allowed for the assessment of substitution intention and perceived acceptability of algorithm-based recommendations.

The methodology therefore integrates quantitative similarity analysis with behavioral evaluation, linking algorithmic logic to consumer decision-making processes. By focusing on attribute-based comparison, the study replicates the functioning of a content-based filtering system in a controlled experimental setting. This approach makes it possible to examine not only the technical feasibility of recommendation mechanisms but also their influence on consumer perceptions and purchase intentions.

Overall, the chosen methodology ensures internal consistency between theoretical framework and empirical investigation, providing measurable evidence on how recommender systems may guide product substitution decisions in a realistic consumption context.

Results. *The experimental design consisted of three main phases: the initial sensory evaluation of three biscuit products, the introduction of a fourth product for comparative analysis, and the validation of the recommendation through a substitution willingness assessment. The overall objective was to identify the biscuit most similar to the newly introduced product and to determine whether consumers would accept the recommendation generated through the similarity analysis. The experiment involved 60 participants, who were asked to evaluate three different biscuit products. The biscuits considered in the first stage of the experiment were:*

Gocciole (Pavesi – Barilla Group)

Gocciolotti (Balocco)

Frollini with chocolate chips (Le Bon – MD supermarkets)

Participants were required to taste the biscuits while blindfolded in order to minimize brand influence and avoid biases related to packaging, marketing, or brand reputation. This methodological choice ensured that the evaluations were based solely on the sensory characteristics of the products rather than on external cues.

Each participant evaluated the biscuits according to nine analytical sensory attributes: Sweetness- Chocolate flavor intensity- Crunchiness- Butteriness- Hardness- Compactness- Texture consistency- Dryness- Saltiness. The ratings were collected through a structured questionnaire using numerical scales that allowed participants to assign a score to each attribute.

Sensory Evaluation of the Initial Biscuit Set

After collecting the responses from participants, the dataset was organized and prepared for statistical analysis. The first step consisted of computing the average score for each sensory attribute for every biscuit. These averages represent the collective perception of the product characteristics among the respondents. The calculation of these averages was performed using the statistical software RStudio, which allowed efficient manipulation and processing of the dataset.

The mean values obtained represent the aggregated sensory profile of each biscuit. These profiles serve as the basis for the similarity comparison conducted in the following phase of the analysis. The descriptive statistics generated from the dataset made it possible to observe the general sensory tendencies associated with each product. Some biscuits displayed higher levels of sweetness or chocolate flavor, while others showed different structural characteristics such as greater crunchiness or dryness. Such variations are important because they form the basis of the similarity analysis that underpins the recommendation system developed in the study.

Introduction of the Fourth Biscuit and Data Collection

In the second phase of the experiment, a new biscuit was introduced into the analysis: Grottoli, produced by Divella. The objective of introducing this fourth product was to test whether it could be recommended to consumers based on its sensory similarity to the biscuits previously evaluated. To ensure methodological consistency, the Grottoli biscuit was presented to a subset of participants who had already taken part in the initial evaluation. Specifically, the second questionnaire was administered to the first 20 participants from the initial sample.

As in the previous tasting session, participants were blindfolded during the sensory evaluation to prevent brand recognition or visual cues from influencing their judgments. Participants were again asked to evaluate the product according to the same nine sensory attributes used in the first phase. Maintaining the same evaluation criteria ensured that the data collected were directly comparable with the evaluations of the other biscuits. This methodological approach allowed the researchers to generate a sensory profile for Grottoli biscuit and subsequently compare it with those of the other products included in the study.

Fig.1: The 4 kinds of biscuits

Similarity Analysis Between Biscuit Products

After obtaining the mean sensory profiles for all biscuits, the next step consisted of measuring the degree of similarity between the Grottoli biscuit and the other products.

The comparison was performed using Euclidean distance, a mathematical measure commonly used in data analysis to determine the similarity between vectors. In this context, each biscuit was represented as a vector containing the mean scores of the nine sensory attributes. The Euclidean distance between two biscuits can therefore be interpreted as the overall difference between their sensory profiles. A smaller distance indicates a higher level of similarity between the two products. The similarity analysis was conducted through three pairwise comparisons:

Gocciole vs Grottoli
Gocciolotti vs Grottoli
Frollini MD vs Grottoli

Each comparison involved extracting the relevant variables from the dataset and computing the mean values for the two biscuits being analyzed. The resulting vectors were then used to calculate the Euclidean distance.

Similarity Between Gocciole and Grottoli

The first comparison examined the relationship between Biscuit 1 (Gocciole) and Biscuit 4 (Grottoli).

The mean sensory values for Gocciole were calculated for all nine attributes, producing the following profile:

Sweetness: 4.60
Chocolate flavor: 4.90
Crunchiness: 5.00
Butteriness: 4.45
Hardness: 4.25
Compactness: 5.70
Consistency: 6.00
Dryness: 2.85
Saltiness: 1.70

These values reflect the average perception of the biscuit's sensory characteristics among the participants.

The Grottoli biscuit, by contrast, displayed a different sensory profile:

Sweetness: 6.10
Chocolate flavor: 3.55
Crunchiness: 4.45
Butteriness: 4.90
Hardness: 4.55
Compactness: 4.95
Consistency: 5.00
Dryness: 3.00
Saltiness: 2.90

The Euclidean distance between the two vectors was calculated using RStudio. The resulting value indicated a moderate level of similarity between the two biscuits, suggesting that while they share some sensory characteristics, their overall profiles are not identical.

Formula of the Euclidean distance: $$d(P,Q) = \sqrt{\sum_{i=1}^{n}(q_i - p_i)^2}$$

The Euclidean distance between Gocciole and Grottoli sensory vectors was 2,7735.

Similarity Between Gocciolotti and Grottoli

The second comparison involved Biscuit 2 (Gocciolotti) and Biscuit 4 (Grottoli).
The average sensory profile for Gocciolotti was as follows:

Sweetness: 5.65
Chocolate flavor: 5.10
Crunchiness: 4.30
Butteriness: 4.65
Hardness: 4.15
Compactness: 4.20
Consistency: 4.30
Dryness: 3.00
Saltiness: 3.05

The Euclidean distance between Gocciolotti and Grottoli sensory vectors was calculated and resulted in a value of 1.9812, which was lower than the distances observed in the other comparisons.

This result indicates that Gocciolotti is the biscuit whose sensory characteristics most closely resemble those of Grottoli. In practical terms, this means that the two products share a highly similar sensory profile across the nine attributes considered in the study.

Similarity Between Frollini MD and Grottoli

The third comparison examined the relationship between Biscuit 3 (Frollini) and Biscuit 4 (Grottoli).
The mean sensory profile of Frollini was:

Sweetness: 6.15
Chocolate flavor: 6.70
Crunchiness: 4.65
Butteriness: 5.20
Hardness: 4.40
Compactness: 3.55
Consistency: 3.50
Dryness: 3.10
Saltiness: 4.15

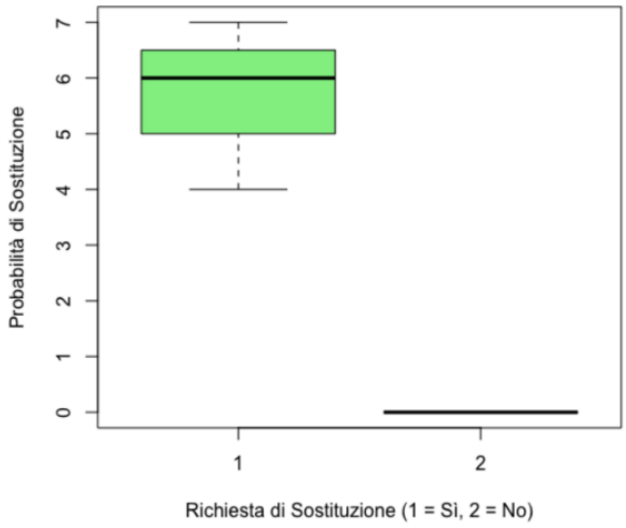
The Euclidean distance between Frollini MD and Grottoli sensory vectors was calculated as 3.9825, which represents a substantially higher value compared to the other comparisons. This result suggests that Frollini is the biscuit that differs the most from Grottoli among the products considered.

Summary of Similarity Results

The comparison of Euclidean distances across the three product pairs revealed a clear ranking of similarity.

Among the biscuits analyzed, Gocciolotti demonstrated the highest degree of similarity to Grottoli, as indicated by the smallest Euclidean distance value. This finding implies that, from a sensory perspective, consumers who appreciate Gocciolotti might also find Grottoli to be a satisfactory alternative.

Comparison	*Euclidean Distance*
Gocciole – Grottoli	*2,7735*
Gocciolotti – Grottoli	*1.9812*
Frollini – Grottoli	*3.9825*



The results clearly show that the second biscuit represents the closest match to the fourth product.

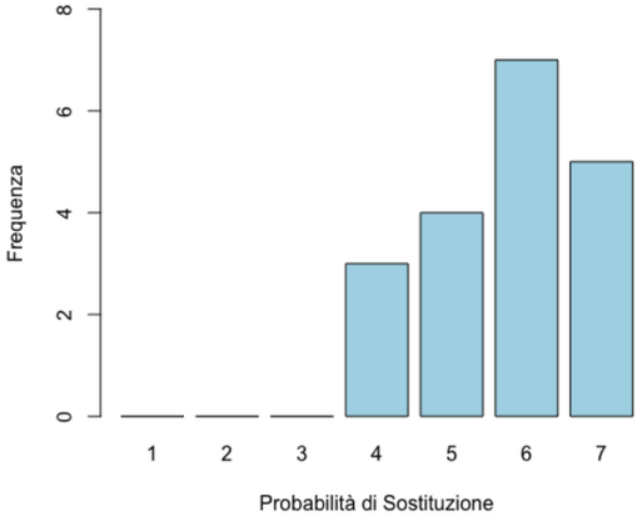
Feasibility Analysis of the Recommendation System

After identifying Gocciolotti as the biscuit most similar to Grottoli, the final stage of the experiment aimed to test the practical feasibility of the recommendation system. Participants who had initially expressed a preference for Gocciolotti were selected for a follow-up test. These individuals were invited to taste both the Grottoli biscuit and the Gocciolotti biscuit and were subsequently asked whether they would consider replacing their preferred product with the recommended alternative. The responses were recorded in a dedicated dataset and analyzed using RStudio.

The analysis involved computing the absolute frequency of substitution responses, which indicated how many participants were willing to replace their preferred biscuit with the recommended product.

Fig.1. Frequency distribution of substitution responses

Source: Our own elaboration



Distribution of Substitution Probability

In addition to the binary substitution responses, participants were also asked to rate the probability of substitution on a scale from 1 to 7, where higher values indicated a greater willingness to accept the recommended product.

The distribution of these responses was visualized through a bar chart generated in RStudio.

The results showed that the highest frequencies corresponded to the values 6 and 7, indicating a relatively strong willingness among participants to accept the substitution. This result provides empirical support for the hypothesis that similarity-based recommendation systems may influence consumer acceptance of alternative products.

Research limitations. *This study should be interpreted as an exploratory proof-of-concept and therefore presents several limitations. First of all, the sample size is relatively small, particularly in the second phase of the experiment, which limits the generalizability of the findings and calls for caution in extending the results to broader consumer populations. Future studies should replicate the analysis on larger and more heterogeneous samples in order to strengthen external validity. The experimental setting- furthermore- was intentionally simplified to isolate the role of sensory similarity in substitution decisions. Participants evaluated products exclusively on the basis of sensory attributes, while other factors that typically influence consumer choice in real market environments—such as price, brand reputation, packaging, promotions, availability, and prior loyalty—were deliberately excluded. As a consequence, the findings do not capture the full complexity of actual purchasing behavior, but rather identify the potential behavioral relevance of attribute-based similarity under controlled conditions. In addition, the similarity analysis relies on aggregated mean ratings across attributes rather than on individual-level preference structures. While this choice is consistent with the exploratory*

purpose of the study and allows for a clear simulation of a simplified content-based recommendation logic, it may mask heterogeneity in consumer tastes and attribute salience. Future research could address this issue by employing individual-level weighting schemes, segmentation procedures, or more advanced predictive models able to account for preference variability. Last but not least, the study does not test a recommender system in a live digital environment, but simulates a recommendation mechanism through attribute-based product comparison in an experimental context. For this reason, the results should not be interpreted as a full validation of recommender systems in online retail platforms; rather, they provide preliminary evidence that perceived product similarity may support substitution acceptance. Further research should extend this framework to real or simulated digital choice environments in order to assess its ecological validity more fully.

Managerial implications. *The results of this study confirm the practical applicability of a simplified content-based recommender system based on product attribute similarity. The empirical analysis demonstrates that it is possible to identify a substitute product through the comparison of sensory characteristics and that this similarity is reflected in consumers' substitution intentions. The findings show that Grottoli is perceptually closest to Gocciolotti and that a majority of respondents declared their willingness to accept the suggested alternative if the original product were unavailable. This indicates coherence between the similarity calculation and consumer behavioral response. The recommendation logic applied in the study therefore appears consistent with actual consumer evaluations.*

The analysis also highlights that certain attributes, such as sweetness and chocolate intensity, contributed more significantly to perceived similarity, as reflected in the comparison of mean values across products. This suggests that similarity based on concrete and measurable product characteristics can effectively support substitution decisions.

From a practical perspective, the study indicates that companies may reduce the negative effects of product unavailability by recommending alternatives that share similar sensory attributes. The results therefore support the feasibility of applying structured attribute analysis in the development of recommendation mechanisms within the food sector.

Originality of the paper. *The study applies recommendation logic to the concept of product substitution in the food sector, an area that has received comparatively less attention in the recommender systems literature. By empirically linking similarity measurement to substitution intention, the research provides a concrete behavioral validation of content-based filtering mechanisms.*

The use of sensory attributes as measurable variables to simulate algorithmic recommendation also represents an innovative methodological contribution, bridging marketing research and algorithmic modeling in a controlled experimental framework.

The study contributes to the literature by linking algorithmic similarity analysis with consumer behavioral responses, providing experimental evidence on how content-based recommendation mechanisms may shape product substitution decisions.

Antropomorfismo visivo, stile comunicativo e tipologia di prodotto come determinanti dell'intenzione d'acquisto: verso un principio di coerenza tri-dimensionale nella progettazione degli assistenti virtuali

SONIA CATERINA GIACCONE[1], MARCO GALVAGNO[2], ANDREA PARASOLE[3]

Abstract. *Il lavoro esamina come la coerenza tra antropomorfismo visivo dell'assistente virtuale, stile comunicativo e tipologia di prodotto influenzi l'intenzione di acquisto del consumatore. Attraverso una ricognizione della letteratura e l'analisi esplorativa di due casi aziendali – Amazon Rufus e Qatar Airways Sama – lo studio evidenzia che non esiste un assistente virtuale universalmente efficace, poiché la sua efficacia dipende dall'allineamento tra le caratteristiche dell'agente e la natura utilitaristica o edonistica dell'offerta. Il lavoro formula tre proposition e propone un principio di coerenza tri-dimensionale come criterio progettuale per gli assistenti virtuali nei contesti di vendita, da verificare nella successiva fase sperimentale della ricerca. Il paper si configura come contributo teorico preliminare all'interno di un progetto di ricerca più ampio attualmente in corso.*
Keywords: *assistenti virtuali; antropomorfismo visivo; stile comunicativo; intenzione di acquisto; prodotti edonistici; prodotti utilitaristici*

Framing of the research. L'utilizzo di assistenti virtuali basati sull'intelligenza artificiale nelle relazioni con i clienti si sta rapidamente diffondendo in numerosi settori, dalla cura della salute (Bavaresco et al., 2020; Laranjo et al., 2018; Montenegro et al., 2019) al retail (Dangol, Rind, 2024; Jan et al., 2023; Kim, Hur, 2023; Leung, Yan Chan, 2020). Ciò ha stimolato un crescente interesse degli studiosi volto a comprendere in che modo questi agenti possano influenzare il comportamento del consumatore. Dai semplici chatbot testuali fino ai digital human fortemente somiglianti agli esseri umani, gli assistenti virtuali operano lungo un ampio spettro di configurazioni visive e comunicative, ponendo una questione centrale su cosa renda efficace un assistente AI nel processo d'acquisto. Alcune ricerche hanno evidenziato come la progettazione di specifici aspetti di un agente conversazionale – tra cui il suo antropomorfismo visivo (cioè il grado in cui un agente non umano incorpora elementi visivi tipicamente umani, tali da evocare una percezione di umanità in chi interagisce), i suoi segnali comportamentali e i tratti identitari – possa influenzare percezioni e comportamenti dei consumatori (Pavone et al., 2023). In particolare, Go e Sundar (2019) hanno dimostrato che i segnali di umanizzazione, siano essi visivi, identitari o comunicativi, plasmano la percezione che i consumatori hanno dei chatbot e influenzano la loro disponibilità a interagire. La ricerca, basandosi sulla teoria della violazione delle aspettative di Burgoon ed Hale (1988), evidenzia altresì che l'incoerenza tra l'aspetto di un agente e il suo comportamento comunicativo genera effetti negativi sul consumatore, tra cui la riduzione della fiducia e il disagio percepito.

La review di Cihodaru-Ștefanache e Podina (2025) ha precisato che questo effetto di incoerenza emerge non soltanto dall'aspetto fisico dell'agente, ma anche dal disallineamento tra caratteristiche visive e comportamento comunicativo, ed è tanto più pronunciato quanto più alto è il grado di antropomorfismo visivo. Pertanto, se un agente appare fortemente umano genera aspettative elevate nel consumatore; ma qualora non comunichi in modo coerente con tale aspetto, gli utenti sperimentano incoerenza cognitiva, riduzione della fiducia e tendenza all'evitamento. Tale meccanismo si ricollega al fenomeno della uncanny valley (Mori et al., 2012; Wang et al., 2015), che descrive il disagio che gli utenti provano quando interagiscono con agenti che si avvicinano eccessivamente all'aspetto umano senza raggiungere un livello di realismo convincente.

Sul piano delle dimensioni valutative, Belanche et al. (2021) hanno dimostrato empiricamente, in un contesto di robot fisici, che la competenza percepita genera valore funzionale mentre il calore percepito genera valore emotivo. Questa distinzione suggerisce che il profilo comportamentale di un agente – ovvero se proietta prevalentemente competenza o calore – determina il tipo di valore che esso offre al consumatore. Zourrig et al. (2025), in un contesto di virtual influencer su Instagram, hanno ulteriormente precisato che le dimensioni di calore e competenza mediano il legame tra antropomorfismo visivo e social presence, e quindi l'intenzione d'acquisto: un agente con elevato antropomorfismo evoca attese di calore e competenza che, se confermate, attivano la presenza sociale e sostengono le intenzioni comportamentali. Altre ricerche hanno esteso questa logica alla dimensione comunicativa degli agenti AI. Cai et al. (2024) hanno identificato due distinti stili comunicativi nelle interazioni con i chatbot: uno stile task-oriented, caratterizzato da dialogo formale, orientato agli obiettivi ed efficiente, e uno stile social-oriented, caratterizzato da comunicazione personalizzata, empatica e relazionale. I loro risultati mostrano che lo stile social-oriented genera percezioni più elevate di calore e, di conseguenza, maggiore soddisfazione nell'interazione, fiducia e intenzione di acquisto nel contesto del recupero da service failure. Chen et al. (2025), attraverso una serie di studi sperimentali sui robot, hanno dimostrato che lo stile social-

[1] Università degli studi di Catania, email: sonia.giaccone@unict.it
[2] Università degli studi di Catania, email: marco.galvagno@unict.it
[3] Università degli studi di Catania, email: andrea.parasole@studium.unict.it

oriented genera una maggiore propensione all'uso rispetto allo stile task-oriented, con le emozioni positive come variabile mediatrice di questa relazione. Il tipo di servizio modera l'intensità di questo effetto: la mediazione delle emozioni positive è significativamente più forte in contesti edonistici che in contesti utilitaristici, sebbene lo stile social-oriented risulti superiore al task-oriented in entrambi i contesti.

Un'ulteriore dimensione rilevante è rappresentata dalla natura del prodotto. In letteratura, la distinzione tra prodotti utilitaristici ed edonistici è consolidata: i prodotti utilitaristici sono caratterizzati da attributi funzionali e strumentali, rispondono a bisogni pratici e attivano una modalità di elaborazione prevalentemente cognitiva e razionale; i prodotti edonistici sono invece associati ad attributi esperienziali, sensoriali ed emotivi, e attivano una modalità di elaborazione affettiva (Batra e Ahtola, 1991; Voss et al., 2003). Longoni e Cian (2022) hanno dimostrato che la preferenza dei consumatori per raccomandazioni generate dall'AI varia in funzione della natura utilitaristica o edonistica del prodotto. Per i prodotti utilitaristici i consumatori si fidano delle raccomandazioni da parte di un agente AI, percepito come razionale e logicamente valutante; per i prodotti edonistici preferiscono invece gli umani, ritenuti più adatti a valutare attributi esperienziali. Ciò non implica che l'AI sia strutturalmente inadatta ai contesti edonistici, ma evidenzia la sfida di ridurre la distanza percepita tra l'agente AI e l'umano attraverso scelte di aspetto e comportamento comunicativo coerenti con le aspettative affettive del consumatore.

In coerenza con questi risultati, Lan et al. (2024), attraverso una serie di studi sperimentali su assistenti vocali AI, hanno dimostrato che gli utenti esprimono una maggiore intenzione di continuare a utilizzare l'assistente quando lo stile linguistico è congruente con il contesto di servizio: il linguaggio astratto è preferito in contesti a dominanza edonistica, mentre il linguaggio concreto è più efficace in contesti a dominanza utilitaristica. Questo effetto è mediato dalla processing fluency, ovvero dalla facilità percepita nell'elaborare le risposte dell'agente. La corrispondenza tra stile linguistico e contesto di servizio genera quindi un effetto di congruità che migliora la valutazione dell'assistente e la propensione al suo uso continuativo. Murtaza et al. (2024), attraverso tre studi sperimentali condotti su campioni statunitensi, hanno esaminato il ruolo dello stile comunicativo del chatbot (task-oriented vs. social-oriented), della complessità del task e della brand personality sulla fiducia del consumatore e sull'intenzione d'uso. I risultati mostrano che lo stile task-oriented genera maggiore fiducia in condizioni di alta complessità del task, e che l'antropomorfismo percepito media il legame tra stile comunicativo e intenzione d'uso. Questo studio, pur offrendo evidenze rilevanti sul ruolo congiunto di stile comunicativo e antropomorfismo percepito, non considera la natura edonistica o utilitaristica del prodotto né la dimensione visiva dell'agente.

Purpose of the paper. Gli studi sopra menzionati, pur evidenziando aspetti rilevanti della progettazione degli assistenti virtuali, non propongono un'analisi che consideri la sinergia tra dimensione visiva, stile comunicativo e natura del prodotto. Go e Sundar (2019) dimostrano che la coerenza tra antropomorfismo visivo e comportamento comunicativo è una condizione necessaria per non violare le aspettative dell'utente, ma non specificano quale stile comunicativo sia più efficace in relazione alla natura del prodotto. Cai et al. (2024) si concentrano sugli stili comunicativi e ne dimostrano l'efficacia, ma non li collegano né alla natura del prodotto né alla dimensione visiva dell'agente. Murtaza et al. (2024) offrono evidenze sul ruolo congiunto di stile comunicativo e antropomorfismo, operazionalizzato però come costrutto percepito, non come dimensione visiva di design, e intenzione d'uso, senza considerare la natura edonistica o utilitaristica del prodotto. Longoni e Cian (2022) analizzano la preferenza per la fonte della raccomandazione (AI vs. umano), in relazione alla tipologia di prodotto (edonistica vs. utilitaristica), ma non lo stile comunicativo dell'agente. Nessuno di questi studi ha testato in modo integrato la triplice relazione tra antropomorfismo visivo, stile comunicativo e tipologia di prodotto come determinanti congiunte dell'intenzione d'acquisto.

Alla luce di questo gap, il presente studio – in fieri e parte di un più ampio progetto di ricerca – si propone di esplorare il grado di antropomorfismo visivo dell'agente, il suo stile comunicativo e la natura del prodotto venduto come determinanti interdipendenti dell'efficacia dell'assistente virtuale sul comportamento del consumatore. La domanda di ricerca è la seguente:

RQ: Quale effetto esercita la sinergia tra antropomorfismo visivo, stile comunicativo e tipologia di prodotto sull'intenzione di acquisto del consumatore?

Il lavoro mira a dimostrare che non esiste un assistente virtuale universalmente efficace e che l'efficacia dipende dalla coerenza tra i tre elementi considerati. Si ritiene che tale coerenza non sia semplicemente auspicabile, ma costituisca una condizione necessaria per massimizzare l'intenzione d'acquisto.

Methodology. Lo studio adotta metodologie differenti nelle due fasi principali del disegno di ricerca. Il presente manoscritto appartiene alla prima fase, di natura logico-deduttiva, in cui è stata condotta un'analisi esplorativa della letteratura e un'analisi di due casi aziendali significativi per le differenti caratteristiche dell'assistente virtuale impiegato: Amazon, con l'assistente Rufus, e Qatar Airways, con l'assistente Sama.

L'analisi dei casi è stata condotta, in questa fase iniziale, attraverso fonti secondarie: report e statistiche aziendali, articoli, comunicati stampa e dati forniti da UneeQ. Si tratta di risultati parziali e preliminari: nel prosieguo della ricerca, l'analisi sarà completata mediante fonti primarie, tra cui interviste a manager aziendali e a consumatori, al fine di comprendere la strategia di progettazione dell'assistente in relazione al posizionamento aziendale e la percezione dei consumatori sull'interazione con l'agente.

La scelta dei due casi, che si riferiscono a tipologie di prodotto differenti – prevalentemente utilitaristico (Amazon) e prevalentemente edonistico (Qatar Airways) – consente di osservare scelte aziendali contrastanti e di sviluppare la riflessione, giungendo alla formulazione di proposition da testare nella seconda fase.

La seconda fase prevede un disegno sperimentale 2×2×2 con variabili manipolate come segue:

- Antropomorfismo visivo: basso livello (assenza di indizi visivi antropomorfi) vs. alto livello (elevata somiglianza all'essere umano);
- Stile comunicativo: task-oriented vs. social-oriented;
- Tipologia di prodotto: utilitaristico vs. edonistico.

Da questa articolazione derivano otto condizioni sperimentali che consentono di confrontare configurazioni coerenti e incoerenti rispetto alla natura del prodotto. La variabile dipendente principale sarà l'intenzione d'acquisto; variabili dipendenti secondarie, quali la competenza percepita e il calore percepito, saranno inserite come mediatori per testare non solo se la coerenza funziona, ma anche perché funziona – colmando così una lacuna metodologica segnalata dalla letteratura (Belanche et al., 2021; Zourrig et al., 2025). Ai partecipanti sarà chiesto di esporsi a specifici scenari di interazione con l'assistente virtuale e di esprimere le proprie valutazioni successive. In tal modo, sarà possibile accertare empiricamente se l'efficacia dell'assistente virtuale derivi non da singoli attributi assunti isolatamente, bensì dalla coerenza complessiva tra dimensione visiva, stile comunicativo e tipologia di prodotto, e se tale coerenza rappresenti una condizione necessaria per favorire l'intenzione di acquisto.

Results. L'analisi della letteratura ha evidenziato l'importanza di due fattori che caratterizzano la progettazione degli assistenti virtuali: il grado di antropomorfismo visivo, che può variare dall'assenza totale di indizi visivi antropomorfi fino all'elevata somiglianza all'essere umano; e lo stile comunicativo, che può essere task-oriented, se l'assistente si concentra a fornire informazioni in modo formale ed efficiente, oppure social-oriented, se risulta empatico e orientato alla relazione. (Cihodaru-Ștefanache, Podina, 2025; Go, Sundar, 2019) Tali elementi devono essere considerati non solo in modo coerente tra loro, ma anche in coerenza con la natura edonistica o utilitaristica del prodotto.

Il caso Amazon – Rufus. Lanciato nel luglio 2024 e integrato direttamente nell'app e nel sito di e-commerce di Amazon, Rufus è un assistente chatbot con assenza di indizi visivi antropomorfi (nessun volto, nessun corpo, nessuna voce), presentando esclusivamente un'icona astratta e una finestra di dialogo testuale. Lo stile comunicativo è task-oriented: sintetico, diretto, formale, privo di small talk. Ogni risposta è orientata al completamento della transazione; la prima cosa che Rufus chiede all'utente è "Per cosa hai bisogno di aiuto oggi?", senza alcun saluto.

Questa configurazione risulta coerente con il marketplace utilitaristico di Amazon, dove il consumatore arriva con un bisogno preciso e vuole trovare il prodotto giusto al prezzo giusto nel minor tempo possibile. Questo attiva una modalità valutativa razionale in cui la competenza percepita dell'assistente vale più del calore "umano". La coerenza tra basso antropomorfismo visivo e stile task-oriented risponde efficacemente a questa aspettativa.

I risultati commerciali, seppure non attribuibili esclusivamente all'assistente virtuale e da interpretare con la cautela metodologica necessaria in assenza di un termine di confronto rigoroso, sono indicativi: secondo quanto riportato da PYMNTS (2026), il CEO Andy Jassy ha dichiarato che nel 2025 circa 300 milioni di clienti hanno utilizzato Rufus; i clienti che interagiscono con l'assistente durante il processo d'acquisto hanno il 60% di probabilità in più di completare una transazione rispetto a chi non lo utilizza. Nel corso del 2025, Rufus ha contribuito a generare vendite incrementali per circa 12 miliardi di dollari (Ebrun, 2026). Durante il Black Friday 2025 le sessioni con Rufus hanno rappresentato circa il 40% del totale ma hanno generato il 66% degli acquisti, con un tasso di conversione pari a 3,5 volte quello delle sessioni senza assistente (The Drum, 2026).

Il caso Qatar Airways – Sama. Sama è una digital human sviluppata dalla società americana UneeQ, accessibile attraverso Qverse, la piattaforma virtuale di Qatar Airways. Il suo grado di antropomorfismo visivo è elevato: presenta un volto umano realistico con micro-espressioni facciali in tempo reale, gestualità naturale, battito delle ciglia, lievi movimenti del capo anche in ascolto, voce espressiva con lip-sync e divisa ufficiale della compagnia. La tecnologia Synanim™ di UneeQ è progettata specificamente per eliminare la staticità tipica degli avatar digitali, che è una delle cause principali dell'effetto uncanny valley.

Lo stile comunicativo di Sama è social-oriented: empatico, narrativo, caldo. Sama non si limita a rispondere a domande ma guida l'utente attraverso gli spazi virtuali con un tono da ospite, incoraggia la conversazione, usa descrizioni sensoriali per evocare il piacere del viaggio e simula ospitalità. La sua presenza travalica il contesto transazionale: Sama possiede un profilo Instagram autonomo (@samaonthemove), lanciato a gennaio 2025 (Qatar Airways Press Release, 2025), dove pubblica contenuti in prima persona – resoconti di viaggio, riflessioni personali, immagini delle destinazioni – costruendo una narrativa identitaria persistente che la configura come virtual influencer, non soltanto come strumento di assistenza. In questo senso, Sama non esiste solo nel momento dell'interazione con il cliente, ma mantiene una presenza continuativa nello spazio digitale.

Questa combinazione di aspetto e atteggiamento è coerente con il posizionamento strategico di Qatar Airways nel segmento premium del trasporto aereo. Il sovrapprezzo che un cliente accetta di pagare rispetto alla tariffa di una compagnia low-cost non remunera la funzione di trasporto in sé, ma l'esperienza sensoriale, emotiva e di status ad essa

associata. In questo contesto, un assistente freddo e funzionale sarebbe inadatto poiché spezzerebbe l'atmosfera esperienziale che l'azienda intende costruire. L'alto antropomorfismo visivo di Sama attiva i meccanismi emotivi tipici delle interazioni umane, trasformando la navigazione sul sito in un'anticipazione dell'esperienza di volo.

Come nel caso Amazon, i dati di performance vanno letti con la necessaria cautela, non essendo possibile, con le sole fonti secondarie disponibili, isolare il contributo dell'assistente da quello di altri fattori strategici: il profilo @samaonthemove ha raggiunto 379.000 follower nel primo anno dal lancio; la campagna immersiva QVerse[4] ha generato un ritorno sulla spesa pubblicitaria superiore al 1000% e un ROI di prodotto superiore al 200% (The Drum, 2023). Per l'anno fiscale 2024/2025 Qatar Airways ha annunciato profitti netti di 7,85 miliardi di QAR (circa 2,15 miliardi di dollari) e una crescita degli utili del 28%, attribuendo questo risultato alla strategia "Qatar Airways 2.0" di cui Sama costituisce un elemento cardine (Qatar Airways, 2025).

La matrice di coerenza tri-dimensionale e le proposition. L'esame congiunto dei due casi, alla luce della letteratura analizzata, induce a ritenere che l'efficacia dell'assistente virtuale non dipenda da singoli attributi isolati, bensì dal grado di coerenza tra le sue caratteristiche, specificamente il grado di antropomorfismo visivo e lo stile comunicativo, e la natura edonistica o utilitaristica del prodotto proposto.

In particolare, riteniamo che lo stile task-oriented in presenza di un basso grado di antropomorfismo visivo dell'assistente, tenda a massimizzare l'intenzione d'acquisto quando si tratta di prodotti utilitaristici; mentre riteniamo che lo stile social-oriented risulti più efficace, in abbinamento a un alto grado di antropomorfismo visivo, in relazione all'acquisto di prodotti edonistici. Tale deduzione trova fondamento teorico nella letteratura sull'uncanny valley (Mori et al., 2012; Cihodaru-Ștefanache, Podina, 2025): un agente che si avvicina all'aspetto umano senza raggiungerlo genererebbe nel consumatore una sensazione di incongruenza percettiva più disturbante – e più dannosa per l'intenzione d'acquisto – rispetto sia all'assenza totale di indizi visivi antropomorfi che alla presenza di un elevato grado di antropomorfismo (si veda Tabella 1).

Tabella 1 – Matrice di coerenza tra antropomorfismo visivo e stile comunicativo

Tipo di prodotto	Stile comunicativo	Basso antropomorfismo visivo	Alto antropomorfismo visivo
Prodotto edonistico	***Social-oriented***	Bassa coerenza	***Alta coerenza (caso Sama)***
	Task-oriented	Bassa coerenza	Bassa coerenza
Prodotto utilitaristico	***Social-oriented***	Bassa coerenza	Bassa coerenza
	Task-oriented	***Alta coerenza (caso Rufus)***	Bassa coerenza

Fonte: Ns. elaborazione

La matrice riportata nella Tabella 1 offre un quadro di sintesi dell'analisi fin qui condotta, mostrando le possibili combinazioni tra livello di antropomorfismo, stile comunicativo e tipologia di prodotto, e concentrandosi, in particolare, sulle configurazioni ad alta coerenza rilevate nello studio dei casi osservati, le quali appaiono maggiormente idonee a favorire l'efficacia dell'assistente virtuale. Le rimanenti combinazioni delle tre variabili identificano sei soluzioni di bassa coerenza e dunque di limitata efficacia, presentando un disallineamento su almeno una delle tre dimensioni considerate.

Quanto sopra evidenziato costituisce la premessa teorica delle proposition formulate qui di seguito:

P1: Un assistente virtuale caratterizzato da un basso livello di antropomorfismo visivo e da uno stile comunicativo task-oriented determina un livello più elevato di intenzione di acquisto nel caso di prodotti utilitaristici.

P2: Un assistente virtuale caratterizzato da un elevato livello di antropomorfismo visivo e da uno stile comunicativo social-oriented determina un livello più elevato di intenzione di acquisto nel caso di prodotti edonistici.

P3: Quando il livello di antropomorfismo visivo e lo stile comunicativo dell'assistente virtuale risultano incoerenti con la tipologia di prodotto proposta, l'intenzione di acquisto del consumatore risulta inferiore rispetto ai casi in cui tali elementi appaiono coerenti.

Research limitations. Il presente lavoro si trova in una fase ancora iniziale e i risultati qui presentati sono preliminari e non definitivi. Questa è la principale limitazione da tenere presente nella valutazione del contributo.

L'analisi empirica è attualmente limitata: i due casi sono stati selezionati per convenienza teorica, in quanto rappresentano configurazioni polari rispetto alle variabili di interesse, il che favorisce l'illustrazione del framework ma non permette generalizzazione. L'analisi è stata condotta esclusivamente attraverso fonti secondarie, senza la possibilità di verificare direttamente le strategie di progettazione degli assistenti né la percezione dei consumatori; l'acquisizione di dati da fonti primarie è pertanto un passaggio necessario del prosieguo della ricerca.

[4] Tramite la piattaforma Qverse il cliente può esplorare cabine, lounge e spazi aeroportuali in ambiente tridimensionale prima della prenotazione, guidato da Sama in qualità di cabin crew virtuale.

La valutazione dei dati di performance di Rufus e Sama richiede cautela: non è possibile isolare il contributo dell'assistente da quello di altri fattori strategici e commerciali. I dati disponibili descrivono performance aziendali aggregate, non relazioni causali tra la configurazione dell'assistente e l'intenzione d'acquisto.

Il collegamento tra natura del prodotto e configurazione ottimale dell'assistente è qui dedotto logicamente dalla combinazione di precedenti studi (Belanche et al., 2021; Cai et al., 2024; Go e Sundar, 2019; Longoni e Cian, 2022; Murtaza et al., 2024), nessuno dei quali ha testato empiricamente la triplice relazione in modo integrato. La validazione sperimentale di questa proposta rimane un passo necessario.

Il modello proposto tratta l'antropomorfismo visivo e lo stile comunicativo come dimensioni binarie, mentre nella realtà entrambe si presentano con sfumature continue. Ricerche future potrebbero esplorare livelli intermedi e verificare se l'intensità dell'effetto uncanny valley varia in funzione del contesto di prodotto. Analogamente, il modello non considera le differenze individuali dei consumatori – propensione all'innovazione tecnologica, familiarità con gli assistenti AI, variabili demografiche e culturali – né la dimensione temporale dell'interazione: l'efficacia di una configurazione potrebbe variare nel corso di esposizioni ripetute, in cui la soglia di accettazione dell'antropomorfismo si aggiorna.

Managerial implications. Qualora le proposition trovassero conferma sperimentale, lo studio offrirebbe alcune implicazioni pratiche per i manager che progettano e gestiscono assistenti virtuali nelle relazioni con i clienti. Il principio di coerenza tri-dimensionale suggerirebbe che la decisione progettuale non debba riguardare singolarmente l'aspetto o lo stile dell'agente, ma la loro combinazione in relazione al posizionamento dell'offerta.

Per prodotti o servizi prevalentemente utilitaristici, la configurazione ottimale prevederebbe un assistente con basso o assente antropomorfismo visivo e stile comunicativo task-oriented. Questa scelta risponde alla modalità valutativa razionale che il consumatore attiva in tali contesti, minimizza i rischi di uncanny valley, e favorisce anche l'ottimizzazione dei costi di sviluppo e gestione dell'agente.

Per prodotti o servizi prevalentemente edonistici, la configurazione ottimale prevederebbe un assistente con elevato antropomorfismo visivo e stile comunicativo social-oriented. In questi contesti l'esperienza d'acquisto si lega all'emozione: l'assistente può colmare il deficit sensoriale dell'e-commerce aiutando il cliente a immaginare mentalmente l'esperienza attraverso narrazioni sensoriali e simulazione di empatia. L'alto antropomorfismo visivo attiva i meccanismi emotivi tipici delle interazioni umane, rafforzando le risposte emotive del consumatore.

Configurazioni intermedie – un agente con livello moderato di antropomorfismo o con stile comunicativo incoerente rispetto all'aspetto – sarebbero sconsigliati: i risultati della letteratura indicano che collocarsi a un livello medio di antropomorfismo produce effetti peggiori rispetto a collocarsi in uno dei due poli. Le imprese dovrebbero pertanto evitare soluzioni di compromesso e optare per configurazioni nette, coerenti con il posizionamento dell'offerta.

Originality of the paper. Dal punto di vista teorico, questo lavoro contribuisce al dibattito sull'uso degli assistenti virtuali nella gestione delle relazioni con i clienti presentando un principio di coerenza tri-dimensionale come criterio progettuale per gli assistenti virtuali nel retail. La novità del contributo risiede nell'integrazione di tre dimensioni – antropomorfismo visivo, stile comunicativo e tipologia di prodotto – che la letteratura ha finora esaminato separatamente o, al più, a coppie. Murtaza et al. (2024) esaminano la relazione tra stile comunicativo, antropomorfismo percepito e intenzione d'uso, ma senza considerare la natura del prodotto; Zourrig et al. (2025) e Belanche et al. (2021) collegano aspetto e dimensioni valutative; Lan et al. (2024) connettono stile linguistico e contesto di servizio. Nessun lavoro ha testato empiricamente la triplice relazione in modo integrato, e questo è il gap specifico che il disegno sperimentale 2×2×2 della seconda fase di questo progetto si propone di colmare.

Il principio di coerenza tri-dimensionale ha implicazioni teoriche che vanno oltre la progettazione degli assistenti virtuali: esso suggerisce che l'efficacia degli agenti AI nelle relazioni con i consumatori dipenda dalla congruità tra le caratteristiche dell'agente e le aspettative che il contesto di consumo attiva nel consumatore – aspettative razionali in contesti utilitaristici, aspettative affettive in contesti edonistici. Questo rappresenta un'estensione della teoria della violazione delle aspettative (Burgoon e Hale, 1988) all'architettura complessiva degli agenti AI nei contesti di vendita.

Beyond positive brand identity: Conceptualizing the Negative Brand Identity System

MARIA VERNUCCIO[1], SARA BOCCALINI, MICHELA PATRIZI, FEDERICA CECCOTTI

Abstract. *Brand identity theory has traditionally conceptualized identity as a system of meanings structured around desirable and aspirational values. Foundational frameworks implicitly assume a positive axiological orientation, leaving the valence of identity values under-theorized as a structural dimension. However, the growing visibility of brands organized around transgression, antagonism, disruption, or selective exclusion challenges this assumption. This paper introduces axiological valence as a missing structural dimension of brand identity and conceptualizes the Negative Brand Identity System (NBIS) as a coherent, purposive, and enduring identity configuration in which negatively oriented values are intentionally embedded across core and extended identity elements. We propose a multidimensional framework where a negative axiological essence (disvalue-based core) is systematically articulated through four extended dimensions: negative brand personality, cultural traits contrary to social and moral norms, controversial expressive signs, and controversial product offering attributes. Adopting an exploratory and interpretive research design, we provide a cross-sectoral mapping of illustrative brand cases across five industries characterized by high symbolic consumption and identity salience: fashion, audiovisual narratives, gaming, music, and combat sports. The findings reveal that in these contexts, negativity functions not as an episodic provocation but as a systemic organizing principle that generates identity distinctiveness and coherence. By reconceptualizing brand identity through an axiological lens, this study extends identity-based branding theory and offers strategic insights into the structural viability of negative value orientations in the contemporary marketplace.*

Keywords: *negative brand identity system; negative brand; systemic negative identity orientation; negative axiological brand essence*

Framing of the research. *Brand identity literature has traditionally conceptualized identity as a coherent and strategically designed system of meanings (Aaker, 1996; Kapferer, 2012). Within this perspective, identity is defined as "a unique set of brand associations that the brand strategist aspires to create or maintain" (Aaker, 1996, p. 68), organized into core and extended components and oriented toward building long-term brand value. Similarly, the Brand Identity Prism (Kapferer, 2012) conceptualizes identity as an integrated architecture that combines physical, cultural, relational, and symbolic dimensions into a coherent and recognizable whole.*

Despite differences in structure and theoretical emphasis, these foundational models share a common normative orientation: brand identity is implicitly grounded in positively valenced meanings. Identity systems are typically conceptualized as mechanisms that enhance symbolic meaning (Park, 1986), facilitate self-congruence between consumers and brands (Sirgy, 1982), and contribute to the creation of brand equity (Keller, 1993). Even within the cultural branding perspective (Holt et al., 2004), the power of brands derives from their ability to resolve cultural tensions by producing myths that offer empowerment, reassurance, or symbolic relief. Across these traditions, brand identity is therefore primarily theorized as an aspirational system that generates positive symbolic, relational, and cultural value.

However, the evolving sociocultural environment raises questions about the universality of this implicit positivity assumption. Contemporary societies are increasingly characterized by ideological polarization, moral fragmentation, and intensified symbolic contestation. Within such contexts, identity formation frequently operates not only through positive value alignment but also through negative differentiation and evaluative contrast. Social Identity Theory (Tajfel & Turner, 1986) emphasizes that identity construction is structurally linked to processes of intergroup comparison and differentiation, through which individuals define their in-group by distinguishing it from negatively evaluated out-groups. Complementarily, psychological research on negativity bias (Baumeister et al., 2001) demonstrates that negative stimuli often generate stronger cognitive processing, emotional intensity, and behavioral responses than positive stimuli.

Several streams of marketing research indirectly reflect these dynamics. Studies on brand activism (Vredenburg et al., 2020), polarizing brands (Paharia et al., 2014), and tribal brand communities (Muniz & O'Guinn, 2001) show that strong brand relationships may emerge not only from shared positive meanings but also from oppositional positioning, ideological alignment, or symbolic boundary construction. Nevertheless, in this literature, polarization is typically examined as an outcome of communication strategies or consumer responses rather than as a structural property of brand identity systems.

More recently, research has begun to explore the role of negatively valenced brand stimuli, particularly at the level of brand naming. For example, Guest et al. (2016) investigate how negative brand names influence memory and liking, demonstrating that the interaction between valence and arousal plays a critical role in shaping consumer responses. Their findings suggest that moderately negative or highly arousing brand names may enhance memorability without necessarily diminishing brand evaluations, whereas extremely negative stimuli can trigger adverse reactions — what the

[1] Sapienza University of Rome

authors refer to as "brand suicide". In their concluding discussion, the authors implicitly distinguish between different forms of negativity, including ironic negativity, high-arousal negativity, and excessively negative brand cues.

Although this stream of research provides important insights into how consumers cognitively process negatively valenced brand stimuli, its analytical focus remains primarily situated at the perceptual and lexical levels of branding. Negativity is treated as a characteristic of discrete stimuli — such as words, names, or messages — rather than as an organizing principle embedded within broader identity architectures. Consequently, existing studies do not address how negatively oriented values might be coherently integrated into the core and extended components that structure brand identity systems.

This limitation points to a broader conceptual gap within brand identity theory. Despite the extensive development of identity frameworks, the literature has largely taken for granted the axiological orientation of brand values. Foundational models conceptualize identity as a coherent configuration of desirable associations, yet they rarely problematize the polarity of those values. As a result, the axiological dimension of identity — whether brand meanings are structured around positively or negatively oriented value constructs — remains under-theorized. At the same time, research on negativity in branding has predominantly focused on episodic manifestations such as controversial campaigns, negative brand names, or polarizing communications, without developing a systemic perspective on negativity as a structural dimension of brand identity. In this context, we introduce the concept of negative brands, defined as brands that deliberately incorporate negative, controversial, or transgressive meanings into their identity to enhance consumer appeal (Dagnino & Lo Presti, 2024; Vernuccio et al., 2025).

Building on these gaps, this study advances the argument that axiological valence represents a missing structural dimension within brand identity theory. Indeed, previous contributions conceptualize identity as a coherent system of meanings that guides brand positioning and long-term value creation (Aaker, 1996; Kapferer, 2012). Within this tradition, the axiological orientation of brand meanings is typically assumed to be positive and aspirational. This study challenges this implicit assumption by proposing that brand identity systems may also be systematically organized around negatively valenced value orientations, such as transgression, provocation, antagonism, cynicism, disruption, symbolic aggression, or the rejection of dominant social and cultural norms. Moreover, rather than viewing negativity as a merely communicative or perceptual attribute of isolated stimuli, we propose that it may also function as a coherent organizing orientation embedded within brand identity systems. Accordingly, we introduce the concept of the Negative Brand Identity System (NBIS), defined as a coherent, purposive, and enduring configuration in which negatively oriented values (e.g., transgression, provocation, antagonism, symbolic aggression) are structurally embedded within the core and extended architecture of brand identity.

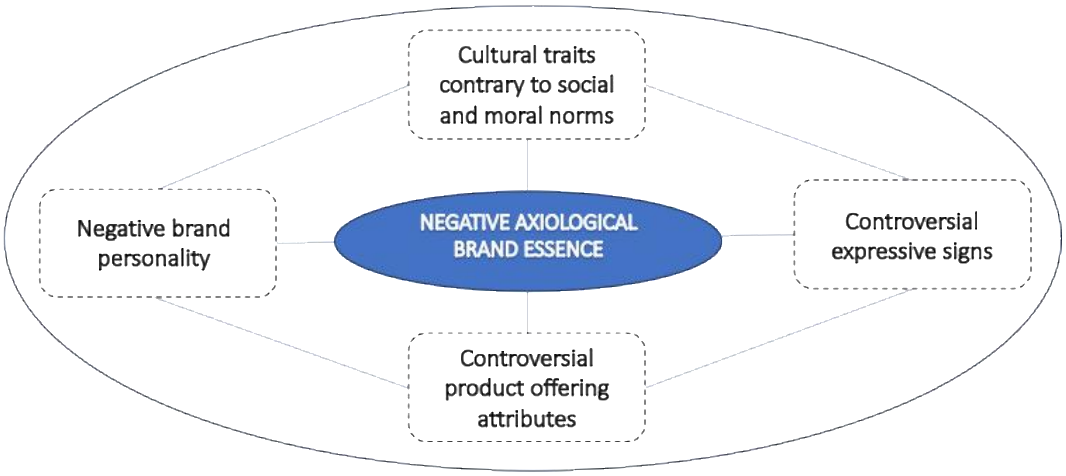
By shifting the analytical focus from stimulus-level negativity to identity-level value orientation, this study conceptualizes negativity as a structural dimension of brand identity rather than as an episodic communicative device focusing on brands whose identity architecture is fundamentally structured around negatively valenced value propositions. and exploring how negative identity systems are configured across different industries.

Purpose of the paper. *This study addresses the following research question: How can negative value orientation be conceptualized as a structural dimension of brand identity systems?*

To address this question, the study pursues two interrelated objectives: (1) to introduce and conceptualize the construct of the Negative Brand Identity System (NBIS) by defining axiological valence as a structural dimension of brand identity and by identifying the key dimensions through which negative value orientation is embedded within identity systems; and (2) to develop a cross-sectoral interpretive framework for exploring how negative identity systems are configured across different industries.

Negative Brand Identity System (NBIS). *We define a Negative Brand Identity System (NBIS) as a coherent and enduring brand identity configuration in which negatively valenced values are intentionally embedded within the central meaning and extended dimensions of the identity system, shaping the symbolic meaning, expressive manifestations, and relational dynamics through which the brand engages with its audiences.*

Importantly, this conceptualization distinguishes systemic negative identity orientation from episodic uses of negative symbolism in brand communication. Many brands occasionally employ provocative or disturbing imagery to attract attention or generate discussion without integrating such meanings into their underlying identity system. For instance, Burger King's "Moldy Whopper" campaign, which deliberately showcased a decomposing burger to emphasize the absence of artificial preservatives, mobilized the aesthetics of decay and disgust as a provocative communicative device. Despite the strong negative symbolism deployed in the campaign, such imagery did not redefine the brand's underlying identity configuration.



In contrast, within an NBIS negativity is strategic rather than tactical. Negative value orientation operates as a structuring principle of the identity system, influencing both the central meaning of the brand and the extended elements through which that meaning is articulated.

Building on the hierarchical identity system proposed by David Aaker (1996) and the multidimensional identity prism developed by Jean-Noël Kapferer (2012), this study conceptualizes brand identity systems as integrated configurations in which axiological orientation permeates both the core axiological brand essence and the surrounding extended identity dimensions. In the case of Negative Brand Identity Systems, negatively valenced meanings are embedded in the disvalue-based brand essence and are expressed across several extended dimensions, including negative brand personality,

cultural traits contrary to dominant social and moral norms, controversial expressive signs, and controversial product offering attributes.

As illustrated in Figure 1, the Negative Brand Identity System is organized around a core axiological essence, surrounded by a set of extended identity dimensions that translate and reinforce this orientation across the broader identity system.

Figure 1. The Negative Brand Identity System

Source: adapted from Vernuccio et al. (2025).

At the center of the system lies the negative axiological brand essence (disvalue-based core meaning), which represents the fundamental value orientation that defines the brand's identity. This core consists of negatively valenced concepts, such as disruption, transgression, antagonism, provocation, or rejection of dominant norms, that serve as the symbolic foundation of the brand. Rather than promoting harmonious or aspirational ideals, the identity is anchored in meanings that challenge, invert, or problematize mainstream cultural expectations. This core axiological essence provides the interpretive lens through which the brand's symbolic positioning, actions, and communications acquire coherence.

Surrounding this core negative meaning are several extended identity dimensions, which articulate the negative value orientation across different facets of the brand system and make it recognizable within the marketplace.

One dimension concerns brand personality, which reflects the set of human-like traits associated with the brand (Aaker, 1997). In NBIS configurations, personality traits may embody characteristics such as rebelliousness, irreverence, aggressiveness, cynicism, or disruptive confidence. These traits reinforce the identity's antagonistic or transgressive orientation and shape how audiences interpret the brand's stance within the cultural landscape. For instance, brands such as Liquid Death cultivate an intentionally aggressive and irreverent personality that transforms an otherwise conventional product category (water) into a symbolically provocative brand identity.

Another dimension concerns cultural traits, which refer to the cultural codes, symbolic attitudes, and value orientations through which the brand engages with broader social discourses (Holt et al., 2004; Kapferer, 2012). These traits shape how the brand interprets and frames its relationship with prevailing cultural norms and institutions, and they ultimately contribute to the brand's cultural positioning within the marketplace, which relates to the way the brand situates itself in relation to dominant social norms, institutions, or cultural conventions. Within NBIS configurations, such traits often express symbolic opposition to established norms, mobilizing narratives of disruption, resistance, or counter-cultural alignment that resonate with specific consumer communities. For example, brands such as Liquid Death mobilize dark humor, anti-corporate irony, and exaggerated themes of death and destruction as cultural traits that support a broader cultural positioning deliberately opposed to the sanitized and wellness-oriented discourse that typically characterizes the bottled water category.

A further dimension concerns controversial expressive signs of identity, through which negative values are translated into visible symbols, narratives, and aesthetic codes (Pastore & Vernuccio, 2008; Romaniuk, 2018). These manifestations may include provocative aesthetics, disturbing visual languages, controversial narratives, ironic messaging, unconventional naming strategies, or communication styles that intentionally depart from conventional brand discourse. For instance, the brand name Liquid Death itself exemplifies how provocative naming can operate as a powerful expressive device that immediately signals the brand's antagonistic symbolic stance.

Finally, a crucial dimension concerns the controversial product offering attributes (Vernuccio et al., 2025). In Negative Brand Identity Systems, the product may embody the brand's negative value orientation through deliberately controversial, transgressive, or norm-breaking attributes. These may involve unconventional product designs, unusual sensory characteristics, or product concepts that challenge established expectations within a category. For example,

brands such as Liquid Death incorporate dark, provocative symbolic references directly into their packaging and product design, embedding themes of death imagery, rebellious humor, and anti-corporate irony within the material design of the offering itself. In these instances, the negative value orientation extends from symbolic communication to the product offering, strengthening the coherence of the identity system.

In conclusion, the core axiological essence and the surrounding extended dimensions form an integrated identity configuration in which negatively valenced meanings permeate the system at multiple levels. In this perspective, negativity is not confined to isolated communicative initiatives but becomes an organizing principle that shapes the brand's symbolic orientation, expressive manifestations, relational positioning, and product offering over time.

Methodology. *Building on the conceptualization developed in the previous section (objective 1), the study adopts an exploratory and interpretive approach aimed at examining how negative value orientations may become embedded within brand identity systems across different cultural industries (objective 2). Rather than producing a quantitative assessment of the incidence of negative brands or an exhaustive identification of them across industries, this framework adopts an interpretive and exploratory perspective that combines theoretical development with an interpretive cross-sectoral mapping of illustrative brand cases (MacInnis, 2011). Its purpose is to identify recurring patterns and strategic configurations through which negative identity systems emerge and operate across sectors.*

In this perspective, the use of illustrative cases functions as an analytical device that helps examine how negative value orientations may become embedded within brand identity based upon the framework of NBIS.

The analysis relies on desk-based research and secondary sources (Yin, 2018), including brand websites, visual and narrative materials, media coverage, interviews with creators and designers, and documentation reported in specialized press and industry outlets (e.g., Owens, 2017).

The mapping was constructed through a two-step selection process. First, sectors were identified in which symbolic positioning and identity expression play a central role in shaping competitive differentiation. On this basis, the analysis focuses on five sectors in which identity signaling and symbolic consumption are particularly salient: fashion, audiovisual narratives, gaming, music, and combat sports.

Second, within each sector, illustrative cases were selected according to a purposive sampling logic (Eisenhardt, 1989). Selection was guided by three criteria: (1) the presence of a recognizable negative value orientation at the level of identity essence; (2) the articulation of this orientation across the elements of the identity system; and (3) the relative persistence of such configuration over time, beyond isolated episodes of controversy or provocation.

The final set of cases includes:

- *Rick Owens and Blackcraft Cult in fashion;*
- *A Clockwork Orange and Black Mirror in audiovisual narratives;*
- *Grand Theft Auto and Manhunt in gaming;*
- *Marilyn Manson and Slipknot in music;*
- *Ultimate Fighting Championship (UFC) and Pride Fighting Championships in combat sports.*

The desk analysis focused on publicly observable manifestations of brand identity, including personality traits, cultural meanings associated with each case, narrative, aesthetic and expressive codes, and product offering attributes. These elements were interpreted through the five identity components articulated in the conceptual framework (Figure 1): negative axiological brand essence, negative brand personality, cultural traits contrary to social and moral norms, controversial expressive signs, and controversial product offering attributes.

Consistent with the exploratory nature of the study, the mapping does not aim to produce a definitive classification of negative brands but rather to identify recurring configurational patterns through which Negative Brand Identity Systems may emerge across heterogeneous cultural industries.

Findings. *The outcome of the interpretive mapping is summarized in Appendix A (Table A1), which provides a cross-sectoral overview of the selected cases and illustrates how negative value orientation may originate at the level of identity essence and subsequently be articulated across the broader identity system.*

The cross-sectoral mapping provides initial support for the conceptual plausibility of the Negative Brand Identity System (NBIS). Across the selected cases, negative value orientation does not appear as an isolated communicative tactic or as an episodic form of brand provocation. Rather, it emerges as a structural organizing principle that permeates multiple dimensions of brand identity.

When the illustrative cases are examined through the five components of the NBIS framework, a recurrent configurational pattern becomes visible. In particular, negative value orientation originates at the level of the negative axiological essence and subsequently permeates the broader framework of brand identity through negative brand personality, cultural traits that challenge dominant social and moral norms, controversial expressive signs, and controversial product offering attributes.

Across the cases analyzed, the negative axiological essence operates as the generative core of the identity system. Instead of promoting aspirational or harmonious values, the identities examined are organized around meanings such as transgression, antagonism, aggression, or distrust toward dominant institutions and cultural norms. For example, within the fashion domain, Rick Owens develops a creative identity grounded in the aesthetic negation of conventional beauty standards, whereas Blackcraft Cult organizes its symbolic meaning around explicit anti-religious antagonism. Within audiovisual narratives, A Clockwork Orange structures its narrative identity around moral transgression and stylized

ultraviolence, while Black Mirror revolves around systemic skepticism toward technological progress. The gaming context offers comparable dynamics: Grand Theft Auto institutionalizes deviance and rule violation as defining elements of its fictional universe, while Manhunt centers its identity on the spectacle of extreme violence and voyeuristic brutality. A similar orientation characterizes the music industry, where the identities of Marilyn Manson and Slipknot are rooted in shock, aggression, and anti-mainstream provocation. Finally, combat sports organizations, such as UFC and Pride Fighting Championships, revolve around ritualized aggression and the spectacle of controlled violence. In all these cases, negative meanings function as the foundational value orientation structuring the identity system, instead of functioning as superficial stylistic elements.

The identity configuration also extends to the relational dimension of the brand through negative brand personality. Across the cases analyzed, the personality traits associated with the brands consistently reflect antagonistic or confrontational characteristics. Traits such as rebelliousness, aggression, dominance, hostility, or provocation frequently emerge as defining elements of the brand character. For instance, in the fashion cases, Rick Owens projects a detached and anti-conventional identity, while Blackcraft Cult conveys explicit antagonism toward institutional religion. Audiovisual narratives, such as A Clockwork Orange and Black Mirror, evoke disturbing and unsettling character profiles that reinforce the moral ambiguity of their worlds. Within gaming, Grand Theft Auto embodies irreverence and rebelliousness, while Manhunt communicates predatory and sadistic undertones. In the music field, the stage personas of Marilyn Manson and Slipknot amplify shock, aggression, and anti-mainstream provocation. Combat sports brands, including UFC and Pride Fighting Championships, cultivate combative and dominant identities centered on confrontation and physical supremacy. Through these personality configurations, the underlying axiological orientation becomes part of the symbolic relationship that audiences establish with the brand.

The identity configuration is stabilized through cultural traits that challenge dominant social and moral norms. Across the selected cases, audiences engage with the brand through forms of symbolic affiliation that reinterpret or embrace oppositional meanings embedded within the identity system. For example, the fashion brand Blackcraft Cult mobilizes a subcultural rejection of dominant religious values. In the audiovisual sphere, audiences of A Clockwork Orange and Black Mirror engage with narratives that problematize morality, authority, and technological progress. Gaming communities, particularly those surrounding Grand Theft Auto, normalize deviant behavior within broader cultural narratives of rebellion and institutional distrust. Music subcultures, such as those associated with Slipknot and Marilyn Manson, embrace themes of aggression, alienation, and anti-mainstream identity. In combat sports, organizations such as UFC and Pride Fighting Championships transform ritualized violence into widely recognized entertainment formats, legitimizing aggression within regulated cultural spaces.

This negative axiological orientation becomes publicly recognizable through a system of controversial expressive signs, which translate disvalues into distinctive symbolic forms. Across sectors, brands employ visual, narrative, or aesthetic codes that make their antagonistic orientation perceptible to audiences. For instance, fashion brands such as Rick Owens communicate aesthetic rupture through brutalist silhouettes and dark visual aesthetics, while Blackcraft Cult relies on occult and satanic imagery as visible markers of anti-religious defiance. Audiovisual productions, including A Clockwork Orange and Black Mirror, deploy disturbing iconography and dystopian visual languages that emphasize moral disorder and technological alienation. In gaming, graphic depictions of violence and criminal environments contribute to the symbolic universes of Grand Theft Auto and Manhunt. Within the music industry, the confrontational iconography associated with Marilyn Manson and the horror-inspired masks adopted by Slipknot transform antagonism into recognizable aesthetic signifiers. Combat sports events reinforce the spectacle of antagonistic rivalry through confrontational promotional narratives and theatrical staging.

The presence of controversial product offering attributes further reinforces this orientation. Here, negativity permeates the design of the product or experiential offering itself, going beyond symbolic communication. In fashion, anti-normative garment structures and symbolic references embedded in apparel design translate ideological opposition into material products. Audiovisual narratives revolve around deviant protagonists, dystopian futures, or morally ambiguous worlds. Gaming experiences, particularly Grand Theft Auto and Manhunt, incorporate criminal activity, rule transgression, and execution-based mechanics centered on extreme violence. Music performances and lyrics, especially in the cases of Marilyn Manson and Slipknot, deliberately cultivate shock, aggression, and confrontation. Combat sports events place physical confrontation and aggressive competition at the center of the entertainment format itself. Through these mechanisms, the negative axiological orientation is materially enacted through the offering.

The analysis across sectors reveals a recurring identity configuration in which negative value orientation originates at the level of axiological essence and subsequently permeates multiple reinforcing dimensions of brand identity. Negative brand personality, cultural traits contrary to social and moral norms, controversial expressive signs and controversial product offering attributes interact in a mutually reinforcing manner, generating systemic coherence across the identity system.

This multilayered coherence distinguishes Negative Brand Identity Systems from brands in which negativity appears only in isolated campaigns or episodic controversies. In NBIS configurations, negativity operates as a structural organizing principle shaping symbolic meaning, experiential offerings, and relational positioning over time, instead of serving as a temporary communication tactic.

Research limitations. *This study presents some limitations that open avenues for future research. First, the research adopts a conceptual and exploratory design supported by an interpretive desk-based mapping of illustrative cases. While appropriate for theory development, this approach does not provide empirical testing of the proposed framework. Future research could therefore operationalize the dimensions of the Negative Brand Identity System and examine their effects on consumer perceptions and brand outcomes. Second, the analysis focuses primarily on brand identity construction, without directly investigating how consumers interpret or respond to negative brand identities. Further studies could explore the conditions under which negative value orientations generate attraction, identification, or rejection among different audience segments.*

Managerial implications. *The proposed framework generates several strategic implications for brand managers, CMOs, and identity strategists.*

First, the findings suggest that brand identity does not necessarily need to be grounded in universally positive values. When coherently structured, negatively oriented value propositions — such as disruption, antagonism, or transgression — may serve as powerful mechanisms of symbolic differentiation, particularly in markets characterized by strong identity signaling and cultural contestation.

However, the effectiveness of such positioning depends on systemic coherence rather than isolated provocation. Brands that employ negative symbolism only in episodic campaigns risk generating reputational inconsistency or credibility loss. By contrast, the cases analyzed show that successful negative brands embed their value orientation across multiple dimensions of the identity system, including expressive signs, product offering attributes, personality traits, and cultural positioning.

Finally, the concept of axiological valence can be used as a strategic diagnostic tool. Managers may map competitors along the positive–negative value continuum in order to identify under-explored identity spaces within their category. In this sense, identity strategy may involve not only defining which values a brand expresses,but also determining the valence orientation through which those values are articulated.

Originality of the paper. *This study contributes to branding and brand identity literature in three main ways.*

First, it introduces axiological valence as a previously under-theorized structural dimension of brand identity systems. While existing identity frameworks conceptualize brands as coherent configurations of associations, they implicitly assume that such associations are positively oriented. By explicitly theorizing the polarity of identity values, this research extends the conceptual foundations of brand identity beyond its traditional positivity bias.

Second, the study develops the concept of the Negative Brand Identity System (NBIS), defined as a coherent and enduring identity configuration in which negatively valenced meanings are systematically embedded across both core and extended identity dimensions. This shifts the analytical focus from stimulus-level negativity — such as negative brand names or controversial communications — to identity-level value orientation as a structural property of brand identity systems. The research introduces a conceptual distinction between episodic negativity and systemic negative identity configurations, highlighting how negative meanings may function not merely as temporary communication tactics but as stable organizing principles shaping brand meaning, positioning, and relational dynamics over time.

Third, by providing an interpretive cross-sectoral mapping of illustrative brand cases, the study offers an initial exploratory framework for identifying recurring patterns through which negative identity systems emerge across industries.

In conclusion, these contributions extend brand identity theory by integrating axiological valence into the conceptual architecture of identity systems and by offering a new analytical lens for understanding the emergence and strategic role of negative brands in contemporary markets.

Appendix A - Table A1. Cross-Dimensional Mapping of Negative Brand Identity Systems

Sector	Brand	Negative Axiological Essence	Negative Brand Personality	Cultural Traits Contrary to Social and Moral Norms	Controversial Expressive Signs	Controversial Product Offering Attributes
Fashion	Rick Owens	Aesthetic negation of conventional beauty	Detached; anti-conventional	Radical aesthetic rupture within fashion norms	Brutalist silhouettes and dark aesthetics	Anti-normative garment structures
	Blackcraft Cult	Anti-religious antagonism	Rebellious; antagonistic	Rejection of dominant religious values	Occult and satanic visual symbolism	Apparel embedding explicit anti-clerical references
Audiovisual	A Clockwork Orange	Moral transgression and ultraviolence	Sadistic; provocative	Subversion of social and institutional order	Disturbing iconography and stylized violence	Narrative centered on a deviant anti-hero
	Black Mirror	Technological distrust	Cynical; skeptical	Suspicion toward technological progress	Dystopian visual language	Narratives depicting the dark consequences of digital innovation
Gaming	Grand Theft Auto	Legitimized deviance	Rebellious; irreverent	Normalization of rule violation	Satirical urban aesthetics	Gameplay mechanics rewarding criminal behavior
	Manhunt	Violence as spectacle	Sadistic; predatory	Voyeuristic fascination with violence	Snuff-inspired visual language	Execution-centered gameplay mechanics
Music	Marilyn Manson	Shock and anti-moral provocation	Antagonistic	Cultural defiance toward mainstream moral norms	Confrontational iconography	Provocative performances and transgressive texts
	Slipknot	Aggression and chaotic hostility	Hostile; aggressive	Alignment with anti-mainstream metal subculture	Horror-inspired masks and disturbing stage aesthetics	Extreme metal sound and intense performances
Combat Sports	UFC	Ritualized aggression	Dominant; combative	Legitimation of controlled violence	Confrontational promotional narratives	Institutionalized physical confrontation format
	Pride Fighting Championships	Spectacularized violence	Dominant; aggressive	Celebration of extreme combat spectacle	Theatrical fighter entrances and hyper-dramatic arenas	Permissive combat rules and extreme match-ups

Breaking the Binary: How Gender-Neutral Branding Shapes Brand Love

FRANCESCA CELIO, ALESSANDRA DOMINIJANNI, ANGELO BACCELLONI, FRANCESCO RICOTTA

Abstract. *As societal expectations for inclusivity reshape marketplace dynamics, gender-neutral marketing has emerged as a strategy that challenges traditional gender segmentation. However, little is known about how gender-neutral product presentation influences consumer–brand relationships. This study examines how gender-neutral branding shapes consumers' emotional attachment to brands. Drawing on branding and consumer identity literature, we propose that gender-neutral product positioning influences brand love through perceived brand uniqueness and perceived brand quality, which in turn foster brand self-connection. A between-subjects experiment with 151 Generation Z consumers tested the proposed model. Results show that gender-neutral product presentation significantly enhances perceived brand uniqueness, which in turn strengthens brand self-connection and ultimately increases brand love. The findings contribute to the emerging literature on gender-neutral marketing by demonstrating how inclusive product positioning can strengthen consumer–brand relationships through both symbolic and evaluative brand perceptions.*
Keywords: *Gender Neutral Marketing; Brand Love; Uniqueness; Inclusivity; Perceived Brand Quality*

Framing of the research. *In contemporary markets, brands are increasingly expected to reflect and engage with broader societal values in their communication strategies. In this context, inclusive branding refers to the deliberate representation of diverse identities and social groups in brand communication and positioning (Srivastava et al., 2025; Hollenbeck and Patrick, 2025). This shift has gained momentum as consumers—particularly younger generations—demand greater alignment between brand actions and evolving cultural norms related to diversity, identity and representation (McKinsey, 2026).*

Building on this shift, inclusive marketing communication has been identified as a key mechanism through which brands translate inclusive positioning into concrete consumer-facing messages. Prior research shows that such communication can influence consumers' purchase decisions and strengthen loyalty toward brands (Brodzik et al., 2021; Madeline and Sihombing, 2019). By thoughtfully representing diversity and including underrepresented groups, brands can create messages that resonate emotionally with consumers and reinforce consumer–brand relationships (Dimitrieska et al., 2019; Xavier, 2020). In turn, these strategies have been shown to foster attachment, happiness and passionate feelings toward brands, contributing to the development of brand love and more favorable brand attitudes (Salsabila and Apriliyanty, 2022; Suh and Lee, 2016).

These dynamics can also be linked to the human need for belonging. As Maslow (1943) suggests, individuals seek membership in social groups, and consumption may serve as a means of expressing identity and shared values (Rokeach, 1979; Karababa and Kjeldgaard, 2014). Consistent with this perspective, consumers respond more positively to brands that signal fairness and respect toward diverse customers (Bourke and Dillon, 2018). This is particularly evident among younger consumers, many of whom report preferring brands whose marketing strategies demonstrate inclusiveness (Accenture, 2018).

Generational differences further highlight the relevance of inclusive and gender-neutral marketing practices. Gen Z consumers, born between 1996 and 2010, are often described as "inclusive consumers" who expect brands to demonstrate purpose, social responsibility, and accountability while promoting equity and opportunities for diverse and underrepresented groups (McKinsey, 2026). At the same time, prior research shows that gender stereotypes have traditionally been used in advertising to strengthen brand–consumer relationships (Lieven et al., 2014; Ellemers, 2018), although recent societal changes have transformed how gender is represented in marketing communication (Aramendia-Muneta, 2020). Despite these developments, research on generational perceptions of gender representations—particularly among Generation Z and Generation Y—remains limited, and empirical studies on gender-neutral advertising and marketing practices are still relatively scarce (Hickman et al., 2019; Stavrianea et al., 2020).

Within this broader discussion on inclusivity, gender represents a particularly relevant dimension. For decades, companies have segmented markets based on gender, categorizing consumers into groups of men and women or boys and girls (Kotler, Keller, and Chernev, 2022). However, this fundamental marketing practice has increasingly been challenged as the meaning of gender evolves beyond the traditional male–female binary (Geiger and Graf, 2019; Minkin and Brown, 2021; Parker, Horowitz, and Brown, 2022). As a result, consumers increasingly demand a marketplace that reflects greater diversity and inclusivity.

In response to these changes, some companies have started adopting gender-neutral marketing strategies that explicitly reject binary gender categorization and stereotypes in product development and communication (Yin et al., 2025). Gender-neutral marketing therefore refers to strategic efforts that avoid gender-specific cues while explicitly signaling inclusivity toward diverse gender identities. Even brands that historically relied on binary gender representations have begun integrating more gender-inclusive messaging into their marketing communications (Lacombe, 2020; Prokopets, 2022).

Despite growing societal interest in gender inclusivity, the adoption of gender-neutral marketing practices remains relatively limited. While consumers appear increasingly supportive of gender-neutral marketplace offerings, marketers may still hesitate to move away from traditional gender segmentation because of the longstanding effectiveness of gendered marketing strategies (Eisend, 2010). At the same time, empirical research specifically examining consumer responses to gender-neutral marketing offers remains relatively scarce. Consequently, insights into whether gender neutrality in marketing is beneficial or potentially harmful from a brand perspective are still limited.

Existing research on gender and marketing has primarily focused on advertising and communication strategies (Stavrianea et al., 2020). However, this perspective often overlooks the important role that product and package design plays in shaping consumer responses and brand evaluations (Bloch, 1995).
This limitation is particularly relevant because many product categories—such as cosmetics, wellness products, fashion, kitchen appliances, and children's products—have historically relied heavily on gendered product design and packaging (Petersson McIntyre, 2018).
Gender-neutral branding can be conveyed through multiple brand touchpoints, including advertising, marketing communication, and product design elements such as packaging and labeling. Prior research shows that marketing cues can shape consumers' reliance on gender stereotypes in product evaluation (Yin et al., 2025), while packaging design itself communicates symbolic meanings about gender and brand identity (Petersson McIntyre, 2018). As a key brand touchpoint, product packaging plays an important role in shaping consumer perceptions and brand evaluations (Silayoi and Speece, 2007).

Moreover, gendered marketing practices may reinforce stereotypes and generate negative consumer responses. Although gender segmentation remains widespread, many consumers do not necessarily agree with traditional gender stereotypes in marketing (Huhmann and Limbu, 2016). Contemporary masculinity is undergoing a structural redefinition of consumption, characterized by a significant migration into market segments historically gendered as feminine. This shift is empirically evidenced by the global male skincare market—valued at approximately $17.6 billion in 2025—and a 15% year-on-year increase in male engagement with non-invasive aesthetic procedures. Driven by the 'wellness' paradigm and a generational erosion of traditional gender binaries, men are increasingly normalizing the use of specialized cosmetics and holistic health practices as essential tools for both identity signalling and professional self-management (Euromonitor, 2025; Statista, 2026).

Consequently, stereotypical gender-based marketing tactics may trigger negative reactions among consumers, particularly among women (Åkestam et al., 2021). In addition, applying gender-specific designs to similar products may limit brands' ability to engage consumers who identify with fluid gender identities or belong to generations that increasingly perceive gender as non-binary (Stavrianea et al., 2020).

Recent research has begun to examine consumer responses to gender-neutral marketing practices. For instance, Nickel and Blijlevens (2025) show that gender-neutral packaging represents a meaningful departure from traditional gendered cues and can influence how consumers evaluate products and brands. Similarly, emerging research suggests that gender-neutral marketing may shape how consumers process product information by reducing reliance on gender stereotypes in product evaluation (Yin et al., 2025).

To further explain why gender-neutral product presentation may influence consumers' perceptions of brand uniqueness, this research draws on uniqueness theory. According to Snyder and Fromkin (1977), individuals are motivated not only by pressures toward conformity but also by a fundamental desire to perceive themselves as different from others. When individuals perceive excessive similarity with others, they may engage in behaviors aimed at restoring their sense of distinctiveness (Fromkin and Snyder, 1980). In consumption contexts, this motivation is often expressed through marketplace choices, as consumers use products and brands as symbolic resources to differentiate themselves and reinforce their personal and social identity (Tian et al., 2001). Brands can therefore serve as tools through which individuals construct and confirm their self-concept and express a unique identity (Fournier, 1998). Prior research further shows that consumers' need for uniqueness can influence how they evaluate brands and engage with them (Abosag et al., 2020). In this respect, brands that deviate from established marketplace conventions—such as traditional gender segmentation—may be perceived as more distinctive and therefore enhance perceptions of brand uniqueness.

Despite these emerging insights, empirical research examining the relational consequences of gender-neutral branding remains limited. Existing studies primarily focus on consumers' perceptions of gender-neutral communication or design cues (Stavrianea et al., 2020; Nickel and Blijlevens, 2025), providing limited understanding of how gender-neutral brand positioning shapes the development of deeper consumer–brand relationships. In particular, little is known about the psychological mechanisms through which gender-neutral product presentation influences consumers' emotional attachment to brands.

Addressing this gap, the present study examines how gender-neutral product presentation influences consumer–brand relationships. Specifically, we argue that gender-neutral brand positioning shapes consumers' perceptions of the brand along two complementary dimensions—perceived brand uniqueness and perceived brand quality. These perceptions, in turn, enhance consumers' psychological connection with the brand (brand self-connection), ultimately fostering stronger emotional attachment in the form of brand love.

Purpose of the paper. *Brands increasingly adopt positioning strategies that challenge traditional product category conventions. One such strategy involves presenting products in a gender-neutral manner, thereby avoiding the conventional gender segmentation that characterizes many consumer goods markets. Gender-neutral branding may*

signal inclusivity, modernity, and social awareness, potentially shaping the way consumers perceive and evaluate the brand.

First, gender-neutral positioning may influence perceptions of brand uniqueness. By deviating from traditional gendered marketing cues and category norms, a brand may appear more original, distinctive, and differentiated from competitors. Accordingly, gender-neutral product presentation may enhance consumers' perceptions of brand uniqueness.

H1: Gender-neutral product presentation positively influences perceived brand uniqueness.

Beyond symbolic perceptions, gender-neutral positioning may also shape evaluative judgments such as perceived brand quality. Inclusive or progressive positioning may lead consumers to infer that the brand is modern, thoughtful, and attentive to contemporary social values, thereby improving perceived quality.

H2: Gender-neutral product presentation positively influences perceived brand quality.

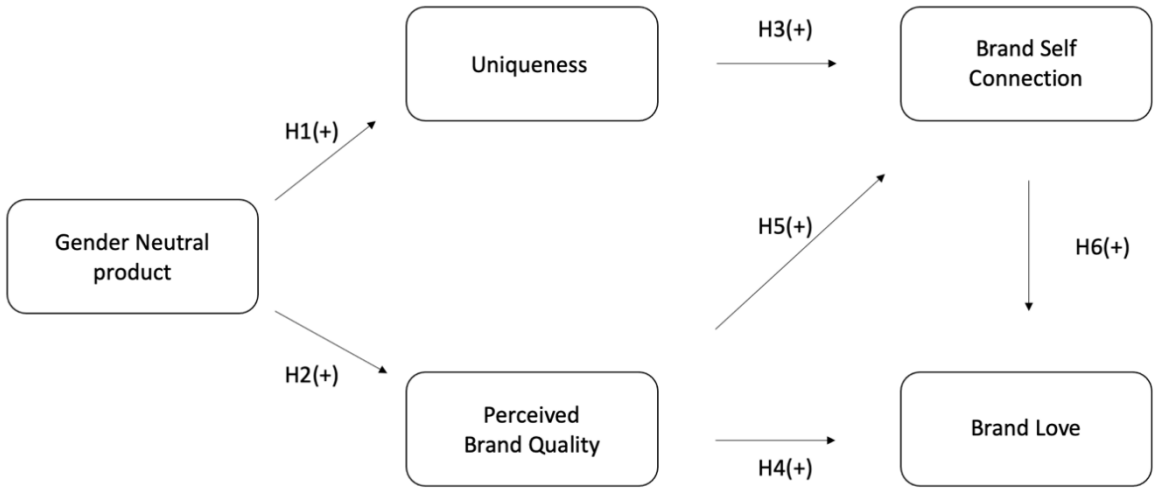
Consumers often form relationships with brands that reflect aspects of their identity and self-concept. Brand self-connection refers to the extent to which consumers incorporate a brand into their self-definition and perceive the brand as representing who they are.

Perceived brand uniqueness can play a key role in fostering such connections. Brands that are perceived as distinctive may serve as effective vehicles for self-expression because they allow consumers to signal individuality and differentiate themselves from others. When a brand is perceived as unique, consumers may therefore be more likely to integrate the brand into their self-concept.

H3: Perceived brand uniqueness positively influences brand self-connection.

Perceived brand quality may also contribute to the development of self-connection. When consumers evaluate a brand as high in quality, they may feel more comfortable associating themselves with that brand, as doing so reflects positively on their identity. Positive evaluations of brand quality can therefore strengthen the psychological bond between consumers and brands.

H4: Perceived brand quality positively influences brand self-connection.



Brand relationships can evolve into deeper emotional bonds over time. Brand love reflects a strong emotional attachment characterized by affection, passion, and closeness toward the brand. Evaluative perceptions such as perceived brand quality may also directly contribute to brand love. Consumers are more likely to develop emotional attachment to brands they perceive as reliable, well-performing, and high in quality.

H5: Perceived brand quality positively influences brand love.

Brand self-connection is widely recognized as a central driver of brand love. When consumers perceive a brand as part of their self-definition, their relationship with the brand becomes more personally meaningful, which increases the likelihood of developing strong emotional attachment.

H6: Brand self-connection positively influences brand love.

Figure 1. Conceptual Model

Source: our elaboration

Conceptual model proposing (Figure 1) that gender-neutral product positioning shapes consumer–brand relationships through two complementary perceptual routes: a symbolic route through perceived brand uniqueness and brand self-connection, and an evaluative route through perceived brand quality, ultimately leading to brand love.

Methodology. *To examine how gender-neutral product positioning influences consumer–brand relationships, we conducted a between-subjects experiment in which participants were randomly assigned to either a gender-neutral or a gender-typed product condition.*

Visual gender neutrality in product and package design refers to the use of marketing visuals that avoid gender stereotypes and gendered design cues (Cakiroglu, 2017). Accordingly, gender-neutral designs rely on neutral visual elements and avoid colours, shapes, or stylistic features typically associated with masculinity or femininity (Stilma, 2010). In contrast, gender-typed designs communicate gender through visual elements commonly linked to masculine or feminine aesthetics.

Participants were first exposed to a product stimulus presenting a perfume from a fictious brand according to the assigned condition. In the gender-neutral condition, participants were presented with two identical perfume bottles displayed side by side. The packaging used neutral colours and minimalist visual elements that avoided gendered cues or associations, and the label described the product as "gender-neutral perfume." In the gender-typed condition, participants viewed two perfume bottles displayed side by side, labelled "for him" and "for her." The bottles incorporated visual elements traditionally associated with specific genders, including gender-coded colours and stylistic features.

After viewing the stimulus, participants completed a questionnaire measuring their perceptions of the brand, including perceived brand uniqueness, perceived brand quality, brand self-connection, and brand love. The order of the measures was randomized to reduce potential order effects. Finally, participants provided demographic information.

A total of 151 Generation Z participants, recruited through Prolific, completed the online study. Responses were screened for completeness prior to analysis, and only fully completed questionnaires were retained.

All constructs were measured using established multi-item scales adapted from prior literature. Responses were recorded on Likert-type scales. Perceived brand uniqueness was measured with items adapted from Anselmsson et al. (2014), perceived brand quality with items adapted from Nath Sanyal and Datta (2011), brand self-connection with items adapted from Jin and Bolebruch (2009), and brand love with items adapted from Carroll and Ahuvia (2006).

To test the hypothesized relationships among the constructs, we estimated a structural equation model (SEM) using maximum likelihood estimation. The model examined the effect of the experimental manipulation (gender-neutral vs. gender-typed condition) on perceived brand uniqueness and perceived brand quality, and the subsequent effects of these perceptions on brand self-connection and brand love.

Results. *A manipulation check confirmed that participants perceived the product presentation as intended. Participants in the gender-neutral condition reported higher manipulation check scores ($M = 5.23$, $SD = 1.54$) than those in the gender-typed condition ($M = 2.55$, $SD = 1.77$), $t(145.12) = 9.89$, $p < .001$, confirming that the manipulation was successful.*

Measurement Model and Construct Validity

Before testing the structural relationships, we assessed the reliability and validity of the measurement model. All constructs demonstrated excellent internal consistency. Cronbach's alpha values exceeded the recommended threshold of .70 (Nunnally and Bernstein, 1994), indicating high reliability for all scales. Specifically, reliability coefficients were $\alpha = .964$ for brand uniqueness, $\alpha = .947$ for perceived brand quality, $\alpha = .948$ for brand self-connection, and $\alpha = .940$ for brand love. Descriptive statistics, reliability coefficients, and correlations among the constructs are reported in Table 1.

Table 1: Descriptive Statistics and Correlations

Construct	*Mean*	*SD*	*Cronbach's alpha*	*1*	*2*	*3*	*4*
1. Brand Uniqueness	*3.42*	*1.59*	*.964*	—			
2. Perceived Brand Quality	*4.70*	*1.12*	*.947*	*.59*	—		
3. Brand Self-Connection	*2.97*	*1.34*	*.948*	*.48*	*.47*	—	
4. Brand Love	*3.98*	*1.23*	*.940*	*.52*	*.70*	*.79*	—

Note: N = 151. All correlations are significant at $p < .001$.

Source: our elaboration

We next assessed convergent validity using the average variance extracted (AVE). All constructs exceeded the recommended threshold of .50 (Fornell and Larcker, 1981), indicating satisfactory convergent validity. AVE values were .868 for brand uniqueness, .859 for perceived brand quality, .759 for brand self-connection, and .694 for brand love.

Discriminant validity was assessed using the Fornell–Larcker criterion. As shown in Table 2, the square root of the AVE for each construct exceeded its correlations with the other constructs, supporting discriminant validity. Although the correlation between brand self-connection and brand love was relatively high ($r = .79$), it remained below the square root of the AVE for both constructs, indicating that the constructs are empirically distinct.

Table 2: Measurement Model Assessment

Construct	*AVE*	*1*	*2*	*3*	*4*
1. Brand Uniqueness	*.868*	***.932***			
2. Perceived Brand Quality	*.859*	*.604*	***.927***		
3. Brand Self-Connection	*.759*	*.504*	*.482*	***.871***	
4. Brand Love	*.694*	*.549*	*.733*	*.831*	***.833***

Note: Diagonal elements (bold) represent the square root of AVE. Off-diagonal elements are latent-factor correlations obtained from the confirmatory factor analysis.

Source: our elaboration

Additional support for discriminant validity emerged from the HTMT criterion (Henseler et al., 2015): the HTMT value between brand self-connection and brand love was .53, well below the recommended .85 threshold. This result provides additional evidence that the two constructs are empirically distinct despite their relatively strong correlation.

Hypothesis Testing and Structural Model Results

To test the proposed relationships among condition, perceived uniqueness, perceived brand quality (PBQ), brand self-connection (BSC), and brand love, we estimated a structural equation model using maximum likelihood estimation with 5,000 bootstrap resamples.

The structural model demonstrated an acceptable fit to the data. Although the chi-square statistic was significant ($\chi^2(3) = 10.25$, $p = .017$), the remaining fit indices indicated acceptable model fit (CFI = .979; TLI = .931), and the standardized root mean square residual suggested low residual error (SRMR = .063). The RMSEA value was .126 (90% CI [.047, .215]). Given the very small number of degrees of freedom in the model, RMSEA should be interpreted cautiously (Kenny et al., 2015). Overall, the pattern of fit indices suggests that the proposed structural model adequately represents the observed data.

We first examined the effect of the experimental manipulation on the two proposed perceptual antecedents. Consistent with H1, gender-neutral brand products significantly increased perceived uniqueness ($\beta = .334$, $p < .001$). Thus, H1 was supported. The effect of condition on perceived brand quality was positive but only marginally significant ($\beta = .154$, $p = .059$). Accordingly, H2 received marginal support.

We then tested the effects of these perceptual variables on brand self-connection. As predicted in H3, higher perceived uniqueness significantly increased consumers' psychological connection with the brand ($\beta = .318$, $p = .001$). Thus, H3 was supported. Similarly, perceived brand quality positively predicted brand self-connection ($\beta = .282$, $p < .001$), providing support for H4.

Next, we examined the antecedents of brand love. Consistent with H5, perceived brand quality positively predicted brand love ($\beta = .430$, $p < .001$). Thus, H5 was supported. In addition, brand self-connection strongly predicted brand love ($\beta = .584$, $p < .001$), supporting H6.

Taken together, these findings (reported in Table 3) indicate that emotional attachment to the brand is shaped by both symbolic and evaluative brand perceptions, although their influence differs in strength and structure. Symbolic perceptions, captured by perceived brand uniqueness, contribute to brand love only indirectly by strengthening consumers' brand self-connection ($\beta = .318$). In contrast, evaluative perceptions reflected in perceived brand quality exert a stronger influence, both indirectly through brand self-connection ($\beta = .282$) and directly on brand love ($\beta = .430$). Consistent with this pattern, brand self-connection emerges as the most powerful proximal predictor of brand love in the model ($\beta = .584$).

The model explained a substantial proportion of variance in the focal constructs (R^2_BSC = .286; R^2_BrandLove = .762).

Table 3: Structural Model Results

Path	*b*	*SE*	*z*	*p*	*β*
Condition → Uniqueness	*1.004*	*.232*	*4.321*	*< .001*	*.334*
Condition → PBQ	*.384*	*.203*	*1.889*	*.059*	*.154*
Uniqueness → BSC	*.278*	*.087*	*3.196*	*.001*	*.318*
PBQ → BSC	*.298*	*.084*	*3.555*	*< .001*	*.282*
PBQ → Brand Love	*.413*	*.046*	*8.935*	*< .001*	*.430*
BSC → Brand Love	*.532*	*.046*	*11.674*	*< .001*	*.584*

Source: our elaboration

Bootstrapped indirect effects (shown in Table 4) further supported the proposed psychological mechanism. Specifically, condition exerted a significant indirect effect on brand self-connection through perceived uniqueness (β_indirect = .106, $p = .005$). Moreover, the sequential pathway condition → perceived uniqueness → brand self-

connection → brand love was significant (β_indirect = .062, p = .010). The total indirect effect of condition on brand love was also significant (β_indirect = .153, p = .008). By contrast, indirect paths involving perceived brand quality were positive but did not reach conventional levels of statistical significance.

Overall, the pattern of results supports the proposed theoretical framework. More specifically, gender-neutral brand framing appears to shape consumer–brand relationships through two complementary perceptual routes. First, the manipulation increases perceived uniqueness, which strengthens consumers' psychological self-connection with the brand and ultimately enhances brand love. Second, the manipulation also shows a weaker but positive association with perceived brand quality, which contributes directly to both brand self-connection and brand love. These findings highlight the joint role of symbolic brand perceptions and evaluative brand perceptions in explaining how consumers develop emotional bonds with brands.

Table 4: Indirect Effects

Indirect Path	*Effect*	*SE*	*p*
Condition → Uniqueness → BSC	*.279*	*.100*	*.005*
Condition → PBQ → BSC	*.114*	*.070*	*.102*
Condition → PBQ → Brand Love	*.159*	*.085*	*.061*
Condition → Uniqueness → BSC → Brand Love	*.148*	*.058*	*.010*
Condition → PBQ → BSC → Brand Love	*.061*	*.037*	*.097*
Total indirect effect on Brand Love	*.368*	*.138*	*.008*

Source: our elaboration

To assess the robustness of the findings, we conducted additional analyses.

First, the structural model was re-estimated using robust maximum likelihood estimation (MLR), which adjusts standard errors and fit statistics for potential non-normality. The results were substantively identical to those obtained with the original estimation approach. In particular, the standardized path coefficients remained virtually unchanged (condition → uniqueness β = .334; uniqueness → BSC β = .318; BSC → brand love β = .584; PBQ → brand love β = .430), and the statistical significance of the focal relationships was unaffected.

Second, additional bootstrapped mediation analyses confirmed the sequential indirect effect of condition on brand love through perceived uniqueness and brand self-connection (β_indirect = .127, p < .001), as well as the mediation effect of perceived uniqueness on the relationship between condition and brand self-connection (β_indirect = .162, p < .001). Overall, these additional analyses replicate the psychological mechanism identified in the structural model and confirm the robustness of the findings.

Research limitations. *Despite its contributions, this research has several limitations that open avenues for future investigation. First, the study relies on a relatively modest sample size. Although sufficient for the structural analyses conducted, future research could employ larger samples to enhance statistical power and generalizability.*

Second, the experimental design employed a single product category and a specific product stimulus (perfume bottles). While this choice allowed for a controlled manipulation of gendered versus gender-neutral product presentation, it may restrict the generalizability of the results across different product categories. Future studies could extend this research by examining gender-neutral product presentation across a wider range of product types, including both hedonic and utilitarian categories.

Third, the study relies on self-reported measures of consumer perceptions and emotional responses. Although such measures are widely used in consumer research, they may be subject to social desirability bias or response tendencies. Future research could complement self-report measures with behavioral or implicit indicators to capture consumer responses more comprehensively.

Fourth, the sample primarily consisted of young consumers belonging to Generation Z. While this focus is theoretically justified given Gen Z's heightened sensitivity to issues of inclusivity and diversity, it may limit the applicability of the findings to other age groups. Future research could investigate whether similar effects emerge among older consumer cohorts with different attitudes toward gender representation in marketing.

Fifth, although the findings provide support for the proposed mechanisms linking gender-neutral product presentation to consumer–brand relationships, the empirical results suggest that the symbolic route through perceived brand uniqueness plays a stronger role than the evaluative route through perceived brand quality. While the effect of gender-neutral presentation on perceived brand quality was only marginally significant, the uniqueness-based pathway emerged as the more robust mechanism driving brand self-connection and brand love. Future research could further explore the conditions under which gender-neutral branding influences quality perceptions and examine additional mediating mechanisms that may explain consumers' relational responses to gender-neutral brand positioning.

Finally, future research could explore potential boundary conditions or individual differences—such as consumers' attitudes toward gender norms or their need for uniqueness—that may shape responses to gender-neutral brand positioning.

Managerial implications. *The findings offer several implications for brand managers. First, the results suggest that gender-neutral product positioning can strengthen consumer–brand relationships by enhancing perceptions of brand uniqueness and fostering consumers' psychological connection with the brand. Managers seeking to build stronger emotional bonds with consumers may therefore benefit from adopting more inclusive and gender-neutral brand strategies. Second, the results highlight that both symbolic perceptions (e.g., uniqueness) and evaluative perceptions (e.g., perceived quality) play a role in fostering brand love, although their influence differs in strength. While perceived quality exerts a stronger and more direct impact on brand love, brand uniqueness contributes indirectly by strengthening consumers' brand self-connection. Accordingly, managers implementing gender-neutral positioning should ensure that such strategies not only signal inclusivity but also reinforce perceptions of product quality and brand distinctiveness. By combining credible quality cues with distinctive positioning, brands can strengthen consumers' identification with the brand and ultimately foster stronger emotional attachment.*

Originality of the paper. *This research contributes to the emerging literature on gender-neutral branding by examining how gender-neutral brand positioning shapes consumer–brand relationships through both symbolic and evaluative perceptions. Specifically, the study integrates perspectives from branding and consumer identity research to explain how gender-neutral positioning influences consumers' emotional relationships with brands through two complementary perceptual pathways: perceived brand uniqueness and perceived brand quality.*

The findings show that gender-neutral products can enhance perceived brand uniqueness, which strengthens consumers' brand self-connection and ultimately fosters brand love. At the same time, the study highlights the role of perceived brand quality as an additional evaluative pathway through which gender-neutral positioning may influence consumer–brand relationships.

By uncovering these mechanisms, the research advances understanding of how gender-neutral branding strategies can shape consumers' perceptions of brands and contribute to the development of deeper emotional relationships between consumers and brands.

Can Brand-Related User-Generated Selfies be Recognized as Brand Hijacking? Preliminary Insights from an investigation of the Louis Vuitton brand

ALFONSO SIANO[1♠], FRANCESCA CONTE[2*], ALESSANDRA BERTOLINI[3·], MARIANNA SQUILLANTE[♦]

Abstract. *Digital environments increasingly expose brands to unauthorized third-party use, particularly through visual user-generated content. Selfies are the most prevalent type of image on social media Although their use has been studied in marketing and branding literature, they remain underexplored in brand hijacking research, especially within the luxury sector. The present exploratory study addresses this gap by investigating whether luxury brand-related selfies can be considered brand hijacking practices and whether they represent constructive or destructive forms of the phenomenon. Indeed, luxury brands are particularly vulnerable to this phenomenon, as they rely on exclusivity, symbolic value, and tightly controlled communication. This study adopted a qualitative approach focusing on the Louis Vuitton (LV) brand. Specifically, a visual content analysis was conducted to compare LV's brand communication with LV-related user-generated selfies posted on Instagram. The findings suggest that most of the selected selfies may constitute destructive brand hijacking, as they include elements inconsistent with LV's brand identity. This research advances luxury branding research by incorporating the brand hijacking practices and contributes to brand hijacking literature by introducing the Destructive Brand Hijacking (DBH) score. It also provides managers with preliminary insights for developing appropriate strategies to monitor and influence brand-related user-generated selfies.*
Keywords: *Brand Hijacking; Brand-Related User-Generated Selfie; Luxury Brand; Louis Vuitton; Visual Content Analysis.*

Framing of the research. Digital has transformed how brands are built. In the digital environment, brand meanings emerge from evolving and often ambiguous interpretations generated by multiple actors involved in the brand-building process (Berthon et al., 2009; Wider et al., 2018). Accordingly, recent branding research has increasingly emphasized a participatory and multi-stakeholder perspective of brand management, conceptualizing the brand as a social, dynamic, and polysemic construct (da Silveira et al., 2013; Michel, 2017; Kristal et al., 2020).

While digital transformation affects brands across sectors, it is especially disruptive for luxury brands (Ye, 2026). Luxury brands, more than others, have traditionally relied on strong symbolic control, coherent storytelling, and exclusivity to preserve consistency across touchpoints and maintain the brand's aura, desirability, and status-signaling function (Kapferer, 2014). The digital environment challenges luxury brands' ability to control brand identity and meanings, posing a risk to the perception of exclusivity and uniqueness. This creates a need to reshape how brands are built and communicated (Christodoulides & Wiedmann, 2022; Gupta et al., 2024). As a result, some brands have reconsidered their strategies, opening to co-creation to avoid a loss of relevance, while others seek to maintain a control-oriented approach to protect their status and unique value (Essamri et al., 2019; Riedmeier & Kreuzer, 2022; Kłeczek & Hajdas, 2025). This creates a growing tension between openness and control in luxury branding (Basile et al., 2024), further intensified by brand hijacking.

Brand hijacking refers to the symbolic appropriation of the brand by stakeholders who reinterpret or manipulate its core elements beyond the company's control (Wipperfürth, 2005; Fournier & Avery, 2011). Indeed, these dynamics have recently been defined as non-collaborative brand co-creation, as consumers contribute to shaping and reinterpreting brand meanings through content creation in digital environments without brand interaction (D'Antonio & Siano, 2023). The phenomenon is treated in the literature from a destructive/constructive perspective (Siano et al., 2022). On the one hand, it can take negative forms aimed at damaging reputation and equity through practices such as parody, satire, or trademark abuse (Fournier & Alvarez, 2013; Kucuk, 2019). On the other hand, it may also produce positive outcomes by generating new meanings or facilitating brand repositioning (Kristal et al., 2018).

In both cases, hijacking practices mainly emerge through the manipulation of visual brand elements such as logos, packaging, slogans, or advertising campaigns (Hewer & Brownlie, 2010; Benton & Peterka-Benton, 2020). The preference for visual elements aligns with the pursuit of virality that characterizes hijacking practices, as visual content tends to be more memorable and more likely to spread on social media (Bainbridge, 2025).

Among the various forms of user-generated visual content spread in social media, selfies have a significant position. Selfies can be defined as self-produced digital self-portraits in which the subject of the image coincides with the author of the photograph. They may be created, for instance, by holding the camera in hand, using a mirror, or setting the device

to capture the image automatically (Papacharissi & Mendelson, 2011). Moreover, the phenomenon includes a variety of visual practices, such as belfies and foot selfies, which portray isolated body parts, as well as images involving multiple individuals (i.e., usies, wefies, and groupfies) (Miller et al., 2016; Rettberg, 2014).

Recent studies further highlight that selfies function as tools of self-presentation and identity performance, enabling individuals to construct and negotiate their identities on social media (Tiidenberg & Cruz, 2015). Consequently, when brands are incorporated into selfies, they become part of users' identity narratives (Presi et al., 2016). Therefore, users appropriate the symbolic meanings of the brand but, by sharing content with their network of friends and followers, they attribute their own social meanings to it (Kozinets et al., 2017; Uzunboylu et al., 2020).

This dynamic may be even more critical for luxury brands. Luxury consumers actively share pictures, posts, product reviews, and feedback on social media platforms such as Instagram and Facebook to signal their status and prestige (Koivisto & Mattila, 2020; Pangarkar et al., 2023). However, luxury brand-related self-representation practices can also produce interpretations that diverge from the intended positioning of these brands.

Therefore, selfies may become a privileged space for brand hijacking in the luxury context. It becomes essential to understand how and to what extent selfies contribute to processes of redefinition of luxury brand meanings on social media.

Purpose of the paper. The effects of brand-related user-generated selfies in terms of brand stabilization and destabilization were addressed by Rokka and Canniford (2016). However, these practices remain largely unexplored in brand hijacking literature, which has mainly focused on advertising parodies or hijacked videos and images shared on social media (Thota & Villarreal, 2020). Addressing this gap, our study investigates whether selfies can be classified as a form of brand hijacking and if so, whether they represent constructive or destructive forms of the phenomenon. Indeed, it considers users' practices of brand reinterpretation not only as potential reputational threats but also as possible strategic resources (Siano et al., 2022).

Accordingly, this study addresses the following Research Questions (RQs).

RQ1: *Could brand-related user-generated selfies represent a form of brand hijacking?*

RQ2: *Could brand-related user-generated selfies be categorized as constructive or destructive forms of brand hijacking?*

To answer the RQs, the present study explores the case of Louis Vuitton (LV), a French fashion house founded in Paris in 1854 by Louis Vuitton and currently part of LVMH, a global leader in the luxury goods sector. Initially specialized in travel trunks, the brand later expanded into leather goods, ready-to-wear, accessories, and jewelry, becoming one of the most iconic and influential luxury brands worldwide (Temirov, 2025). Its economic and symbolic relevance is reflected in its presence in the Interbrand Best Global Brands 2025 ranking, where LV holds the 12th position worldwide with an estimated brand value of USD 48.4 billion (Interbrand, 2025). It is also ranked fourth in the Top 10 luxury brands in the world by the Glion Institute of Higher Education (2025).

Moreover, the brand has a highly codified symbolic system. Although it has recently opened its creative universe to collaborations with artists and designers, including Yayoi Kusama (Kłeczek & Hajdas, 2025), it continues to maintain careful and strategic control over its symbolic capital.

In addition, LV has a strong presence on social media, particularly on Instagram. The brand has published over 9,000 posts and has approximately 56 million followers, generating high levels of engagement, exceeding those of other leading luxury brands (Torregrosa et al., 2023).

Overall, these elements make Louis Vuitton a suitable case for addressing the RQs, as it provides a rich and relevant empirical context.

Methodology. To ensure consistency with the purpose of the paper, this study adopted a qualitative approach. We began by defining the intended identity of LV following Kapferer (1992; 2004), based on an analysis of content disseminated through the brand's owned media, including its official website and social media accounts. We then conducted a visual content analysis to compare official brand images with brand-related user-generated selfies (Rokka & Canniford, 2016). Visual content analysis is a systematic method of examining visual materials through explicit and replicable coding categories (Rose, 2012). The method analyzes visual content into analytical units and assigns meanings based on predefined categories, ensuring consistency, transparency, and comparability of results (Gleeson, 2011). In the present study, this method helps to identify the predominance of brand-related meanings in both official brand images and brand-related user-generated selfies and detects potential processes of re-signification associated with brand hijacking (RQ_1 and RQ_2).

Data collection involved two groups of images. Group A consists of official images published on the Instagram account @louisvuitton. Posts published between 2016 and 2026 were considered and gathered by hand. Only visual content depicting people was included. Videos were excluded. Due to platform limitations, posts prior to 2021 could not be fully retrieved. Therefore, the initial corpus included n = 1335 LV's posts. Given the exploratory nature of this preliminary study, only a random sample of 50 images was extracted to enable an in-depth qualitative analysis. Group B consists of brand-related user-generated selfies published on Instagram during the same period (2016–2026). Images were identified through hashtags containing #lv or #louisvuitton combined with #selfie or #selfies and were collected manually. Videos were excluded. The initial corpus included n = 104 LV-related user-generated selfies, from which a random sample

of 50 images was retained. Therefore, the two groups were obtained through simple random sampling. They contain an equivalent number of images, ensuring comparability.

For the purposes of the coding process, interpretive categories were defined to assess both the predominance of meanings associated with the brand and their consistency across the two groups of images. The coding scheme was developed using a hybrid approach combining data-driven and theory-driven strategies. In the first phase, an inductive ("bottom-up") analysis was conducted through visualization and open coding of the entire sample to identify patterns, similarities, and differences within and across the two groups. In the second phase, a deductive ("top-down") approach was adopted, whereby the emerging categories were systematically compared with existing literature, allowing their refinement and integration and improving the clarity and objectivity of the coding process (Tuckett, 2005).

Specifically, we identified the macro-category "expression of luxury", articulated into several sub-categories, namely heritage (e.g., iconic products, historical monograms or emblems), magic (e.g., surreal settings, fairy-tale dresses), elegance (e.g., formal clothing, composed posture), craftsmanship (e.g., close-up details, scenes of the atelier or workshop), exclusivity (e.g., private events, prestigious or elite locations, celebrity endorsement), creativity (e.g., artistic collaborations, experimental use of colors, shapes, and lighting), and excellence (e.g., product packaging design, refined and high-quality materials). These sub-categories were grounded in prior research on luxury branding (Ko et al., 2019; Christodoulides et al., 2009; Rokka & Canniford, 2016; Jacob et al., 2020).

In addition, we included the macro-category "expression of narcissism". This macro-category was operationalized through visual cues associated with vanity (e.g., self-focused poses, body emphasis, mirror use) and ostentatious display (e.g., gestures and postures that demonstrate ownership of the product). Indeed, while vanity reflects the psychological dimension of narcissism, ostentation captures its manifestation in consumption practices and its orientation toward signaling status (Neave et al., 2020).

To capture the tone of the images analyzed, a further macro-category, "expression of humor", was considered, following Vanden Bergh et al. (2011). This category comprises three sub-dimensions: cool (e.g., fashionable and trendy outfits), funny (e.g., playful or entertaining situations, expressions of joy), and witty (e.g., ironic and playful gestures, such as winking or sticking out the tongue).

Each image from groups A and B was examined, classified, and labeled through an iterative process of reading and re-reading, using the same categories. Images from Group B were also analyzed using two macro-categories (disparaging humor and offensiveness) to assess destructive brand hijacking, in line with the approach taken by Vanden Bergh et al. (2011) and previous studies by Thota & Villarreal (2020).

Regarding the disparaging humor macro-dimension, we considered the following sub-categories:

- *mocking (i.e., gesture intended to ridicule the brand or its products);*
- *teasing (i.e., ironic expressions associated with playful, harmless misuses of the brand or its products);*
- *joke (i.e., comical poses or situations associated with the brand or its products);*
- *making fun of (i.e., expressions of disapproval toward the brand or its products);*
- *critical (i.e., gestures of criticism or expressions of explicit contempt that draw attention to a visible defect in the brand's product).*

We considered offensiveness macro-categories in terms of the following sub-categories:

- *gross (i.e., unclean or unhygienic places or vulgar poses associated with the brand and its products);*
- *disgusting (i.e., repulsive or grotesque elements in connection with the brand and its products);*
- *disturbing (i.e., dangerous objects or weapons shown with the brand);*
- *mean (i.e., aggressive or crude gestures in association with the brand or its products);*
- *distorted (i.e., visual elements that clearly deviate from the brand's image).*

Each subcategory was coded as present (1) or absent (0). For each selfie, the scores were summed to obtain a Destructive Brand Hijacking (DBH) score ranging from 0 to 10. Scores were then classified into five levels: low (1–2), medium–low (3–4), medium (5–6), medium–high (7–8), and high (9–10).

To reduce subjective interpretations, a parallel coding of the two image groups was conducted by two independent coders. Inter-coder reliability reached 93% for images in group A and 96% for those in group B, exceeding the 80% recommended by Krippendorff (2012).

Finally, in line with the study objectives, coding frequencies were calculated for the analyzed images, and the consistency between group A and group B was assessed based on differences in the frequency of the categories considered.

Results.

LV intended identity

The LV brand is defined by a strategic combination of heritage, artisanal savoir-faire, and creative innovation (LVMH, 2026), elements recognized as central pillars of contemporary luxury branding (Ko et al., 2019). This identity configuration can be comprehensively analyzed through the Brand Identity Prism, a theoretical model developed by Kapferer (1992; 2004), which conceives a brand as an articulated system of six interconnected dimensions.

- *Physique: this includes tangible elements that ensure instant recognition, such as the patronymic brand name, the "LV" monogram, and iconic products like travel trunks and handbags. The color palette further cements this*

visual identity: the brown of the Monogram Canvas evokes tradition, gold signals exclusivity, and black communicates refined elegance.

- *Relationship: LV builds a privileged connection with consumers via diverse touchpoints, including its official website, physical boutiques, social media accounts, and exclusive events like runway shows. These interactions foster prestige and trust, strengthening the emotional bond with the consumer.*
- *Reflection: this refers to the "ideal" consumer profile. LV's reflection is an individual who is elegant and successful, a perception reinforced by the brand's frequent association with global celebrities and influential figures.*
- *Personality: the brand expresses elegance and creativity with a strong innovative drive. It primarily embodies the Creator archetype, focused on design and innovation, balanced with the Ruler archetype, representing prestigious and leadership.*
- *Culture: deeply rooted in French artisanal tradition and the value of savoir-faire, the brand focuses on excellence in leatherwork. It blends its European luxury heritage with constant creative collaborations.*
- *Self-Image: this is the internal mirror of the consumer. When using LV, customers perceive themselves as sophisticated and part of an exclusive social circle. The brand acts as a symbolic tool for expressing personal distinction.*

Overall, the framework highlights how LV utilizes integrated dimensions to reinforce consistency and distinctiveness in the global luxury landscape, creating significant symbolic value for its audience.

Preliminary content analysis results: group A and B coding frequencies. The visual content analysis of images published on LV's Instagram account (group A) reveals a communication strategy strongly aligned with the symbolic codes of luxury. The most frequently occurring dimensions are exclusivity (90%), excellence (74%), and elegance (66%). Exclusivity is often conveyed through the presence of celebrities (about 32%) or house ambassadors (about 18%) and through prestigious settings such as private events or iconic locations (about 26%). Excellence is mainly expressed through the visual emphasis on product quality, while elegance emerges from the posture of the subjects and their tailored clothing (e.g., tuxedos, suits, jackets, and long dresses). The dimension of creativity (42%) also appears frequently. Creativity emerges through artistic settings or references to the brand's collaborations with artists. The dimensions of heritage/tradition (24%), craftsmanship (22%), and magic (14%) are less frequent. Heritage appears through references to iconic products, historical monograms, or reinterpretations of past designs. Craftsmanship is conveyed through images that emphasize artisanal processes and product details, whereas magic appears in images featuring evocative scenery, fairy-tale atmospheres, and dresses. The cool/trendy sub-dimension dominates among humor categories (76%) (Vanden Bergh et al., 2011), reflecting in the presence of urban contexts, stylish outfits, etc. The funny (16%) and witty (14%) sub-categories appear only marginally, respectively in entertainment situations or in playful poses adopted by the models. Elements associated with narcissism are almost absent; only the vanity dimension appears with a frequency of 36%. Inter-coder reliability reached 93% in group A.

Brand-related selfies (group B) were analyzed using the same categories. Luxury elements appear much less frequently: elegance (30%), exclusivity (20%), and excellence (16%). These dimensions mainly emerge from selfies taken in LV contexts, such as LV stores and restaurants (about 22%). Indeed, most selfies are taken in indoor environments, particularly in domestic (e.g., bedrooms and bathrooms) (about 38%) and non-domestic settings (i.e., restaurants, stores, gyms, elevators, hotels) (26%). The categories of creativity (10%) and magic (2%) appear only marginally, whereas the dimensions of heritage/tradition (0%) and craftsmanship (0%) are absent. In contrast, elements related to individual expression are far more prominent in line with Mishra & Mohapatra's studies (2025). The ostentatious and vanity dimensions appear at very high frequencies (96% and 90%, respectively). In particular, ostentation emerges as subjects display an LV product in the foreground. The most frequently represented LV items are accessories (62%) (e.g., bags, belts, hats, and scarves), followed by clothing (6%), jewelry and watches (4%), and other items (10%) (i.e., face masks, phone cases, etc.). Among the humor sub-categories, the cool/trendy (56%) and witty (50%) dimensions are the most frequent, followed by funny (30%). In several cases, the brand appears in entertainment contexts or in situations where subjects adopt ironic poses or expressions. In group B, the inter-coder reliability reached 96%.

Table 1. Preliminary coding frequencies of group A and group B.

Categories	Coding frequencies	
	LV brand account images	*LV-related user-generated selfie*
Expression of luxury		
exclusivity	90%	20%
excellence	74%	16%
elegance	66%	30%

creativity	42%	10%
heritage/tradition	24%	0%
craftsmanship	22%	0%
magic	14%	2%
Expression of narcissism		
vanity	36%	90%
ostentatious	0%	96%
Expression of humor		
cool/trendy	76%	56%
funny	16%	30%
witty	14%	50%

Source: our elaboration

As shown in table 1, the preliminary results reveal differences in coding frequencies, reflecting diverging meanings associated with LV by the company and their users. Group A (LV's official posts) emphasizes traditional luxury codes such as elegance, reflecting a prestigious brand positioning. In contrast, group B (LV-related user-generated selfies) does not adhere to these symbolic codes and communicative registers. Indeed, LV-related user-generated selfies exhibit a broader range of playful and ironic expressions, which shift the brand away from its established aura of exclusivity and magic. The users of the analyzed selfies use the brand in everyday contexts, thereby distancing it from the elitist settings depicted in official posts. Moreover, these users do not aim to highlight product excellence in terms of heritage, craftsmanship, or creativity. In the analyzed selfies, users display the brand and its products mainly to perform their personal identity, as confirmed by the high coding frequencies observed for the narcissism dimensions.

Therefore, these inconsistencies across images in groups A and B allow the analyzed selfies to be interpreted as instances of brand hijacking.

Preliminary DBH score results based on visual content analysis. Most of the selfies analyzed depict LV in a way that deviates from the brand's luxury identity, potentially harming and diluting its positioning and value. Overall, considering the definition provided by Siano et al. (2022), these preliminary findings suggest that the analyzed selfies can be interpreted as potentially destructive forms of brand hijacking, as they reinterpret the brand's meaning through associations with contexts perceived as inappropriate or inconsistent with the LV intended identity built over the years. For example, they associate the brand with unclean or nasty contexts (e.g., bathrooms) and, in some cases, with vulgarity (e.g., nudity or inappropriate poses), potentially distorting LV's image, undermining its luxury status, and compromising the prestige historically associated with the brand.

Specifically, 16 out of 50 selfies (32%) cannot be classified as destructive brand hijacking. These selfies reinforce the brand's positioning, but they are not categorizable as constructive forms of brand hijacking, as they reproduce the brand's established symbolic codes without introducing reinterpretations or alternative meanings. Conversely, 34 out of 50 selfies (68%) can be classified as potential cases of destructive brand hijacking, as they fall into at least one of the ten subcategories used in the analysis (mocking, teasing, joke, make a fan of, critical, gross, disgusting, disturbing, means, distorted).

The sample shows heterogeneity in the number of subcategories represented. Most selfies exhibit a low level of DBH: 42% of the total selfies (21 out of 50), accounting for 62% of the selfies that are classified as destructive brand hijacking (21 out of 34). Instead, 24% of all selfies (12 out of 50) have a medium-low DBH score, representing 35% of those classified as brand hijacking (12 out of 34). Only 2% of the analyzed selfies (1 out of 50) received a high DBH score, making up 3% of the selfies categorized as brand hijacking (1 out of 34). Accordingly, the average value of DBH obtained for the 34 selfies classified as destructive brand hijacking is 2.26 (in the range from 0 to 10), which is relatively low, representing a limited average presence of heterogeneous dimensions associated with brand hijacking among those considered in the methodology section.

Therefore, these preliminary findings provide affirmative answers to both RQ_1 and RQ_2, which guided this study, offering initial insights into how luxury brand-related selfies may be considered as destructive forms of brand hijacking.

Managerial implications. The preliminary findings suggest several managerial implications for luxury brand managers facing the growing diffusion of visual user-generated content on social media. In the case of LV, the findings reveal a significant inconsistency between the controlled communication disseminated through the brand's official Instagram account and the representations emerging from brand-related user-generated selfies. This may indicate that, in digital environments, luxury brands face increasing difficulties in maintaining full control over their symbolic representation. Consequently, brand managers may adopt more proactive strategies for monitoring and influencing visual user-generated content. As noted by Uzunboylu et al. (2020), users do not only consume brand meanings in digital environments but also contribute to their production. From this perspective, selfies can be interpreted as a branding tool that may incentivize the co-creation process. However, in the luxury sector, these dynamics require careful management, as excessively broad participation could undermine the perception of exclusivity that characterizes luxury brands (Riedmeier & Kreuzer, 2022; Basile et al., 2024). Therefore, brand managers may promote forms of controlled co-creation, encouraging consumers to express themselves creatively within a narrative framework that remains consistent with the brand's values and meaning (Koivisto & Mattila, 2020), avoiding the dilution of brand image (Park et al., 2020). For instance, brand managers can run online contests, providing clear guidelines and defining key values and narrative directions to guide user-generated content creation.

Monitoring selfies not only offers insight into consumers' perceptions, brand meanings (brand associations), and consumption experiences - but also assists brand managers in understanding how they are reinterpreted in a digital environment. By strengthening social media listening, brand managers can identify potentially harmful brand representations early on. Such representations may damage the symbolic capital and prestige on which luxury brand positioning is based, and compromise brand equity. In this context brands may adopt differentiated response strategies, such as engaging in dialogue with users, publicly dissociating from the content, or implementing containment strategies, depending on the nature and severity of the hijacked user-generated content (Siano et al., 2022).

In this context, the involvement of Online Brand Communities (OBCs) may be critical for safeguarding the brand. Actively engaging with these communities, particularly with members who show strong emotional involvement with the brand, may foster brand defense behaviors (Hassan & Casaló Ariño, 2016) and encourage the emergence of brand evangelists who support and defend the brand in digital environments (Cavadas & Moreira, 2025). Hence, brand managers should critically evaluate current initiatives aimed at strengthening relationships with the brand community, as well as those that can be implemented to increase brand loyalty and emotional attachment.

Research limitations and future research. This study presents several limitations that suggest future research directions. First, the use of a single case restricts the generalizability of the findings (Yin, 2009). Therefore, future research could extend the analysis to multiple cases belonging to different luxury industries (e.g., Ready-to-Wear, Perfumes and Cosmetics, Leather Goods, Wines and Spirits, Jewelry and Watches).

Moreover, the study is subject to typical limitations of content analysis techniques (Krippendorff, 2012). The categorization of content into analytical groups may not fully capture the complexity of the visual material, while the relatively small sample of images may limit the generalizability of the findings (Veum & Undrum, 2018). Measurement procedures should be refined in future research and tested on a larger scale in different contexts and time periods.

Finally, the present study considers brand-related selfies as a potential form of brand hijacking, reflecting the researcher's perspective. Future research could incorporate the viewpoints of brand managers and members of luxury OBCs - including influencers, brand lovers, creatives, and artists. On the one hand, considering the perspective of brand managers, as custodians of the brand (Capon et al., 2001), may help accurately capture whether the selected brand-related selfies are constructive or destructive forms of brand hijacking. On the other hand, OBCs represent key contexts for the production and negotiation of brand meaning, characterized by deep, enduring, and emotional relationships between consumers and brands that go beyond mere loyalty (Muniz & O'Guinn, 2001; Cavadas & Moreira, 2025). Therefore, members of these communities constitute relevant stakeholders, whose perspectives could clarify whether brand-related user-generated selfies are socially legitimized as coherent brand expressions or interpreted as practices of re-signification that may reflect brand hijacking dynamics.

Originality of the paper. This study contributes to luxury branding research (Ko et al., 2019) by incorporating the concept of brand hijacking. To the best of our knowledge, it is the first study to explore this perspective.

Furthermore, our preliminary findings may help to extend the conceptual boundaries of brand hijacking. Unlike previous studies, we propose that destructive brand hijacking does not necessarily occur through explicit or disruptive forms of brand sabotage (Fournier & Alvarez, 2013). In the context of luxury brands, even deviations from the established luxury brand identity can distort brand meanings, constituting a form of destructive brand hijacking.

In addition, we introduce a first DBH score to empirically measure brand hijacking, which could facilitate its systematic assessment across visual context. In this regard, the study contributes to ongoing efforts in branding research to develop more robust and measurable constructs (Sarasvuo et al., 2022).

Finally, by focusing on visual user-generated content, this research advances brand hijacking understanding by considering an everyday visual practice, i.e., selfies, as a potential driver of the phenomenon. Accordingly, it opens a new avenue for research at the union of brand-related user-generated selfies and brand hijacking.

Congruency Matters.
Physiological Responses to Nutritional Claim–Product Fit

DONATA TANIA VERGURA[1], SETTIMIO ZICCARELLI[2], CRISTINA ZERBINI[3], GUIDO CRISTINI[4]

Abstract. *Among packaging elements, nutritional claims play a crucial role by providing concise information about product attributes and health-related benefits. However, their effectiveness is not straightforward, as consumers' evaluations are influenced by cognitive biases and contextual factors, including the perceived relationship between healthiness and tastiness. Building on Schema Congruity Theory, this study investigates how the effectiveness of packaging claims depends on the degree of congruence between the claim and the product category. In particular, the research examines whether alignment or misalignment between the communicated benefit (gustatory gratification oriented vs. health oriented claim) and the product's nutritional identity influences consumers' physiological and evaluative responses.*

A between-subjects experimental design was conducted with 40 participants who were exposed to packaging images of two breakfast snacks differing in perceived healthiness (indulgent vs. healthier product). Each product was presented with either an indulgent claim emphasizing taste or a health-related claim highlighting nutritional benefits. Psychophysiological measures, including electrocardiography (ECG) and electromyography (EMG), were used to capture automatic physiological responses related to arousal and emotional valence, while self-reported preferences were collected to assess consumption intentions.

Results showed that emotional valence and product evaluation are strongly influenced by claim–product congruence. Congruent combinations elicit more positive affective responses, while incongruent pairings lead to less favourable emotional evaluations despite higher arousal levels. Behavioural choices further confirm this pattern. These findings highlight that the persuasive effectiveness of nutritional claims depends not only on their informational content but also on their symbolic coherence with the product category schema. Theoretical contributions to research on effectiveness of claims and practical implications for the strategic design of packaging communication are provided, emphasizing the importance of aligning nutritional claims with the product's perceived identity to enhance consumer evaluation and purchase intention.

Keywords: *nutritional claims; congruency; packaging; physiological responses; neuromarketing*

Framing of the research. *Packaging plays a strategic role in the purchasing decision-making process thanks to its ability to create identity and differentiation, as well as to establish a direct channel of communication with consumers (Brennan et al., 2021; Kukreja and Patil, 2025; Rundh, 2016; Underwood, 2003). Among its communicative elements, claims represent a particularly powerful lever that combines strong symbolic value with high informative capacity (Ballco e Gracia, 2022; Prada et al., 2021; van Trijp e van der Lans, 2007). In the food sector, claims are commonly used to convey information about specific product or about the relationship between products and health. These include nutrition claims, which refer to the nutritional properties of a product and its positive effects on bodily functions (Neale and Tapsell, 2022). By providing concise and easily accessible information, nutrition claims perform a useful communication function for consumers supporting them in the comparative evaluation of products and guiding them toward healthier food choices (Ballco and Gracia, 2022; Choi and Reid, 2015; Kristal et al., 1998; Talati et al., 2017).*

In this perspective, nutritional information on packaging does not merely describe product attributes. Rather, it actively shapes consumers' perceptions and influences their behavioural responses, ultimately affecting how products are evaluated and chosen (Abbas et al., 2024; Prada et al., 2021; Stoltze et al., 2021).

Literature has consistently shown that the impact of nutritional claims on consumers' expectations and product evaluations is far from straightforward, as it is shaped by a complex interplay of cognitive, perceptual, and contextual factors. First, some authors have demonstrated that their effectiveness depends on the consumer's correct interpretation and understanding of the information conveyed (e.g., Anastasiou et al., 2019; Campos, 2011). For example, a claim such as "low cholesterol" may be misinterpreted as "low fat", leading to inaccurate inferences about the product's overall nutritional profile (Reid and Hendricks, 1994). In such cases, claims do not merely inform but may activate simplified heuristics that shape expectations in unintended ways. Beyond issues of comprehension, nutritional claims can also trigger deeper evaluative biases linked to lay beliefs about the relationship between health and taste. In particular, research has documented the so-called "unhealthy = tasty intuition", according to which consumers implicitly associate healthiness with inferior taste (Haasova and Florack, 2019). When a claim highlights beneficial ingredients or specific nutritional properties, it may enhance perceptions of healthiness while simultaneously diminishing expected tastiness,

thereby reducing desire and purchase intention (Garaus and Lalicic, 2021; Paakki et al., 2022; Raghunathan et al., 2006). Importantly, this bias operates not only during actual product consumption but also in the pre-consumption phase: it influences the construction of expectations, guiding product evaluations and behavioural intentions even in the absence of direct sensory experience.

However, more recent research suggested that the association between healthiness and reduced tastiness is not universal, but rather context-dependent. In certain communicative or cultural contexts, and for categories perceived as naturally healthy, healthiness can strengthen taste expectations, especially when integrated with complementary hedonic communication (Dubé et al., 2016; Garaus and Lalicic, 2021). Overall, these findings suggest that the effectiveness of health claims cannot be understood solely in terms of their informational content. Instead, their impact depends on the symbolic meanings they activate and the perceptual context in which they are embedded. When a health claim is consistent with prior expectations (for example, in categories perceived as "naturally healthy") or accompanied by hedonic cues that trigger positive inferences about taste, the traditional opposition between health and palatability weakens or even reverses. Conversely, when healthiness appears incongruent with the taste imagery of a product category, the health claim risks activating the "unhealthy = tasty" heuristic, ultimately reducing the product's perceived attractiveness and desirability.

Purpose of the paper. *The present paper aims to contribute to the literature on the communicative power of nutrition claims by examining how their effectiveness depends on the degree of alignment between the claim and the product to which it is associated. In particular, the research focuses on the level of claim–product fit, analysing how perceived congruence or incongruence between the information conveyed through the claim and the product's nutritional identity influences consumers' evaluation processes.*

The notion of congruence refers to the degree of correspondence or discordance between the object of evaluation and the associated attributes (Clemente et al., 2014). According to Schema Congruity Theory (Meyers-Levy & Tybout, 1989), individuals interpret new information through pre-existing cognitive schemas that guide expectations and facilitate information processing (Gao et al., 2022; Meyers-Levy & Tybout, 1989). When incoming information is consistent with these schemas, it tends to be processed more fluently, which generally results in more favourable evaluations and higher perceived credibility. Conversely, incongruent information may require more elaborate cognitive processing and can generate uncertainty, ambivalence, or cognitive dissonance when the message conflicts with established expectations (Peracchio and Tybout, 1996).

In the context of food claims, marketing research has shown that their persuasive effectiveness depends not only on the informational content conveyed, but also on the degree of perceived congruence between the claim, the product, and the consumer's system of expectations (Choi and Reid, 2015; Luo et al., 2025; Magnier and Schoormans, 2015). For instance, health-related claims tend to be more persuasive when associated with products that are already perceived as healthy, as they reinforce existing category schemas. Conversely, when applied to indulgent or hedonic products, such claims may create a mismatch between the communicated benefit and the product's symbolic meaning, potentially reducing credibility or generating cognitive tension (Choi and Reid, 2015).

Building on these theoretical premises, this experimental study used psychophysiological research methodologies to thoroughly investigate the role of congruence/incongruence between packaging claims and category schemas. Specifically, the objective was to verify how different types of claims influence product perception and interest depending on the degree of consistency between the communicated benefit and the product category. To address this objective, the study compared two types of claims: hedonic claims, which emphasise taste and hedonic benefits (indulgent claims), and health-related claims, which highlight nutritional properties (healthy claims). The underlying assumption is that greater alignment between the claim and the product identity will result in more positive implicit attitudes as well as stronger purchase intentions. In contrast, incongruent contexts are expected to elicit more negative automatic cognitive and physiological mechanisms. Therefore, when the emphasised benefit is consistent with the category schema (claim-product congruence condition), the claim may reinforce inferences about the product's characteristics and desirability. Conversely, when a discrepancy exists between the claim and the product (claim–product incongruence condition), the resulting cognitive tension may lead to more critical evaluations and less favourable perceptions of the product. Based on this reasoning, the following research hypotheses are proposed:

H1: Claim-product congruence will lead to a greater physiological activation (arousal) toward the product compared to claim-product incongruence.

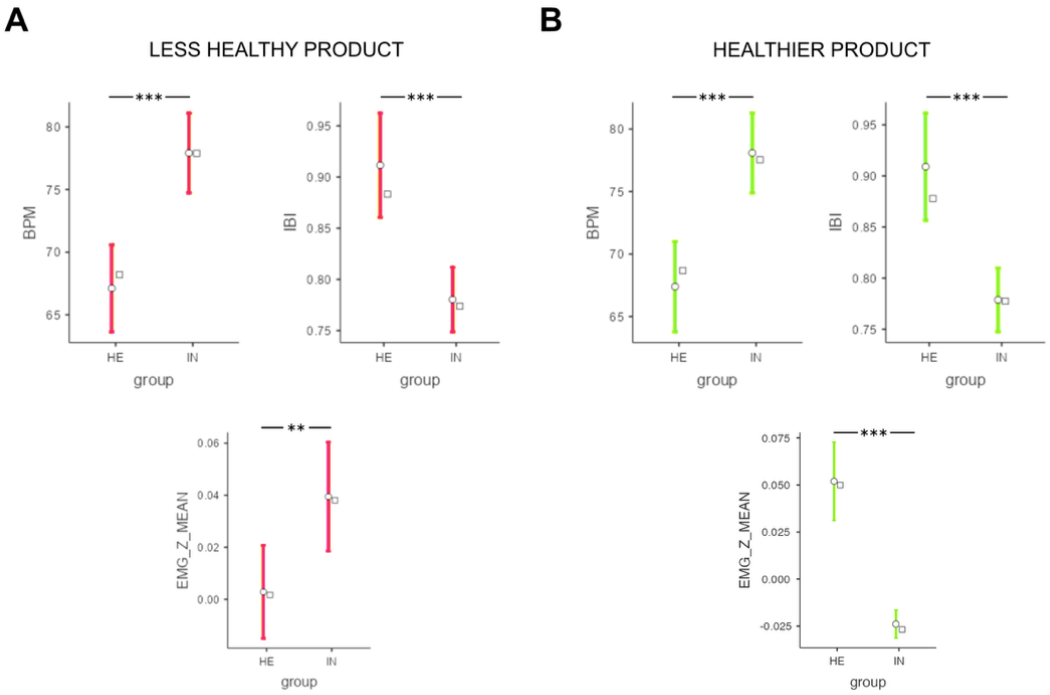
H2: Claim-product congruence will lead to a greater affective evaluation (valence) toward the product compared to claim-product incongruence.

H3: Claim-product congruence will lead to a greater consumption intention toward the product compared to claim-product incongruence.

The empirical context of the study is the breakfast snack category, which is characterized by a structural tension between hedonic and health-related consumption motivations. Within this category, products differ significantly in their perceived healthiness and nutritional composition, making it a particularly relevant context in which to investigate claim–product congruence. For less healthy products, a health-related claim may be perceived as less consistent with the product's category schema, potentially generating ambiguous or sceptical evaluations and reducing persuasive effectiveness compared to indulgent claims. Conversely, for healthier products, health claims may appear more coherent

with the product's identity, reinforcing positive inferences without necessarily undermining taste expectations and thereby mitigating the traditional trade-off between healthiness and pleasantness.

Methodology. *A between-subjects experimental design was developed involving a sample of 40 participants (24 Females and 16 Males, Average Age = 23.6). The subjects were shown packaging images of two breakfast snacks: a) one more indulgent in terms of nutritional composition (IN product); and b) the other with a nutritional profile more oriented towards well-being and healthiness (HE product). The four experimental conditions were obtained by combining the two independent variables (higher/lower level of healthiness of the product and indulgent/healthy claim). Therefore, two version of each product image were developed. The two images were absolutely identical, with the only difference being the type of claim (healthy or indulgent) featured on the packaging. The sample was divided into two subgroups. Each group observed both products in only one of the two claim versions (indulgent claims N = 20; healthy claims N = 20).*



To assess the physiological responses to congruence and incongruence between claims and products, instruments capable of measuring cardiac (electrocardiogram) and facial muscle (electromyogram) responses were used. These instruments enable highly precise detection of the automatic responses triggered by changes in physiological state, which are often mediated by the autonomic nervous system through its orthosympathetic and parasympathetic branches. After viewing the stimuli and measuring physiological parameters, participants were asked to express a final choice preference between the two products (healthy product vs. indulgent product with the same type of claim). Moreover, to investigate whether participants perceived the claim-product pairing as congruent or incongruent, judgements on perceived congruence were also collected (on a scale from 1 = very incongruent to 10 = very congruent).

Results. *The manipulation check confirmed that participants attributed different levels of congruence to the claims, depending on the product in question. For the IN product, the indulgent claim was considered more coherent than the healthy claim ($U = 47.5$, $p < .001$, $r_{rb} = .76$) while for the HE product, the healthy claim was considered more consistent ($U = 127.0$, $p < .046$, $r_{rb} = -.37$).*

The data derived from the electrocardiographic responses showed that arousal is independent of the degree of consistency of the claim with the product. For both products, in fact, the indulgent claim increases physiological activation towards the stimulus, eliciting a higher arousal than the health claim (Heart Rate – HR; Interbeat Interval – IBI) (Figure 1). Therefore, regardless of the degree of congruence with the product, the more indulgent claim activates the organism more (IN product: BPM, $t(38) = -4.50$, $p < .001$, $d = -1.42$; IBI, $t(38) = 4.30$, $p < .001$, $d = 1.36$; HE product: BPM, $t(38) = -4.36$, $p < .001$, $d = -1.38$; IBI, $t(38) = 4.20$, $p < .001$, $d = 1.33$), automatically recalling highly activating and salient characteristics. Hypothesis H1 is therefore not supported. The results from electromyographic measurements, however, highlighted how the emotional valence of the product was strictly dependent on the degree of consistency with the claim, supporting hypothesis H2. Although the indulgent claim generally triggers greater arousal, this does not automatically translate into a positive emotional response for all products. Analysis of the EMG data showed that it is in congruent combinations (IN product with indulgent claim and HE product with healthy claim) that an attribution of positive valence is detected. Conversely, the perception of pleasantness decreases in the case of incongruent stimuli, i.e., indulgent product with healthy claim ($t(38) = -2.61$, $p = .013$, $d = -0.82$) and healthy product with indulgent claim ($t(38) = 6.74$, $p < .001$, $d = 2.13$). This highlights how, despite the high level of physiological arousal, the perceived incongruence between the claim and the product penalizes the latter, implicitly making it more negative in terms of automatic emotional response. Participants' behaviours confirm this result. When faced with a choice between more or less indulgent products, participants exposed to a health claim expressed a preference for the HE product, while participants exposed to an indulgent claim opted primarily for the IN product. Therefore, hypothesis H3 appears to be supported.

Research limitations. *Despite the contributions of this research, some limitations should be acknowledged. First, the study relied on a relatively small sample of participants (N = 40) which, although sufficient to have a certain statistical power in physiological studies, may limit the generalizability of the findings. Future research could replicate the experiment with larger samples to verify the robustness of the observed effects also across different demographic segments. Second, the experiment was conducted in a controlled laboratory setting. Although this approach allowed to control for several confounding variables that could have altered the data and reduced sources of noise that could have compromised the integrity of the physiological recorded signal, it may not fully reproduce the complexity of real purchase environments, where consumers are exposed to multiple stimuli simultaneously and make decisions under time pressure. Further studies could therefore investigate this congruence effect in more ecologically valid contexts. Finally, the research focused on the breakfast snack category and on two specific types of claims (hedonic versus health-related). While this was the category of focus for this current research and allowed for a clear experimental manipulation, the results may not necessarily extend to other food categories or to different types of claims. Future research could explore whether similar congruence effects emerge across a broader range of products and communicative strategies.*

FIGURE 1. ECG and EMG results

Managerial implications. *The study offer several managerial insights for companies involved in the design of food packaging and the strategic use of nutritional claims. First, the results highlight that the effectiveness of packaging claims cannot be evaluated solely in terms of their informational content or their orientation toward health or indulgence. Rather, their persuasive power depends critically on the degree of perceived congruence between the claim and the symbolic and nutritional identity of the product category. When a claim is aligned with consumers' pre-existing expectations about the product, it reinforces the cognitive schema associated with that category and facilitates the formation of positive product evaluations. In the case of the indulgent breakfast snack, the healthy claim appears to conflict with the product's hedonic image, triggering less favourable physiological and evaluative reactions, thereby undermining the credibility of the communication. For companies, this implies that the indiscriminate use of health claims across product portfolios may be ineffective or even counterproductive when such claims are not coherent with the underlying product positioning. Conversely, when nutritional claims are applied to snacks whose identity is already associated with healthier consumption, they tend to strengthen positive inferences and reinforce the product's positioning. In these cases, the claim is easily integrated into the consumer's existing schema and does not generate cognitive dissonance or doubts about taste expectations. This alignment enables to consolidate the product's health-oriented positioning and enhance perceived value without negatively impacting the overall evaluation or consumption intention.*

The physiological measurements employed in this research also provide an important managerial insight: higher attention or arousal does not necessarily translate into more favourable product evaluations. While incongruent claims may attract attention due to their novelty or unexpectedness, this increased salience can simultaneously activate cognitive tension and less positive emotional responses. This result can be explained by the cognitive processing mechanisms described by Schema Congruity Theory: the discrepancy between the product image and the message conveyed by the claim requires greater interpretative effort, which can activate dissonance resolution mechanisms resulting in a less positive overall evaluation of the product. For practitioners, this suggests that capturing consumer attention through surprising or unconventional claims is not sufficient to ensure persuasive effectiveness. Instead, communication strategies must carefully balance distinctiveness with coherence to avoid triggering scepticism or negative implicit reactions.

From a strategic perspective, these results underline the importance of designing claims as part of a coherent communication system that integrates product attributes, category symbolism, and consumer expectations. Using health claims on products that are perceived as indulgent can be ineffective, or even counterproductive, as it risks undermining the credibility of the message and prompting negative associations. Conversely, for products with a well-established health-oriented identity, health claims can reinforce positive inferences, consolidate the health positioning and differentiate the product without lowering expectations. In synthesis, managing the congruence between claims and product identity emerges as a key lever for maximizing the persuasive effectiveness of packaging communication and for guiding consumers' product evaluations and purchase decisions.

Originality of the paper. *By employing physiological responses measurement tools, this study seeks to understand the cognitive and affective mechanisms underlying the processing of nutritional claims, examining whether product evaluations and consumer engagement can be modulated by the broader communication context and by the degree of symbolic congruence between the product and the message conveyed. In doing so, the research moves beyond purely declarative assessments to capture more implicit, real-time reactions that accompany the formation of judgments.*

More specifically, the study contributes to the literature by disentangling the distinct roles of physiological activation (arousal) and affective evaluation (valence), showing that claim–product congruence exerts a stronger and more consistent effect on evaluative responses than on mere activation. Moreover, the integration of physiological indicators with self-reported data enables a more comprehensive understanding of how product–claim congruence shapes perception and influences food-related decision-making. Overall, the research contributes to a deeper understanding of the role of communicative congruence as a key factor in shaping expectations and the choice processes relating to breakfast products, offering theoretical and managerial implications for the strategic design of nutritional claims.

Delegating distress: Evaluating LLMs as protective tools for coding sensitive advertising content

FABIO CORONA[1], SOFIIA KATSIUBA[2], NATALIIA KOCHKINA[3], GIUSEPPE MELIS[4]

Abstract. *This preliminary research examines the adoption of Large Language Models (LLMs) as collaborative tools for qualitative analysis of sensitive video advertisements, with the objective of mitigating the researchers' exposure to vicarious trauma. Although LLMs frequently encounter difficulties in comprehending implicit cultural nuances, their "emotional detachment" is a potential safeguard when analyzing distressing qualitative content. The study analyzed 40 Ukrainian broadcast advertisements from the 2012–2024 period. Initially, two human coders from different cultural backgrounds (Italian and Ukrainian) manually coded the data using a 13-variable codebook. Subsequently, the same advertisements sample was given for analysis to three different LLMs (Gemini Pro 2.5, GPT-4o, and Perplexity Sonar Pro). Preliminary results suggest that LLMs have unique advantages but cannot currently function as independent coders, since they struggled with implicit, subjective variables like archetypes and tone due to their reliance on literal interpretation of advertisements. However, specific models proved to be effective at identifying explicit elements: GPT performed best for explicit symbolism, while Gemini was more effective for identifying character roles and gender stereotypes. Based on the preliminary results, this work proposes a trauma-informed idea for qualitative research where LLMs function as auxiliary coders for explicit, potentially distressing elements of advertisements. Future research will evaluate the framework by examining the actual buffering of researchers' stress, aiming to define a workflow that protects researchers' well-being, particularly in critical situations.*

Keywords: *large language models; qualitative coding; vicarious trauma; advertising research; trauma-informed research*

Framing of the research. *Within marketing and advertising research, researchers are increasingly adopting Large Language Models (LLMs) and AI-based systems to process vast amounts of unstructured consumer data, such as focus group transcripts and social media engagement (Verma et al., 2021). These models possess strong capabilities: they can operate at immense scale, maintain consistency, allow for rapid iteration, and follow rules for explicit, deductive coding (Törnberg, 2024; Xiao et al., 2023), being also able to extract and analyze essential elements from video footage (Liu et al., 2024). By rapidly summarizing narratives and extracting themes using "chain-of-thought" reasoning, LLMs are fundamentally transforming how researchers integrate interpretive tasks (Dunivin, 2025; Mehta et al., 2025). However, deploying these models comes with significant elements to be taken into account.*

While highly effective at surface-level sentiments or information, LLMs frequently struggle with tacit meaning, irony, and the nuanced, culturally grounded motivations driving human behaviors (Mehta et al., 2025; Xiao et al., 2023). In particular, because AI tools are shaped by their training data distributions, their performance differs drastically across cultural contexts, often defaulting to Western norms, hallucinating or misattributing quotes, and carrying inherent biases that can influence different data interpretations (Liu, 2024; Mehta et al., 2025; Törnberg, 2024). However, despite these cultural biases and limitations, LLMs offer a profound methodological advantage: they are entirely immune to the emotional risks determined by the eccessive empathy. This element is particularly useful when considering the analysis of data that contains elements related to war, violence, or more generally, difficult contexts. Research showed that long-term exposure to traumatic material or content, can cause the so defined secondary or vicarious trauma in qualitative researchers, significantly impacting transcription, analysis, and supervision (Kiyimba & O'Reilly, 2015; Smith et al., 2023; Williamson et al., 2020).

This is particularly applicable in the context of interviews, as well as when researchers are exposed to video or picture content containing traumatic elements. Literature emphasises how researchers could behave to protect vulnerable participants in such research conditions, for example by maintaining neutrality when feasible (West & Blom, 2016). Nevertheless, certain studies are concentrating on safeguarding the researchers themselves, which is particularly crucial during data analysis—a stage that necessitates intense intellectual and emotional effort. Throughout the manual coding and content analysis process of such material, researchers encounter recurrent exposure to distressing content, which can produce a considerable cumulative burden over time, potentially leading to intrusive imagery, emotional dysregulation and burnout (Coles et al., 2014; Smith et al., 2023).

[4] University of Cagliari, e-mail: gemelis@unica.it

Researchers' well-being is often treated solely as an individual responsibility; however, trauma exposure is not limited to fieldwork and it's present also during the processes of replay, transcription, and data analysis. For this reason, structural and project-level assistance is necessary (Karcher et al., 2024). It is not advisable (and possible) to depend exclusively on human resilience to cope with trauma exposure; instead, targeted measures, such as structured rehabilitation, regular assessments, explicit cessation guidelines, and measured evaluation should be implemented (Karmakar & Duggal, 2023; Silverio & Sandall, 2022). In light of these elements, the ability of tools like LLMs to analyse data with "emotional detachment" while simultaneously being capable of extracting relevant information renders them appropriate for integration as a method to safeguard researchers' well-being. By incorporating LLMs into the research design to manage the preliminary analysis of potentially distressing qualitative content, researchers can implement trauma-informed principles as a safety measure that proactively reduces harm (Coles et al., 2014; Diab & Al-Azzeh, 2024). Thus, LLMs may be seen as collaborative, auxiliary helpers. This methodology necessitates that researchers conduct systematic audits of LLM outputs and prioritise human experts to guarantee thorough and culturally precise results (Barari & Eisend, 2024; Mehta et al., 2025; Törnberg, 2024; Xiao et al., 2023), while concurrently protecting these experts from the significant psychological burden of qualitative analysis, or at least by distributing the workload between human and LLM coders.

Purpose of the paper. *The principal objective of this work is to investigate how LLMs can be integrated as collaborative tools for human researchers during the content analysis and coding of sensitive video advertising. While the underlying conceptual motivation is to explore their potential to mitigate researchers' exposure to traumatic content and reduce the risk of vicarious trauma, the empirical focus of this study is practice-oriented. This preliminary paper serves as a technical feasibility study; while it doesn't yet quantify stress alleviation, it evaluates if LLMs can achieve sufficient interpretive alignment with humans to justify their future use as protective buffers. Because this phase of the research does not directly measure the alleviation of researchers' stress, it concentrates instead on evaluating the comparative capabilities of different LLMs to interpret specific elements of advertisements in a way that can be compared to human coders. Ultimately, the purpose is to establish a methodological framework that guides the optimal selection of specific AI tools for distinct coding tasks and helps redefine the role of the human coder, laying the technical groundwork for future trauma-informed research practices.*

Methodology. *The research employed content-based coding of 40 advertising from the Ukrainian broadcast schedule between 2012 and 2024. The sample was extracted by a broader set (N = 260) of advertisements and served as a "gold set" to train LLMs to further code other advertisements. The first phase of manual content and coding analysis were conducted by two human coders from distinct cultural backgrounds: one Italian and one Ukrainian. This choice was primarily driven by the ethical need to protect the Ukrainian researcher: although it was impossible to eliminate the exposure to potential traumatic advertising content, working in parallel with an external researcher allowed for the distribution of the emotional burden (when needed) and provided a neutral psychological "anchor" during data discussion and interpretation. Furthermore, utilizing a cross-cultural team supported a more balanced interpretation of data, mitigating the Ukrainian coder's inevitable emotional involvement through the Italian coder's objective detachment, consequently reducing the incidence of cultural bias. The content and coding analyses were performed using a codebook that outlined aspects to be retrieved from the advertisements, composed by a total of 13 variables, including 7 binomial (yes/no) and 6 multi-categorical variables. The examined variables encompassed the presence or absence of elements associated with war or crisis elements, the archetypes of different advertisements, the representation of female and male stereotypes, the tone of the advertisement, and the overall characteristics of the depicted characters. The codebook was used in the first phase of manual coding conducted by human coders, who later evaluated their agreement rate on the responses. The codebook and the rules were subsequently modified to address any discrepancies or ambiguities among human coders, defining more precise guidelines for the analysis. The set of advertisements was subsequently re-evaluated using the revised regulations. The data was structured in a tabular format, with each variable corresponding to a designated category, then analysed with RStudio software (v. 2025.9.2.418; Posit team, 2025).*

After the initial step of manual coding and consensus validation among human coders, the codebook containing the coding parameters was attached to three separate LLMs: Gemini Pro 2.5, GPT-4o, Perplexity Sonar pro. The selection of the three models followed an exploratory logic. While the first two models possess native multimodal capabilities for direct video processing, the inclusion of Perplexity (a more search-oriented model) was intended to test the versatility of different LLMs in a qualitative coding context. Then, the 40 video files of the advertisements were attached individually, one by one, paired with the English translated transcription of each advertisement (when applicable). For each video, the LLMs were queried with the following specific prompt: "Analyze the advertisement, verify the presence of the variables contained in the codebook, and assign the categories based on the instructions provided within the codebook. Give the results in a tabular format. If it's not possible to extract a variable, indicate it with NA". The advertising sample size was chosen to have an adequately large sample for result comparison, while concurrently averting model overload, which could increase the risk of hallucinations. After the coding was completed by the LLMs, evaluation of agreement levels was performed between two human coders and one LLM coder at a time. This was conducted to ascertain the most reliable model for element recognition. The level of agreement was assessed using Cohen's kappa for pairwise coder comparisons (Cohen, 1960), whereas Krippendorff's alpha (Krippendorff, 2019) was employed for collective agreement including multiple coders. Moreover, considering the peculiar nature of some of the chosen variables to code (especially

binary ones), also percentage agreement was considered, to further have support in evaluating the actual agreement between coders.

Results. *The results obtained are preliminary, and they come from an initial investigation of the potential role of AI tools in helping code particular elements of advertisements, which have a critical nature. As for the agreement between human coders, the agreement rate that was reached was moderate, since kappa reported values higher than the cut-off of 0.60 (McHugh, 2012) in almost every coded variable, and this was further supported by a general medium-high percentage agreement between coders (Table 1). Specifically, the highest inter-coder agreement was reached for the Character_gender variable (κ = 0.83), and agreement level was also moderate for the Character_role variable (κ = 0.75); these results can be attributed to the fact that basic character traits are more readily identifiable across different advertising scenarios. Moreover, the variables related to male and female stereotypes reported a moderate agreement (κ = 0.77 and κ = 0.65, respectively), indicating that the coders consistently identified the same underlying stereotypes for both male and female characters across the advertising sample. These values are particularly significant given the multi-categorical nature of these specific variables (i.e., which stereotype is represented?) and their more complex interpretation. In contrast, the symbolism variables exhibited a more complex pattern. While they displayed generally homogeneous (and high) levels of percentage agreement, their statistical indices varied significantly. For example, solidarity symbolism yielded a high Cohen's kappa (0.84) but a lower percentage agreement compared to militaristic symbolism, which, conversely, showed a very low kappa (0.41) despite a near-perfect percentage agreement. This phenomenon is probably attributable to the binomial nature of these variables (i.e., present/absent) combined with the relatively small sample size. In fact, certain symbolic characteristics were either consistently present or consistently absent across almost all advertisements. Under such conditions of high trait prevalence (or absence), a single disagreement between coders carries a disproportionate mathematical weight in the calculation of the statistical index, thus lowering the kappa or alpha values despite high agreement in absolute terms (Feinstein & Cicchetti, 1990).*

The Archetype and Tone variables reported generally low levels of inter-coder agreement, reflected in both percentage terms and statistical indices (κ = 0.54 and κ = 0.48, respectively). These levels can likely be attributed to the inherently "cultural" and subjective nature of these constructs. Although the archetypes were clearly defined using an adaptation of Mark and Pearson's (2001) framework, their interpretation—particularly within the constrained timeframe of short advertisements (e.g., under 20 seconds)—remained ambiguous. Specifically, the coders frequently emphasised different advertisements' characteristics as the primary identifying features of a specific archetype, leading to divergent categorisations. The coders explicitly acknowledged this subjective "weighting" during their discussion of agreement results. During this same discussion, the impact of cultural background became especially apparent regarding the Tone variable. For example, the Italian coder overlooked particular sarcasm aimed at the Ukrainian audience, categorising the advertisement's tone as simply "light".

Table 1. Agreement between the two human coders

Variable	*Cohen's kappa*	*Pct_Agreement*
Char_Gender	*0.830*	*87.5*
Char_role	*0.754*	*82.5*
Archetype	*0.542*	*60.0*
Stereotype_man	*0.769*	*82.5*
Stereotype_woman	*0.654*	*72.5*
National_symbolism	*0.630*	*92.5*
Solidarity_symbolism	*0.844*	*95.0*
Militaristic_symbolism	*0.413*	*97.5*
Hedonic_symbolism	*0.383*	*70.0*
Healthcrisis_symbolism	*0.634*	*100.0*
Domesticity_symbolism	*0.377*	*85.0*
Professional_technical_symbolism	*0.584*	*80.0*
Tone	*0.481*	*67.5*

After evaluating inter-rater agreement between the two human coders to study which LLM performed better, the agreement rate between groups of 3 coders (two humans and one AI) was calculated. Results are synthesised in Table 2. Looking at the results, it can be observed that, in terms of the "best" model, GPT reports most of the higher levels in terms of agreement (8 out of 13 variables), followed by Gemini (6 out of 13 variables). Perplexity reported the higher score for only one variable (Healthcrisis_symbolism). Specifically, GPT reports higher scores for the symbolism variables (Solidarity, Militaristic, Hedonic, Domesticity, Professional technical), while Gemini works best for variables as Character role, Stereotype man and woman; GPT also scored the highest for the Archetype variable, even if the value is

generally low in this last case (0.54). Considering the agreement scores in general terms, the variables for which the higher agreement score was reached are represented by Militaristic symbolism (0.900), National symbolism (0.758) and Character gender (0.773). The binomial (or, in the case of Character gender, a three-level) nature of these variables can explain why they scored higher for the agreement with LLMs coders.

Variables of increased complexity, such as character role and gender stereotypes, proved more challenging for the LLMs to code. As a result, for these categories agreement levels with human coders were acceptable yet relatively low (0.714, 0.674, and 0.710, respectively). The greatest issues emerged with the Archetype (maximum value of 0.540) and Tone (maximum value of 0.343) variables. As previously mentioned, these represent the most complex variables, heavily dependent on a "watching" experience and the subjective interpretation of character behaviours and interactions in both explicit and implicit contexts. It is also noteworthy that for specific variables, high percentage agreement frequently coincided with low Krippendorff's alpha values (e.g. solidarity, hedonic and professional/technical symbolism). This discrepancy, aligned with the trends noted among human coders, suggests that these specific features are highly prevalent (or totally absent) within the dataset. Due to coders' consensus regarding a variable's almost constant presence or absence, any rare instance of disagreement carries a disproportionately heavy "penalty" in the calculation of the reliability index.

Overall, the preliminary results suggest that LLM coders currently provide insufficient standalone support for the human coding process, as these models require a precisely defined reality and inherently find it challenging to grasp nuanced subtleties or implicit meanings. This limitation potentially arises from underlying technical constraints: instead of watching and processing the advertisements holistically, the models must infer events by analyzing the video footage frame-by-frame, which forces a strictly literal interpretation of the narrative. Consequently, if narrative elements are not explicitly represented, the model is unable to "see" them, unlike a human coder who can perceive subtext. These findings are consistent with the literature highlighting that while LLMs are proficient at extracting surface-level information, they fail when the analysis context is more complex (Mehta et al., 2025). Even with the guidance of a comprehensive codebook, the models' fundamental lack of "tacit knowledge" significantly limits their ability to interpret the multidimensional complexities of advertising content. Paradoxically, this inability to "read" emotional context serves a protective function: it makes LLMs suitable for coding specific explicit variables that can carry a strong emotional weight (e.g. the presence of war images), thereby helping to safeguard human coders and reduce their overall stress.

Table 2. Differences in agreement between human coders and single AI model

Variable	***Kripp_alpha***			***Pct_agreement***		
	GEMINI	*PERPL.*	*GPT*	*GEMINI*	*PERPL.*	*GPT*

Note: In bold are reported the highest levels of agreement for each variable

Research limitations. The present research, especially due to its preliminary and exploratory nature, presents a set of limitations. First, *despite employing three distinct LLMs for coding, only two human coders were involved, and just one cross-cultural comparison (Italy vs. Ukraine) was conducted. Future studies could incorporate human coders from different cultural backgrounds. Moreover, the current (advertising) sample size is relatively constrained, especially for the annual distribution of commercials, and the results will be more robust once the supplementary corpus of advertisements will be incorporated in the data analysis. Moreover, although the choice to utilise Ukrainian advertisements as the sample was justified by the nation's current state of emergency, this does not permit the results to be entirely generalised to other contexts with analogous conditions.*

From a "technical" point of view, an important limitation is represented in the "black-box" nature of the models' mechanisms regarding video analysis. Specifically, parameters such as frame sampling rates, resolution, and the

potential reliance on keyframes rather than holistic video processing were not veryfied. As this is a preliminary feasibility study focused on output alignment rather than optimisation, these variables were not controlled, limiting the reproducibility of the study. Also, our understanding of the potential impact of other LLMs is constrained by the use of a single, very simple prompt and the consideration of only three models. Particularly, the lack of application of the Chain-of-thought reasoning (Dunivin, 2025) constitutes a methodological limitation This likely hindered the models' performance on "difficult" variables such as Archetype and Tone, which in the current study was based on a simple classification prompt. Finally, the inability to perform interviews (at the moment) and evaluate stress or vicarious trauma levels prior to and subsequent to the data processing process constitutes another notable limitation. This will be executed in the succeeding phases of the investigation. Our forthcoming research intends to investigate these elements more comprehensively.

Managerial implications. *Based on the preliminary findings of this study, the immediate managerial implications for research practitioners center on the methodological integration and strategic selection of LLMs in qualitative analysis (content analysis and coding) workflows. Results suggest that specific AI models must carefully be selected based on the distinct nature of the variables being analyzed, as performance varies significantly between tools. For instance, when analyzing cultural influenced elements such as archetypes and gender stereotypes, models like Gemini demonstrate higher (even if not strong) agreement rates with human coders. Conversely, for identifying variables related to explicit symbolism—such as solidarity, militaristic, or domestic symbols—GPT appears to be a more effective tool. These preliminary results suggest a potential functional specialization of LLMS (e.g. GPT for explicit symbolism and Gemini for cultural influenced indicators), though these should be treated as a baseline for human auditing and as a support Furthermore, practitioners should avoid combining multiple AI coders indiscriminately; the data indicates that combining all human and AI coders together drastically reduces agreement rates, making consensus a matter of chance rather than accuracy. The current technical constraints of LLMs also necessitate a redefinition of the human researcher's role within the analytical process. Because LLMs analyze videos frame-by-frame and struggle with tacit meaning, they are best deployed as auxiliary helpers for identifying the objective presence or absence of explicit elements. Consequently, human coders must transition into dual roles as cultural interpreters and systematic auditors. Humans remain essential for grasping the nuanced, culturally grounded motivations and implicit tone within advertisements. Finally, while the core conceptual motivation of this methodology is to safeguard researchers from the distress of sensitive material, the actual implementation of LLMs as a structural mental health safeguard remains a potential implication requiring further study. The current phase of this research primarily evaluated the technical capabilities of LLMs to interpret advertising elements. Because stress and vicarious trauma levels were not quantified prior to and following the data analysis procedure, the definitive impact of this workflow on reducing cumulative researcher burden must be addressed in subsequent stages of the research. However, the preliminary success of LLMs in coding explicit variables suggests a promising framework where the preliminary analysis of distressing content can be delegated to AI, reducing harm and supporting trauma-informed research principles.*

Originality of the paper. *The originality of this paper lies not merely in applying LLMs to qualitative content analysis in marketing, but in proposing a novel methodological framework strategically designed to safeguard human coders from potential stress and trauma. By delegating the initial coding of distressing stimuli—such as content related to war and conflict—to LLMs, this work highlights how these technologies can support, rather than supplant, human researchers. Another key element of novelty is the comparative evaluation of different LLMs for video content analysis, alongside the explicit definition of distinct analytical roles for AI and human coders. Specifically, the study highlights that different LLMs possess distinct strengths in identifying the objective presence or absence of specific elements, whereas human coders remain essential for interpreting the deeper cultural and "human" elements within video advertisements. Furthermore, this study considered a multicultural perspective by employing human coders from diverse cultural backgrounds, ensuring cultural sensitivity when analyzing war-related advertisements. Ultimately, this provides the base for an adaptable, trauma-informed framework for similar research contexts involving potentially sensitive content.*

Designing Sustainable Delivery Choices at Checkout: Evidence from Digital Nudging Experiments

JACOPO BALLERINI[1], BALAZS LAJOS PELOCSI[2], ALBERTO FERRARIS[3]

Abstract. *As e-commerce continues to expand, last-mile delivery has become a major source of environmental impact. Although research on sustainable logistics has traditionally focused on upstream operational solutions, delivery choices are increasingly made by consumers during the checkout phase. This research examines how digital choice architecture at checkout influences sustainable delivery decisions, focusing on informational complexity and default preselection. Drawing on Cognitive Load Theory, we argue that sustainability information embedded in checkout interfaces imposes varying cognitive processing demands that can shape delivery choices. Across one preliminary study and two experiments conducted with Italian consumers, we test how informational nudges and default preselection affect the adoption of Click & Collect as a more sustainable delivery option. Results show that informational nudges exhibit a non-linear effect: moderate informational complexity increases Click & Collect adoption, while highly detailed information reduces it. Process evidence indicates that this effect is mediated by perceived cognitive effort. Default preselection consistently increases Click & Collect adoption but does not reduce perceived cognitive effort. By conceptualizing checkout as a cognitively constrained decision environment, this research contributes to digital nudging literature and sustainable last-mile delivery research. The findings highlight the importance of balancing informational and structural nudges in digital interfaces designed to promote sustainable consumer behaviour.*
Keywords: *first; second; third; fourth; fifth; sixth*

Framing of the research. The rapid expansion of e-commerce has significantly increased the environmental impact of last-mile delivery. The growing number of shipments, fragmented delivery routes and consumer expectations for rapid delivery contribute to emissions, congestion and logistical inefficiencies (Nogueira et al., 2021; Biancolin & Rotaris, 2024). Although technological innovations such as electrification or route optimisation aim to mitigate these impacts, the role of consumer decisions in shaping delivery outcomes has received comparatively less attention.

In online retail environments, the selection of delivery options typically occurs during the checkout stage. This moment represents a critical decision point where consumers choose between alternatives such as home delivery or pickup options including Click & Collect or parcel lockers. Research shows that consumers frequently prioritise speed and convenience over environmental considerations (Ignat & Chankov, 2020; Caspersen & Navrud, 2021). However, behavioural research suggests that consumer decisions are not fixed and can be influenced by the design of digital choice environments (Johnson et al., 2012; Thaler & Sunstein, 2008).

In digital contexts, choice architecture interventions such as informational cues or default settings can significantly influence consumer decisions. Informational nudges, including environmental labels or sustainability indicators, can increase the salience of ecological consequences and guide consumers toward more sustainable choices (Rai et al., 2021; Thomas et al., 2022). Structural interventions such as default preselection can be even more powerful, as consumers often interpret defaults as recommendations or rely on them due to inertia (Pichert & Katsikopoulos, 2008; Jachimowicz et al., 2018).

Despite this growing literature, relatively little attention has been devoted to the cognitive constraints under which checkout decisions occur. Online checkout environments present consumers with multiple simultaneous decisions, including payment options, delivery choices and administrative information. Research on decision making suggests that complex decision environments increase the likelihood of heuristic processing and simplified decision strategies (Chernev et al., 2015).

To address this issue, the present study adopts Cognitive Load Theory as a theoretical framework. Cognitive Load Theory proposes that individuals possess limited working memory resources and that the structure and complexity of information influence decision processes (Sweller, 1988; Paas et al., 2003). When information exceeds individuals' processing capacity, decision quality may decline or individuals may avoid cognitively demanding alternatives.

Applying this perspective to digital checkout environments allows sustainability information to be interpreted not only as communication but also as a cognitive processing task. Sustainability indicators often involve numerical or abstract information, such as carbon emissions or environmental impact metrics. While such information may enhance awareness, excessive complexity may increase cognitive effort and reduce engagement with sustainable options.

Building on these insights, the present research investigates how informational complexity and default preselection influence sustainable delivery choices in online checkout environments.

Purpose of the paper. The purpose of this research is to examine how digital choice architecture embedded in e-commerce checkout interfaces can influence consumers' selection of sustainable delivery options. Specifically, the study focuses on two widely used digital nudging strategies—informational cues and default preselection—and investigates how these interventions shape the adoption of Click & Collect as a more sustainable last-mile delivery option.

In online retail environments, the checkout stage represents a critical decision moment in which consumers select delivery options under conditions of limited attention and time pressure. While sustainability information can make environmental consequences more salient, its effectiveness depends on how such information is presented. Previous research has shown that sustainability-related information can encourage environmentally responsible behaviour when it is clearly interpretable and easily comparable across alternatives (Rai et al., 2021; Thomas et al., 2022). However, studies on consumer decision-making also highlight that excessive informational complexity may increase cognitive effort and reduce decision quality (Chernev et al., 2015).

Drawing on Cognitive Load Theory (Sweller, 1988; Paas et al., 2003), this research proposes that the relationship between sustainability-related information and delivery choice may be non-linear. Moderate informational cues may improve evaluability and facilitate decision-making, whereas highly detailed information may increase perceived cognitive effort and discourage the adoption of sustainable delivery options.

Accordingly, the first objective of this research is to examine whether the presence of sustainability-related informational cues at checkout influences the likelihood that consumers select the Click & Collect delivery option. Based on prior literature on sustainability communication and environmental labelling, we expect informational nudges to increase the adoption of the sustainable delivery alternative relative to a condition without such cues.

H1: The presence of sustainability-related informational cues at checkout increases the likelihood that consumers select the Click & Collect delivery option.

Second, the study investigates whether informational complexity influences sustainable delivery choice in a non-linear manner. While simple informational cues may not sufficiently communicate the environmental benefits of alternative delivery modes, highly detailed information may impose excessive cognitive processing demands.

Therefore, building on Cognitive Load Theory and research on information overload (Chernev et al., 2015), the study proposes that moderate informational complexity will be more effective than either minimal or highly detailed messages.

H2: Informational complexity has an inverted U-shaped relationship with the likelihood of selecting Click & Collect, such that moderate informational complexity produces the highest adoption rates.

Third, the research examines the psychological mechanism underlying these effects. Cognitive Load Theory suggests that individuals possess limited working memory resources and that increasing informational complexity can increase perceived cognitive effort (Sweller, 1988; Paas et al., 2003). Higher perceived effort may reduce consumers' willingness to engage with more effortful decision alternatives, leading them to rely on simpler or more convenient options.

Accordingly, we expect perceived cognitive effort to mediate the relationship between informational complexity and sustainable delivery choice.

H3: Perceived cognitive effort mediates the relationship between informational complexity and the likelihood of selecting the Click & Collect delivery option.

Finally, the study examines the effect of default preselection as a structural choice-architecture intervention. Defaults are widely recognised as one of the most powerful tools of choice architecture because they influence behaviour while preserving freedom of choice (Thaler & Sunstein, 2008; Johnson et al., 2012). Empirical evidence shows that preselecting sustainable options can significantly increase their adoption across multiple domains (Pichert & Katsikopoulos, 2008; Jachimowicz et al., 2018).

Therefore, we expect that preselecting Click & Collect as the default delivery option will increase its adoption regardless of the informational complexity presented in the checkout interface.

H4: Default preselection of Click & Collect increases the likelihood that consumers select this delivery option compared with a non-preselected condition.

Overall, the study aims to contribute to the literature on digital nudging and sustainable consumption by examining how informational design and structural choice architecture interact in shaping sustainable delivery decisions in online retail environments.

Methodology. To test the proposed hypotheses, the research employs an experimental approach consisting of one preliminary study and two main experimental studies. Experimental methods are particularly suitable for examining digital nudging interventions because they allow the causal effects of interface design elements to be isolated and systematically manipulated.

The preliminary study served to validate the manipulation of informational complexity and to assess whether different sustainability cues were perceived as varying in informational intensity. Participants were presented with different informational messages associated with the Click & Collect option during a simulated checkout scenario. The messages ranged from simple visual cues, such as a sustainability icon, to more detailed environmental information including CO_2 emission calculations. The primary objective of this pre-study was to confirm that participants perceived these messages as differing in complexity and that increasing informational detail was associated with higher perceived cognitive effort.

The main empirical tests were conducted in two experimental studies involving Italian consumers recruited through online panels. Across both studies, participants were asked to imagine completing an online purchase and were exposed to a simulated e-commerce checkout interface presenting two delivery options: home delivery and Click & Collect.

Study 1 employed a between-subjects design manipulating informational complexity and default preselection. Participants were randomly assigned to experimental conditions representing different levels of informational complexity. In addition, some participants were exposed to a default condition in which Click & Collect was preselected, while others were required to actively choose between the two delivery options.

Following exposure to the checkout interface, participants completed a short questionnaire measuring perceived cognitive effort using Likert-scale items. In addition to the binary delivery choice task, participants also reported their level of consideration for selecting the Click & Collect option. Standard demographic and behavioural variables such as age, gender, education level, environmental attitudes and online shopping frequency were included as control variables.

Study 2 served as the main behavioural experiment and employed a simulated e-commerce interface that replicated a full purchasing journey. Participants were asked to select a product and proceed through a checkout process in which they encountered different informational cues and default settings associated with the Click & Collect option. The experiment included several informational conditions corresponding to increasing levels of informational complexity, ranging from minimal visual indicators to detailed environmental information.

In total, more than 400 participants completed the final experimental study. Data were collected through an online platform and participants were randomly assigned to experimental conditions. Statistical analyses included regression models and mediation analyses to examine the effects of informational complexity, perceived cognitive effort and default preselection on delivery choice outcomes.

Results. The results provide empirical support for several of the proposed hypotheses regarding the influence of digital choice architecture on sustainable delivery decisions.

First, the analyses show that the presence of sustainability-related informational cues at checkout influences consumers' delivery choices. Informational conditions characterised by moderate levels of informational complexity significantly increased the probability that participants selected the Click & Collect option compared with the control condition. These results provide partial support for H1, indicating that sustainability information can encourage the adoption of more environmentally friendly delivery alternatives.

Second, the findings reveal a non-linear relationship between informational complexity and delivery choice. Informational cues with moderate complexity generated the highest rates of Click & Collect adoption, whereas both very simple cues and highly detailed environmental messages were associated with lower adoption rates. Statistical analyses confirmed the presence of an inverted U-shaped relationship between informational complexity and sustainable delivery choice, supporting H2.

For example, intermediate informational conditions increased Click & Collect adoption rates by approximately 15–25 percentage points relative to the control condition, whereas the most complex informational message produced adoption rates similar to those observed in the absence of informational cues. These findings suggest that excessive informational detail may impose cognitive processing costs that discourage engagement with sustainability information.

Third, mediation analyses provide evidence for the role of perceived cognitive effort as an explanatory mechanism. Higher levels of informational complexity were associated with significantly higher levels of perceived cognitive effort. In turn, perceived cognitive effort was negatively related to the likelihood of selecting the Click & Collect option. Once cognitive effort was included in the model, the direct effect of informational complexity on delivery choice decreased substantially. These results provide support for H3, indicating that cognitive effort mediates the relationship between informational complexity and sustainable delivery choice.

Finally, the results demonstrate a strong effect of default preselection. Across experimental conditions, participants exposed to a default setting in which Click & Collect was preselected were significantly more likely to retain that option compared with participants who were required to actively choose between delivery alternatives. On average, default preselection increased Click & Collect adoption by approximately 20–25 percentage points across conditions. This finding supports H4 and confirms the powerful behavioural influence of default settings previously documented in the literature (Pichert & Katsikopoulos, 2008; Jachimowicz et al., 2018).

Overall, the results highlight that informational cues and default settings influence sustainable delivery choices through distinct mechanisms. Informational nudges operate primarily through cognitive processing dynamics, whereas default preselection directly shapes behaviour by structuring the decision environment.

Research limitations. This research presents several limitations that should be acknowledged and that provide opportunities for future research.

First, the empirical studies rely on a single-country sample consisting of Italian consumers. Although this context is relevant due to the rapid growth of e-commerce and increasing attention to sustainable delivery solutions, consumer responses to digital nudging interventions may vary across countries due to differences in logistics infrastructure, digital maturity and sustainability norms (Caspersen & Navrud, 2021; Rai et al., 2021). Future studies could therefore test the proposed framework in cross-country settings to examine the generalizability of the findings.

Second, the research adopts an experimental design based on simulated checkout environments. Experimental methods allow strong internal validity and causal inference, which are essential when studying digital nudging interventions. However, simulated decision contexts cannot fully replicate the complexity of real online purchasing situations, where additional factors such as time pressure, delivery urgency, promotions or habitual preferences may

influence consumer decisions (Chernev et al., 2015). Future research could complement experimental evidence with field experiments conducted in real e-commerce platforms.

Third, the study focuses on short-term behavioural responses to nudges embedded in the checkout interface. Although previous research shows that choice architecture interventions can influence immediate decisions, their long-term effects on behaviour remain less clear (Jachimowicz et al., 2018). Future studies could therefore examine whether repeated exposure to sustainability-related nudges leads to persistent behavioural change or whether their effects diminish over time.

Finally, the present research examines informational complexity and default preselection as two specific nudging strategies. While these interventions are among the most widely studied tools of choice architecture (Johnson et al., 2012; Thaler & Sunstein, 2008), future research could investigate how other forms of digital nudges—such as social norms, framing strategies or recommendation systems—interact with informational design in shaping sustainable delivery choices.

Managerial implications. The findings provide several implications for e-commerce managers, digital channel designers and logistics providers seeking to promote more sustainable delivery choices.

First, the results suggest that the design of sustainability information in checkout interfaces should carefully balance informativeness and cognitive simplicity. While providing environmental information can increase the adoption of sustainable delivery options, overly complex messages may impose cognitive burdens that reduce engagement. Managers should therefore prioritise concise and easily interpretable sustainability cues, such as simplified environmental labels or icons, rather than highly detailed technical information.

Second, default preselection emerges as a particularly effective intervention to encourage sustainable delivery choices. Consistent with prior research on choice architecture, preselecting the sustainable option significantly increases the probability that consumers adopt it (Pichert & Katsikopoulos, 2008; Jachimowicz et al., 2018). For online retailers, implementing a "green default" in which Click & Collect is preselected at checkout represents a relatively low-cost and scalable strategy for promoting sustainable logistics.

Third, the findings highlight the strategic importance of the checkout stage as a behavioural intervention point. While sustainability initiatives in logistics are often implemented upstream through technological innovations or infrastructure investments, the checkout interface represents a powerful yet underutilized opportunity to influence consumer behaviour. Designing checkout environments that facilitate sustainable choices can therefore complement operational sustainability strategies.

Finally, the results are also relevant for logistics providers and policymakers interested in reducing the environmental impact of last-mile delivery. Encouraging the adoption of pickup-based delivery solutions such as Click & Collect can significantly reduce emissions and delivery inefficiencies (Nogueira et al., 2021; Biancolin & Rotaris, 2024). Digital nudging interventions embedded in online retail interfaces may therefore represent a flexible and scalable complement to regulatory or infrastructural policies aimed at promoting sustainable urban logistics.

Originality of the paper. This research contributes to the literature on digital nudging, sustainable consumption and last-mile logistics in several related ways.

First, the paper contributes to research on sustainable delivery decisions by conceptualizing checkout as a cognitively constrained decision environment rather than as a purely transactional stage of the online purchase journey. While prior studies have shown that sustainability information can influence consumers' delivery preferences, less attention has been devoted to the role of information processing constraints in shaping these effects. By applying Cognitive Load Theory (Sweller, 1988; Paas et al., 2003), this study shows that the effectiveness of sustainability-related informational cues depends not only on their presence, but also on their level of complexity and on the cognitive effort they require.

Second, the paper contributes to the digital nudging literature by distinguishing more clearly between informational nudges and structural nudges within the same empirical setting. Existing studies often examine individual nudging tools in isolation, whereas real digital environments expose consumers to multiple cues simultaneously (Johnson et al., 2012; Thaler & Sunstein, 2008). By analysing informational complexity and default preselection together, the study provides a more realistic account of how different forms of digital choice architecture shape behaviour at checkout.

Third, the study offers a more process-based interpretation of sustainable delivery choice. Rather than treating the selection of Click & Collect simply as a preference outcome, the paper highlights the cognitive mechanism through which checkout design may facilitate or hinder sustainable choice. In particular, the findings indicate that perceived cognitive effort helps explain why moderate informational nudges are more effective than highly detailed ones. This adds nuance to previous evidence on sustainability-related information and supports the idea that more information is not necessarily better in digital decision environments (Chernev et al., 2015).

Fourth, the research contributes to the emerging intersection between marketing and last-mile logistics by treating delivery mode selection as a consumer behaviour problem as well as an operational one. In much of the logistics literature, sustainable last-mile delivery is approached mainly through infrastructure, technology or efficiency lenses (Nogueira et al., 2021; Biancolin & Rotaris, 2024). This paper instead emphasises that the consumer-facing interface is itself part of the sustainability challenge, because the final delivery outcome is also shaped by how options are presented at the moment of choice.

Finally, the originality of the study also lies in its managerial relevance. By focusing on checkout design, the paper identifies a practical and scalable intervention point through which firms can promote more sustainable delivery behaviour without removing consumer freedom of choice. In this sense, the research advances current understanding of how digital retail design can support sustainability objectives through relatively light-touch behavioural interventions.

Directive vs. Non-Directive Front-of-Pack Nutritional Labels: Evidence on Healthiness Perceptions and Purchase Intentions from Private Label and National Brands in Poland

ALESSANDRO CASADEI[1], MARCO FRANCESCO MAZZÙ[2],
ANGELO BACCELLONI[3], ROSAMARIA DEL VILLANO[4]

Abstract. *This exploratory study examines how directive (Nutri-Score) vs non-directive (NutrInform Battery) front-of-pack nutrition labels (FOPL) influence Polish consumers' perceptions of product healthiness and purchase intentions in the breakfast cereal category, while controlling for brand type (national brand vs private label). Using a 2 × 2 between-subjects experimental design with 202 Polish primary grocery shoppers, we compare Nutri-Score and NutrInform applied to fictitious cereal brands. Results from a MANOVA followed by univariate tests show that FOPL significantly affect perceived healthiness and, to a lesser extent, purchase intentions (with small effect sizes), while no significant differences emerge for brand attitude, trust, word-of-mouth or loyalty-related outcomes. Brand type does not significantly moderate these effects, suggesting that FOPL act primarily as category-level informational cues rather than as brand-differentiating levers. The findings reinforce the informational role of FOPL in supporting more informed choices and highlight their limited immediate impact on broader brand-relationship metrics, offering insights for both retailers and policy makers in non-harmonized FOPL environments.*
Keywords*: Front-of-Pack Nutritional Label (FOPL), Nutri-Score, NutrInform Battery, Perceived Healthiness, Private Labels, Attitude Toward the Brand, Purchase Intention, Poland.*

1. Introduction. The increase in the consumption of specific nutrients, together with the growing prevalence of sedentary lifestyles, has contributed to the rise of overweight and obesity globally (World Health Organization, 2021). In response, institutions and companies have promoted several initiatives aimed at guiding consumers towards healthier food choices, including Front-of-Pack Nutrition Labelling (FOPL) systems that make nutritional information more salient during purchase decisions (Hamlin et al., 2015; Deren et al., 2021). At the same time, the spread of heterogeneous FOPL systems across European countries has fueled the debate on the identification of a harmonized model at the EU level (Mazzù et al., 2023). From a conceptual point of view, FOPL systems can be divided into two macro-categories. Directive labels, such as the Nutri-Score, provide a synthetic assessment of the overall nutritional quality of the product through simplified and algorithmic indicators. In contrast, non-directive labels, such as the NutrInform Battery, present detailed numerical information related to the main nutrients, requiring greater cognitive effort on the part of the consumer (De la Cruz-Góngora et al., 2017). This distinction implies that different labelling formats can activate different decision-making mechanisms. Directive labels may serve as simple evaluative heuristics focused on the individual product, whereas non-directive labels may foster more analytical processing and spill over to brand-level evaluations such as transparency and competence.

Considering these differences, the present study examines the interaction between label format (FOPL format) and brand type, postulating that the effects of FOPL vary according to the type of information provided and the competitive context. A heterogeneous impact on consumer responses is assumed: directive labels would exert a more immediate influence on product evaluations (e.g., healthiness or nutritional quality), while non-directive labels would foster perceptions of transparency, reliability and competence at the brand level. To investigate these dynamics, the Polish market represents a relevant empirical setting, allowing to evaluate the complementary role of FOPL not only as a public health tool, but also as a strategic signaling mechanism in consumer decision-making. In fact, Poland has one of the highest rates of overweight in Europe with about 76% of the adult population classified as overweight and 32% as obese (EUFIC, 2025), despite not having adopted an official national FOPL system or a uniform dissemination of specific schemes (World Obesity Federation, 2025). This context, characterized by high obesity prevalence and limited prior exposure to harmonized FOPL schemes, offers a relevant testbed to assess the informational role of FOPL in a market where their adoption is still largely voluntary (Storcksdieck Genannt Bonsmannet al., 2020).

Although prior research has extensively investigated the impact of FOPLs on product evaluations and purchase intentions, less attention has been devoted to the interaction between label format and brand context. In particular, limited research has explored whether directive and non-directive labeling systems generate different responses when associated with private labels versus national brands. This study contributes to the literature in three ways. First, it compares directive and non-directive FOPL formats within a unified experimental framework. Second, it examines

[1] LUISS Guido Carli University, Department of Business and Management, Viale Romania 32, 00197 Rome, Italy
[2] LUISS Guido Carli University, Department of Business and Management, Viale Romania 32, 00197 Rome, Italy
[3] John Cabot University, Department of Business Administration, Via della Lungara, 233, 00165 Rome, Italy
[4] LUISS Guido Carli University, Department of Business and Management, Viale Romania 32, 00197 Rome, Italy

whether label format interacts with brand type (private label vs national brand). Third, it extends prior research by considering both product- level evaluations (e.g., healthiness) and brand-level responses.
Accordingly, this study investigates whether directive and non-directive FOPLs activate different cognitive processing mechanisms and how these mechanisms influence both product-level evaluations and brand-related responses.

2. Literature Review.

2.1. FOPL and consumer decision making

Previous research has demonstrated that consumer behavior towards food products is shaped by a variety of factors, including the presence of nutritional labels, price, and the product's ability to satisfy hedonic needs (Cornil & Chandon, 2016; Hagen et al., 2017; Liu et al., 2019). Concurrently, several studies have highlighted the effectiveness of front-of-pack nutrition labelling systems in enhancing consumers' perceptions of product healthiness and in strengthening positive attitudes towards the brand (Baccelloni et al., 2021; Egnell et al., 2022; Post et al., 2010). Within this framework, improvements in perceived product healthiness are associated with more favorable brand attitudes, which in turn exert a positive influence on purchase intentions. This relationship is consistent with existing literature suggesting that positive health-related perceptions foster more favorable attitudinal evaluations and stronger behavioral intentions among consumers (Küster-Boluda & Vila, 2020). Furthermore, the literature underscores the role of nutritional labels in influencing consumer behavior through cognitive and evaluative mechanisms that enhance perceptions of healthiness and generate positive brand attitudes during the purchase decision-making process. In this phase, consumer perceptions and attitudes interact dynamically, whereby perceptions of a product shape attitudes towards it, which subsequently influence purchasing decisions and behaviors (Wang, 2024).

2.2. Directive vs non-directive labels

FOPLs differ not only in the information they provide but also in how they structure consumers' interpretation of nutritional information. Directive labels such as Nutri-Score provide an immediate evaluative signal that simplifies nutritional information, facilitating heuristic processing. Conversely, non-directive systems such as NutrInform Battery require consumers to process numerical information and perform a more analytical interpretation of nutritional values.

2.3. Brand context

In addition, prior research emphasizes the pivotal role of the brand as an interpretative framework within the consumer decision-making process, capable of guiding evaluations and behaviors. Consumers who predominantly purchase manufacturer brands tend to place greater emphasis on brand-related cues and prefer branded products, to which they attribute higher value (Goldsmith et al., 2010). In response, many brands have implemented initiatives aimed at introducing or enhancing nutritional labelling systems to improve the accessibility and usability of nutritional information. These initiatives are designed to support consumers during the purchase process by offering more immediate and intuitive information, thereby complementing the traditional back-of-pack nutritional label (Ikonen et al., 2019; Medina-Molina et al., 2021). Beyond the effects of labelling alone, brand familiarity further contributes to consumers' perceptions of food healthiness, often leading to more favorable evaluations compared to less familiar alternatives (Ponnam et al., 2015; Godden et al., 2023). This effect can be attributed to the strong brand equity developed by firms, as well as to a reduction in cognitive effort through established mental and social associations linked to branded products (Cobb-Walgren et al., 2016; Franca et al., 2025). Building on this evidence, it can be hypothesized that regular private label consumers may respond more strongly to the presence of front-of-pack nutrition labelling systems. In such cases, the informative role of labels may not only affect product evaluations but also influence overall brand perceptions, with indirect effects on consumers' purchase intentions (De Temmerman et al., 2021).

2.4. Hypothesis

Overall, prior studies suggest that FOPL primarily affect cognitive evaluations, such as perceived healthiness, with potential downstream effects on purchase-related outcomes, while their impact on broader brand-relationship metrics (e.g., trust, loyalty, loyalty program enrolment) remains more ambiguous. This study therefore examines a broad set of product, brand and retailer-related responses to investigate where directive vs non-directive labels exert the strongest influence. In addition to product-level outcomes, exploratory analyses examine whether FOPL formats influence broader brand-related responses such as brand attitude, trust, and word-of-mouth.
Formally:

- H1: Exposure to a directive FOPL will result in higher perceived healthiness compared to a non-directive FOPL
- H2: FOPL format will positively affect purchase intention, with stronger effects for the directive label.
- H3: Brand type (national brand vs. private label) will moderate the relationship between FOPL format and consumer evaluation.

Methodology. A breakfast cereal package was used as the experimental stimulus, with all brand-identifying elements removed to avoid brand-related biases. Front-of-pack nutrition labels (FOPL) were subsequently digitally applied in a prominent and clearly visible position on the packaging, in line with the procedure adopted by (Mazzù et al., 2024). Specifically, the Nutri-Score was used as the directive labelling system, whereas the NutrInform Battery was adopted as the non-directive labelling system.
A pre-test on 86 Prolific participants identified fictitious brand names for the national brand and private label conditions. Zenya (M = 4.48; SD = 1.24) was selected as the private label name and Olympia (M = 5.16; SD = 1.23) as the national brand name (Figure 1). This procedure minimized potential perceptual biases among respondents, confirming that

respondents associated Olympia with a national brand and Zenya with a private label: $\chi^2(1, N = 84) = 8.60$, $p = .003$.

Figure 1. Experimental stimuli

The main study was conducted on a sample of 202 Polish primary grocery shoppers recruited through Prolific. Most respondents were aged between 18 and 44 years and held at least a secondary education degree; women represented 34.7% of the sample. Participants were randomly assigned to one of four experimental conditions in a 2 × 2 between-subjects design (Brand: national brand vs private label; Label: Nutri-Score vs NutrInform Battery). Data were analysed using a multivariate analysis of variance (MANOVA) conducted using SPSS. The analysis examined the effects of Brand and Label on multiple dependent variables simultaneously, including perceived healthiness, attitude toward the brand, purchase intention, tastiness, word-of-mouth, trust, familiarity, and private label usage. In order to capture potential spillover effects from product evaluation to broader retailer-related outcomes, the study also includes variables related to retailer loyalty and loyalty program enrolment. All scales were measured using multi-item 7-point Likert scales adapted from validated sources (see Appendix) and showed satisfactory reliability.

Results. A two-way MANOVA was conducted with Brand and Label as independent variables and the ten dependent variables. Using Pillai's Trace, the multivariate effect of Label was significant,
$V = .132$, $F(10, 189) = 2.87$, $p = .002$, partial $\eta^2 =$
.132. In contrast, neither the multivariate effect of Brand, $V = .046$, $F(10, 189) = 0.91$, $p = .525$, nor the Brand × Label interaction, $V = .041$, $F(10, 189) = 0.81$, $p = .618$, reached statistical significance. Levene tests indicate that the homogeneity assumption of variances is satisfied for most dependent variables. Although some violations were observed for RBL and TR, the use of Pillai's Trace and the absence of significant univariate effects for these variables suggest that the results can be considered robust.
Follow-up univariate ANOVAs showed a significant effect of Label on perceived healthiness, $F(1, 198) = 17.75$, $p < .001$, partial $\eta^2 = .082$, indicating a moderate effect size, and a smaller but significant effect on purchase intention, $F(1, 198) = 4.14$, $p = .043$, partial $\eta^2 = .020$. No significant effects of Label emerged for the remaining dependent variables. Descriptive statistics show that Nutri-Score is associated with higher perceived healthiness than NutrInform Battery ($M = 4.18$ vs. $M = 3.28$). Differences between the labels for the remaining variables are limited, in line with the non-significant univariate results. This result is consistent with the heuristic nature of directive labels, which provide a simplified evaluative cue that consumers can process quickly during product evaluation.

Discussions. This study investigated the effects of different types of front-of-pack nutrition labelling on consumers' responses to a food product and its brand, focusing on the interaction between label format and brand type. The findings confirm that FOPLs primarily act as informational cues that increase perceived product healthiness, with Nutri-Score outperforming NutrInform Battery. Behavioural outcomes such as purchase intention are only modestly affected, and no significant differences emerge for broader brand-relationship indicators (attitude, trust, loyalty, word-of-mouth).
This result suggests that the impact of FOPL manifests itself mainly at the perceptual and cognitive level, influencing perceptions in the short term, while broader and relational evaluations related to the brand or retailer tend to remain relatively stable. Therefore, the inclusion of heterogeneous variables allows us to grasp how different labeling formats can influence distinct levels of consumer response: from product evaluations to brand inferences, up to possible repercussions on brand-related outcomes.
A further result concerns the absence of significant Brand and Brand × Label effects, which indicates that, in this setting, FOPLs operate largely at the product-category level rather than as brand-differentiating tools. In a market where FOPLs are not yet institutionalized, consumers seem to use them as generic nutritional shortcuts instead of brand-specific signals. The distinction between directive and non-directive labels helps to interpret this evidence. Directive systems, such as Nutri-Score, reduce cognitive effort by offering concise and immediate evaluation, thus being more effective in rapid product evaluations. On the contrary, non-directive labels, such as the NutrInform Battery, require more analytical processing and may be less incisive in immediate evaluations, but potentially more relevant from a retailer and strategic positioning perspective, as they can help communicate greater information transparency, nutritional expertise and support consumers in choosing between comparable alternatives. Overall, the results suggest that FOPL can contribute to strengthening the perception of healthiness and supporting consumer decision-making, without generating strongly differentiated effects on the other dimensions considered.

Conclusions. This exploratory study examines the role of front-of-pack (FOPL) nutrition labels in the process of consumer evaluation of food products. The results show that the presence of FOPL represents a relevant information element in the product evaluation process, contributing in particular to influencing the perception of food healthiness. At the same time, the differences between the different labelling formats are generally small, suggesting that these tools operate mainly as information aids that facilitate the interpretation of nutritional information by consumers.
However, it is important to underline that the experimental design made use of controlled stimuli represented by fictitious marks, a choice that allowed to guarantee a high internal validity of the analysis. Future studies could extend the investigation to real market contexts, comparing the effectiveness of FOPL between private labels and industrial brands present on the market, to verify whether brands characterized by different levels of notoriety and brand equity can moderate the impact of different nutrition labels on consumer evaluations.
Overall, empirical evidence supports the role of FOPL as cognitive and evaluative levers, capable of influencing short-term variables, such as the perception of product healthiness, brand attitudes, and purchase intention. At the same time, it is important to investigate how these labels can also affect long-term relational dimensions for retailers, for example in terms of loyalty to the brand or adherence to loyalty programs. Further research could also analyze more deeply the cognitive and attitudinal mechanisms through which the perception of healthiness translates into a greater purchase intention.
This research contributes to the literature by outlining differentiated effects between directive systems (such as the Nutri-Score) and non-directive systems (such as NutrInform Battery) and opens more advanced perspectives on the strategic role of retailers in contexts characterized by the absence of mandatory regulation of FOPL. In these contexts, the voluntary choice of specific labelling formats can be a significant distribution lever: retailers can adopt FOPL not only to provide nutritional information, but also to signal a commitment to health and transparency, differentiating their offer from competitors and strengthening perceptions of responsibility towards consumers. In this perspective, FOPL can take on managerial value, potentially contributing to influencing purchase intent and loyalty, particularly in the case of private labels. Future research could therefore quantify these effects in real competitive contexts, characterized by shelf competition dynamics between different brands and labeling formats.
Finally, the results of the study can also offer useful indications to policy makers, helping to deepen the role of FOPL in promoting healthier and more informed food choices, enhancing the complementarity of information between the different labeling systems. Extending the analysis to different geographical contexts, including countries where FOPL are not yet widespread or institutionalized, would allow for a comparative perspective that would provide relevant insights for both public decision-makers and distribution operators.
In summary, this study strengthens the evidence on the effectiveness of FOPL as tools to support more informed consumption choices, while paving the way for future research aimed at consolidating not only their information potential, but also their strategic and competitive value for companies and institutions.

Funding. This research received non-conditional funding from Federalimentare (Rome, Italy, http://www.federalimentare.it/), the Italian Federation of Food Industries, according to the partnership principles and the scientific research protocol set forth by a specific State-Private Sector memorandum of understanding.

	I have a favorable opinion of this food brand		
	I like this food brand		
	This food brand is appealing to me		
	This food brand gives me a positive impression		
	Overall, my attitude toward this food brand is positive		
Brand Trust (TR)		.808	Delgado-Ballester, 2004
	This brand inspires trust in me		
	This brand's products are reliable		
Purchase Intention (PI)		.929	Mazzù et al., 2021
	I would like to try this product		
	I would seriously consider buying this product		
Word-of-Mouth (WOM)		.962	Mazzù et al., 2022
	I am likely to spread positive word of mouth about this brand		
	I would recommend the brand's product to my friends		
Retailer Brand Loyalty (RBL)		.839	Chaudhuri & Holbrook, 2001
	I intend to continue shopping at this supermarket in the future		
	This supermarket would be my first choice for grocery shopping		
	I am likely to keep buying groceries from this supermarket		
	I would not easily switch to another supermarket		
Loyalty Program Enrolment (LPE)		.974	Yi & Jeon, 2003
	I would be willing to join this supermarket's loyalty program		
	I intend to sign up for the loyalty program offered by this supermarket		
	If available, I would probably enroll in this supermarket's loyalty program		
	I would consider becoming a member of this supermarket's loyalty program		
Familiarity with the product category (FAM)		.776	Park et al., 1994
	How informed are you with different types/ brands of cereal?		
	How would you rate your knowledge of branded product relative to other people?		
Private label usage (PLUse)		.886	Ailawadi et al., 2001
	I regularly buy supermarket-brand products		
	I look for supermarket-brand products when I go grocery shopping		
	Buying supermarket-brand products encourages me to shop there more often		

Framing the Complex Interplay of Ultra-Processed Foods, Nutrition Labeling, and Consumer Response: A Systematic Review

MARA SELLA GIANOT[1], MARCO FRANCESCO MAZZÙ[2], ANGELO BACCELLONI[3]

Abstract. *In recent decades, rising rates of obesity and diet-related chronic diseases have turned consumer food choices into a central public health issue. Increasing evidence identifies ultra-processed foods (UPFs) as a major driver of this trend, raising concerns about how consumers perceive, select, and integrate these products into their daily diets. In response, governments and international institutions have introduced a range of policy tools aiming to influence consumer decision-making-such as Front-of-Pack Nutritional Labels (FOPLs), food processing classification systems (such as NOVA), marketing restrictions, and product reformulations intended to steer choices toward healthier options. Despite recent expansion, research on consumer behavior within the UPF field remains fragmented. While many studies examine health effects or nutrient composition, fewer explore how consumers interpret food processing information, react to labelling systems, or internalize policy interventions that frame UPFs as problematic. This study conducts a systematic literature review spanning 2000–2026, leveraging PRISMA methodology. A total of 297 scientific articles were identified through Web-of-Science and Scopus and analyzed to map consumer-oriented research trends. Results reveal a substantial and accelerating increase in publications and identify major sequential research streams: (i) consumer perceptions of food processing and health risk; (ii) behavioral responses to FOPLs; (iii) public debates on NOVA and nutrient profiling systems; and (iv) policy interventions shaping everyday food environments. Finally, it outlines future research directions to strengthen the conceptual coherence and policy relevance of the UPF field.*

1. Framing of the research

In recent decades, obesity and diet-related chronic diseases have become major global public health concerns. Numerous studies link the consumption of ultra-processed foods to adverse health outcomes such as obesity, type 2 diabetes, cardiovascular disease and premature mortality (Monteiro et al., 2013; Elizabeth et al., 2020; Pagliai et al., 2021). This epidemiological shift reflects a broader nutritional transition driven by the global expansion of industrialized food systems, the restructuring of retail distribution, and the growing availability of packaged and UPFs. Within this context, the UPFs—formalized through the NOVA classification—have gained prominence by reframing dietary quality not solely in terms of nutrient intake, but as a function of the degree and purpose of industrial processing. UPF attributes confer convenience, affordability, and long shelf life, but at the cost of diminished nutritional integrity and potential impacts on appetite regulation, satiety, and metabolic health. As a consequence, increasing attention has been devoted to policy tools aimed at improving the food environment and guiding healthier and more informed consumer choices, particularly FOPL systems (Julia & Hercberg, 2017; Taillie et al., 2020, Mazzù et al., 2023). Food policies such as marketing restrictions and mandatory reformulation have emerged as complementary strategies to reduce the consumption of UPFs and facilitate informed decision-making. However, UPFs counter-measures rely on different conceptual foundations. For instance, the NOVA framework situates health outcomes within the industrial and sociotechnical processes that underpin modern food production, whereas nutrient-profiling models used in most FOPLs assess products based on their nutrient composition (e.g., salt, sugar, and fat content). This theoretical divergence raises practical and communicative challenges, as nutrient scores provide immediate, easily interpretable information, whereas they may not capture the broader implications of extensive food processing. Accordingly, the literature remains fragmented, with studies on UPFs, labeling systems, and consumer behavior often developing in parallel rather than in a unified framework centered on consumers' understanding and decision-making processes. From a consumer perspective, the coexistence of processing-based classifications (such as NOVA) and nutrient-profiling labels (such as Nutri-Score, NutrInform Battery or Warning Labels) introduces a potential interpretative tension. While nutrient-profiling labels summarize the nutritional composition of products, the UPF paradigm emphasizes industrial transformation and formulation practices. Understanding how these frameworks coexist is therefore essential to clarify how consumers interpret food quality signals. The present study therefore reconstructs the evolution of the scientific literature through a consumer-centered perspective, positioning ultra-processed foods as a conceptual lens through which behavioral, nutritional, and policy debates can be integrated. By distinguishing between core UPF research, policy instruments such as FOPLs, and adjacent streams addressing consumer perception and choice, the review aims to clarify how these debates have evolved over time and across geographical contexts, and to identify where consumers' role remains theoretically and empirically underrepresented. In doing so, this paper

contributes to the literature in several ways. First, it offers a structured review of 297 scientific articles published between 2000 and 2026, systematically selected and analyzed following PRISMA guidelines. Second, it delineates four evolutionary phases in the development of research on UPFs and consumer-oriented food policy, tracing how conceptual and methodological orientations have shifted over time. Third, it synthesizes the main areas of debate and current research gaps, highlighting disconnections between processing-based classifications, labeling frameworks, and consumer behavior literature. Finally, it proposes a set of future research directions articulated from the findings, outlining how an integrated consumer perspective can strengthen the conceptual coherence and policy relevance of the UPF field. This review also provides relevant theoretical and managerial implications. Theoretically, it advances the literature by connecting health-oriented, policy-oriented, and consumer-centered approaches within a unified interpretative framework, thus highlighting the multidimensional evolution of the UPF debate.

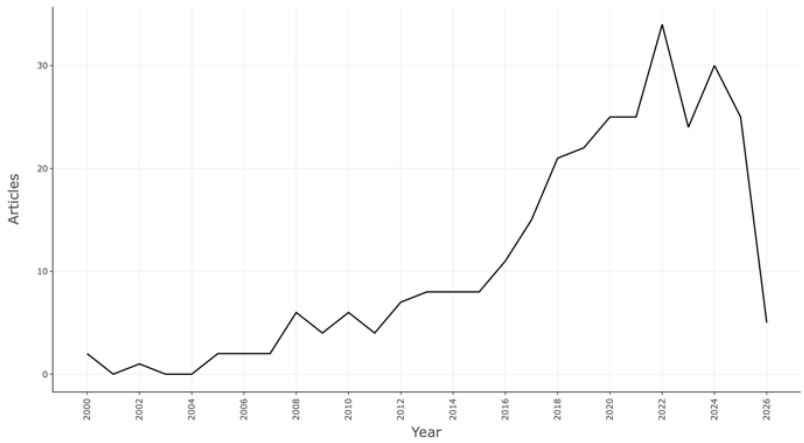
2. Purpose of the paper. In recent years, several reviews have examined the relationship between ultra-processed food (UPF) consumption and health outcomes observed in consumers. For instance, Elizabeth et al. (2020), Pagliai et al. (2021), and Lane et al. (2021) consistently link UPF intake to adverse health outcomes—such as obesity, cardiovascular disease, diabetes, and higher mortality—consolidating the scientific basis of the UPF–health debate.
Beyond epidemiological associations, scholars have also examined how the industrial organization of food supply and retail affects consumption patterns and health disparities (Moodie et al., 2013; Baker et al., 2020). Studies on labeling policy—particularly those on FOPLs—have explored consumers' nutritional understanding and purchase behavior (Hawley et al., 2013; Cecchini & Warin, 2016; Egnell et al., 2020; Mazzù et al., 2024), but few have explicitly connected these behavioral insights to the structural diffusion of UPFs and the regulation of the food environment. As a result, three research domains—UPFs and processing, food policy instruments, and consumer behavior—have largely evolved in parallel. This review positions itself at the intersection of these three research domains. It analyzes and organizes existing work by adopting a consumer-centered perspective to bridge research on industrial food processing, nutrition policy, and behavioral responses. By systematically mapping these domains and reconstructing their temporal evolution, it clarifies how the UPF paradigm has interacted with labeling policies and consumer-oriented research. Through this lens, UPFs are examined as elements of consumers' food environments shaped by labeling, marketing and policy interventions.

3. Methodology. The study adopted a multi-step systematic review protocol to identify, select, and analyze scientific literature on UPF, food labeling systems, policies and consumer perceptions and behaviors. The selection process of the items followed the traditional phases provided for by the PRISMA protocol (Figure 1).

Figure 1. PRISMA Flow Diagram of the Literature Selection Process

First, all potentially relevant records were identified, considering the literature's interdisciplinary scope. The research was conducted in the Web-of-Science and Scopus databases. The search strategy was designed to identify literature situated at the intersection of three core dimensions: ultra-processed foods (industrial processing), nutrition labeling (regulatory tools), and consumer behavior (perceptions and choices). To this end, a search string was defined by combining terms related to UPF, food labeling, and consumer behavior. The string used was as follows: TS=((“ultra-processed food” OR “ultra processed food” OR UPF OR NOVA OR “processed food*” OR “industrial food*”) AND (label* OR labeling OR labelling OR “front-of-pack" OR “warning label*” OR “nutrition label*” OR “food label*” OR

NutriScore OR "traffic light") AND (consumer* OR perception* OR behavior* OR "food choice*" OR "purchase intention")). Duplicate records were then removed prior to screening. The remaining articles were subjected to an initial screening phase through the reading of titles and abstracts, with the aim of excluding contributions that were not relevant to the objectives of the review. In the next phase, the full reading of the articles considered potentially relevant was carried out. At this stage, studies were excluded when, despite containing relevant keywords, they lacked a substantive focus on ultra-processed foods or on the research areas under review. At the end of the selection process, 297 scientific papers were included, published between 2000 and 2026. Inclusion decisions were not based solely on keyword matching but were guided by an interpretative framework centered on ultra-processed foods. During screening, articles were assessed for relevance to UPFs and grouped into research on the NOVA classification, policy instruments (e.g., FOPLs), and broader food system components (e.g., packaging, claims, marketing). Studies were excluded if unrelated to UPFs or processing, non–peer-reviewed, non-English, or lacking conceptual relevance.



Data analysis. The selected articles were examined through a mixed analytical strategy that combined (i) descriptive quantitative analysis in R with (ii) in-depth qualitative examination of content. This dual approach made it possible to organize the literature into distinct evolutionary phases and to identify areas of convergence as well as persistent research gaps. From a quantitative perspective, the dataset was analyzed with Biblioshiny in R to map publication trends, geographical distribution, and main outlets, allowing the identification of four main historical phases in the development of the UPF literature between 2000 and 2026. These phases reflect shifts in the prominence of different themes and policy debates and provide the temporal scaffold for interpreting changes in how UPF, nutrition policy, and consumer behavior have been studied. In parallel, a qualitative thematic analysis was conducted to identify the primary research streams and reconstruct the evolution of the scientific debate. Articles were coded using an iterative thematic coding procedure. Each study was classified according to predefined analytical dimensions, including year of publication, geographical focus, main topic, conceptual orientation, policy relevance, and the presence or absence of explicit references to UPF or the NOVA classification. On this basis, contributions were iteratively grouped into thematic categories, which were refined throughout the analysis until a stable set of research streams and crosscutting themes emerged.

4. Results. This combined process highlighted four dominant strands: (i) the relationship between UPF consumption and health outcomes; (ii) the role of industrial food processing in shaping diet quality and food systems; (iii) the conceptual interplay between the NOVA classification and nutrient profiling models; and (iv) the impact of policy tools—particularly FOPLs—on consumer understanding and food choice. By examining how these strands evolve across the four phases, the review identifies points of convergence between health, policy, and consumer research, as well as domains where conceptual or methodological integration remains limited. A temporal perspective was therefore central to the analysis, enabling the reconstruction of key milestones in the UPF debate and clarifying how attention progressively shifted from nutrient based framings to broader discussions encompassing processing, food environments, and consumer facing nutrition policies. Additionally, the geographical distribution of scientific production was analyzed to highlight the territorial and political contexts in which different research strands are most concentrated, and to explore how regulatory and institutional dynamics—such as the adoption of Warning Labels in Latin America or FOPL debates in Europe—have influenced the configuration of the literature.

4.1 Main research streams on ultra-processed foods, from a descriptive quantitative perspective

The analysis of 297 scientific articles identifies several interconnected research streams on ultra-processed foods (UPF), showing how the literature has developed over the last two decades (Figure 2). In the early 2000s, output was very low, with only a few articles per year. From 2012 onwards, publications increased more sharply, accelerating after 2016 and peaking around 2022.

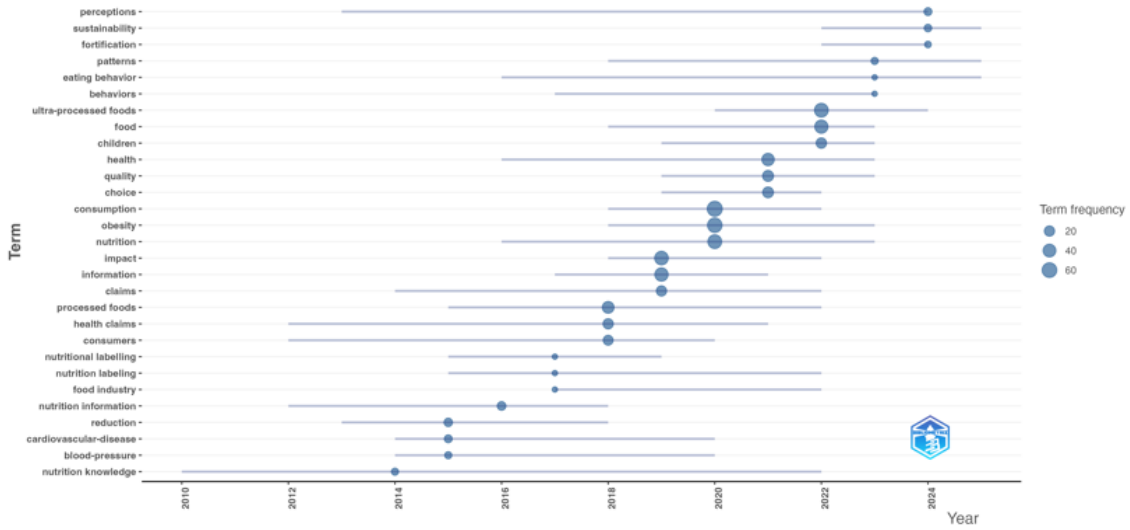


Figure 2. Annual scientific production related to ultra-processed foods, food labeling, and consumer behaviour (2000-2026).

4.1.2. Temporal evolution of literature, from a qualitative perspective

Additionally, the analysis of the corpus shows a significant growth in the number of publications over time and allows us to identify different evolutionary phases of scientific debate. The temporal analysis further reveals that the evolution of the literature does not follow a linear trajectory, but is divided into four distinct phases, each characterized by a different combination of nutrient-based approach, increasing attention to industrial processing, development of front-of-pack labeling systems and progressive integration with the policy debate (Figure 3). In the corpus analyzed, publications increased from 19 articles in 2000–2008 to 164 in 2020–2026, showing a strong acceleration in the most recent phases. This dynamic suggests that the issue of UPF and related policies is consolidated, especially after the formalization of the NOVA paradigm and, subsequently, with the international spread of regulatory tools such as FOPLs as NutrInform Battery, Warning Labels, Traffic-Light and the Nutri-Score. This acceleration reflects the growing institutionalization of the UPF paradigm within both public health research and food policy debates.

Figure 3. Evolution of Research Streams in Ultra-Processed Food Literature.

4.2.1 First phase: centrality of the nutrient-based approach and information transparency (2000–2008). In the first phase, the literature was primarily shaped by a nutrient-based perspective, with strong attention to transparency, consumer information, and the growing use of labels on packaged foods. Early studies focused on monitoring the spread of nutrition labeling and claims in the food market, showing that these instruments were becoming increasingly relevant in consumers' interactions with packaged products (Legault et al., 2004). At the same time, scholars began to examine whether consumers were actually able to understand and use this information effectively. Evidence suggested that many consumers found detailed nutritional information difficult to interpret, especially when labels were complex or overloaded with technical data (Cowburn & Stockley, 2005). Research then explored the value of nutritional information in food choice, showing that labels were effective only when simple, familiar, and easy to interpret (Loureiro et al., 2006; Grunert & Wills, 2007). This explains the growing attention to simplified FOPL systems, while food processing had not yet become central to the debate (Feunekes et al., 2008). Overall, this phase remained firmly centered on nutrients, readability, and information clarity.

4.2.2 Second phase: emergence of the UPF/NOVA paradigm and conceptual transition phase (2009–2014). Between 2009 and 2014, the literature entered a phase of conceptual transition, in which the traditional nutrient-based framework began to be challenged by a new way of understanding diet quality. A major turning point was Monteiro's argument that the key issue was not only food composition in terms of nutrients, but also the degree and purpose of industrial processing (Monteiro, 2009). This marked the beginning of a broader shift in the literature, which moved from asking whether foods were high or low in specific nutrients to questioning how foods were produced, transformed, and incorporated into daily diets. This transition became more structured with the introduction of the NOVA classification, which proposed a new categorization of foods based on the extent and purpose of processing (Monteiro et al., 2010). NOVA provided the conceptual basis for later work on ultra-processed foods and helped reframe the debate beyond the nutrient profile alone. However, during this phase, research on FOPL and consumer understanding did not disappear. On the contrary, studies continued to show that consumers responded favorably to simplified labeling systems and that front-of-pack information could support better understanding under certain conditions (Kim & Kim, 2009; Barreiro-Hurlé et al., 2010; Campos et al., 2011). At the same time, the literature increasingly linked dietary change to broader structural transformations in food systems (Fanzo et al., 2014). Overall, this phase represented the bridge between a purely informational view of nutrition and the emergence of the processing paradigm.

4.2.3 Third Phase: Empirical Consolidation of UPFs and Policy Shift (2015–2019). From 2015 to 2019, the literature moved from conceptual discussion to empirical consolidation of the UPF/NOVA framework. Research increasingly documented the concrete dietary and environmental implications of ultra-processed foods, showing that higher levels of processing were associated with poorer nutritional quality in household food purchases and food environments (Poti et al., 2015; Luiten et al., 2016). In addition, studies on the composition of national diets demonstrated that ultra-processed foods contributed substantially to excessive sugar intake and to broader patterns of nutritional imbalance, reinforcing concerns about their public health significance (Martínez Steele et al., 2016). This phase was also characterized by stronger evidence linking ultra-processed food consumption to diet quality and health outcomes (Moubarac et al., 2017; Schnabel et al., 2019; Srour et al., 2019). At the same time, the literature became more policy-oriented. Research on traffic-light systems and warning labels demonstrated that simplified FOPL tools could improve understanding of nutritional risk and raise awareness of unhealthy foods (Freire et al., 2017; Olivares-Cortés et al., 2017). Comparative work on different FOPL schemes also showed that the format of the label mattered significantly for consumer interpretation and use (Egnell et al., 2019; Mazzù et al., 2022). Overall, this phase marked the transformation of the UPF paradigm into an empirically grounded and policy-relevant field, supported by evidence from dietary studies, supermarket environments and regulatory experiments.

4.2.4 Fourth phase: globalization of the debate, comparison of schemas and integration of nutrients and processing (2020-2026). In the most recent phase, the literature became broader, more international, and more explicitly connected to regulatory and policy debates. Reviews, meta-analyses and umbrella reviews played an important role in consolidating the evidence linking ultra-processed food consumption with multiple adverse health outcomes, thereby strengthening the epidemiological basis of the field (Elizabeth et al., 2020; Lane et al., 2021; Lane et al., 2024). Compared with earlier phases, the debate was no longer limited to defining ultra-processed foods or documenting their spread; it increasingly focused on how this evidence should inform consumer policy, dietary guidelines and public health action. At the same time, comparative research on FOPL systems became more central. Studies showed that different schemes, such as interpretive summary labels and other front-of-pack formats, influence consumer understanding and food choices in different ways, suggesting that the design of the label is crucial for policy effectiveness (Egnell et al., 2020). Another important development was the growing recognition that food evaluation should not rely only on nutrient profiles but should also incorporate the degree of processing. This perspective is well reflected in work arguing that nutritional value and processing represent two distinct yet complementary dimensions of food quality (Romero Ferreiro et al., 2021). In parallel, the literature expanded to include the ways in which consumers interpret ultra-processed foods in everyday life. Studies showed that consumers often rely on heuristics and simplified judgments when assessing the healthiness of packaged foods, which helps explain why labels, packaging cues, and cultural meanings matter so much in food choice (Machín et al., 2020). The field also became more geographically diverse, with research highlighting the policy dynamism of Latin America in the development of warning labels and stronger regulatory tools (Reyes & Corvalán, 2020; Nieto et al., 2021), as well as the social and symbolic meanings attached to highly processed foods (Venkateshmurthy et al., 2021), also expanding to the broader structure of food supply (Sylvetsky et al., 2020). Overall, this phase reflects the global maturation of the field, where health evidence, consumer behavior, labeling policies and food system transformation are increasingly integrated. This phase highlights the growing importance of consumer perception as the interface between scientific evidence, regulation, and market practices.

5. Managerial implications. The paper highlights several implications for policymakers, food producers, and retailers operating in markets increasingly shaped by nutrition policies and consumer health concerns. These findings suggest that policy design benefits from maintaining analytical clarity between process-based classifications and nutrient-based labeling systems, while remaining open to their complementary application in public health interventions. For food companies, the coexistence of nutrient-profiling labels and processing-based classifications implies that product reformulation strategies must consider multiple dimensions of food evaluation. For policymakers, the results suggest that communication strategies addressing ultra-processed foods should acknowledge how consumers interpret both nutrient-based and processing-based signals when making food choices.

6. Originality of the paper. The review shows that research on ultra-processed foods has rapidly expanded from a relatively narrow topic into a broad and multidimensional field, driven by growing evidence on health outcomes and by increasing attention to the role of industrial processing in diet quality. First, a key finding concerns the conceptual tension between the UPF paradigm and FOPL systems. While FOPL summarizes nutritional composition and NOVA focuses on the degree and purpose of industrial processing, the literature increasingly suggests that these frameworks, though conceptually distinct, may be deployed in complementary ways within integrated food policies. Second, the analysis highlights the strong link between scientific research and policy development. The literature increasingly interacts with debates on how to regulate food environments and address the rise of obesity, with different regions experimenting with various strategies such as labeling systems, warning labels, taxes, or marketing restrictions. Geographical differences also play an important role, as research trajectories often reflect national policy priorities and transformations in local food systems. Lastly, the historical perspective reveals that this paradigm shift - from nutrient-based to processing-based frameworks - has not been linear or uncontested. Debates on NOVA's operationalization, comparisons with alternative

profiling systems, and the practical constraints of food policy implementation suggest that both frameworks coexist and interact in shaping contemporary regulatory and consumer information strategies.

7. Research limitations. This review has some limitations. Its future research agenda remains conceptual rather than empirically tested, and the breadth of topics covered means that several important areas—such as digital food environments, industry responses, and sustainability—are identified as promising directions but not examined in depth.

Hedonic and Utilitarian Orientations Embedded in AI Agents: Implications for Emotions and Impulsive Buying

SAVINO SANTOVITO[1], LUCREZIA MARIA DE COSMO[1], LUIGI PIPER[2],
RAFFAELE CAMPO[1], FABRIZIO BALDASSARRE[1]

Abstract. *Questo studio analizza come l'orientamento edonico e l'orientamento utilitaristico incorporati nel design di un AI agent influenzino le emozioni e l'intenzione di acquisto impulsivo. Adottando il modello Stimulus–Organism–Response, è stato realizzato un esperimento tra soggetti (N=135) con assegnazione casuale a due scenari: un agente AI con orientamento edonico, focalizzato su esperienza, piacere e coinvolgimento emotivo, e un agente con orientamento utilitaristico, centrato su efficienza, performance e ottimizzazione della scelta. Dopo l'interazione, sono state rilevate le risposte emotive e l'urgenza di acquisto impulsivo. I risultati evidenziano che l'orientamento utilitaristico incrementa le emozioni positive, che mediano positivamente l'acquisto impulsivo, pur mostrando un effetto diretto negativo. L'originalità risiede nella prospettiva intra-AI, che dimostra come differenti orientamenti valoriali, simulati dall'agente attraverso il framing di comunicazione, producano effetti psicologici e comportamentali distinti.*
Keywords: *AI agent, Hedonic orientation, Utilitarian orientation, Emotions, Impulsive buying.*

Framing of the research. L'intelligenza artificiale sta ridefinendo il processo decisionale di acquisto, comprimendo i tempi, riducendo lo sforzo cognitivo e favorendo risposte rapide e spesso automatiche (De Cosmo and Guido, 2025; Dellaert et al., 2020). In questo contesto emergono gli Agenti di Intelligenza Artificiale (AI agent), una nuova generazione di sistemi intelligenti con elevata autonomia decisionale rispetto alle applicazioni AI tradizionali (Wiesinger et al., 2024), la cui diffusione è in crescita nello smart retailing e nell'e-commerce, con un impatto economico stimato rilevante nei prossimi anni (Hale, 2025; Kim, 2025).

Nei contesti di servizio, gli AI agent sono progettati per interagire in modo naturale attraverso caratteristiche antropomorfiche – linguaggio conversazionale, nomi umani, avatar e voci simili a quelle umane – aumentando percezione di calore, coinvolgimento emotivo e risposte affettive positive, influenzando fiducia, gradimento e intenzioni comportamentali (Araujo, 2018; Liu et al., 2024; Schillaci et al., 2024). I progressi nel linguaggio naturale e nell'adattamento al contesto consentono agli AI agent di assumere un ruolo sempre più assimilabile a quello umano nei processi decisionali e nelle dinamiche interattive (Ali et al., 2024). Grazie ai Large Language Models, questi sistemi possono sostenere conversazioni coerenti, apprendere dall'esperienza e adattare le proprie azioni lungo il funnel di acquisto, ampliando la loro capacità di influenzare le scelte dei consumatori (Gonzalez et al., 2026).

Gli AI agent non sono strumenti passivi, ma partecipano attivamente al processo decisionale, influenzando intenzioni, fiducia e comportamenti. Operano sia sul piano cognitivo, semplificando le informazioni e riducendo lo sforzo decisionale, sia su quello emotivo, generando coinvolgimento e sicurezza. Per questo, la loro adozione dipende non solo da fattori funzionali, ma anche da dimensioni socio-emotive e relazionali, grazie alla capacità di creare connessioni affettive con l'utente (Affandi et al., 2025; Badghish et al., 2024; Huh et al., 2023). Attraverso la personalizzazione dell'interazione favoriscono legami emotivi tra consumatore e brand (Cachero-Martínez and Vázquez-Casielles, 2021), rafforzando il ruolo delle emozioni e aumentando la probabilità di scelte rapide e impulsive (Lo and Lin, 2024).

In ambito online, l'acquisto d'impulso è guidato dal valore edonico e dal coinvolgimento emotivo, mentre l'orientamento utilitaristico favorisce decisioni più razionali (Shamim and Misra, 2025). I sistemi AI sono percepiti come più competenti nelle valutazioni utilitaristiche, mentre gli umani in quelle edoniche, dando origine al "word-of-machine effect" per effetto della credenza secondo cui l'importanza di attributi utilitaristici aumenta la preferenza per l'AI (Longoni and Cian, 2022).

Inoltre, gli utenti sviluppano orientamenti utilitaristici o relazionali verso gli agenti in funzione di caratteristiche individuali come tolleranza all'imprevedibilità e sensibilità alla privacy e all'autonomia (Kim et al., 2021), mentre compiti fortemente edonici possono ridurre la percezione di calore e accettazione dell'AI (Kim et al., 2021; Yanit et al., 2023).

La letteratura si è concentrata principalmente su antropomorfismo e confronto AI–umano, evidenziando effetti su fiducia, coinvolgimento ed empowerment decisionale (Araujo, 2018; Longoni & Cian, 2022) ed ha attribuito la distinzione edonico–utilitaristica principalmente a prodotti e contesti (Botti and McGill, 2011; Jin and Zhang, 2025). Tuttavia, ha trascurato il ruolo dell'AI come attore attivo capace di generare e orientare tali dimensioni valoriali attraverso le proprie modalità di interazione.

Sebbene le emozioni favoriscano l'acquisto d'impulso (Baumeister, 2002; Bagozzi, 1999; Zhang et al., 2024), resta poco chiaro come specifiche configurazioni di design dell'AI — in termini di orientamento valoriale e framing — influenzino stati emotivi e impulsività (Longoni and Cian, 2022).

[2] University of Salento

Nonostante i contributi esistenti, persistono lacune teoriche ed empiriche, con evidenze prevalentemente concettuali e pochi studi sperimentali sul design (Anayat et al., 2025). In particolare, la distinzione edonico–utilitaristica è stata raramente applicata agli AI agents (Babin et al., 1994; Botti & McGill, 2011), lasciando poco esplorato il loro impatto su emozioni e acquisto impulsivo.

Per colmare questo gap, lo studio interpreta gli orientamenti edonico e utilitaristico come valori simulati dall'AI agent e veicolati attraverso il framing: edonico, che enfatizza esperienza e coinvolgimento, ed utilitaristico, che privilegia efficienza e ottimizzazione, configurando l'AI come partner esperienziale o strumentale.

Purpose of the paper. Lo scopo di questo articolo è indagare come l'orientamento edonistico o utilitaristico incorporato in un AI agent, attraverso framing comunicativi, influenzi le risposte emotive e l'intenzione di acquisto impulsivo dei consumatori, adottando il modello teorico Stimulus–Organism–Response (S–O–R) di Mehrabian e Russell (1974) come cornice interpretativa. In questa prospettiva, l'orientamento comunicativo e di raccomandazione dell'AI agent — di natura edonica o utilitaristica — rappresenta lo stimolo (S), ossia un input ambientale in grado di incidere sull'esperienza decisionale. Tale stimolo attiva l'organismo (O), inteso come l'insieme dei processi interni del consumatore, in particolare le risposte emotive generate dall'interazione con l'AI agent, che possono variare in intensità e valenza a seconda che l'agente sia percepito come strumento funzionale o come partner esperienziale. Queste risposte emotive costituiscono il meccanismo attraverso cui lo stimolo tecnologico si traduce in una risposta comportamentale (R), rappresentata dall'intenzione d'acquisto impulsivo, caratterizzata da decisioni rapide, automatiche e poco deliberate.

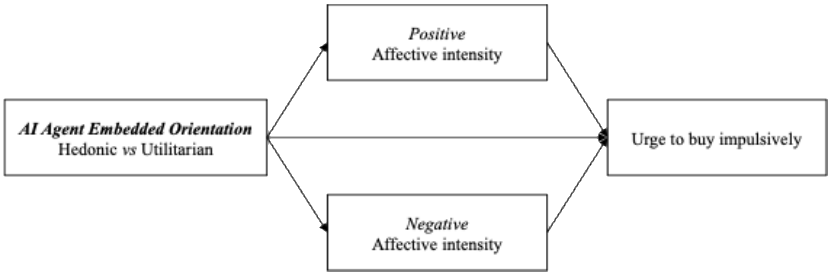
Integrando dimensioni cognitive e affettive, lo studio mette in luce il percorso causale alla base delle interazioni mediate dall'intelligenza artificiale, evidenziando come il design valoriale dell'AI agent, modulato dal framing comunicativo, attivi stati emotivi che finiscono per orientare l'intenzione di acquisto impulsivo.

Le neuroscienze evidenziano che le emozioni influenzano in modo decisivo i processi cognitivi e le decisioni di acquisto attraverso circuiti legati a piacere e gratificazione (Bechara and Damasio, 2005). Da una visione universalistica (Ekman, 1992), la letteratura le interpreta oggi come fenomeni dinamici e contestuali costruiti attraverso valutazioni cognitive e influenzati da esperienza e cultura (Barrett, 2006; Russell, 2003). In questa prospettiva, le emozioni emergono dall'interazione tra valutazione degli stimoli, attivazione fisiologica e risposta comportamentale (Izard, 2009; Scherer, 2009) e contribuiscono ad orientare i comportamenti di consumo (Sun et al., 2024).

In marketing, la teoria dell'attaccamento mostra come i legami emotivi con brand e prodotti influenzino fedeltà e acquisto impulsivo (Guido et al., 2016; Thomson et al., 2005). Le emozioni positive favoriscono l'intenzione di acquisto, mentre quelle negative la inibiscono (Fredrickson, 2013; Liu et al., 2025), rendendo il marketing emozionale particolarmente efficace (Bagozzi et al., 1999; Guo, 2024).

La letteratura evidenzia che l'acquisto impulsivo è fortemente guidato da emozioni, attaccamento al brand e stimoli digitali contestuali. Un attaccamento emotivo profondo, come l'attaccamento fervido, aumenta la propensione agli acquisti non pianificati quando il brand diventa parte dell'identità del consumatore (Guido et al., 2016; Thomson et al., 2005). L'acquisto impulsivo è definito come una decisione immediata, emotivamente carica e poco deliberata, favorita da bassi livelli di autocontrollo, tratti di impulsività e stimoli ambientali (Baumeister, 2002; Verplanken and Herabadi, 2001).

Nel contesto digitale, piattaforme online, social media, live streaming, mobile shopping e ambienti immersivi amplificano tali dinamiche riducendo le barriere cognitive e temporali all'acquisto (Borges-Tiago et al., 2023; Cho and Sagynov, 2015). Studi basati sul modello Stimolo–Organismo–Risposta mostrano che strategie come personalizzazione, interazione sociale, scarsità e promozioni attivano emozioni di piacere ed eccitazione, rafforzano la risonanza del brand e aumentano l'urgenza di acquisto (Lazaris et al., 2022; Park and Lin, 2020; Safeer, 2024;). In particolare, tecnologie emergenti come live streaming, influencer virtuali e realtà virtuale intensificano l'arousal emotivo e l'interesse parasociale, rendendo l'acquisto impulsivo più frequente e guidato da processi affettivi piuttosto che razionali (Wang et al., 2024; Yan et al., 2024; Zhang et al., 2024).



Le emozioni e i comportamenti di acquisto sono collegati sia ai valori utilitaristici sia a quelli edonistici dello shopping. La distinzione tra valore edonico e valore utilitaristico rappresenta una delle cornici teoriche più consolidate per comprendere il comportamento del consumatore. Secondo Babin, Darden e Griffin (1994), il valore utilitaristico è legato all'efficienza funzionale dell'esperienza di consumo e al raggiungimento di obiettivi strumentali, mentre il valore edonico deriva dal piacere, dall'intrattenimento e dal coinvolgimento emotivo generati durante l'esperienza.

Anche se la letteratura distingue tra dimensioni utilitaristiche ed edoniche dell'esperienza, l'interazione uomo–AI è stata prevalentemente analizzata in chiave strumentale, con un focus su task e usabilità (Wittek et al., 2019). In questo quadro, efficienza funzionale, riduzione dello sforzo cognitivo e risparmio di tempo sono stati considerati i principali driver del valore percepito delle tecnologie intelligenti. In linea con questa prospettiva, nella scelta dell'AI agent gli utenti, pur attratti da componenti edoniche, tendono a privilegiare opzioni utilitaristiche, percepite come più razionali; in caso di conflitto tra piacere ed efficienza, reinterpretano le componenti edoniche in termini funzionali per ridurre la dissonanza cognitiva (Diefenbach & Hassenzahl, 2011).

La letteratura evidenzia che il valore edonico dello shopping favorisce l'acquisto impulsivo attraverso l'attivazione di emozioni positive (Aggarwal et al., 2025; Park et al., 2006), mentre dimensioni edoniche e utilitaristiche interagiscono nel definire l'esperienza complessiva (Vieira et al., 2018). Di conseguenza, anche un orientamento utilitaristico può generare emozioni positive quando l'interazione è percepita come fluida ed efficace.

In linea con questa prospettiva, studi recenti sullo smart retailing mostrano che la voice AI è prevalentemente percepita come uno strumento di supporto decisionale efficiente e conveniente, più che come un attore relazionale (Huh and Kim, 2025). Tuttavia, tale ottimizzazione cognitiva può attivare emozioni positive funzionali — come soddisfazione e riduzione di incertezza — che riducono la resistenza decisionale e favoriscono scelte rapide, aumentando la propensione all'acquisto impulsivo.
Pertanto:
HP – L'intensità affettiva positiva (positive affective intensity) media positivamente la relazione tra l'orientamento utilitaristico dell'agente AI, veicolato tramite il framing comunicativo, e l'urgenza di acquisto impulsivo (urge to buy impulsively).

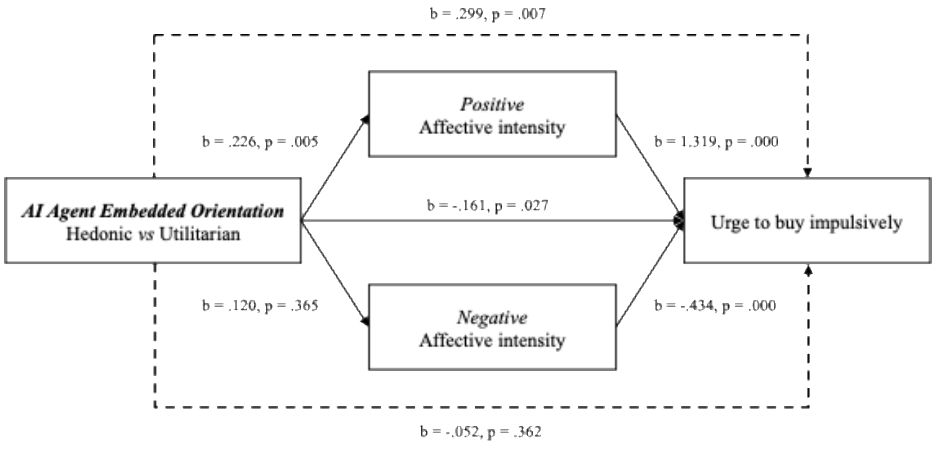
Figure 1. Conceptual framework

Methodology. Per verificare le ipotesi formulate, è stato condotto uno studio sperimentale quantitativo volto ad analizzare l'effetto dell'orientamento edonico e utilitaristico di un AI agent sulle risposte emotive e sull'intenzione di acquisto impulsivo. Lo studio ha coinvolto un campione di 135 partecipanti, 76 uomini e 59 donne, di etá compresa tra i 22 e i 67 anni (M= 33,94 e SD = 13,17), di cui il 69,3% possedeva un titolo almeno universitario.

Tramite un focus group (composto da 8 componenti esperti di marketing e un moderatore) è stato selezionato uno stimolo per l'esperimento. Il prodotto doveva essere caratterizzato da un consumo con finalità sia di natura edonistica sia utilitaristica. La scelta è ricaduta su una scarpa sneaker. L'esperimento principale, ha previsto che i partecipanti interagissero con un agente di intelligenza artificiale configurato tramite la piattaforma Algho di The Digital Box, utilizzata per il design conversazionale e la marketing automation, che proponeva il prodotto adottando uno specifico framing comunicativo. Sono stati predisposti due scenari sperimentali (between-subject study): nel primo scenario il messaggio era strutturato secondo un framing edonico (gruppo EU = 0), caratterizzato da uno stile comunicativo orientato all'esperienza edonica e alla gratificazione emotiva; nel secondo scenario, invece, il framing era di tipo utilitaristico (gruppo EU = 1), con una comunicazione focalizzata su efficienza e performance. Un manipulation check ha verificato la differenza degli stimoli. I partecipanti sono stati assegnati casualmente a una delle due condizioni sperimentali e indirizzati, tramite link o QR code, a una conversazione con l'AI agent sulla piattaforma dedicata. All'interno della chat, l'agente presentava brevemente lo scenario sperimentale e lo scopo generale dello studio, invitando poi i partecipanti a compilare il questionario. Prima della compilazione venivano garantiti anonimato, riservatezza e uso esclusivamente scientifico dei dati, al fine di ridurre bias di desiderabilità sociale e common method bias.

Il questionario è stato strutturato per misurare le risposte emotive attivate dall'esperienza con l'AI agent e la conseguente urgenza di acquisto impulsivo, oltre a raccogliere alcune informazioni socio-demografiche utili alla descrizione del campione e al controllo statistico del modello. Per rilevare l'intensità delle emozioni sperimentate è stata utilizzata la versione breve dell'International Positive and Negative Affect Schedule (I-PANAS-SF o PNAS; Thompson, 2007). L'intenzione di acquisto impulsivo è stata misurata attraverso la scala Urge to Buy Impulsively sviluppata da Beatty e Ferrell (1998), opportunamente adattata allo scenario sperimentale con AI agent.

Infine, il questionario includeva una sezione dedicata alle variabili socio-demografiche: età (espressa in anni), genere e livello di istruzione, misurato attraverso categorie ordinali corrispondenti ai principali gradi di formazione. Tali variabili sono state utilizzate per descrivere il profilo del campione.



Data analysis and Results. L'analisi dei dati è stata condotta seguendo un percorso progressivo volto a verificare le assunzioni statistiche, la qualità del modello di misura e la robustezza delle relazioni strutturali. In primo luogo, è stata testata la normalità multivariata mediante il test di Mardia. I risultati hanno evidenziato una skewness multivariata pari a 1,104.97 ($p < .001$) e una kurtosis multivariata pari a 9.37 ($p = .000$), indicando un discostamento dalla normalità multivariata. Pertanto, per le analisi principali è stata utilizzata la tecnica del bootstrapping (k = 1,000), così da ottenere stime robuste degli effetti e delle relative significatività. Per valutare l'eventuale presenza di Common Method Variance (CMV), è stata applicata la tecnica del Common Latent Factor (CLF). La varianza attribuibile al fattore comune è risultata pari al 31.8%, valore inferiore alla soglia critica del 50% generalmente considerata problematica in letteratura. Tale evidenza suggerisce che il bias non rappresenti una minaccia sostanziale per l'interpretazione dei risultati.

Successivamente, è stata condotta un'analisi fattoriale confermativa (CFA) al fine di testare il modello di misura relativo alle tre dimensioni considerate: affettività positiva (PANAS_P), affettività negativa (PANAS_N) e urgenza di acquisto impulsivo (UBI). Gli indici di fit del modello hanno mostrato valori complessivamente accettabili: $\chi^2/df = 2.141$, $p < .001$; CFI = .918; TLI = .899; RMSEA = .089; SRMR = .089. Sebbene il chi-quadrato risulti significativo, come frequentemente accade in modelli con più indicatori, gli indici incrementali (CFI e TLI) e quelli di errore (RMSEA e SRMR) indicano un adattamento del modello complessivamente adeguato. Per quanto riguarda i loadings fattoriali standardizzati, gli item relativi all'affettività positiva hanno mostrato saturazioni comprese tra .561 e .873 (tutti $p < .001$), mentre quelli relativi all'affettività negativa hanno evidenziato loadings compresi tra .573 e .816 (tutti $p < .001$), confermando la solidità delle due dimensioni emotive. Con riferimento alla scala di Urge to Buy Impulsively, tre item (UBI1, UBI2 e UBI3) hanno mostrato loadings elevati e statisticamente significativi (.892, .867 e .918; $p < .001$). Al contrario, l'item UBI4 ha presentato una bassa saturazione standardizzata (.447), pur risultando significativa. Poiché tale valore indica una debole coerenza con il costrutto latente e compromette la qualità della misura complessiva, si è proceduto alla sua esclusione dalle analisi successive. L'indice composito di urgenza di acquisto impulsivo è stato pertanto calcolato sulla base dei tre item rimanenti, garantendo maggiore affidabilità e coerenza interna della scala.

La Path Analysis rivela come l'orientamento dell'agente AI influenzi l'intenzione di acquisto impulsivo attraverso una complessa dinamica emotiva. Sebbene l'orientamento utilitaristico sia efficace nel generare risposte emotive specifiche, esso produce effetti contrastanti sul comportamento finale rispetto all'orientamento edonico. L'agente con orientamento utilitaristico (focalizzato su efficienza e ottimizzazione) ha generato un aumento significativo dell'affetto positivo ($b = .226$, $p = .005$) rispetto all'agente edonico. Questo suggerisce che un linguaggio focalizzato su efficienza e ottimizzazione della scelta sia in grado di suscitare una risposta di gratificazione superiore rispetto a un approccio puramente esperienziale. Al contrario, lo scenario non ha influenzato in modo significativo l'affetto negativo ($b = .120$, $p = .365$), indicando che lo stile utilitaristico non viene percepito come più frustrante o irritante rispetto a quello edonico. L'affettività positiva (PNAS_P) si conferma la determinante principale dell'acquisto impulsivo ($b = 1.319$, $p < .001$), al contrario, l'affetto negativo deprime fortemente tale intenzione ($b = –.434$, $p < .001$). Poiché l'orientamento utilitaristico è in grado di stimolare queste emozioni positive, esso esercita anche un effetto indiretto positivo sull'acquisto impulsivo ($b = .299$, $p = .007$) al contrario l'effetto indiretto tramite le emozioni negative non è significativo ($b = –.052$, $p = .362$). I risultati evidenziano inoltre un effetto diretto negativo dell'orientamento utilitaristico sull'acquisto impulsivo ($b = –.161$, $p = .027$). Questo risultato indica che, al netto della componente emotiva, un framing fortemente orientato all'efficienza attiva un'elaborazione più razionale e deliberata, che attenua la spontaneità della risposta impulsiva.

Tra le variabili di controllo, il livello di istruzione è emerso come un predittore critico della reattività emotiva. I soggetti con una scolarizzazione più alta hanno riportato livelli significativamente inferiori sia di affetto positivo ($b = –.326$, $p = .001$) che di affetto negativo ($b = –.382$, $p = .038$), manifestando una risposta psicologica più distaccata e meno polarizzata verso l'agente. L'età ($b = .003$, $p = .417$) e il genere ($b = .076$, $p = .359$) non hanno invece mostrato impatti rilevanti sulla genesi delle emozioni durante l'interazione.

Figure 2. Risultati della path analysis

Research limitations. Lo studio presenta alcune limitazioni. L'utilizzo di uno scenario sperimentale controllato può non riflettere pienamente la complessità delle decisioni reali online, influenzate da molteplici stimoli contestuali. Inoltre, il campione, pur adeguato al test del modello, limita la generalizzabilità dei risultati, rendendo opportune future replicazioni su campioni più ampi e in diversi contesti culturali. L'acquisto impulsivo è stato misurato tramite intenzioni auto-riferite e non comportamenti effettivi, suggerendo la necessità di studi basati su dati osservabili. Infine, l'analisi si concentra su un'unica categoria di prodotto e considera esclusivamente le emozioni come mediatore, aprendo a ricerche che includano ulteriori variabili psicologiche, quali fiducia e percezione di umanità dell'agente.

Managerial implications. I risultati offrono implicazioni rilevanti per retailer, brand e sviluppatori di AI agent nei contesti di smart retailing e digital commerce. In primo luogo, l'orientamento incorporato nell'AI agent non è neutrale: un framing utilitaristico può attivare emozioni positive funzionali, come soddisfazione e senso di efficacia, che incrementano indirettamente l'intenzione di acquisto impulsivo. Tuttavia, lo stesso orientamento produce anche un effetto diretto negativo sull'impulsività, suggerendo che un approccio eccessivamente focalizzato su efficienza e performance possa generare una forma di resistenza decisionale. Per i manager, ciò implica che la progettazione degli AI agent dovrebbe evitare configurazioni esclusivamente strumentali, privilegiando un equilibrio tra efficienza cognitiva e coinvolgimento emotivo, agendo sulla comunicazione verbale, paraverbale e non verbale dell'agente e sull'antropomorfismo (Barros et al., 2024; Wölfel et al., 2022). In secondo luogo, lo studio conferma che le emozioni positive rappresentano il principale driver dell'acquisto impulsivo mediato da AI. Le imprese dovrebbero progettare interazioni capaci di generare attivazione emotiva non solo tramite contenuti edonici, ma anche attraverso fluidità conversazionale, personalizzazione dinamica e riduzione dello sforzo cognitivo (Araujo and Bol, 2024). L'ottimizzazione del journey interattivo diventa così una leva strategica per stimolare decisioni rapide e meno deliberate. In terzo luogo, il design valoriale dell'AI agent costituisce una leva di marketing strategico: la configurazione dell'orientamento comunicativo può modulare stati emotivi e comportamenti d'acquisto in tempo reale, trasformando l'AI da strumento operativo a interlocutore capace di influenzare il processo decisionale, richiedendo un approccio integrato tra marketing, UX design e data analytics. Infine, il livello di istruzione emerge come variabile significativa. Consumatori più istruiti mostrano risposte emotive più attenuate, suggerendo la necessità di strategie adattive: gli AI agent dovrebbero modulare tono, intensità e contenuti comunicativi in funzione delle caratteristiche del target.

Originality of the paper. L'articolo contribuisce alla letteratura sul consumo basato su AI offrendo una spiegazione teoricamente fondata dei meccanismi psicologici ed emotivi che collegano l'orientamento edonico o utilitaristico incorporato nel design dell'agente AI agli esiti di acquisto impulsivo nel contesto decisionale in tempo reale (Piper, de Cosmo and Guido, 2024). Il contributo principale consiste nell'adottare una prospettiva intra-AI, superando il tradizionale confronto AI vs. umano e mostrando che l'AI non è una categoria neutra: differenti orientamenti valoriali si traducono in contenuti comunicativi distinti, capaci di generare effetti psicologici e comportamentali diversi. Lo studio estende così il word-of-machine effect (Longoni and Cian, 2022), evidenziando che un orientamento utilitaristico dell'agente, coerente con le aspettative di razionalità attribuite alle macchine, attiva emozioni positive funzionali che mediano significativamente l'intenzione di acquisto impulsivo, confermando l'ipotesi proposta. Questo contributo assume particolare rilevanza alla luce dell'emergere dell'intelligenza artificiale agentica, caratterizzata da sistemi dotati di crescente autonomia decisionale nelle interazioni digitali (de Cosmo and Piper, 2020; de Cosmo, Piper and Di Vittorio, 2022; Mileti et al., 2025).

How to Innovate Personalization

CHIARA OTTOLENGHI [1], GENNARO IASEVOLI[2]

Abstract. *This study develops the Innovation Patterns for Personalization (IPP), a parsimonious pattern map that integrates fragmented personalization and customization taxonomies with emerging managerial design concerns. Drawing on a comparative synthesis of influential frameworks in marketing, operations, and information systems, IPP organizes personalization design decisions into five orthogonal dimensions—Where, What, Who, How, and Why. Specifically, the map captures the execution locus of personalization (Design, Production, Distribution, Consumption, After-sales), the personalization object (Product, Content, Structure, Function, Appearance) complemented by interface modality (Physical, Digital, Phygital), governance choices (Firm, Prosumer, Customer, with prosumer and customer roles such as Proposer, Selector, Assembler, Authoring), delivery logic (AI-based decisioning, Individual vs. Collaborative collaboration mode, and R&D Driven vs. Market Driven decision approach), and scaling conditions. The resulting framework provides a structured lens for describing, comparing, and intentionally recombining personalization configurations as innovation patterns, supporting both cumulative academic analysis and actionable managerial design choices. While conceptual, IPP is designed for empirical validation through interviews and broader cross-industry applications.*
Keywords: *personalization; customization; innovation; pattern; framework;*

Framing of the research. *Over the past decade, personalization has moved from a premium differentiator to a strategic requirement as consumers increasingly expect offerings that feel tailored to them. Large-scale evidence already signaled this shift: McKinsey reports that 71% of consumers expect companies to deliver personalized interactions, and 76% become frustrated when personalization does not occur (McKinsey, 2021). At the firm level, the performance stakes are equally material: companies that excel at personalization can generate 40% more revenue from those activities than average players, and McKinsey estimates that reaching top-quartile personalization performance could unlock more than $1 trillion in value across US industries (McKinsey, 2021).*

These trends have been further amplified by advances in Artificial Intelligence (AI). By learning from prior interactions and behavioral traces, AI-enabled systems can anticipate customer needs and preferences and scale personalization beyond what rule-based approaches can realistically deliver (Forbes, 2021). It is therefore unsurprising that personalization and customization have attracted sustained scholarly attention, from early foundational work to more recent contributions (Lampel and Mintzberg, 1996; Gilmore and Pine, 1997; Da Silveira et al., 2001; Piller, 2022). Moreover, personalization can be conceptualized as operating across levels of value creation—shifting goods into services, services into experiences, and experiences into more meaningful personal transformations (Pine, 2022).

Building on prior work, we introduce the Innovation Patterns for Personalization (IPP) as a unifying scaffold for understanding and designing personalization innovation in products and services. While extant scholarship has produced valuable taxonomies of personalization and customization (e.g., Da Silveira et al., 2001; Rincon-Guevara et al., 2018; Altoe and Pinto, 2023), these frameworks primarily describe what personalization is at a point in time. What remains underdeveloped is an explicit, cumulative understanding of how personalization becomes innovative: the strategic moves, recombinations, and sequencing decisions through which firms expand personalization from bounded experiments into routinized, organization-wide capabilities. In other words, the literature lacks a systematic map of innovation trajectories—the pathways by which personalization is progressively developed, governed, and scaled. Accordingly, we ask: What are the recurrent patterns through which firms innovate personalization, and how can these patterns be systematically identified, compared, and used to guide managerial decision-making? Our study addresses this gap by integrating theoretical perspectives with observed managerial practice and by extending the design space to reflect the rapidly evolving frontier of contemporary personalization, thereby constructing the IPP.

Purpose of the paper. *The purpose of this short paper is to advance research and practice on personalization by introducing the Innovation Patterns for Personalization (IPP), a structured framework for explaining how personalization is innovated—not only what personalization is. As personalization has become a strategic necessity rather than a premium option (Piller, 2022), prior work has clarified key forms and levels of customization and personalization, distinguishing cosmetic versus deeper approaches and separating changes to the offering from changes to its representation (Gilmore & Pine, 1997), as well as positioning personalization along a continuum of customer involvement from standardization to design-stage customization (Lampel & Mintzberg, 1996; Da Silveira et al., 2001). Subsequent research has increasingly framed personalization and customization as a multi-dimensional design problem*

[1] Postdoc PhD Fellow in Economics and Business Management, SECS-P/08 – Economics and Business Management, Department of Human Sciences, University of Rome LUMSA, Italy c.ottolenghi@lumsa.it –Corresponding author;

rather than a single continuum. Early taxonomies located differentiation along the value chain (design, fabrication, assembly, distribution) (Lampel & Mintzberg, 1996) and specified levels of customization from standardization and usage through packaging/distribution and upstream production stages (Da Silveira et al., 2001). In parallel, marketing frameworks distinguished approaches to customization—cosmetic, transparent, adaptive, and collaborative—based on how the customer is addressed and what is adapted (Gilmore & Pine, 1997), while operations research emphasized feasibility constraints such as customer involvement and modularity (Duray, 2002). Reus (2006) further clarified that customization regimes vary by product and delivery context (physical vs. digital; bundled vs. unbundled; online vs. offline). In digital settings, taxonomies have formalized personalization through user modeling (data type, acquisition method, lifespan) and system adaptation (object of change—content/presentation/structure—volatility, scope, and control) (Weinmann et al., 2013), and extended these distinctions to SaaS by specifying stakeholders, layers/assets, and lifecycle timing of customization (Ali et al., 2019). Complementary work has highlighted boundary conditions in product architecture and flexibility (Rincon-Guevara et al., 2018), as well as decoupling/COPP logic (e.g., MTS/ATO/MTO) and manufacturing process typologies that constrain scalable variety (Tien, 2011; Bayou & Reinstein, 2003; Piller, 2022). More recent contributions have also refined governance by detailing control locus and customer roles (inputter/selector/assembler/designer), degrees of freedom, and collaboration mode (individual vs. community) (Pallant et al., 2020), and by introducing AI-relevant distinctions such as supervised versus unsupervised approaches and explainability (Altoe & Pinto, 2023). At the same time, the rapid diffusion of AI-driven personalization in digital marketing highlights how algorithmic systems increasingly tailor content and experiences at scale (Aguirre et al., 2015; Bleier & Eisenbeiss, 2015; Qadri et al., 2026), while digital transformation expands personalization across touchpoints and organizational processes (Galindo-Martín et al., 2019; Arya et al., 2019). Despite this rich body of work, existing studies largely focus on classifying personalization features and design choices, rather than systematically mapping the innovation pathways through which firms develop, extend, and operationalize personalization capabilities over time. To address this gap, we draw on the broader innovation literature on pattern-based approaches, with particular relevance from business model innovation research that codifies recurrent innovation logics into actionable patterns (Sawhney et al., 2007; Gassmann et al., 2013; Clauss, 2016; Weking et al., 2018). Notably, Sawhney et al. (2007) propose the "innovation radar" as a 360-degree view of innovation organized around interrelated dimensions of what, who, how, and where firms innovate. Building on this logic, IPP synthesizes prior theory and observed managerial approaches into an integrative design space that organizes the key patterns underlying personalization innovation and supports both cumulative academic comparison and actionable managerial design choices.

Methodology. *To build the Innovation Patterns for Personalization (IPP) that is both academically rigorous and managerially useful, we carried out a broad review of prior work on product and service personalization and customization. We examined conceptual frameworks developed in the academic literature as well as practitioner-oriented models produced by major consulting firms. Our procedure was guided by the taxonomy development method introduced by Nickerson et al. (2009), which blends inductive, deductive, and intuitive reasoning. This approach was adopted to ensure that the resulting IPP satisfies core taxonomy criteria, including conciseness, inclusiveness, comprehensiveness, and extendibility.*

Following this method, we first compiled a set of eighteen theoretical and managerial models on personalization and customization published over the last three decades, starting from 1996. Model selection relied on two criteria. The first was alignment with the specific scope of this study, and the second was citation frequency, which served as a proxy for scholarly visibility and influence. Beyond highly cited contributions, we also incorporated additional classifications with clear managerial relevance, even when they were not indexed in Scopus or widely cited. This choice allowed us to capture emerging viewpoints that are shaping the field in practice.

The analysis proceeded through three iterative phases, as described in Table 1. In Phase 1 (Inductive), we systematically extracted, compared, and organized the variables and dimensions used across the eighteen frameworks, identifying both shared themes and distinctive elements. In Phase 2 (Deductive), we leveraged these comparisons to consolidate the most recurrent and consequential variables into an integrated set of patterns. In Phase 3 (Intuitive), we further expanded the model with patterns that reflect the evolving frontier of personalization, drawing on recent industry developments, technological progress, and insights from practitioner reports.

Overall, this structured process anchors the proposed IPP in established scholarship while keeping it responsive to the fast-moving and continually reconfigured nature of personalization in contemporary business contexts.

Table 1: Method used (Authors' elaboration)

Phase	Objective	Process	Output
Phase 1 - Inductive	Identify the full set of dimensions used in prior work	Conducted a systematic literature review in Scopus, complemented by backward and forward snowballing to expand coverage; extracted and coded variables/dimensions from the resulting academic and practitioner sources; compared definitions and labels; clustered recurring constructs and noted divergent assumptions	Comprehensive variable inventory (full set of dimensions) + preliminary clusters and overlap notes
Phase 2 - Deductive	Consolidate recurrent variables into a parsimonious structure	Selected the most recurrent and consequential dimensions; formalized higher-order groupings; defined boundaries to reduce overlap and enforce orthogonality	Draft IPP structure (core dimensions and sub-dimensions) + consolidated labels and definitions
Phase 3 - Intuitive	Extend the structure to reflect emerging practice and the technological frontier	Added/refined dimensions to capture developments underrepresented in older models; aligned terminology with recent practitioner frameworks; integrated patterns observed in contemporary personalization practice	IPP map

Results. *The literature review included foundational typologies of personalization approaches and customer involvement (Gilmore & Pine, 1997; Lampel & Mintzberg, 1996; Da Silveira et al., 2001), operations-based boundary conditions and feasibility logics (Duray, 2002; Tien, 2011; Bayou & Reinstein, 2003; Piller, 2022; Rincon-Guevara et al., 2018), digital personalization mechanisms centered on user modeling and system adaptation (Weinmann et al., 2013), SaaS-specific customization layers and lifecycle timing (Ali et al., 2019), and recent work capturing configurator-based inputs and the function–appearance distinction (Cadenas USA, 2025), as well as emerging AI-related distinctions such as explainability and mining approaches (Altoe & Pinto, 2023). Across these streams, the analysis revealed two persistent patterns. First, existing contributions offer strong classification logics for what is personalized (e.g., content vs. structure vs. functionality) and where personalization is introduced (e.g., design vs. production vs. distribution), but they often treat governance, delivery mechanisms, and scalability conditions as secondary or implicit design choices. Second, more recent technology-driven advances—especially AI-based decisioning and platform ecosystems—expand personalization beyond isolated product or interface tweaks into configurations that span value-chain locus, decision rights, and explicit monetization and legitimacy considerations.*

Synthesizing these insights, our main result is our four design dimensions—Where, What, Who, and How— and a Why conditioning layer, so that any initiative regarding innovation for personalization can be described as a coherent configuration of interdependent choices rather than as a standalone feature. We propose a Innovation Patterns for Personalization (IPP), presented in Figure 1, as a directional chart useful to focus different ways to innovate. The figure's first contribution is to make execution locus explicit and comparable: Where captures whether customer-specific information is first translated into differentiated output in Design, Production, Distribution, Consumption, or After-sales, thereby distinguishing upstream specification- and fulfillment-based personalization from channel-time, in-use, and post-purchase interventions. This locus framing consolidates value-chain perspectives in the customization literature while highlighting that "personalization" may be operationally enacted in very different parts of the system, with distinct feasibility and governance implications. Second, IPP provides an object-level grammar for specifying what changes: What distinguishes five personalization targets—Product, Content, Structure, Function, and Appearance—and complements them with the interface modality through which personalization is experienced (Physical, Digital, Phygital). This separation clarifies two frequent ambiguities in prior work: (i) distinguishing changes to contractual/entitlement composition (Product) from changes to behavioral logic (Function) and from changes to choice architecture (Structure), and (ii) separating the personalization object from the medium through which it is encountered. In doing so, IPP supports consistent comparison across initiatives that may share a locus (e.g., distribution) but differ fundamentally in object (e.g., content vs. structure), or that share an object (e.g., content) but differ in interface modality (digital vs. phygital). Third, IPP elevates governance from a contextual assumption to a core design dimension. Who formalizes personalization governance by locating decision authority in the Firm, Prosumer, or Customer and, when authority resides with Prosumer or Customer, characterizes the contribution role through which the outcome is produced (Proposer, Selector, Assembler, Author). This makes explicit whether personalization is firm-determined, mediated by external producers, or customer-determined, and it distinguishes between different modes of customer contribution that are often conflated in "involvement" measures. As a result, the same personalization object (e.g., product configuration) can be represented as materially different innovation patterns depending on where decision rights sit and what role the customer plays in producing the final outcome. Finally, IPP specifies delivery as a set of mechanism choices rather than a residual technical detail. How captures three elements: AI-based decisioning, Collaboration mode (Individual vs. Collaborative), and Decision approach (R&D Driven vs. Market Driven). This decomposition clarifies whether personalization is produced through automated decision policies, whether the option space is built from firm-provided elements versus co-created or

community-sourced corpora, and whether decisioning is oriented primarily toward customer-fit optimization or toward commercial steering objectives. By disentangling these elements, the framework avoids treating "AI" as a single monolithic innovation lever and instead locates innovation in the specific way decisioning, collaboration, and steering are configured.

IPP anchors personalization as an innovation initiative by specifying conditions under which it can scale. IPP includes a Why layer, but Why is not an innovation pattern in the same sense as the design choices captured in Where, What, Who, and How. Instead, Why specifies the boundary conditions, the various benefits to be gained and selection criteria that determine which personalization configurations are strategically appropriate and scalable in a given context. In particular, it shapes the feasibility, acceptability, and sustainability of any pattern, and can therefore steer firms toward different configurations (or constrain multiple configurations simultaneously). Making Why explicit addresses a recurring limitation of prior taxonomies: personalization initiatives may be readily classifiable by object and locus, yet fail to scale when they lack an articulated capture logic, enforceable legitimacy safeguards, or institutionalized learning routines.

Moreover, consistent with structured diagnostic approaches used in practitioner frameworks (e.g., BCG, 2025), each IPP dimension is intended to be operationalized through a second-step "deepening" layer—i.e., a set of focused diagnostic prompts and sub-criteria that guide systematic assessment and design choices within each variable.

Taken together, IPP consolidates fragmented pattern insights into a single, managerially usable representation that supports systematic comparison across cases and explicit design of personalization innovation patterns. In practical terms, the map enables researchers to code initiatives as configurations across the four pattern dimensions (Where–What–Who–How) and enables managers firstly to asses them through the Why conditioning layer, to diagnose misalignment across design choices (e.g., AI-based decisioning without clear authority or without explicit legitimacy and learning provisions) and to intentionally explore alternative innovation patterns by shifting locus, object, governance, delivery logic, or scaling conditions.

Figure 1: Innovation Patterns for Personalization (Source: Authors' elaboration)

Research limitations. *This analysis is conceptual and integrative in nature; accordingly, its contributions are subject to several limitations. First, the IPP map is derived from a structured synthesis of existing taxonomies and frameworks, rather than from primary empirical evidence. As a result, the framework should be interpreted as a theoretically grounded design representation that still requires empirical corroboration, particularly through expert and managerial interviews aimed at verifying interpretability, completeness, and practical usability. Second, although IPP is anchored in established streams of personalization, customization, and innovation research, its congruence with the broader literature should be further assessed through additional systematic coverage and triangulation across adjacent domains (e.g., service operations, platform governance, and algorithmic accountability), to ensure that no relevant dimensions or boundary conditions have been inadvertently omitted. Third, IPP prioritizes parsimony to meet the constraints of a short paper; consequently, it does not capture all sector-specific contingencies and should not be read as a fully specified causal model. Fourth, several constructs—especially within How and Why—may be partly unobservable from public descriptions of personalization initiatives, limiting replicable coding without access to firm-internal documentation.*

Finally, because personalization technologies and governance practices evolve rapidly—particularly with the diffusion of generative AI—the IPP map should be viewed as iterative and extensible, requiring refinement as new decisioning paradigms, interaction modalities, and legitimacy expectations emerge.

Managerial implications. *IPP provides managers with a practical map to design, diagnose, and evolve personalization initiatives as coherent configurations rather than isolated features. First, it supports structured design by forcing explicit choices across Where, What, Who, How, and Why, thereby reducing ambiguity in cross-functional decision making and aligning personalization with a 360-degree innovation logic akin to the "innovation radar" perspective (Sawhney et al., 2007). Second, IPP helps managers anticipate feasibility and operational trade-offs: shifting personalization upstream (Design/Production) typically raises modularity, flexibility, and process requirements (Duray, 2002; Rincon-Guevara et al., 2018; Piller, 2022), whereas downstream personalization (Distribution/Consumption/After-sales) increases reliance on data and decisioning capabilities characteristic of digital personalization systems (Weinmann et al., 2013). Third, the map enables governance-by-design by making decision authority and customer roles explicit, helping managers choose participation architectures (e.g., selector vs assembler vs authoring) that fit both operational constraints and strategic objectives (Pallant et al., 2020). Fourth, IPP supports risk and legitimacy management by treating acceptability as a design requirement, consistent with evidence that personalization effectiveness can be offset by perceived intrusiveness and privacy concerns if trust and control are not managed (Aguirre et al., 2015; Bleier & Eisenbeiss, 2015). Finally, IPP encourages scalable implementation by embedding business model logic and learning routines: managers are prompted to specify value capture mechanisms and KPIs (Clauss, 2016; Weking et al., 2018), and to institutionalize experimentation and monitoring before scaling personalization initiatives.*

Originality of the paper. *This analysis is original in that it reframes personalization from a feature-level classification problem—dominant in prior taxonomies that separately emphasized customization approaches (Gilmore & Pine, 1997), value-chain and production loci (Lampel & Mintzberg, 1996; Da Silveira et al., 2001; Piller, 2022), product architecture and flexibility constraints (Duray, 2002; Rincon-Guevara et al., 2018), and digital user modeling/system adaptation (Weinmann et al., 2013; Ali et al., 2019)—to an innovation-pattern and configuration problem. Building on the logic of pattern-based innovation perspectives in adjacent domains (Sawhney et al., 2007; Gassmann et al., 2013; Clauss, 2016; Weking et al., 2018), we introduce the Innovation Patterns for Personalization (IPP) as an integrative pattern map that organizes personalization design decisions into Where, What, Who, How, and Why.*

The contribution is not merely integrative. First, IPP provides a common representational grammar for personalization innovation, enabling initiatives to be described as combinations of interdependent design choices rather than as isolated tactics (e.g., "adding recommendations" or "adding AI"). This configuration logic supports cumulative comparison across studies and sectors by making explicit which dimension is changing (locus, object, authority, mechanism, or rationale) when personalization is said to "innovate." Second, IPP resolves a recurring limitation in existing classifications: while prior frameworks often specify where personalization occurs or what is adapted, they tend to leave the governance problem implicit. IPP makes decision rights and customer participation core design variables by distinguishing authority (Firm, Prosumer, Customer) and customer roles (e.g., proposer/selector/assembler/author), allowing researchers and managers to compare personalization strategies that may look similar on the surface but differ fundamentally in accountability and responsibility allocation (Piller et al., 2010; Pallant et al., 2020; Loef et al., 2017). Third, IPP clarifies the delivery logic of personalization by separating technology-enabled decisioning from the structure of collaboration and the dominant decision orientation—capturing how AI-based decisioning, collaboration mode, and decision approach jointly shape the space of feasible personalization designs, rather than treating "AI" as a monolithic innovation lever.

Finally, by incorporating these constraints explicitly, IPP connects personalization design to broader pattern-based innovation work in business models and organizational learning (Clauss, 2016; Weking et al., 2018), and offers a compact, theory-grounded lens for analyzing how firms expand personalization from bounded experiments into routinized innovation capabilities over time.

Neurodiversity in the Agentic Economy: A Systematic Literature Review

CHIARA COLACCHIO [1], DANIELA CORSARO [2]

Abstract. *Negli ultimi due decenni, il fenomeno della neurodivergenza si è evoluto da un inquadramento clinico-patologico verso una prospettiva sociale e organizzativa. Tuttavia, la sua integrazione nella Consumer Research e nella Marketing Research rimane marginale.*

Il presente lavoro analizza sistematicamente come la neurodivergenza sia stata concettualizzata nella letteratura accademica non clinica, con l'obiettivo di valutarne la presenza nel dibattito scientifico e il modo in cui viene trattata in relazione ai processi di consumo.

Attraverso una Systematic Literature Review (SLR), lo studio identifica i pattern ricorrenti e le traiettorie evolutive del campo, delineando lo stato dell'arte della neurodivergenza all'interno del dominio del Business & Management.

L'analisi evidenzia tre fasi principali: un'eredità medico-psichiatrica, una transizione identitaria-comunitaria e un consolidamento nella prospettiva del capitale umano (contesti organizzativi e formativi). I risultati rivelano una persistente marginalità teorica nel marketing: la neurodivergenza è raramente considerata una dimensione identitaria dotata di agency nei processi di creazione di valore.

Il contributo dimostra che l'invisibilità del consumatore neurodivergente non è una mera lacuna tematica, ma il risultato di un modello implicito di consumatore cognitivamente omogeneo che ha storicamente orientato la disciplina (Smith, 1776/2003). Oltrepassando il binomio neurodivergenza-vulnerabilità, il lavoro fornisce le basi concettuali per integrare la diversità cognitiva nelle teorie contemporanee di Consumer Research.

Keywords: *Neurodiversity; Consumer Research; Consumer Agency; Market Heterogeneity; Symbolic Consumptions; Systematic Literature Review.*

Framing of the research. La presente analisi della letteratura esamina come il tema della neurodivergenza viene trattato nell'ambito della Consumer Research (Muniz & O'guinn, 2001; Schau, 2009).

A partire dai primi anni Duemila, il concetto di neurodivergenza è progressivamente passato da un inquadramento clinico-patologico (Happé, 2008; Baker, 2006) alla prospettiva della neurodiversità. Tale transizione, supportata dai contributi seminali di Singer (1998) e successivamente sistematizzata da Walker (2014), sottrae la divergenza neurologica alla sola sfera clinica per estenderla a dimensioni sociali, educative e organizzative che ne riconoscono il valore come variazione naturale dell'umanità.

L'integrazione di queste prospettive nasce da un processo di maturazione epistemologica consolidatosi a partire dagli anni '90. In quel periodo, nonostante la letteratura specifica sulla neurodiversità fosse quasi esclusivamente limitata ai contributi seminali di Singer (1998), si affermarono riferimenti teorici fondamentali come il modello sociale della disabilità e il postmodernismo liberatorio (Firat & Venkatesh, 1995). Tali istanze hanno fornito gli strumenti concettuali per mettere in discussione l'assunto di un "consumatore standard" (Lancaster, 1966), riconoscendo i mercati come contesti caratterizzati da soggettività plurali che sfidano i modelli tradizionali basati sulla normalità statistica (Porter & Kramer, 2011; Zuboff, 2019). Tale evoluzione teorica amplia il campo di analisi oltre i confini istituzionali dell'apprendimento e del lavoro, aprendo la strada a un'indagine sulla agency della persona neurodivergente come soggetto attivo nei mercati. In questa prospettiva, Armstrong (2015) contesta il "mito del cervello normale", osservando che, a differenza delle misure fisiche standardizzate (come il metro), non esiste un prototipo biologico universale a cui paragonare il funzionamento cerebrale umano. Argomentando che la neurodiversità è per la specie umana ciò che la biodiversità è per l'ecosistema, Armstrong evidenzia come i modelli dominanti abbiano storicamente ignorato i punti di forza evolutivi associati alla divergenza (come le capacità sistemizzanti o la creatività superiore) per focalizzarsi esclusivamente sulle mancanze. In linea con questo orientamento, Dwyer (2022) propone di spostare l'attenzione dalla "correzione" del deficit individuale alla trasformazione dei sistemi di potere e delle architetture sociali. In questo quadro, Dwyer introduce il concetto di neuro-neutralità, suggerendo che le organizzazioni e i contesti istituzionali non dovrebbero favorire sistematicamente i funzionamenti neurotipici, ma strutturarsi per accogliere la varietà neurologica naturale, riconoscendo che la disabilità emerge spesso dall'interazione tra caratteristiche individuali e contesti escludenti, piuttosto che da una condizione intrinseca del soggetto.

Nonostante questa evoluzione teorica, la letteratura mostra una marcata polarizzazione tematica: l'attenzione si è finora concentrata prevalentemente su contesti istituzionali circoscritti, quali i luoghi di lavoro e i sistemi educativi, dove la neurodivergenza viene esaminata attraverso la lente delle pratiche di gestione, del supporto pedagogico e dell'integrazione funzionale.

In tali ambiti, il focus è posto sulle condizioni atte a favorire la partecipazione e la performance nelle organizzazioni

[1] IULM University, e-mail: chiara.colacchio@studenti.iulm.it
[2] IULM University, e-mail: Daniela.corsaro@iulm.it

(es: Austin & Pisano, 2017; Walkowiak, 2024), lasciando inesplorate le implicazioni del funzionamento divergente in ambiti non istituzionalizzati. Tale asimmetria riflette una visione della neurodivergenza legata al concetto di vulnerabilità (Baker, 2006), interpretata come una deviazione da correggere o una fragilità da tutelare, oppure come una risorsa strategica da valorizzare in termini di performance e inclusione (Austin & Pisano, 2017; Walkowiak, 2024; Lai, Aoki & Seera, 2025). Sebbene queste prospettive abbiano contribuito a rendere visibili soggetti precedentemente esclusi, tendono a inscriverli in una logica di protezione e compensazione.

In tale configurazione, l'invisibilità concettuale del consumatore neurodivergente nella letteratura non rappresenta solo una lacuna tematica, ma il risultato di una specifica "costruzione culturale della conoscenza" (O'Dell et al., 2016). Secondo questa prospettiva, la comprensione della neurodiversità è mediata dalle comunità epistemiche dominanti.

La Consumer Research ha dedicato finora un'attenzione marginale al tema: i processi di consumo sono raramente considerati come contesti di analisi primaria e la persona neurodivergente non viene esplicitamente concettualizzata come soggetto dotato di agency nelle dinamiche di scambio o di creazione di valore. Quando presenti, i riferimenti al consumo risultano indiretti, spesso mediati da prospettive istituzionali o da attori terzi come caregiver e organizzazioni (Paletta, 2013; Cascio, 2015; Houdek, 2022; Sutherland et al., 2025). Questa configurazione della letteratura è particolarmente critica se si considera che il marketing interpreta i mercati come sistemi complessi in cui si intrecciano dimensioni economiche, simboliche ed esperienziali (Hirschman & Hirschman, 1982).

Nel contesto di un'economia sempre più descritta come "agentica", caratterizzata dalla diffusione di sistemi autonomi e tecnologie di agentic AI che partecipano ai processi decisionali e alla creazione di valore (Ratten et al., 2024; Martinelli, 2025; Mathew et al., 2026), emergono nuove forme di soggettività economica che includono attori umani, organizzativi e artificiali. Questa trasformazione sta ridefinendo modelli di business, confini organizzativi ed ecosistemi di mercato (Chatterjee et al., 2023; Secundo et al., 2025), rendendo necessario interrogarsi sui modelli impliciti di soggetto che guidano la teoria e la pratica manageriale. Se l'agentic economy presuppone pluralità di attori e configurazioni di agency, la persistenza nei modelli di marketing di consumatore cognitivamente omogeneo (Lancaster, 1966; Holbrook & Hirschman, 1982) rappresenta una tensione teorica rilevante. Nel caso della neurodivergenza, questa tensione evidenzia i limiti di framework che continuano a presupporre processi cognitivi standardizzati (Simon, 1955; Lancaster, 1966) nell'interpretazione dei segnali di mercato. In tale prospettiva, il presente contributo si inserisce nel dibattito sulla trasformazione dei modelli manageriali e di marketing, proponendo una riflessione critica sugli assunti cognitivi che guidano la concettualizzazione del consumatore nei mercati contemporanei.

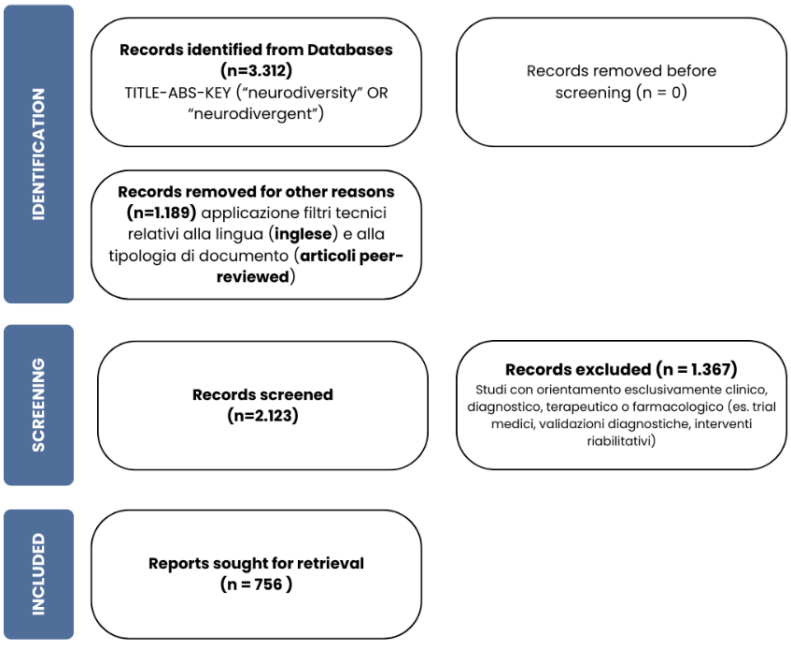
Purpose of the paper. Lo scopo della presente Literature Review è analizzare la concettualizzazione della neurodivergenza nella letteratura accademica non clinica, valutandone l'integrazione nella Consumer Research con riferimento alle dinamiche di mercato e alla comunicazione di marca. A tale scopo, la ricerca risponde alla seguente domanda di ricerca:

Come è stata concettualizzata la neurodivergenza nella letteratura accademica non clinica?
Come la Consumer Research affronta il tema della neurodivergenza?

A fronte della marginalità della prospettiva market-based, la presente SLR esamina l'evoluzione del dibattito sulla neurodivergenza e identifica gli orientamenti teorici dominanti. L'analisi della letteratura mira a distinguere le dimensioni del fenomeno già consolidate, da quelle che rimangono marginali o assenti nella ricerca orientata al marketing. Il lavoro intende quindi offrire una base analitica per integrare la diversità cognitiva nella Consumer Research, definendo le premesse per future ricerche teoriche ed empiriche sul rapporto tra neurodivergenza, agency e consumo.

Methodology. Per analizzare il tema della neurodivergenza nella letteratura accademica, è stata condotta una revisione sistematica della letteratura, secondo il modello PRISMA 2020 (Page et al., 2021). Questo approccio ha garantito la tracciabilità di ogni fase, attraverso una valutazione sequenziale di titoli, abstract e testi completi.

Il disegno metodologico segue un protocollo definito a priori e articolato in fasi sequenziali di pianificazione, identificazione, selezione, estrazione e sintesi dei contributi, in linea con l'approccio di Sauer e Seuring (2023) e con i principi di trasparenza e replicabilità suggeriti da Tranfield et al. (2003).



Il processo è iniziato con la definizione dell'ambito di analisi e la costruzione di un quadro metodologico volto ad individuare le lacune rilevate nella letteratura esistente. In questa fase sono stati inoltre definiti la strategia metodologica e il protocollo di ricerca, sviluppati sulla base dei criteri consolidati da Davies e Crombie (1998). Coerentemente con le linee guida del Cochrane Handbook (Chandler et al., 2019), il protocollo ha stabilito chiaramente gli obiettivi e i criteri di eleggibilità prima dell'inizio della ricerca, assicurando che la selezione degli studi non fosse influenzata dai risultati. La ricerca bibliografica è stata condotta utilizzando il database Scopus, scelto per l'ampia copertura di fonti accademiche e per gli strumenti avanzati di filtraggio e analisi disponibili (Franceschet, 2010).

Lo screening dei titoli e degli abstract, nonché la valutazione full-text dei contributi, sono stati condotti da due ricercatori. I casi di disaccordo classificatorio sono stati risolti attraverso discussione congiunta fino al raggiungimento del consenso; nei casi di ambiguità persistente, è stato coinvolto un terzo valutatore esterno, in linea con le raccomandazioni di Tranfield et al. (2003).

Successivamente, l'analisi si è concentrata sull'esame qualitativo dei contributi attraverso operazioni di estrazione e sintesi dei dati finalizzate a raccogliere gli insight più rilevanti. Infine, i risultati sono stati organizzati sistematicamente in un report complessivo, finalizzato a una comunicazione efficace delle evidenze riscontrate.

Le principali fasi del processo di revisione sono sintetizzate nel diagramma metodologico riportato in Figura 1.

Figura 1. Diagramma metodologico

La stringa di ricerca iniziale, volutamente ampia, è stata costruita utilizzando gli operatori booleani e combinando i termini "neurodiversity" OR "neurodivergence", con l'obiettivo di intercettare l'insieme più esteso possibile dei contributi pertinenti. Tale interrogazione ha restituito 3.312 documenti complessivi.

Sebbene le radici del dibattito risalgano agli anni '90, il periodo di osservazione analitica considerato in questo studio inizia dal 2006, primo anno in cui il database Scopus registra contributi scientifici indicizzati e coerenti con i criteri di ricerca adottati. L'analisi si estende fino al primo trimestre del 2026 per includere i contributi in fase di pubblicazione (Early Access).

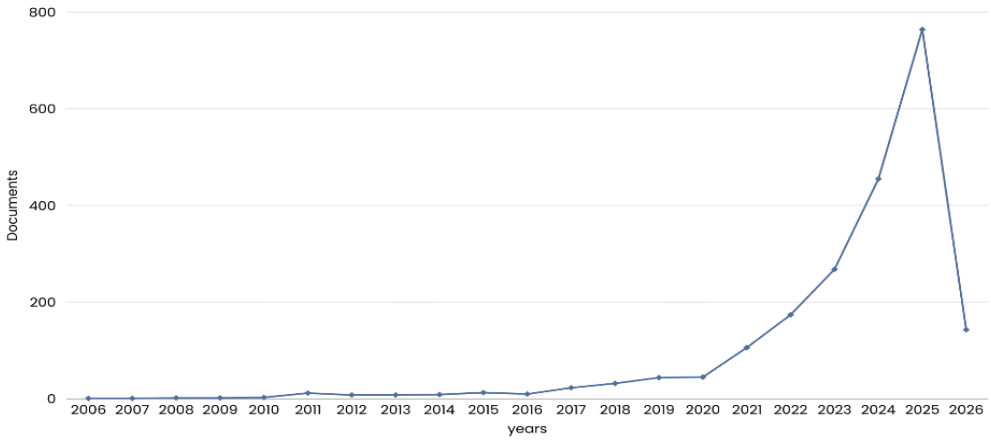
Nel processo di raffinamento del dataset sono stati applicati filtri relativi alla tipologia di documento (articoli peer-reviewed) e alla lingua (inglese), ottenendo un database di 2.123 contributi. Successivamente, per verificare l'eventuale presenza di studi esplicitamente collocati nell'ambito della Marketing Research o della Consumer Research, sono state effettuate ulteriori interrogazioni nello stesso database utilizzando stringhe di ricerca più restrittive, combinando termini relativi alla neurodivergenza con parole chiave collegate agli ambiti di interesse.

Durante lo screening preliminare sono stati esclusi i contributi con un focus esclusivamente clinico, diagnostico o terapeutico. Sono stati inoltre esclusi studi il cui impianto teorico e metodologico risultava prevalentemente orientato a finalità mediche o sanitarie, in quanto non coerenti con l'obiettivo della ricerca. Questo processo ha permesso di isolare un corpus di 756 articoli, focalizzati su prospettive sociologiche, educative e manageriali.

In questa fase, i criteri di inclusione hanno privilegiato studi che, pur partendo da basi sociologiche o organizzative, offrissero spunti per un'analisi della neurodivergenza come soggettività economica potenzialmente rilevante nei processi di creazione di valore e nelle interazioni di mercato. Gli articoli individuati sono stati inizialmente sottoposti a uno screening di titoli e abstract; solo quelli ritenuti potenzialmente pertinenti sono stati successivamente analizzati in full-text per verificarne l'effettiva rilevanza teorica.

L'architettura della ricerca adotta il metodo di Gioia et al. (2013) per l'analisi e la sintesi sistematica delle informazioni, superando la descrizione cronologica degli studi attraverso un processo di codifica qualitativa articolato su tre livelli. L'analisi muove dall'identificazione dei concetti di primo ordine, basati sulla terminologia originale dei contributi, per risalire attraverso un'astrazione teorica ai temi di secondo ordine e, infine, alla definizione delle dimensioni aggregate. Tale approccio favorisce un'integrazione critica basata su temi trasversali (Papaioannou et al., 2016) e permette di mappare pattern ricorrenti e ambiti marginali all'interno del campo d'indagine.

I contributi analizzati sono stati classificati nelle tre fasi evolutive sintetizzate nella Tabella 1 sulla base di criteri definiti a priori. Per ciascun contributo sono state estratte e codificate cinque dimensioni analitiche: il focus disciplinare, la definizione di neurodivergenza adottata, l'obiettivo dichiarato della ricerca, il contesto applicativo primario e gli autori principali di riferimento. L'attribuzione di ciascun contributo a una delle tre fasi è stata effettuata considerando congiuntamente queste dimensioni, con particolare peso assegnato all'orientamento teorico prevalente e al contesto applicativo.



Results. I risultati presentati hanno una natura preliminare ed esplorativa, coerente con gli obiettivi della presente SLR. Il contributo si configura come una ricognizione sistematica di un dominio emergente, con l'obiettivo di valutarne la praticabilità come area di ricerca autonoma nell'ambito della Consumer Research, piuttosto che di fornire conclusioni

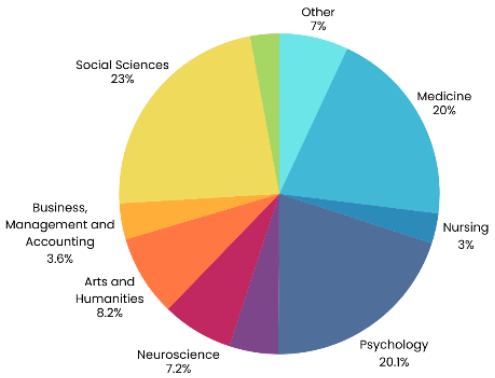
definitive. In questa prospettiva, i pattern identificati segnalano tendenze significative e aprono uno spazio teorico per indagini future, configurando il presente contributo come una feasibility analysis di un dominio di ricerca emergente.

L'analisi evidenzia un'evoluzione temporale nel modo in cui la neurodivergenza è affrontata nei contributi accademici dal 2006 al 2026, distinguibile in tre fasi principali.

Sebbene la produzione scientifica indicizzata parta formalmente dal 2006, essa affonda le proprie radici nei contributi pionieristici degli anni '90, riconducibili a studi seminali come il discorso di Jim Sinclair (1993), "Don't Mourn for Us", e il lavoro della sociologa Judy Singer (1998), "Odd People In", che ha formalizzato il termine "neurodiversity" per descrivere la variazione neurologica umana come categoria sociale. Nel periodo compreso tra la fine degli anni '90 e il 2006, il dibattito sulla neurodivergenza ha attraversato una fase di consolidamento extraaccademico, evolvendo dalle prime comunità di attivisti verso la stampa generalista e preparando il terreno per la successiva legittimazione scientifica. È da questo substrato teorico che il dibattito accademico si è poi strutturato nel ventennio analizzato, riflettendo una progressiva maturazione del tema.

Figura 2. Documents by year (Scopus, 2026)

Nel periodo iniziale, a partire dal 2006, prevale un inquadramento di tipo medico e psichiatrico, in cui la neurodivergenza è principalmente descritta, classificata e interpretata all'interno di un framework clinico, con un'attenzione concentrata sulle differenze neurologiche e sulle dimensioni diagnostiche (Faraone et al., 2006; Ronald et al., 2006; Gillberg, 2010). In questa fase, la ricerca accademica si focalizza sull'identificazione di biomarcatori, sull'ereditarietà genetica e sulla definizione di deficit cognitivi specifici (Happé & Ronald, 2008; Thapar et al., 2007).



A partire dal 2010, si osserva una progressiva integrazione delle dimensioni sociali e collettive. In questa seconda fase, un numero crescente di studi si concentra sulla formazione di community neurodivergenti, analizzate come spazi di conversazione, condivisione di esperienze e costruzione di consapevolezza. Questo orientamento è stato alimentato dal consolidamento del movimento neurodivergente, che ha rafforzato il modello sociale della disabilità applicandolo specificamente alla neurodivergenza (Kapp et al., 2013). Tale dinamica si è concretizzata nella nascita delle prime community online autogestite, come la lista Independent Living on the Autistic Spectrum (InLv), la cui evoluzione è analizzata da Dekker (2019), che ha rappresentato uno spazio di confronto per lo sviluppo di concetti legati all'identità e all'auto-advocacy. In questo contesto si afferma una prospettiva che promuove la rimozione delle barriere sociali attraverso l'adozione di un linguaggio positivo e il superamento delle categorizzazioni basate esclusivamente sul deficit (Woods, 2017). Tali contributi enfatizzano il ruolo delle pratiche di advocacy e delle relazioni sociali, aprendo una riflessione sull'impatto di tali dinamiche nei contesti organizzativi (Silverman, 2015). Ciò segna un parziale allontanamento dalle interpretazioni esclusivamente cliniche, pur senza abbandonarle del tutto, ponendo le basi per il passaggio dall'"integrazione" del singolo alla valorizzazione della diversità neurologica (Doyle, 2020). Questa integrazione concettuale prepara il terreno per la successiva fase di managerializzazione del tema, in cui la neurodivergenza viene inquadrata come una risorsa strategica per il capitale umano.

L'eredità del cambiamento di prospettiva consolidato da Silverman (2015) apre la strada, a partire dal 2017, ad una terza fase in cui la neurodivergenza viene sempre più frequentemente associata a contesti organizzativi e formativi (Gurbuz et al., 2019). In particolare, la letteratura progressivamente considera la neurodivergenza in relazione ad employability, inclusione lavorativa, capitale umano e ambienti di apprendimento, spostando il focus dalla pedagogia speciale al supporto alla carriera accademica (Gurbuz et al., 2019). Questo filone conosce un'ulteriore intensificazione nel periodo compreso tra il 2020 e il 2026, durante il quale si registra un aumento significativo dei contributi che interpretano la neurodivergenza come possibile vantaggio competitivo (Austin & Pisano, 2017), consolidando il cosiddetto "Business Case" per la neurodiversità (Kirby & Smith, 2021). Tale prospettiva dimostra come l'inclusione di stili cognitivi differenti non risponda solo a istanze etiche, ma generi valore economico attraverso l'innovazione di processo, la riduzione dei bias decisionali e il miglioramento del benessere organizzativo complessivo (Doyle, 2020). Tuttavia, la letteratura evidenzia come la piena espressione del capitale umano neurodivergente sia ostacolata dalla "minaccia dello stereotipo", che incide sulla scelta individuale di manifestare apertamente la propria condizione –

disclosure (Lindsay et al., 2021) - o, al contrario, di celarla attraverso strategie di adattamento – masking (Hull et al., 2017) - nei contesti professionali (Priscott & Allen, 2021). Questo costante sforzo di mimetizzazione sociale, pur favorendo un'apparente integrazione, genera un elevato carico cognitivo (Cage & Troxell-Whitman, 2019) e aumenta il rischio di burnout, limitando di fatto l'efficacia delle politiche di inclusione aziendale (Hurley-Hanson et al., 2020).

Questa progressiva associazione tra neurodivergenza e contesti organizzativi non implica un ampliamento della prospettiva disciplinare in senso economico o di mercato. L'analisi della distribuzione per subject area (fig.3) evidenzia infatti una marcata concentrazione nelle Social Sciences (23%), nella Medicine (20%) e nella Psychology (20,1%), mentre l'area Business & Management rappresenta una quota relativamente contenuta (3,6%).

Figura 3. Documents by Subject Area (Scopus, 2026)

È importante sottolineare che, anche all'interno dell'area Business & Management, la letteratura non si apre a una prospettiva di Consumer Research: pur richiamando la nozione di "valore", essa la circoscrive prevalentemente all'inserimento lavorativo, interpretandola come una risorsa strategica capace di generare innovazione e vantaggio competitivo (Austin & Pisano, 2017; Doyle, 2020). Sebbene la neurodivergenza sia ormai un fenomeno sociale consolidato, la sua integrazione nelle Marketing Theories rimane ancora limitata, riflettendo un ritardo rispetto all'ambito delle risorse umane, dove la letteratura sul tema risulta più consolidata (Khan et. al., 2023). In questo contesto, la letteratura di marketing ha finora adottato un modello di "consumatore standard", trascurando le specifiche esigenze sensoriali e decisionali di circa un quinto della popolazione globale (Doyle, N., 2020). In questa direzione, emerge la necessità di riconoscere la neurodivergenza come una legittima variazione del comportamento di consumo che richiede nuove strategie di mercato.

La Tabella 1 sintetizza l'evoluzione concettuale della letteratura e le principali configurazioni tematiche emerse dall'analisi. Come evidenziato dalla sintesi dei temi, la ricerca risulta prevalentemente concentrata nei contesti lavorativi e istituzionali, mentre non emergono contributi specificamente orientati a indagare la soggettività economica dell'individuo neurodivergente nei mercati e nei processi di consumo.

Tabella 1. Data Structure dell'evoluzione della letteratura sulla neurodivergenza

Dimensioni analitiche	**FASE 1 (2006 – 2010)**: Clinico-Diagnostica	**FASE 2 (2010 – 2017):** Sociale e Advocacy	**FASE 3 (2017 – 2026)**: Managerial, Educational e del Capitale Umano
Focus disciplinare	*Psichiatria, Genetica, Neuroscienze cliniche.*	*Sociologia, Disability Studies, Attivismo online.*	*Business & Management, Higher Education, HRM, Digital Transformation.*
Definizione della neurodivergenza	*Patologia/Deficit: Condizione medica da diagnosticare, classificare e trattare.*	*Identità/Differenza: Categoria politica e sociale; variazione naturale del genoma umano.*	*Risorsa Strategica/Talento: Vantaggio competitivo e leva di innovazione organizzativa e accademica.*
Obiettivo della ricerca	*Eziologia, identificazione di biomarcatori e standardizzazione diagnostica.*	*Empowerment, rimozione delle barriere sociali, auto-advocacy e costruzione di community.*	*Employability, inclusione lavorativa, supporto alla carriera accademica e neuro-inclusion.*

Contesti prevalenti di analisi	*Cliniche, centri di ricerca medica, contesti di riabilitazione.*	*Community online (InLv), movimenti sociali, stampa generalista di alto profilo.*	*Organizzazioni (Aziende tech/corporate), Università (Atenei), Processi di HRM e Digital Learning.*
Autori principali di riferimento	*Ronald et al. (2006); Faraone et al. (2006); Gillberg (2010); Happé & Ronald (2008); Pennington (2006); Thapar et al. (2007); Ronald et al. (2006); Belmonte et al. (2004); Constantino & Todd (2003).*	*Sinclair (1993); Singer (1998); Dekker (2019); Kapp et al. (2013); Silberman (2015); Woods (2017); Hull et al. (2017); Blume (1998); Molloy & Vasil (2002); Ortega (2009).*	*Silverman (2015); Austin & Pisano (2017); Gurbuz et al. (2019); Doyle (2020); Priscott & Allen (2021); Lindsay et al. (2021); Walkowiak (2024); Kirby & Smith (2021); Hurley-Hanson et al. (2020); Higgins (2020); Acquah et al. (2025).*

La gap analysis conferma questa polarizzazione, classificando i contributi non clinici in due macro-ambiti:

1. Education/Social, focalizzato su advocacy e processi socioculturali (es. Sarret, 2018; Clouder et al., 2020; Botha et al., 2025)
2. Workplace/HR, orientato a performance e human capital (es. Austin & Pisano, 2017; Kirby & Smith, 2021; Walkowiak, 2024).

L'analisi rileva l'assenza di un ambito strutturato riconducibile al marketing, evidenziando come la neurodivergenza non emerga ancora come categoria teorica nelle pratiche di mercato. Questa lacuna non indica necessariamente l'assenza di studi sulla disabilità o sull'inclusione nei mercati, ma la mancata tematizzazione della neurodivergenza come costrutto concettuale autonomo nel campo del consumo. La gap analysis evidenzia quindi non solo uno squilibrio quantitativo tra ambiti tematici, ma anche una discontinuità di natura epistemologica. Mentre la neurodivergenza è progressivamente incorporata nel management come variabile di capitale umano e inclusione organizzativa (Kirby & Smith, 2021; Acquah et al., 2025), rimane marginale come categoria interpretativa delle soggettività di mercato, riflettendo un frame disciplinare che privilegia la dimensione produttiva rispetto a quella economico-simbolica.

Tale dinamica di invisibilità dei soggetti nei mercati (Callon, 1998) è coerente con il cosiddetto Double Empathy Problem (Milton, 2012; Ekdahl, 2024), secondo cui le difficoltà comunicative non derivano da un deficit individuale, ma da una mancata reciprocità intersoggettiva tra individui con stili cognitivi differenti. Da questa prospettiva, l'assenza della neurodivergenza nella Consumer Research deriva da modelli di marketing cognitivamente omogenei, che assumono un consumatore allineato ai codici simbolici del mercato.

Alcuni studi recenti iniziano tuttavia a indicare nuove direzioni di ricerca. Lee et al. (2024) mostrano come lo storytelling credibile possa favorire una rappresentazione più autentica della disabilità nel branding del lusso, mitigando il rischio di reazioni negative legate ai canoni di perfezionismo del settore. Parallelamente, l'utilizzo dei big data (come l'analisi dei flussi di Twitter) ha consentito una prima segmentazione "bottom-up" degli utenti neurodivergenti, identificando cluster di consumatori basati su specifiche preoccupazioni e dinamiche di benessere, piuttosto che su etichette cliniche (Go Jefferies & Ahmed, 2022). A queste prospettive si affianca il filone emergente della service innovation, in cui l'impiego di tecnologie immersive come il Metaverso viene analizzato come uno strumento per migliorare l'accessibilità dei servizi attraverso il concetto di "customer augmentation" (Alimamy & Saifeddin, 2024). Tale approccio supera la visione della neurodivergenza come limitazione, posizionando il service design come strategia per valorizzare le risorse operanti dei clienti e favorire la co-creazione di valore durante le interazioni di servizio. In questo quadro, la diversità neurologica può essere interpretata come una risorsa sociale e di innovazione, capace di aprire nuove prospettive nei mercati. Tuttavia, in letteratura la neurodivergenza non emerge ancora come categoria interpretativa negli studi dedicati ai settori simbolicamente più densi, come quello del lusso, considerato un caso emblematico delle dinamiche simboliche del consumo.

Research limitations. Lo studio presenta alcune limitazioni da considerate nell'interpretazione dei risultati.

In primo luogo, la revisione si basa su articoli peer-reviewed pubblicati in lingua inglese e indicizzati nel database Scopus. Sebbene questa scelta sia giustificata dalla natura esplorativa del contributo e dall'ampia copertura accademica garantita da tale database (Franceschet, 2010), essa può aver comportato l'esclusione di contributi rilevanti presenti nella letteratura grigia, in pubblicazioni professionali, in altri contesti linguistici o in altri archivi come Web of Science. Future ricerche potranno estendere la copertura includendo database multipli e fonti non indicizzate, al fine di aumentare la completezza della revisione. Considerata inoltre la natura interdisciplinare e in parte community-driven del dibattito sulla neurodiversità, è possibile che alcune prospettive emergenti non siano pienamente rappresentate nel corpus analizzato.

In secondo luogo, la SLR ha una finalità prevalentemente mappante ed esplorativa. L'approccio consente di ricostruire l'evoluzione temporale e tematica del campo e di identificare polarizzazioni disciplinari, ma non permette di valutare in modo approfondito la qualità metodologica dei singoli studi né di trarre conclusioni causali sulle relazioni tra neurodivergenza, mercati e consumo.

Infine, l'analisi si concentra sulle modalità attraverso cui la neurodivergenza è stata concettualizzata nella letteratura accademica non clinica, senza includere dati empirici primari né il punto di vista diretto delle persone neurodivergenti. Questa scelta, coerente con l'obiettivo di chiarificazione concettuale, limita la possibilità di esplorare empiricamente le

esperienze di consumo e le forme di agency nella Consumer Research.

In prospettiva, è opportuno riconoscere alcune barriere metodologiche rilevanti che la ricerca empirica sul consumatore neurodivergente dovrà affrontare. Una prima sfida concerne l'accesso ai dati, poiché il reclutamento di campioni neurodivergenti sufficientemente ampi presenta sfide etiche, logistiche e di privacy che, pur non essendo insormontabili, richiedono un'attenta progettazione metodologica e protocolli di consenso informato adeguati alle specificità della popolazione studiata. A ciò si aggiunge la complessità interpretativa legata all'eterogeneità intra-individuale: il comportamento di consumo neurodivergente non è solo variabile tra individui, ma anche all'interno dello stesso individuo nel tempo, in funzione del contesto sensoriale, del carico cognitivo e delle strategie di adattamento adottate (Hull et al., 2017; Cage & Troxell-Whitman, 2019). Queste sfide segnalano la necessità di sviluppare disegni di ricerca ad hoc (metodologie partecipative, longitudinali e multi-method) capaci di restituire la complessità del consumatore neurodivergente senza ridurla a categorie diagnostiche standardizzate.

Managerial implications. La SLR evidenzia come la gestione della neurodivergenza sia stata finora confinata quasi esclusivamente all'ambito organizzativo e alla gestione delle performance interne (Austin & Pisano, 2017; Walkowiak, 2024), trascurando il potenziale della neurodiversità come dimensione identitaria attiva nei processi di consumo. Da una prospettiva di marketing, tale lacuna riflette una forma di miopia strategica che spinge le imprese ad adottare modelli di consumatore "standard", alimentando il "mito del cervello normale" (Armstrong, 2015). Operativamente, questo si traduce in strategie di segmentazione e posizionamento uniformi, che presuppongono erroneamente una ricezione dei messaggi di marca basata su schemi cognitivi omogenei.

Il superamento di questa logica di standardizzazione richiede l'integrazione della variabilità neurocognitiva nei processi di progettazione della Customer Experience e nella gestione dei touchpoint lungo il customer journey. Da una prospettiva market-based, ciò implica ripensare la progettazione delle esperienze di marca in funzione della diversità percettiva e cognitiva dei consumatori, introducendo indicatori in grado di monitorare come i diversi stimoli di mercato vengano recepiti nei vari momenti di interazione. Tali indicatori possono includere metriche relative alla chiarezza dei messaggi di marca, alla fruibilità sensoriale degli ambienti di consumo e alla prevedibilità delle interazioni nei diversi touchpoint.

Riconoscere la neurodivergenza come una componente dell'eterogeneità di mercato permette inoltre di rivedere criticamente i presupposti che orientano segmentazione, il design dell'offerta e la comunicazione di marca. In termini manageriali, questo significa integrare la variabilità percettiva e cognitiva nei processi di progettazione dei prodotti, dei servizi e delle esperienze di consumo. Non si tratta di una semplice istanza etica, ma di una leva di innovazione radicale (Hamel, 2001), capace di trasformare la diversità neurologica da variabile da "gestire" a driver di valore distintivo.

Le raccomandazioni operative che emergono da questo lavoro invitano il management a riconsiderare le fondamenta delle strategie di mercato, superando la logica della semplice aggiunta di nuove categorie ai modelli esistenti. Seguendo la prospettiva dell'innovazione radicale (Hamel, 2001), le imprese sono chiamate a ripensare l'idea di normalità cognitiva su cui i mercati sono stati storicamente progettati. In questo modo, la neurodivergenza può diventare una lente strategica per ridefinire l'esperienza di marca e il design dell'offerta, contribuendo allo sviluppo di forme di valore più sensibili alla diversità delle esperienze di consumo. Un esempio applicativo di queste dinamiche può essere osservato nei mercati ad alta intensità simbolica e relazionale, come il settore del lusso. In tali contesti, la neurodivergenza consente di riconsiderare i driver del valore percepito. Mentre il marketing del lusso tradizionale si è storicamente focalizzato sul prestigio sociale e sull'esibizione di status (Veblen, 1899; Wiedmann, 2009), l'analisi della neurodiversità suggerisce uno spostamento verso il valore edonico e sensoriale intrinseco dell'esperienza di consumo.

Queste considerazioni confermano la rilevanza strategica di un approccio market-based alla neurodivergenza, i cui benefici si estendono a molteplici categorie di attori.

Coerentemente con la natura esplorativa e di ricognizione preliminare del presente lavoro, i risultati si rivolgono a tre categorie principali di beneficiari, ciascuna delle quali può utilizzare le evidenze in modo differenziato e complementare rispetto alle proprie finalità. Gli accademici di Consumer Research e Marketing possono utilizzare le lacune identificate come punto di partenza per sviluppare nuovi framework teorici ed empirici che integrino la neurodivergenza come categoria interpretativa del comportamento di consumo. I manager e i professionisti del marketing possono trarre indicazioni operative per ripensare i processi di segmentazione, design dell'offerta e comunicazione di marca in chiave neuro-cognitivamente inclusiva, riducendo il rischio di escludere sistematicamente circa un quinto della popolazione globale (Doyle, 2020). Infine, i policy maker e le organizzazioni che si occupano di inclusione possono trovare in questo lavoro una base concettuale per estendere il dibattito sulla neurodiversità oltre i confini istituzionali del lavoro e dell'istruzione, verso una prospettiva più ampia che riconosca il consumatore neurodivergente come soggetto attivo nei mercati.

Originality of the paper. L'originalità della ricerca risiede nell'integrazione sistematica di due domini finora disallineati: la letteratura sulla Neurodivergenza e la Consumer Research. A differenza dei contributi esistenti, prevalentemente concentrati su contesti clinici, educativi o organizzativi, il paper propone una prospettiva esplicitamente market-based, trattando la neurodivergenza come possibile dimensione identitaria e simbolica rilevante nei processi di consumo. Il contributo consiste nell'individuazione di una lacuna nella letteratura, mostrando come l'invisibilità del consumatore neurodivergente non sia una semplice svista quantitativa, ma il risultato di frame disciplinari che hanno storicamente

ignorato la variabilità neurocognitiva. Coerentemente con la prospettiva della Service-Dominant Logic (Vargo & Lusch, 2008), questo contributo apre la strada a studi futuri che riconoscono l'individuo come attore capace di partecipare attivamente ai processi di co-creazione di valore, integrando le proprie risorse cognitive nelle interazioni di mercato.

Sul piano del posizionamento teorico, il presente contributo intrattiene un rapporto di prossimità con due tradizioni di ricerca, senza tuttavia coincidere con esse.

La prima è la letteratura sui Vulnerable Consumers, che ha storicamente incluso individui con disabilità cognitive o sensoriali in categorie di consumatori meritevoli di protezione e supporto (Baker, 2006; Higgins, 2020). Il presente lavoro condivide l'interesse per soggetti sistematicamente esclusi dai modelli dominanti di Consumer Research, ma se ne distanzia nel frame interpretativo: anziché inquadrare la neurodivergenza come condizione di fragilità da tutelare (Baker, 2006), la tratta come una dimensione identitaria dotata di agency nei processi di consumo. L'obiettivo non è estendere pratiche di marketing assistenziali a una categoria vulnerabile, ma riconsiderare i presupposti cognitivi impliciti su cui i mercati sono stati progettati.

La seconda è la letteratura sulla Consumer Neuroscience: la presente ricerca non si colloca all'interno di tale tradizione né ne rappresenta un sottocampo. La Consumer Neuroscience studia i meccanismi neurali sottostanti ai processi decisionali d'acquisto (Kenning & Plassmann, 2005; Ariely & Berns, 2010), con l'obiettivo di identificare pattern del comportamento del consumatore attraverso metodologie quantitative e strumenti di misurazione neurofisiologica. Il presente contributo si distanzia da questo approccio adottando una prospettiva critica sulla variabilità neurologica tra i soggetti, riconoscendola come dimensione identitaria e dotata di agency rilevante nei processi di mercato. Il rapporto tra i due ambiti è quindi da intendere come un'intersezione parziale: condividono l'oggetto di interesse - il consumatore e le sue basi neurologiche - ma divergono nell'impostazione teorica e negli obiettivi. Il presente contributo si inscrive nella tradizione critica della Consumer Research (Firat & Venkatesh, 1995; O'Dell et al., 2016), riconoscendo la neurodivergenza come prospettiva attraverso cui riconsiderare i presupposti cognitivi impliciti che orientano la disciplina. L'approfondimento dei meccanismi cognitivi sottostanti al comportamento di consumo rappresenta uno sviluppo futuro auspicabile che richiede strumenti metodologici specifici, non affrontati in questa sede.

Su queste basi, le direzioni di ricerca future identificate dalla presente SLR si articolano in una sequenza logica che riflette la progressiva maturazione del campo. Il lavoro contribuisce al dibattito accademico proponendo un'agenda di ricerca articolata in tre direzioni principali:

1. l'esplorazione dei customer journey non lineari derivanti da diverse modalità di elaborazione sensoriale;
2. l'analisi delle subculture di consumo neurodivergenti e delle loro pratiche di resistenza o adattamento ai mercati "neurotipici";
3. lo sviluppo di metodologie di ricerca partecipative (co-design) che includano attivamente i consumatori neurodivergenti nella validazione degli stimoli di marketing.

Sul piano organizzativo, lo sviluppo di questo campo richiede un approccio interdisciplinare che sappia connettere Consumer Research, Disability Studies e scienze sociali, riconoscendo nel metodo partecipativo non solo una scelta metodologica, ma una condizione per garantire che la ricerca sul consumatore neurodivergente non riproduca i bias dei modelli che intende superare.

Senza limitarsi a una critica dei modelli esistenti, il lavoro apre uno spazio teorico per ripensare le fondamenta cognitive implicite su cui si costruiscono le strategie di mercato contemporanee, configurandosi come un intervento critico volto a ridefinire il perimetro analitico entro cui la neurodivergenza può essere concettualizzata nei mercati, fornendo le basi concettuali per una teoria del marketing che sia realmente rappresentativa della complessità umana.

Perceived Brand Honesty: An Exploratory Study on Consumer Perceptions of Honest (vs. Dishonest) Brands

CHIARA MAURI[1], GRETA SIRACUSA[2], AULONA ULQINAKU[3]

Abstract. *Brand honesty is increasingly mentioned as a desirable brand quality, yet it remains under-specified and is often addressed only indirectly through related constructs such as trust, transparency, sincerity, and equity/fairness. This study explores how consumers form honesty and dishonesty judgments about brands by combining a qualitative grounding phase with an exploratory survey. We first ran ZMET interviews to surface consumers' metaphor-based meanings of honesty, then used these insights to build a survey where participants named an honest or dishonest brand and rated it "as if it were a person" on a 7-point scale. The instrument included personality-like items grouped into four batteries: honesty-related traits, sincerity, equity/fair dealing, and ZMET-derived meanings. Using paired comparisons of the four batteries within each condition, we find an asymmetric pattern in consumers' inference routes. Perceptions of an honest brand are most strongly associated with equity/fair dealing cues, whereas perceptions of a dishonest brand are most strongly associated with lack of sincerity. The findings suggest that brand honesty is not simply the opposite of brand dishonesty and highlight the need for a multidimensional view of perceived brand honesty that integrates fair dealing and sincerity-based cues. Implications are discussed for both future measurement development and managerial strategies aimed at credibly signaling honesty.*
Keywords: *perceived brand honesty; honesty; fairness; ZMET*

Framing of the research. Consumers increasingly evaluate brands not only on functional performance but also on perceived character, whether a brand "plays fair", communicates truthfully, and deserves confidence. Conceptually, these judgments map onto a broader honesty domain that extends beyond simple truth-telling to include sincerity, fairness/justice, and restraint from opportunism (Ashton et al., 2000; Ashton and Lee, 2007; Ashton and Lee, 2008). Despite its relevance, however, brand honesty remains comparatively underdeveloped and rarely measured as a distinct consumer perception in marketing research, where adjacent work more commonly examines trust, transparency, fairness, or brand equity as separate constructs rather than as components of an honesty judgement (Mayer et al., 1995; Morgan and Hunt, 1994; Schnackenberg and Tomlinson, 2016).

Two theoretical foundations motivate a focused treatment of Perceived Brand Honesty (PBH). First, psycholexical research provides a robust anchor. Across languages, researchers repeatedly recover a sixth personality factor labeled with honesty-relevant terms (e.g., integrity, trustworthiness, truthfulness) and defined by adjectives such as truthful, honest, fair/just, and sincere versus sly, greedy, and hypocritical (Ashton et al., 2000; Ashton and Lee, 2007). Importantly, the semantic core of this domain is interpreted as reluctance versus willingness to exploit others, particularly when exploitation is profitable and low-risk (Ashton et al., 2000). This conceptualization implies that honesty is inherently tied to non-opportunism and fair dealing, making it especially relevant to marketplace contexts characterized by information asymmetries and persuasive communication.

Second, trust and transparency research clarifies why honesty-related perceptions matter in exchange relationships. Trustworthiness judgments hinge on perceived integrity (i.e., adherence to principles the evaluator finds acceptable) and on cues such as justice and congruence between words and actions (Mayer et al., 1995; Simons, 2002). In parallel, transparency theory conceptualizes transparency as information quality, a three-dimensional construct composed by disclosure, clarity, and accuracy, and shows that transparency predicts perceived trustworthiness, including integrity (Schnackenberg and Tomlinson, 2016; Schnackenberg et al., 2021). Together, these perspectives suggest that PBH can be theorized as an integrative perception grounded in (i) non-exploitation and fairness (Honesty-Humility), (ii) sincere word–deed alignment (integrity/behavioral integrity cues), and (iii) clear, accurate, and sufficiently disclosed communication (transparency as information quality).

At the same time, honesty is abstract and morally loaded, which makes it likely that consumers represent it through metaphors and images rather than only through explicit verbal definitions. For this reason, we use the Zaltman Metaphor Elicitation Technique (ZMET) as a qualitative foundation to surface consumer-native meaning structures of honesty through participant selected images and metaphor-based probing (Zaltman, 1997; Coulter et al., 2001). Building on this foundation, the present paper structures PBH around four conceptual pillars that are both theory-consistent and meaning-grounded: (1) honesty-humility, (2) sincerity, (3) equity/fair dealing, and (4) ZMET-derived meanings.

To explore how consumers apply honesty meanings to real brand targets, we conducted a two-condition survey. Participants were assigned to one condition, either honest or dishonest, and were asked to first identify a brand they personally consider honest (or dishonest), and then to evaluate the chosen brand "as if it were a person" on a 7-point

[3] aulqinaku@liuc.it

Likert scale using personality-like items. This anthropomorphic framing is consistent with the brand personality tradition, which shows that consumers naturally ascribe human-like traits to brands and use those traits to structure evaluations (Aaker, 1997). Items were organized into four batteries aligned with the four conceptual dimensions identified through literature and the ZMET approach.

Because the aim of this study is exploratory, seeking to clarify what consumers draw on when they judge brand honesty, rather than to validate a finalized PBH scale, we focus on the relative salience of the underlying honesty-related dimension. Specifically, we address the following research questions:

1. When consumers evaluate a brand they perceive as honest, which underlying honesty-related dimension is most salient in shaping that judgment? In other words, what characteristics must a brand exhibit to be perceived as honest?

2. When consumers evaluate a brand they perceive as dishonest, which underlying dishonesty-related dimension is most salient in shaping that judgment? In other words, what characteristics lead consumers to perceive a brand as dishonest?

From a managerial perspective, clarifying what consumers mean by "honest brand" is strategically relevant because honesty claims are increasingly used in positioning (e.g., transparent, authentic, fair), yet firms often lack guidance on which cues actually drive honesty inferences. If perceived honesty is constructed from multiple components, such as fair dealing, sincerity, word–deed alignment, and information quality, then investments in communication alone may be insufficient when behavioral cues contradict the message. By identifying the dimensions consumers rely on when they label brands as honest versus dishonest, this research helps managers prioritize actions and touchpoints that most credibly signal honesty (e.g., pricing and terms, complaint handling, claims substantiation, consistency across channels), and it offers an evidence-based basis for auditing honesty-related risks before they escalate into trust erosion.

Purpose of the paper. Honesty-humility. A recurring challenge in studying brand honesty is conceptual clarity: "honesty" is often treated as self-evident, yet consumer judgments draw on layered and sometimes competing meanings. Psycholexical research provides unusually strong guidance here, because it derives construct structure directly from everyday language (Ashton and Lee, 2007). Across languages, a sixth major dimension of personality – beyond the Big Five (i.e., surgency, agreeableness, conscientiousness, emotional stability, and intellect/imagination) – consistently emerges and is labeled honesty (Ashton et al., 2000). Its semantic content has been characterized across lexical studies through terms such as integrity, trustworthiness, and truthfulness at the positive pole, and slyness, greed, and hypocrisy at the negative pole (Ashton et al., 2000; Ashton and Lee, 2007). Importantly, Ashton et al. (2000) interpret the semantic core of this factor not as accurate communication per se, but as the disposition to refrain from exploiting others, particularly when exploitation would be profitable and carry little risk. This reframing shifts honesty from a purely epistemic property to a moral commitment to non-opportunism. Subsequent research has formalized this structure within the HEXACO model, a six-dimensional personality framework whose factors are Honesty–Humility (H), Emotionality (E), Extraversion (X), Agreeableness (A), Conscientiousness (C), and Openness to Experience (O) (Ashton and Lee, 2007). The Honesty–Humility dimension specifically captures sincerity and fairness as defining features and is directly implicated in tendencies toward unethical, exploitative, and self-serving behavior (Ashton and Lee, 2007; Ashton and Lee, 2008). This body of work carries a clear implication for the study of perceived brand honesty: consumer honesty judgments are unlikely to rest on informational accuracy alone. When consumers invoke "honesty" as an evaluative lens for brands, they are likely drawing on cues that signal restraint from opportunism and a disposition toward fair dealing, not merely on whether the brand communicates truthfully. Accordingly, perceived brand honesty should be theorized and measured in ways that capture this broader moral dimension, rather than reducing it to communicative transparency.

Sincerity. While Honesty-Humility captures the broader moral core of honesty, consumer judgments often turn on a more proximal diagnostic cue: sincerity, or whether the brand is perceived to mean what it says and to act consistently with what it claims. Behavioral integrity theory provides a clear theoretical mechanism, defining integrity judgments as perceived alignment between an actor's words and deeds, with particular emphasis on promise keeping and consistency between espoused and enacted values (Simons, 2002). Trust theory reinforces this logic: in the Ability-Benevolence-Integrity (ABI) model, integrity is the perception that a party adheres to principles the evaluator finds acceptable, and integrity judgments are shaped by cues such as justice and congruence between words and actions (Mayer et al., 1995).

Together, these perspectives establish sincerity as a distinct pillar within PBH: sincerity translates brand communications into credibility and attenuates perceived opportunism by signaling that the brand is unlikely to misrepresent its motives or conceal inconsistencies between its claims and conduct.

Equity and Fair Dealing. In the present study, the equity/fair dealing dimension is conceptualized not as a comprehensive measure of customer-based brand equity, but as a set of honesty-relevant brand associations (e.g., perceptions of fairness, non-deception, and worthwhile exchange) that plausibly contribute to brand equity rather than constituting it in full. Customer-based brand equity is commonly defined as the differential effect of brand knowledge on consumer response to marketing activity, with favorable, strong, and unique brand associations playing a central role (Keller, 1993). Aaker (1991) similarly defines brand equity as a set of brand-linked assets and liabilities that add to or subtract from value for both the firm and its customers, and later proposes the "Brand Equity Ten" as a multi-dimensional measurement framework (Aaker, 1996). Within this tradition, perceptions of fairness, non-deception, and mutually valuable interaction can be understood as honesty-relevant associations that reinforce brand meaning and shape downstream consumer responses, making them legitimate components of an honesty-centered framework even if they do not exhaust the brand equity domain.

Transparency fits naturally within this dimension as well. Transparency theory conceptualizes transparency as information quality, encompassing disclosure, clarity, and accuracy, and demonstrates that these perceptions predict perceived trustworthiness, including integrity (Schnackenberg and Tomlinson, 2016; Schnackenberg et al., 2021). When a brand is seen as transparent, communicating clearly and accurately rather than selectively, consumers may infer reduced opportunism and greater fairness, thereby reinforcing overall honesty judgments. In this sense, equity/fair dealing associations offer a marketplace translation of Honesty-Humility's non-exploitation core: a brand appears honest because it is perceived to create value without exploiting, deceiving, or withholding material information.

It is therefore theoretically coherent that consumers may arrive at an "honest brand" judgment primarily through cues of equitable exchange and non-deceptive conduct - cues that are also central to perceived value and long-term brand strength. By drawing on this body of work, we incorporate equity/fair dealing into our framework in order to capture the perceived moral and communicative reliability that underlies consumer honesty attributions.

Methodology. We adopted an exploratory sequential design in which qualitative insight grounds construct meaning and supports subsequent quantitative operationalization. Specifically, we first employed the Zaltman Metaphor Elicitation Technique (ZMET) to elicit consumers' deep meaning structures of honesty, leveraging participant-selected images and metaphor-based probing to surface constructs that may remain implicit in purely verbal approaches (Zaltman, 1997). We then translated this conceptual domain into a brand-as-person survey instrument, consistent with the view that consumers readily ascribe human-like traits to brands and use those inferences to structure their evaluations (Aaker, 1997). The survey operationalizes PBH through four complementary measurement dimensions: (1) Honesty-Humility-based scale, (2) sincerity as word–deed alignment, (3) equity and fair dealing associations, and (4) ZMET-derived meanings.

Study 1: ZMET interviews (construct elicitation). ZMET is designed to elicit metaphors and deep meaning structures through visual stimuli and guided probing, enabling researchers to move from concrete image descriptions to abstract constructs and to map the relational links among them (Zaltman, 1997; Coulter, Zaltman, and Coulter, 2001). In the present study, 22 in-depth interviews were conducted to explore what "honesty" means to individuals and which cues people rely on to recognize honesty versus dishonesty in practice. Participants were asked to express the concept through self-selected images and to explain why those images represented honesty to them. This procedure allowed the research team to identify recurring constructs, including fairness, non-exploitation, authenticity, transparency, and manipulation avoidance, as well as the perceived relationships among them.

The output of the ZMET phase served two purposes. First, it supported domain specification for perceived brand honesty by clarifying which facets of honesty are salient in consumer meaning (Zaltman, 1997). Second, it informed the development of a ZMET-derived item battery that captures consumer-native honesty meanings in survey form, complementing the theory-driven batteries derived from established literature on honesty-humility, sincerity, and equity/fair dealing. Details on the qualitative coding procedure and theme synthesis are reported in the item development subsection below.

The survey was developed following established principles for construct operationalization in marketing research, combining theory-driven content with qualitatively grounded items to strengthen content validity (Churchill, 1979). Because the goal of this study is exploratory and brand honesty remains underdeveloped in prior measurement work, items were not drawn verbatim from any single published scale. Instead, each battery reflects the theoretical meaning associated with its respective literature, with wording adapted to a brand referent through a brand-as-person framing. Participants were explicitly instructed to think about the brand they had selected "as if it were a person" and to evaluate the extent to which each trait described that person, consistent with brand personality logic and the anthropomorphic brand inference tradition (Aaker, 1997).

The instrument comprises four measurement batteries.

- The first, Honesty–Humility (four items), captures honesty as truthfulness and authenticity, as well as deserved trust, consistent with the honesty domain's emphasis on sincerity and fairness over opportunism and deception. Representative items include descriptors such as "direct and transparent", "authentic", and "deserves trust".
- The second battery, Sincerity (four items), captures promise-keeping and authentic communication as word–deed alignment cues, consistent with integrity-based inference (Simons, 2002) and with integrity as a component of trustworthiness (Mayer et al., 1995).
- The third battery, Equity and Fair Dealing (five items), captures perceptions of interaction value and fair conduct, including whether the brand is seen as fair, whether interaction with it is worthwhile, and whether it refrains from winning consumers over through deceptive means. Conceptually, these items represent honesty-relevant brand associations that plausibly contribute to customer-based brand equity (Aaker, 1991; Aaker, 1996; Keller, 1993) while remaining directly aligned with the non-exploitation and fairness core of the honesty domain.
- The fourth battery, ZMET-derived meanings (ten items), was developed from the qualitative elicitation results to capture consumer-native meanings such as non-exploitation of trust, justice and fairness, manipulation avoidance, and balanced exchange, consistent with ZMET's purpose of surfacing deep meaning structures (Zaltman, 1997; Coulter et al., 2001).

Study 2: Survey procedure and design. The quantitative phase employed a between-subjects framing design in which participants were randomly assigned to evaluate either an honest or a dishonest food brand. The survey was administered online via Qualtrics. A total of 301 participants were recruited through Prolific and were welcomed, informed that their

data would be treated anonymously and used solely for academic research purposes, and asked to provide informed consent before proceeding.

Participants first completed a brand elicitation task. In the honest condition, they were asked to think of a brand they personally considered honest and to enter the brand name. In the dishonest condition, the prompt followed the same procedure for a brand they considered dishonest. Participants were then instructed to imagine the brand they had named as if it were a person, with an illustrative example provided to clarify the type of human characteristics that might be attributed to a brand. They were asked to indicate their agreement with a series of statements describing that person on a 7-point Likert scale.

The 23 personality-like items were presented in blocks corresponding to the four batteries described in the previous section. In the honest condition, items were positively valenced, with descriptors such as "direct and transparent" and "deserves trust". In the dishonest condition, items used parallel negatively valenced wording, such as "not transparent", "does not deserve trust", and "uses manipulative communication strategies".

For each respondent, four composite scores were computed corresponding to the four batteries: Honesty–Humility, Sincerity, Equity/fair dealing, and ZMET-derived meanings. Paired-samples t-tests were then conducted within each framing condition to compare the relative endorsement of these four dimensions and to identify which pillar was most salient in shaping participants' honesty and dishonesty judgments respectively.

Results. Honest-brand condition. Table 1 reports the paired-samples comparisons among the four composites in the honest-brand condition. Equity/fair dealing received significantly higher endorsement than Honesty–Humility (Mean Diff = 0.145, t(149) = 3.075, p = .003), Sincerity (Mean Diff = 0.150, t(149) = 2.671, p = .008), and ZMET-derived meanings (Mean Diff = 0.109, t(149) = 2.539, p = .012). By contrast, the Honesty–Humility, Sincerity, and ZMET composites did not differ significantly from one another. Taken together, when participants described an honest brand as a person, their judgments were most strongly aligned with equity, fair dealing, and perceived value of interaction, rather than with the other honesty-related dimensions.

Dishonest-brand condition. In the dishonest-brand condition, all items were negatively worded such that higher scores reflect stronger endorsement of dishonest traits. As reported in Table 2, the Sincerity composite received significantly higher endorsement than the Honesty–Humility composite (Mean Diff = 0.161, t(150) = 2.734, p = .007), the Equity/fair dealing composite (Mean Diff = 0.517, t(150) = 6.865, p < .001), and the ZMET composite (Mean Diff = 0.239, t(150) = 4.296, p < .001). The Honesty–Humility composite was also endorsed significantly more strongly than Equity/fair dealing (Mean Diff = 0.357, t(150) = 5.323, p < .001), while it did not differ significantly from the ZMET composite. Finally, the Equity/fair dealing composite received significantly lower endorsement than ZMET-derived meanings (Mean Diff = 0.278, t(150) = 5.037, p < .001). Overall, judgments of a dishonest brand were most strongly anchored in perceived insincerity and inauthenticity, pointing to a failure of word–deed alignment as the primary driver of dishonesty attribution.

Conclusions. This study explores how consumers construct a judgment of brand honesty when asked to evaluate a chosen brand through a brand-as-person lens.

Two patterns emerge clearly from the results. In the honest-brand condition, respondents' evaluations were most strongly anchored in the equity/fair dealing dimension, a cluster of cues capturing fairness, non-deceptive conduct, perceived value of interaction, and transparency. This finding is theoretically consistent with psycholexical work showing that the honesty domain is centrally concerned with reluctance to exploit others rather than being reducible to factual accuracy alone. It also aligns with the HEXACO framing of Honesty-Humility as sincerity and fairness in contrast to greed and manipulation. In marketing context, "honesty" appears to be inferred most readily from fair exchange and non-opportunism, which consumers may treat as the most diagnostic evidence that a brand will not take advantage of information asymmetries.

In the dishonest-brand condition, judgments were most strongly anchored in lack of sincerity, with the sincerity construct exceeding the other three batteries by a significant margin. This pattern is compatible with integrity-based inference in trust research, where integrity is defined as adherence to principles the evaluator finds acceptable and is shaped by cues of justice and congruence between words and actions (Mayer et al., 1995). It also fits behavioral integrity theory, which centers evaluations on the perceived alignment between words and deeds (Simons, 2002). When consumers characterize a brand as dishonest, they appear to rely heavily on cues of inauthentic intent and value-pretense, such as manipulative communication and lack of authenticity, even more than on perceptions of inequitable conduct.

A key implication of these two patterns is that honest and dishonest brand judgments do not operate as simple opposites along a single continuum. Rather, consumers appear to draw on different diagnostic routes depending on the valence of the judgment: honesty is most strongly inferred from equitable conduct and non-exploitation, whereas dishonesty is most strongly inferred from insincerity and word–deed misalignment. This asymmetry is consistent with the broader finding in the trust literature that negative evaluations tend to be driven by perceived intent violations and credibility failures, while positive evaluations are more sensitive to evidence of fair dealing (Simons, 2002). Regarding transparency, it did not emerge as a dominant standalone dimension in either condition, though it is embedded within the equity/fair dealing battery and is conceptually present in several individual items. This is consistent with transparency research that conceptualizes transparency as disclosure, clarity, and accuracy, and links these properties to perceived trustworthiness and integrity (Schnackenberg and Tomlinson, 2016; Schnackenberg et al., 2021). Our results suggest that transparency cues may carry greater persuasive weight when they are bundled with fair dealing and perceived interaction value, rather than when they are presented as abstract or self-referential claims.

Research limitations. Taken together, the findings support conceptualizing perceived brand honesty as an integrative perception grounded in three complementary components: non-exploitation and fair dealing, reflecting the honesty–humility core; sincerity and behavioral integrity as word–deed alignment cues; and transparency as information quality. A natural next step is to move from mean comparisons to measurement modeling: confirming dimensionality through confirmatory factor analysis, testing measurement invariance across the honest and dishonest framing conditions, and assessing nomological validity by linking PBH dimensions to relational outcomes such as trust and commitment (Morgan and Hunt, 1994). Because multiple paired comparisons were conducted in the present study, future work should also evaluate the robustness of these findings under multiplicity controls and through model-based approaches.

Managerial implications. PBH functions not merely as an ethical aspiration but as a practical lever for relationship building and risk reduction. Trust research suggests that integrity-based judgments govern whether stakeholders are willing to accept vulnerability in exchange relationships, meaning that perceived dishonesty can rapidly undermine willingness to buy, repurchase, or forgive failures (Mayer et al., 1995; Morgan and Hunt, 1994). The challenge for managers is that honesty is frequently communicated as a broad corporate value, yet consumers appear to infer it through specific, concrete signals that sit at the intersection of conduct, consistency, and communication quality. The present findings help identify where those signals are most diagnostic.

First, honesty perceptions are most likely earned through observable fair dealing rather than through honesty claims in communication alone. This aligns with the semantic core of the honesty domain as a disposition to refrain from exploiting others (Ashton et al., 2000) and with the principle that integrity is inferred from justice and principle-consistent conduct (Mayer et al., 1995). In practice, managers should treat honesty positioning as a cross-functional governance issue in which pricing mechanics, clarity of terms and conditions, complaint handling, and the trade-offs offered to consumers become key touchpoints where fairness, or perceived opportunism, is diagnosed. Honest brand narratives are most credible when they are grounded in equitable exchange design, encompassing transparent conditions, non-exploitative pricing policies, and straightforward guarantees, rather than in messaging alone.

Second, perceptions of dishonesty appear to be strongly connected to insincerity and perceived word-deed misalignment, consistent with integrity-based inference and behavioral integrity theory (Mayer et al., 1995; Simons, 2002). For managers, this points to a fragility dynamic: even a brand that is broadly perceived as fair may still attract dishonesty attributions when its communications are read as value-pretense, manipulative persuasion, or inconsistency between stated values and observed actions. This underscores the importance of claim-delivery alignment, including substantiation of product claims, consistency across channels, and the avoidance of vague virtue-signaling.

Originality of the paper. The originality of this study lies in integrating a meaning-centered qualitative approach with an exploratory quantitative test to clarify what consumers mean by "honest brand." Instead of importing honesty indirectly from adjacent constructs, we anchor the construct domain through ZMET-derived metaphors and translate them into a survey alongside theory-based batteries (honesty-related traits, sincerity, and equity/fair dealing). In addition, our honest-versus-dishonest framing offers an uncommon lens to examine whether consumers use asymmetric inference routes, advancing conceptual clarity and measurement development for perceived brand honesty.

Smart Labeling Impact on Consumer Behavior Perception in Agrifood Production: A Systematic Literature Review

YOUSRA BELLAHCENE[1], ANNUNZIATA TARULLI[2], DOMENICO MORRONE[3]

Abstract. *Increasing concerns about food safety, sustainability, and transparency have heightened consumer expectations in agrifood systems. Traditional labeling often limits access to product information, reducing trust and informed decision-making. Smart labeling technologies such as QR codes, and intelligent packaging enable consumers to access detailed information on origin, production practices, and sustainability. This study systematically reviews the literature to examine how these technologies influence consumer perceptions. The primary findings indicate that smart labels enhance perceived authenticity and food safety while fostering informed purchasing decisions, though challenges remain regarding awareness, usability, and adoption.*
Keywords: *Smart labeling, QR code, consumer behavior, traceability, agrifood systems*

1. Framing of the research. In the last few years, concerns about food safety, sustainability, and transparency have been major factors affecting consumer perceptions regarding food products and the agrifood chain as a whole. The availability of information regarding a product's origin, production process, environmental impact, and ethical issues is more important to modern consumers (Grunert, 2011). However, traditional labeling methods do not usually provide adequate information to a consumer, which leaves a gap between consumers and producers. This gap might affect consumers' perceptions and their ability to make informed purchasing decisions.
Considering the above issues and challenges, the agrifood sector is increasingly using smart labeling technologies to provide consumers with adequate and reliable information about the product through digital interfaces such as smartphones and other digital platforms. For instance, QR codes are used to provide consumers with adequate information about the product's origin, production process, and other related attributes (Lombardi et al., 2017). Similarly, blockchain technology is used to develop transparent traceability systems to verify production and distribution processes along the entire agrifood chain (Casino et al., 2019).
The adoption of smart labeling technology has the potential to alter a more transparent and trust worthy connection between consumers and food. Existing literature expects that smart labeling technology is likely to have a positive impact on consumers' perceptions of food safety, product authenticity, and sustainability (Galati et al., 2019). Consumers are also prepared to pay more for products that offer reliable traceability and sustainability.
In spite of these advances in smart food labeling technology, existing literature is fragmented, with a majority of studies focusing on technological and consumer behavior separately. However, there is a lack of understanding of how smart food labeling technology impacts consumer perception and behavior in food production.

2. Purpose and research question. This study is guided by the following research question: How do smart labeling technologies influence consumer behavior and perception in agrifood production systems?
The growing digitalization of agrifood supply chains has stimulated the development of innovative labeling solutions aimed at improving transparency, traceability, and consumer access to product information. Digital labeling technologies, such as QR codes and interactive information platforms, are increasingly recognized as effective tools for reducing information asymmetry between producers and consumers and for supporting more informed purchasing decisions.
Existing studies suggest that these technologies can positively influence consumer perceptions by providing detailed and verifiable information regarding product origin, production processes, and food safety attributes (Lombardi et al., 2017; Bradford et al., 2022; Lau et al., 2022). For instance, QR code–based traceability systems have been shown to increase consumers' willingness to pay by communicating reliable information about product provenance and production practices (Lombardi et al., 2017).
Similarly, digital labeling tools that convey information related to food safety, sustainability, and production standards can reduce perceived risks and strengthen consumer purchase intentions (Bradford et al., 2022; Lau et al., 2022). Collectively, these findings highlight the growing relevance of smart labeling technologies as mechanisms for shaping consumer perceptions and promoting greater transparency in agrifood systems. The purpose of this study is therefore to provide a comprehensive understanding of how smart labeling technologies influence consumer perceptions and behavioral responses within agrifood production systems. Through a systematic literature review, this research synthesizes existing empirical and conceptual studies to identify the key mechanisms through which digital labeling affects trust formation, perceived product authenticity, risk perception, and willingness to pay.

[2] LUM University, e-mail: tarulli@lum.it
[3] LUM University, e-mail: morrone@lum.it

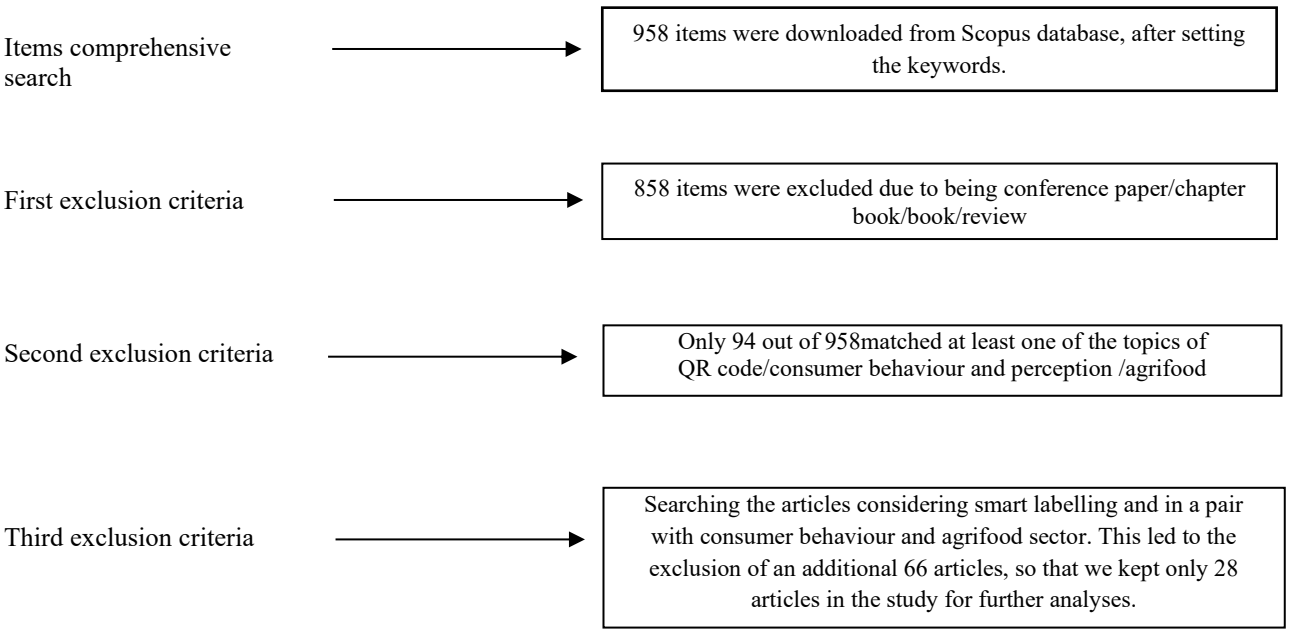
By consolidating current knowledge in this emerging research domain, the study contributes to the broader discussion on digital innovation in agrifood systems and provides insights for researchers, policymakers, and industry stakeholders seeking to design effective labeling strategies that enhance transparency, strengthen consumer confidence, and support the transition toward more sustainable and accountable agrifood supply chains.

3. Methodology.

3.1 Database and search strategy

The systematic literature review was conducted using the Scopus database, which provides extensive coverage of peer-reviewed academic journals in the fields of business, management, economics, and food systems research.
The literature search was performed using the following keywords:
Query: QR OR "Quick Response" OR " smart label" OR "smart packaging" OR "digital technology" AND "consumer behavior" OR perception* and food OR agrifood OR agriculture OR "food product"

3.2 Methodology



Selection bias develops in an SLR, whenever the subject area is taken into account. Relevant articles run a risk of being left out if it is hard to define SLR literature, however, offers strategies to lower this risk. Identifying which papers to include in a thorough literature search is a further step to take. To select the papers that should be included, we focused on the Scopus database. This choice is coherent with previous studies argument which concurs that Scopus database provides extensive coverage of academic journals as it embraces more than20,000 peer-reviewed journals (Mishra et al., 2017). According to (Secondo et al, 2020) in another study similar to our article following the PRISMA protocol, which precisely confirms what was highlighted by the aforementioned authors.

Table1. Inclusion and exclusion criteria

Inclusion criteria	Exclusion criteria
Peer-journal articles, reviews	Books, book chapter, conference proceedings, editorials, and grey literature
Articles published in journals indexed the subject areas of business, management and accounting, economics and economics and finance	Articles primarily classed in other disciplinary domains
Articles published in the English languages	Articles published in languages other languages than English

Author's collaboration

The analysis was conducted in January 2026, all records were independently screed for typical relevance in line with established review practices (Grafton et al.,2011) with titles and abstracts independently screed by two researchers to identify studies eligible for in-depth analysis.

4. Results. Based on the systematic screening and assessment of the selected articles' relevance to the research topic, it is noted that the emerging body of research on QR code technology in agrifood systems creates an important foundation for understanding the impact of digital traceability tools on consumer behavior and product transparency and trust in agrifood systems. At the same time, the analysis of the articles reveals some gaps regarding the use of behavioral theories and cross-sector comparisons and sustainability communications in the context of QR codes in agrifood systems, which is an important aspect to be further explored in the specific research domain.

A first highly relevant contribution is offered by the study of (Fiore et al.,2024), which focuses on the theme of the integration of blockchain technology and QR code technology in the regional agrifood supply chain of Apulia, Italy. The purpose of the investigation is to evaluate the impact of digital traceability tools on the theme of transparency and trust of consumers with regard to the quality of food products. By adopting a case study method with the support of a survey of consumers, the authors of the study examine the use of QR codes to access information on the origin of the product, the production process, and the actors of the supply chain. The results of the investigation highlight the potential of the use of QR technology to improve the theme of trust of the consumer with regard to the authenticity of the product.

Another notable contribution is provided by (Daoud et al.,2019). The study aims to explore consumer perceptions regarding smart packaging solutions, including QR codes, used in food products. The main aim of the research is to identify how smart packaging solutions, which allow consumers to interact with the packaging, can impact consumer behavior during the purchase decision. The study also aims to evaluate the usefulness of smart packaging solutions to consumers. According to the research findings, consumers believe that having access to detailed product information via QR codes is a means to enhance product reliability. The research findings also indicate that smart packaging solutions, including QR codes, can impact consumer behavior favorably. This is because consumers believe that having access to detailed product information via QR codes is a means to enhance product reliability.

A third study that is pertinent to the topic is conducted by (Barone and Aschemann-Witzel .,2018). This study examines the relationship between QR code labeling and the purchase intention of consumers in the context of the food market. The aim of the study is to find out if the additional information provided by the QR code has the ability to affect the attitudes of the consumers towards the purchase of the product. The study uses a quantitative survey method combined with behavioral intention modeling to evaluate the attitudes of the consumers towards the purchase of food products with QR codes containing information about the origins, ingredients, and methods of production used to produce the food. According to the study, the purchase intention of the consumers is positively affected by the QR codes, especially if the information provided is credible and meaningful.

A related perspective is offered by a study on the willingness to pay for QR codes on food labeling (2017). The purpose of this research is to assess the economic value that consumers assign to digital traceability technologies in food products. Using a discrete choice experiment and willingness to pay analysis, the research measures consumer responses to products that include traceability information through QR codes. The results show that consumers are willing to pay a price premium for products that include digital transparency, particularly when the use of QR codes provides verifiable information on food safety, production processes, and geographical origin. This indicates that the use of QR codes on food labeling can potentially add economic value to food producers through a price premium strategy.

Another important contribution is offered by the research on consumer purchase intention regarding QR codes on food labels (2022), which focuses on the psychological factors affecting consumers' willingness to use QR codes on food packaging. The research uses structural equation modeling to explore the impact of perceived usefulness, trust, and information quality on consumer behavior. The findings show that perceived usefulness and trust are the most important factors affecting consumers' willingness to scan the QR codes on food packages, and that the quality and relevance of the information affect consumers' satisfaction. The authors conclude that QR codes can be an effective tool to engage consumers when used to provide them with clear and valuable information on food safety, sustainability, and production processes.

Additional insights into the matter can be found in the study on "Customer Perceptions of Traceable Meat Products" (2024). The purpose of the study is to examine the role of digital traceability tools, like QR codes, on the trust of customers within meat supply chains. The authors of the study use the method of perception analysis to examine how the potential to access information on the origin of the animal, farming practices, and quality labels by means of scanning the QR code on the packaging of the meat product affects the trust of the customers. The results of the study demonstrate the potential of traceability tools like QR codes to build trust within meat supply chains by increasing the perceived safety of the meat product.

Another important contribution is centered on consumer perceptions of the use of QR codes in technology related to food products (2022). The aim of the research is to evaluate consumer attitudes regarding the use of QR codes as a medium for obtaining additional product information. Based on consumer acceptance surveys and technology adoption analysis, the research evaluates the factors affecting consumer interaction with the technology. The findings suggest that the use of QR codes increases consumer awareness regarding product origin and sustainable practices, and younger consumers show a higher adoption rate of the technology. The importance of using QR codes as a digital medium of communication between consumers and the supply chain is highlighted.

A current contribution by research on bio-QR codes for sustainable packaging (2024) further broadens the scope of the topic by relating digital traceability technologies to environmental sustainability. The purpose of the research is to investigate the consumer acceptance of biodegradable QR code technology in sustainable food packaging. Using an experimental consumer research approach, the authors investigate the perception of consumers regarding the relationship

between digital traceability and environmental sustainability in packaging materials. The findings show that consumers have a positive perception of products that associate both digital traceability and environmental sustainability.
Another relevant study deals with the heterogeneity of the preferences of consumers regarding the use of traceability technologies for food products (2021). The main purpose of the research is to evaluate the importance of the use of traceability information by means of digital tools such as QR codes for different segments of the population. The results of the study reveal the existence of important differences between the preferences of the consumers depending on some personal, risk perception, and buying-related factors. The results of the study highlight the importance of traceability for specific segments of the population concerned with the safety of the food product.
Finally, the research on QR code application in the dairy industry of Slovenia (2023) is a study that offers relevant insights into QR code application in a specific industry. The purpose of the research is to explore how QR codes are used to convey to consumers various aspects of milk origins, production methods, or quality marks. The research utilizes a case study method along with a consumer perception study to highlight how QR codes improve consumer engagement by providing a clear farm-to-table experience. The research findings highlight how QR codes improve consumer interaction with dairy brands, leading to increased trust levels. This is a relevant example of how QR codes can improve consumer interaction with various brands.
Collectively, these studies collectively demonstrate that QR-code-based traceability systems offer a potentially promising technological means for enhancing consumer trust, transparency, and engagement within agrifood systems, while also pointing to a need for further research on behavioral aspects, sustainability communications, and cross-sector extensions of digital food label technologies.

5. Research limitations. Despite the fact that the study provides informative results regarding the impact of smart labeling technologies in affecting the perceptions of consumers within the agrifood system, the current study has some limitations that must be addressed. First and foremost, it is crucial to remember that the current study is based on a systematic literature review approach, which is subject to limitations depending on the availability of literature. In the current study, the Scopus database was used, which is well known for containing a large volume of publications. However, the use of only one database may have left out significant literature that was published on other databases such as the Web of Science or Google Scholar.
The current study was based on the use of English literature only. This may have been a limitation since literature published in other languages may have been ignored. In the agrifood system, it is possible that literature on traceability is often published at the regional or national level.
Thirdly, the review mainly emphasizes consumer perception and behavioral responses to QR-code-based smart labeling technologies without incorporating any primary empirical data from consumers and/or firms. Therefore, although the research attempts to synthesize the existing knowledge base on the topic, it fails to test behavioral models and/or measure consumer interactions with smart labeling technologies.
Last but not least, the reviewed literature on smart labeling primarily focuses on certain product groups and/or specific regions, such as the dairy and meat sectors and/or regional studies. As a result, the applicability of the findings to other product groups and/or regions might be limited. The research could be further expanded to solve some of the above-mentioned weaknesses by conducting consumer experiments and/or cross-country studies on the adoption of smart labeling technologies in the agrifood sector.

6. Managerial implications. The research findings offer several key managerial implications for agrifood businesses and stakeholders in the value chain who are interested in leveraging the advantages of transparency, trust, and competitiveness in the marketplace through the adoption of smart labeling systems.
The research findings suggest that agrifood businesses can leverage the advantages of QR-code-based labeling systems in enhancing consumer trust and product authenticity. Therefore, agrifood businesses can consider leveraging the advantages of smart labeling systems in creating a strategic communication tool to communicate in detail with consumers about product origin, production processes, sustainability standards, and quality standards. By leveraging the advantages of QR-code-based labeling systems, agrifood businesses can leverage the advantages of creating long-term trust with consumers. In the marketplace, there is an increased demand for transparency among consumers. Therefore, the adoption of digital traceability tools can serve as a key competitive advantage in the marketplace to differentiate agrifood products on the basis of product authenticity.
Second, the literature review used in this study also revealed that consumers are willing to pay a premium price for food products that ensure reliable traceability and transparency. From a managerial point of view, it is also important to note that smart labeling technologies can be used to support value creation and differentiation strategies. Firms that use digital traceability technologies can be able to differentiate their products and place them in a higher market segment. In other words, it is important to note that smart labeling should not be considered solely as a technological innovation, but also as a tool that can be used to support brand and product positioning strategies in a highly competitive market environment.
Third, it is also important to note that the information quality, accessibility, and usability are critical success factors for the success of smart labeling technologies. It is important for the manager to ensure that the digital platforms used in conjunction with the QR codes are capable of providing information to the consumers in a clear, concise, and relevant manner. Too much technical information may limit the success of the digital platforms used to support the smart labeling

technologies. It is also important to note that firms can consider the use of narrative storytelling approaches to ensure that the consumers are capable of understanding the information provided through the digital platforms.
Finally, there is scope for the application of smart labeling technologies to contribute to the development of more resilient forms of sustainability communication and accountability within the agrifood sector. Agrifood businesses are able to utilize the QR codes to access the digital platforms, which are capable of providing information pertaining to the environmental practices, ethical sourcing policies, and food safety certifications, to meet the increasing demand for responsible and sustainable forms of agrifood production.
This approach to transparency has the potential to contribute to the development of more resilient corporate reputations, while at the same time meeting the requirements of emerging regulatory requirements pertaining to the development of more resilient forms of agrifood supply chains. From a strategic perspective, the application of smart labeling technologies within the wider context of sustainability and transparency has the potential to contribute to the development of more resilient forms of agrifood supply chains.

7. Originality of the paper. This study presents a valuable contribution to the increasing volume of research on the digital transformation of agrifood systems by providing a comprehensive synthesis of the relationship between smart labeling technologies and consumer behavior perception. While prior investigations on the topic addressed either technological advancement in food traceability systems or consumer behavior within food markets individually, this research attempts to integrate both perspectives by specifically examining the impact of QR-code labeling technology on consumer behavior perception.
The originality of the paper is its interdisciplinary approach to the topic, which brings together concepts from consumer behavior research, digital technology adoption, and agrifood system transparency. Through a comprehensive synthesis of existing research on the topic, the research was able to identify the major behavioral drivers that explain the impact of smart labeling technology on consumer behavior perception.
Moreover, the paper also points to emerging research gaps, such as the limited use of behavioral theories, the importance of cross-sector comparisons in agrifood systems, and the role of smart labeling technologies in communicating sustainability attributes. In doing so, the paper creates a foundation for future empirical research on the topic of how digital labeling innovations can be used to promote more transparent and sustainable agrifood supply chains.

The Institutionalization of Person-Centredness: A Three-Stream Convergence Model Across Management Fields

SABINA DE ROSIS

Abstract. *Person-centredness has become one of the most pervasive principles in contemporary management discourse. Across private, public, and healthcare settings, organisations are increasingly expected to be customer-oriented, citizen-centred, patient-centred, or people-centred. This apparent convergence has often been interpreted through a diffusion narrative, according to which person-centredness originated in private-sector management and was later transferred to public management and healthcare through managerial reforms. This paper challenges that interpretation.*

The study develops a cross-field, theory-building analysis of person-centredness across three managerial streams: private management, public management, and healthcare management. Rather than treating person-centredness as a concept invented in one field and exported to others, the paper argues that contemporary person-centred governance emerged through the convergence of three semi-autonomous institutional streams: professional-relational ethics, public-service normative commitments, and managerial measurement rationality.

Methodologically, the paper adopts a structured integrative review combined with abductive theory building and mechanism-based institutional analysis. The review does not aim at bibliometric exhaustiveness; instead, it seeks theoretical saturation through the selection of foundational and conceptual contributions across the three streams. The analysis reconstructs the temporal evolution of person-centred constructs, distinguishes ethical and professional origins from later managerial institutionalisation, and interprets convergence through the combined lenses of institutional isomorphism and translation theory.

The paper develops a three-stream convergence model of person-centred governance. The preliminary model shows that the central innovation of late managerial developments was not the moral discovery of the person, but the emergence of measurement infrastructures, accountability systems, and governance architectures capable of embedding person-centredness at organisational and system levels. In this perspective, convergence across fields does not imply conceptual identity: similar instruments travel across fields, but are translated and hybridised according to sector-specific institutional logics.

The paper is currently a work-in-progress and want to contribute to management scholarship in three ways. First, it clarifies the genealogy of person-centredness by distinguishing proto relational centrality from institutionalised person-centred governance. Second, it integrates institutional isomorphism and translation theory to explain convergence without conceptual homogenisation. Third, it proposes person-centredness as a site of institutional complexity across management fields. More broadly, the study suggests that person-centredness should not be understood only as a normative ideal or a managerial technique, but as a hybrid governance construct emerging from the intersection of multiple value regimes.

Keywords: *person-centredness; institutional logics; translation; institutional complexity; public value; customer orientation*

Framing of the research. *The centrality of the person has become one of the most pervasive principles in contemporary management discourse. Across sectors and institutional contexts, organisations are increasingly urged to be customer-oriented, client-focused, citizen-centred, patient-centred, or people-centred. Although the vocabulary changes, the underlying imperative appears similar: organisations are expected to recognise, involve, and respond to the needs, experiences, and values of their direct stakeholders. In management scholarship, this broad convergence is often read through a diffusion narrative, according to which person-centredness was first developed in private-sector management, especially in marketing and service management, and later transferred to public management and healthcare through reform waves such as New Public Management (Hood, 1991; Osborne & Gaebler, 1992). However, this interpretation is analytically too narrow.*

What makes the diffusion narrative problematic is that it conflates two different phenomena: the earlier emergence of person-related sensibilities within professional and public-service traditions, and the later managerial institutionalisation of person-centredness through organisational tools, measurement systems, and governance architectures (DiMaggio & Powell, 1983; Czarniawska & Sevón, 1996). Long before marketing and service management formalised customer orientation and service quality models, public and healthcare-related fields had already developed forms of relational attention to the person. In social case work, for instance, the "culture of the client" was already recognised as central in the 1930s (Boie, 1937). In psychotherapy, client-centred therapy placed the individual's subjective experience at the core of professional action (Rogers, 1946; Rogers, 1951). In medicine and healthcare, critiques of paternalistic and biomedical models progressively foregrounded the person beyond the disease, through patient-centred medicine and the biopsychosocial perspective (Balint, 1969; Engel, 1977; Mead & Bower, 2000; Stewart et al., 2003). These developments did not originate from private-sector managerial logic, but from professional ethics, care relationships, and evolving understandings of responsibility and dignity.

A similar argument applies to public management. Public administration has long embedded the idea that public officials serve citizens and communities, and not merely organisational efficiency goals. The concept of public value further consolidated this orientation by arguing that the legitimacy of public action derives from its capacity to contribute to citizens' and society's wellbeing (Moore, 1995; Benington & Moore, 2011; Osborne, 2010). Thus, the normative foundations of person-centredness cannot be reduced to imported market principles. Rather, they are also deeply rooted in public-service traditions and collective value frameworks.

The relevant analytical question, therefore, is not whether person-centredness originated in private management, public management, or healthcare. The more important question is how person-centredness became institutionalised as an organisational and governance paradigm that can be formalised, measured, compared, and scaled across sectors. In this respect, private management did play a major role, not by inventing the moral salience of the person, but by developing managerial tools capable of embedding experiential and relational dimensions into performance and organisational systems. Service quality and customer orientation models made perceptions and experiences actionable through formal measurement infrastructures (Parasuraman et al., 1985; Parasuraman et al., 1988; Cronin & Taylor, 1992). Later developments around value co-creation and customer experience further reinforced the treatment of experience as a managerial object (Vargo & Lusch, 2004; Prahalad & Ramaswamy, 2004; Lemon & Verhoef, 2016).

This distinction makes it possible to reframe the issue more productively. Rather than asking which sector first generated person-centredness, this paper asks how distinct institutional logics converged to produce the contemporary model of person-centred governance. Institutional theory is particularly useful here. Institutional isomorphism explains why organisations across different fields tend to adopt similar forms under conditions of uncertainty, accountability pressures, and professionalisation (DiMaggio & Powell, 1983). However, isomorphism alone is not sufficient, because it cannot explain why person-centredness retains different meanings across sectors. Translation theory complements this perspective by showing that ideas do not travel unchanged: they are edited, reframed, and hybridised within new contexts (Czarniawska & Sevón, 1996; Røvik, 2007). In this sense, customer orientation, public value, and patient-centred care should not be interpreted as identical concepts diffusing intact from one field to another, but as different institutional articulations of a broader shift toward relational and service-based governance (Osborne et al., 2016; Thornton et al., 2012).

This paper addresses that gap by developing a cross-field interpretation of person-centredness across three management streams: private management, public management, and healthcare management. It argues that contemporary person-centred governance emerged not through linear diffusion, but through the convergence of three semi-autonomous streams: professional-relational ethics, public-service normative commitments, and managerial measurement rationality. On this basis, the paper proposes a three-stream convergence model and positions person-centredness as a hybrid institutional construct shaped by convergence, translation, and institutional complexity across management fields.

Purpose of the paper. *The purpose of this paper is to develop a cross-field theoretical explanation of how person-centredness became institutionalised as a governance paradigm across different management domains. While the concept is widely used across private management, public management, and healthcare management, existing literature often treats these developments either as sector-specific phenomena or as the outcome of a linear diffusion from private-sector managerial thought. This paper challenges that interpretation and proposes an alternative explanation grounded in institutional theory.*

More specifically, the study aims to distinguish between early forms of relational attention to the person—rooted in professional ethics and public-service traditions—and the later managerial institutionalisation of person-centredness through organisational design, measurement systems, and governance mechanisms. By reconstructing the historical trajectories of person-centred constructs across marketing and service management, public management, and healthcare management, the paper seeks to clarify how similar governance principles emerged across sectors while retaining distinct normative meanings.

To address this objective, the study develops a cross-field theoretical synthesis based on a structured integrative review of foundational contributions across the three domains. The analysis focuses on identifying the institutional mechanisms that explain the convergence of person-centred governance across fields. In particular, the paper integrates insights from institutional isomorphism and translation theory to explain how organisational forms and managerial instruments spread across sectors while being reframed according to sector-specific institutional logics.

The paper therefore addresses the following research question: How did person-centredness become institutionalised as a governance paradigm across private management, public management, and healthcare management, and what institutional mechanisms explain the convergence of these trajectories?

This paper is presented as a work in progress. The current version develops the theoretical framing and the initial architecture of the proposed three-stream convergence model. Further stages of the research will refine the conceptual boundaries of the model and expand the cross-field literature base in order to strengthen the explanatory mechanisms and support future empirical applications.

By addressing this research question, the study aims to contribute to management scholarship in three ways. First, it clarifies the genealogy of person-centredness by distinguishing its ethical and professional origins from its later managerial codification. Second, it proposes a three-stream convergence model that explains the emergence of contemporary person-centred governance as the intersection of professional-relational ethics, public-service normative

commitments, and managerial measurement rationality. Third, it positions person-centredness as a site of institutional complexity across management fields, highlighting how similar governance mechanisms can embody different value logics depending on their institutional context.

Methodology. *This study adopts a structured integrative review combined with abductive theory development to reconstruct and theorise the institutional evolution of person-centredness across different management fields. The objective of the research design is not to provide an exhaustive bibliometric mapping of the literature, but rather to develop a theoretically informed explanation of how person-centredness became institutionalised as a governance paradigm across private management, public management, and healthcare management.*

The methodological approach is grounded in the recognition that person-centredness does not belong to a single disciplinary field. Instead, it has emerged through parallel developments in heterogeneous institutional environments governed by different normative frameworks and institutional logics. Consequently, the methodological challenge is not simply literature aggregation, but cross-field synthesis capable of identifying conceptual trajectories, temporal developments, and institutional mechanisms that explain convergence across sectors.

The research design follows three main analytical principles.

First, the study adopts a field-comparative perspective. The analysis is organised around three semi-autonomous managerial streams: private management (including marketing and service management), public management, and healthcare management. Each stream is treated as an institutional field characterised by its own epistemic traditions, normative foundations, and evaluative criteria. This structure helps avoid retrospective diffusion bias, namely the tendency to interpret later managerial codifications as evidence of conceptual origin.

Second, the study combines historical reconstruction and mechanism-based theorising. Rather than simply documenting the appearance of terms such as customer orientation, citizen-centred governance, or patient-centred care, the analysis aims to explain how and why these concepts became institutionalised within organisational and governance systems. Particular attention is paid to identifying the institutional mechanisms that contributed to convergence across fields.

Third, the research adopts an abductive orientation. The study began with the empirical observation that similar forms of person-centred discourse appear across different management literatures. Through iterative engagement with scholarship in marketing, public administration, healthcare management, and institutional theory, the research progressively refined the conceptual distinctions and explanatory mechanisms underlying this convergence.

The literature review was structured around the three institutional streams described above.

The private management stream includes research on customer orientation, service management, service-dominant logic, customer experience, and value co-creation. Foundational contributions in service quality measurement and customer-centric organisational models were prioritised because they represent key moments in the managerial formalisation of experiential dimensions of value.

The public management stream includes literature on public value, public service logic, citizen engagement, co-production, and governance reforms. Particular attention was given to conceptual contributions that interpret value creation as a collective and multi-actor process and that examine the translation of managerial tools into public-sector contexts.

The healthcare management stream includes scholarship on patient-centred care, patient engagement, shared decision-making, patient experience, and the governance institutionalisation of patient-reported outcome and experience measures.

Across all streams, the literature selection prioritised: (i) conceptual and theoretical contributions rather than purely empirical case studies; (ii) foundational texts that shaped field-level discourse; (iii) publications in influential journals in management, organisation studies, public management, and healthcare management.

The aim was to reach theoretical saturation, meaning the point at which additional sources no longer significantly altered the emerging cross-field explanation.

The analytical process developed in four stages. First, a temporal reconstruction identified key conceptual inflection points within each stream, distinguishing early relational and professional formulations from later managerial codifications. Second, a conceptual differentiation stage analysed terminological variations (customer, citizen, patient, user) as indicators of underlying institutional logics rather than simple semantic diversity. Third, a mechanism identification stage interpreted convergence through institutional theory, focusing on institutional isomorphism and translation processes as key explanatory mechanisms. Finally, the findings were synthesised into a three-stream convergence model, which conceptualises person-centred governance as the outcome of the interaction between professional-relational ethics, public-service normative commitments, and managerial measurement rationality.

This methodological approach is consistent with theory-building traditions in management research. Rather than introducing a new construct, the study seeks to re-theorise an established but conceptually fragmented one, offering a structured explanation of how person-centredness emerged as a hybrid governance paradigm across management fields. As noted earlier, the present paper represents a work in progress, and further stages of the research will refine the conceptual model and expand the empirical and theoretical grounding of the proposed framework.

Results *(*work in progress). *The analysis provides preliminary insights into how person-centredness evolved and became institutionalised across different management fields. Although the study is still in progress, the cross-field synthesis conducted so far allows the identification of three main analytical results that support the development of the proposed three-stream convergence model.*

A first result concerns the distinction between proto relational centrality and institutionalised person-centred governance. The literature review shows that early forms of attention to the person emerged primarily within professional and public-service traditions. In healthcare and social care, relational approaches developed in response to paternalistic models of intervention and emphasised the importance of understanding the individual beyond technical or clinical dimensions (Balint, 1969; Mead & Bower, 2000). Similarly, in public administration, traditions of public service and later public value scholarship emphasised responsiveness to citizens and societal wellbeing (Moore, 1995; Osborne, 2010).

These early developments, however, did not initially take the form of organisational governance systems. The managerial transformation occurred when person-centred principles were translated into measurement infrastructures, performance indicators, and organisational design mechanisms capable of embedding experiential dimensions into organisational decision-making. Contributions from service management and marketing scholarship played a key role in this process by formalising tools for measuring service quality and customer experience (Parasuraman et al., 1985; Cronin & Taylor, 1992; Lemon & Verhoef, 2016).

A second result is the identification of three semi-autonomous institutional streams that evolved in parallel before intersecting. The first stream can be described as professional-relational ethics, where attention to the individual emerges as part of professional responsibility and care relationships, particularly in healthcare and social care contexts. The second stream concerns public-service normative commitments, where responsiveness to citizens and the pursuit of public value shape the relationship between organisations and the individuals they serve. The third stream is managerial measurement rationality, developed especially in private management literature, which introduced analytical tools and performance systems capable of translating subjective experience into managerial signals.

The preliminary analysis suggests that contemporary person-centred governance emerged when these three streams gradually intersected, enabling relational principles to be embedded within organisational and governance architectures.

A third result concerns the mechanisms that explain convergence across fields. The analysis indicates that two institutional mechanisms appear particularly relevant.

First, institutional isomorphism helps explain why organisations in different sectors increasingly adopt similar forms of person-centred language, feedback systems, and engagement mechanisms under conditions of accountability pressure and organisational uncertainty (DiMaggio & Powell, 1983).

Second, translation processes explain why these similar forms maintain different meanings across sectors. When managerial tools travel across institutional fields, they are adapted and reframed according to local value frameworks and professional traditions (Czarniawska & Sevón, 1996; Røvik, 2007).

Taken together, these preliminary findings support the development of a three-stream convergence model in which contemporary person-centred governance emerges from the intersection of professional relational ethics, public-service normative commitments, and managerial measurement rationality. Because the study is still ongoing, the current results should be interpreted as initial theoretical insights rather than definitive conclusions. Further stages of the research will refine the model and expand the literature base in order to strengthen the explanatory mechanisms underlying the convergence of person-centred governance across management fields.

Research limitations. *This study presents several limitations that should be acknowledged, particularly given its current stage as a work in progress.*

First, the paper relies on a structured integrative review aimed at theory development rather than on a systematic bibliometric review or empirical analysis. Although the literature selection prioritised foundational and influential contributions across the three management streams, the review does not claim exhaustive coverage of all relevant publications. The objective was theoretical saturation rather than comprehensive mapping of the field.

Second, the analysis focuses on conceptual and theoretical contributions within private management, public management, and healthcare management. As a consequence, empirical studies examining the practical implementation of person-centred approaches across sectors are not systematically included at this stage. Future research could complement the theoretical model proposed here with empirical investigations exploring how the convergence of person-centred governance unfolds in organisational practice.

Third, the reconstruction presented in this paper primarily reflects developments within Western advanced service economies, where service-sector expansion, public management reforms, and digital accountability infrastructures have jointly influenced organisational evolution. The historical trajectories and institutional dynamics identified here may therefore require adaptation when considering other institutional contexts.

Finally, the three-stream convergence model proposed in this paper remains a preliminary theoretical framework. While the integrative review provides initial support for the model, further research will be necessary to refine the conceptual boundaries of the construct and to test its explanatory power across different organisational and institutional settings.

Managerial implications. *The preliminary findings of this study offer several implications for managers and policymakers operating in organisational contexts where person-centredness is promoted as a governance principle.*

First, the analysis suggests that person-centredness should not be approached as a universal managerial template that can be transferred unchanged across sectors. Although similar instruments—such as experience measurement systems, feedback mechanisms, or engagement strategies—are increasingly adopted across organisations, their effectiveness depends on their alignment with the institutional logic of the sector in which they are implemented. Managers should therefore avoid treating person-centred approaches as purely technical tools and instead consider how they interact with professional norms, organisational values, and accountability frameworks.

Second, the results highlight that measurement alone does not constitute person-centred governance. The introduction of indicators, satisfaction surveys, or experience metrics does not automatically produce meaningful organisational change. Person-centred governance requires the integration of these tools into broader organisational processes, including decision-making routines, performance management systems, and service design practices.

Third, the findings underline the importance of recognising the layered origins of person-centredness. In many sectors, especially healthcare and public services, relational traditions already play a central role in professional practice. Reforms that attempt to impose standardised managerial instruments without acknowledging these traditions may encounter resistance or symbolic compliance. Managers should therefore design person-centred initiatives in ways that build upon existing professional and organisational cultures.

Finally, the study suggests that contemporary organisations increasingly operate within hybrid institutional environments, where market-oriented, public-service, and professional logics coexist. In such contexts, person-centred governance can function as a bridging concept that facilitates coordination among different stakeholders. However, this potential can be realised only if managers recognise the underlying institutional complexity and actively translate person-centred principles into governance arrangements that are coherent with the organisation's broader mission and value framework.

Originality of the paper. *This paper contributes to management scholarship by offering a cross-field theoretical interpretation of person-centredness across private management, public management, and healthcare management. While the concept is widely used across these domains, existing literature typically examines it within sector-specific boundaries or assumes a diffusion from private-sector managerial thought to public and healthcare contexts. This study challenges that assumption by proposing an alternative explanation based on institutional convergence.*

The paper advances the literature by distinguishing between proto relational centrality, rooted in professional and public-service traditions, and institutionalised person-centred governance, which emerges when relational principles are embedded within organisational structures, measurement systems, and accountability frameworks. This distinction helps clarify the historical evolution of person-centredness and prevents conflating its ethical origins with its later managerial codification.

The study also contributes to institutional theory by combining insights from institutional isomorphism and translation theory to explain why similar person-centred governance mechanisms appear across sectors while maintaining different normative meanings. By doing so, the paper conceptualises person-centredness as a hybrid institutional construct resulting from the convergence of three streams: professional-relational ethics, public-service normative commitments, and managerial measurement rationality.

More broadly, the paper positions person-centredness as a site of institutional complexity across management fields, offering a theoretical framework that enables more precise cross-sector comparison and a deeper understanding of how relational governance principles become institutionalised in contemporary organisations.

The Internal Brand Equity Lift: How Internal Marketing Strategies and Brand Fit Influence Employees' Identification in Nonprofit Partnerships

ALESSANDRO SIGNORINI

Abstract. *Corporate–nonprofit partnerships are widely employed to enhance corporate social responsibility (CSR) and strengthen external brand equity. However, their impact on internal brand perceptions remains largely unexplored. Grounded in Social Identity Theory (SIT) and Self Categorization Theory (SCT), this study investigates how employees internalize, or fail to internalize, the values of nonprofit partners, and how internal marketing strategies and brand personality fit shape this process.*

While existing CSR literature assumes that social impact initiatives naturally translate into positive internal values, employees often detect inconsistencies, potentially causing skepticism and weakened identification. Internal marketing practices are essential to establish whether a partnership is perceived as an authentic commitment or as a superficial reputational strategy. Also, when the company and nonprofit show brand personality fit, employees are more likely to view the partnership as a genuine extension of company's ethical principles.

To examine these mechanisms, a scenario-based experiment is conducted with 600 employees of an Italian coffee company. Participants evaluated one of two nonprofit partnerships, one with high brand-fit vs. one with low brand-fit, and assigned to one of three communication conditions: transactional (financial-based), transformational (narrative storytelling), or participatory (active employee involvement). Organizational Identification (OI) served as the primary dependent variable.

Preliminary findings indicate that narrative and participatory communication styles result in significantly higher OI than transactional messaging, as they are perceived as more emotionally resonant and personally relevant. Brand fit moderates these effects since high-fit partnerships are more readily internalized, while low-fit collaborations risk appearing as opportunistic unless communicated with transparency.

These insights suggest that companies should prioritize narrative communication that emphasizes nonprofit missions and social impact, and provide meaningful employee engagement opportunities treating nonprofits as true co-branding partners. Nonprofits, in turn, can demonstrate a deeper partnership value proposition by stressing internal brand benefits for companies, including, improved employee attitudes, stronger OI, and potentially lower turnover.

Keywords*: Internal Brand Equity; Internal Marketing; Brand Personality Fit; Organizational Identification; Nonprofit Organizations; Corporate Fundraising*

Framing of the research. Traditionally, Corporate Social Responsibility (CSR) has been defined as a set of voluntary corporate practices, which address social and environment problems beyond legal and regulatory requirements. Foundational Stakeholder Theory (Donaldson & Preston, 1995; Freeman, 2010) states that companies are accountable and responsible not only to shareholders but to a multi-constituent model formed by consumers, employees, communities, regulators, and civil society organizations. Therefore, CSR functions turn out to be mechanisms to reconcile and mediate the conflicting interests of these various groups. Within the context of corporate fundraising, nonprofit organizations function less as autonomous partners and more as operational mechanisms through which firms absolve their corporate social responsibility (Harrison et al., 2010).

In recent times, Instrumental (McWilliams & Siegel, 2001; Porter & Kramer, 2006) and Partnership (Austin & Seitanidi, 2012; Porter & Kramer, 2011) CSR Theories frame responsibility as a strategic instrument to enhance firm performance and differential advantage. CSR is reshaped as a process of value co-creation where social and economic value are jointly produced through partnerships. CSR becomes embedded in the business model and is an integral part of the corporate reputation and its market appeal. In the corporate fundraising perspective, nonprofits become strategic resources and are co-producers of social value. Social causes are leveraged to achieve corporate objectives, and funding decisions are tied to visibility, measurability, and brand consistency (Seitanidi & Crane, 2009). Nonprofits provide expertise and implementation capacity, and are assessed as partners rather than beneficiaries. However, this creates increased corporate influence and blurred boundaries between mission and market logic (Barnett, 2007).

Corporate sponsorship to nonprofits is connected with the external halo effect, which refers to the phenomenon where consumers' perceptions of a for-profit brand are positively moderated by the association with a charitable cause or nonprofit organization (Lafferty & Goldsmith, 2005). Through this associative mechanism, positive attributes of the nonprofit, specifically, its social impact, moral legitimacy, or its active social campaigns, are transferred to the corporate brand. This transfer influences consumer evaluations even if consumers get no direct information on the product quality or performance (Becker-Olsen et al., 2006; Sen & Bhattacharya, 2001).

Theoretically, the external halo effect is based on the associative learning (Till & Nowak, 2000) and signaling theories (Connelly et al., 2011; Herbig & Milewicz, 1995). In environments with information asymmetry, where consumers often

have incomplete information about corporate strategies or CSR quality, they rely on charitable partnerships as cues when evaluating firms. Consequently, the nonprofit may become a symbolic asset that improves the brand's equity (Bendapudi et al., 1996).

Nevertheless, while corporations make substantial investments in nonprofit partnerships to strengthen external brand equity, these initiatives often fail to generate comparable positive effects within the company's employees at different ranking levels. Research (Bernardino, 2021; Gupta et al., 2025) confirms that when companies engage in external collaborations with non-profits with no authentic internal integration within their own organizations, numerous negative consequences can emerge. Employees, in particular, may act as internal detectors of corporate authenticity. If they perceive that a partnership is driven by self-interest or purely promotional motives rather than altruistic reasons, their levels of cynicism may increase (Ji & Jan, 2019). This cynicism can generate deep skepticism in the organization's motives, and often leads to reduced job performance and lower organizational commitment (Ji & Jan, 2019; Serrano Archimi et al., 2018). The failure to integrate a nonprofit partnership within the organization is defined in academic literature as CSR decoupling. This occurs when an organization publicly adopts social initiatives and high-visibility charity collaborations but makes little or no changes to internal practices (Forliano et al., 2025). Employees who observe this gap often assess the company's actions as symbolic CSR rather than substantive CSR, which can generate a sense of work alienation and even counterproductive workplace behaviors (Elshaer et al., 2025; Vollero et al., 2016). For CSR investments to be effective internally, they should be supported by transparent, consistent, and structured internal communication (Gupta et al., 2025), otherwise, employees may perceive the company's claims as insincere or hypocritical. Authenticity in CSR communication is essential in employee trust and engagement because employees sense that the corporate actions are consistent with its own values and actions and promote internal brand advocacy (Bernardino, 2021; Gupta et al., 2025).

In addition, CSR initiatives, in many cases, do not enable employees to identify with the values behind the sponsorship activities or with the mission of the nonprofit organization. As employees struggle to develop a meaningful connection with these initiatives, they get the impression that nonprofit collaborations are exclusively employed for "social washing" purposes to refine the reputation of corporate marketing efforts (Siano et al., 2017). To mitigate this risk, this research investigates the for-profit/nonprofit partnerships not as marketing investments or financial transactions, but instead grounds the analysis in the Social Identity Theory. This approach sets to bridge the gap between the corporate projected external brand equity and the employees' internal brand perceptions.

Social Identity Theory (SIT) (Tajfel et al., 1971), and the following Self-Categorization Theory (SCT) (Tajfel et al., 2001) state that people tend to categorize others, identify in internal groups ("in-groups"), even when groups are formed for completely trivial reasons, and discriminate against the external groups ("out-groups"). In-group members tend to apply cognitive mechanics to "depersonalize" their identities and adopt group norms (Turner, 1987). Moreover, in-group members desire their groups to perform better that the out-groups boosting their individual self-esteem, even if this implies that in-group members will take less for themselves in absolute terms (Abrams & Hogg, 2006).

This research seeks to examine how corporate employees evaluate the values conveyed through sponsorships and partnerships with non-profit organizations and the extent to which they internalize, or fail to internalize, these values as components of the broader corporate identity. Within a Social Identity framework, it is investigated how partnership values are incorporated into the broader corporate identity (the "in-group" identity) and how employees come to perceive themselves as members of this in-group.

Social Identity Theory has been extensively applied across a wide range of research topics on charity organizations, with numerous articles that employ the framework in various contexts, for example, organizational support and volunteering (Traeger et al., 2023), stakeholders' responses to major nonprofit crises (Ma, 2023), barriers to informal caregiving among older people (Pettigrew et al., 2019), and issues related to women's and girls' advocacy (Dale et al., 2018). However, despite these several applications, a review of the current literature shows that the SIT theory has not yet been integrated in the field of internal marketing. There are no major studies that explore the reactions of corporate employees to nonprofit sponsorships and partnerships.

Moreover, the concept of internal marketing has not been applied to understanding employees' attitudes and responses toward collaborations with nonprofit organizations. In contrast, internal marketing theories have been used to study volunteer dynamics in nonprofits, who are essential resources for these organizations. Specifically, the Employee Brand Equity (EBE) models have been adapted to examine the role that volunteers play in shaping nonprofit brand equity (Nogueira et al., 2020). Internal marketing applications are positively linked to volunteers' supportive behaviors toward a nonprofit. The relationship with the organization is mediated by volunteer satisfaction and their organizational identification (Gross & Rottler, 2019). In addition, it is explored how collaborations with for-profit organizations can encourage nonprofits to adopt internal marketing practices and how these practices may influence overall nonprofit performance (Álvarez-González et al., 2017). In conclusion, internal marketing practices are recommended for nonprofits to improve managerial effectiveness and knowledge sharing, however, duplicating corporate internal strategies may be challenging in unique nonprofit environments, and value propositions for internal marketing must be carefully evaluated (Hume & Hume, 2015).

Purpose of the paper. The primary objective of this research is to investigate how partnerships with nonprofit organizations influence Organizational Identification (OI) among employees through the conceptual foundations of Social Identity Theory (SIT) and Self-Categorization Theory (SCT). When a company contributes to and engages in a partnership

with a nonprofit organization, the nonprofit's symbolic attributes, in detail, its mission, values, and social impact, can be transmitted to the corporate external brand equity through the external halo effect. Within this context, OI measures the degree by which corporate employees identify with the values of the nonprofit and consequently with the broader corporate organizational identity of their employer. Therefore, OI provides a measure of how employees feel part of and internalize the nonprofit's value system as an element of their own organizational membership. Specifically, this paper aims to identify the internal marketing strategies that favor the employee value identification and minimize employee skepticism toward corporate/nonprofit collaboration. Internal marketing practices may play a critical role in shaping whether employees interpret a partnership as sincere and genuine or as superficial way to boost brand reputation.

Additionally, the paper plans to analyze to which extent the brand personality consistency between a corporation and a nonprofit affects the internal adoption of the partnership. The assumption here is that when the values of the two entities differ, employees are more likely to perceive that the collaboration is driven by strategic self-interest or promotional motives. In contrast, when the values show consistency, employees are more inclined to internalize the initiative as a true extension of the corporate ethical commitments.

In conclusion, this paper proposes a new strategic contribution to the field of corporate fundraising. In detail, it argues that nonprofit organizations may reinforce their value proposition to potential corporate donors by showing how sponsorships can generate an internal brand equity lift. Nonprofit may offer corporations a more compelling reason for long-term engagement because partnerships can be significant contributors to internal brand identification and higher employee morale.

To summarize, this paper aims to investigate:

1) How Organizational Identification (OI) is affected by partnerships with nonprofit organizations among corporate employees
2) How the level of brand personality consistency between a corporation and a nonprofit organization influences the internal adoption of the partnership
3) How the internal brand equity lift can serve as a new variable for nonprofits to include in their value proposition to corporate donors

Ultimately, this research tries to demonstrate that the strength of the employee-organization connection is not only determined by the financial relevance of a corporate donation but also by its genuineness and sincerity as well as the narrative of the partnership internal communication. The perceived authenticity of a corporation's social engagement, more than the quantitative scale of its contribution, is expected to shape employees' identification with the firm and reinforces their sense of belonging with its values.

Methodology. This research adopts a scenario-based experimental design (Lelo de Larrea, 2025; Werner & Muradova, 2022) to identify the causal effects of different nonprofit marketing strategies and communication approaches on employees' Organizational Identification (OI). Scenario experiments allow researchers to manipulate core independent variables and ensure a high degree of internal validity and control over extraneous factors.

In this study, participants will be randomly assigned to one partnership with nonprofit organizations, and subsequently one of three experimental conditions, each representing a distinct marketing communication style commonly employed by companies.

The empirical setting involves an Italian coffee roasting and processing company. The partnerships under investigation are established with two Italian nonprofit organizations. The first nonprofit focuses on sustainable coffee production and fair remuneration for local producers in developing countries, while the second nonprofit provides humanitarian aid, medical support, and emergency response in conflict-affected areas. Methodologically, the first partnership can be classified as a "high-fit" collaboration given its consistency with the company's brand identity and core operations, while the second partnership represents a "low-fit" condition, due to its peripheral connection with corporate brand identity and operational activities.

A sample of 600 employees will be recruited through an online panel provider. Eligibility criteria will include being currently employed full-time and being involved in office-based, administrative, and intellectual roles. Participants will first complete baseline socio-demographic questions, including, age, educational level, income, professional expertise, and more specific questions on their engagement with humanitarian activities, including, general interest in humanitarian issues and sectors, past donation or volunteering in non-profit organizations outside corporate partnerships, prior exposure and detailed knowledge to CSR or corporate-supported charitable initiatives.

At first, participants will be assigned to one of the partnership conditions. Following this initial allocation, they will then be exposed to one of the three experimentally manipulated communication scenarios:

Condition A – Transactional Frame: Participants will view a marketing message that emphasizes the tangible, economic, and Environmental, Social, and Governance (ESG)-related outcomes of charitable giving. The scenario highlights the specific monetary contribution, tax incentives, and reputational and sustainability benefits. This condition reflects a traditional transactional CSR approach.

Condition B – Transformational/Narrative Frame: Participants will read a message that emphasizes narrative storytelling, including beneficiary testimonials, long-term community outcomes, and the broader social impact of the nonprofit operations. This condition employs a transformational communication style that fosters emotional resonance and perceived significance of the sponsorship.

Condition C – Participatory Frame: Participants will be exposed to a message centered on employee involvement, such as volunteering opportunities, skill-based contributions, and co-creation of social initiatives. This condition tests the effects of a participatory approach on employee engagement and identification.

Manipulation checks will verify that participants perceived the intended message characteristics, e.g., transactional cues, narrative depth, opportunities for participation. Participants will then complete validated scales measuring Organizational Identification (OI), as well as potential co-variates such as perceived CSR authenticity and general attitudes toward corporate giving.

A multiple regression analysis will be accomplished using OI as the dependent variable to test the hypothesized relationships. Dummy coding will be used to represent the three experimental conditions, with the transactional condition designated as the reference group. The model incorporates two key predictors:

$OI=\beta0+\beta1(\text{Narrative Style})+\beta2\ (\text{Employee Participation})+\epsilon$

In this model, Narrative Style summarizes the extent to which the message relies on storytelling and transformational approach and should be the highest in Condition B, while Employee Participation reflects perceived opportunities for employees for active engagement in the partnership initiative and should be the highest in Condition C.

The OI should be significantly higher for the "high-fit" first group, where a perceived consistency between the corporate identity/values and the nonprofit's mission and operations is most relevant.

The regression model will allow to examine both the direct effects of message approaches and the potential mediating or moderating roles of brand fit and employee participation. Additional robustness checks will be implemented to ensure the reliability of results.

Results. At this stage of the study, the questionnaires are nearly fully completed, and only initial results are currently available.

Preliminary expectations suggest that employees will respond more positively to communication strategies that portray authenticity, emotional engagement, and a sense of individual relevance. Specifically, participants exposed to the Transformational/Narrative condition (Condition B) and the Participatory condition (Condition C) are expected to show significantly higher levels of Organizational Identification (OI) relative to those in the Transactional condition (Condition A). Purely instrumental, transactional messages, which focus on financial contributions or ESG compliance benefits, often fail to generate emotional engagement or a perception of shared purpose. Employees typically do not connect with the abstract notion of a monetary donation, but they rather connect with narratives of social impact and opportunities to contribute to social change. This phenomenon can be described as a sincerity premium, where employees interpret narrative or participatory approaches as more genuine, human, and consistent with real motivations. Under these conditions, identification processes are reinforced because the organization is perceived as acting out from a sincere commitment to society, rather than reputational management or institutional obligation.

Brand Fit is expected to have a moderating role in the intensity and direction of identity transfer. High-Fit partnerships offer a coherent organizational narrative that employees can easily integrate into their perception of the corporate identity. In these cases, consistency between the corporate competencies and values and the nonprofit's mission and operations facilitates a readier and faster internalization of the partnership as part of the real identity as an organization. Conversely, Low-Fit partnerships may cause identity friction, especially when the nonprofit's mission appears in contradiction with the company's industry or historical reputation. In such cases, employees may view the initiative as inconsistent or strategically opportunistic ("social washing"), which can weaken trust and reduce identification. Importantly, the negative effects of Low-Fit partnerships may be mitigated only when internal communication adopts radical transparency and openly acknowledges potential tensions rather than hiding them.

It is particularly relevant to examine how employees perceive the Low-Fit partnership under investigation in this study. The partnership is distant from the corporate brand core values, however, the nonprofit involved operates with reputable humanitarian goals and is active in highly sensitive conflict zones such as Syria, Iran, and Ukraine. These contexts are risky, politically delicate, and can cause reputational problems to the external brand image of the company. Therefore, the nonprofit humanitarian mission makes it more difficult for employees to attribute opportunistic motives to the partnership. In addition, the company sponsors a project located in a region from which the company buys a substantial amount of high-quality coffee beans and is likely to be a direct consequence of some employees directly experiencing the poor conditions of the region and encouraging the sponsorship. Therefore, employees are expected to perceive the tension with the brand identity less significantly, although, a moderating variable can be the detailed and long-term knowledge of the nonprofit operations and historical relationship with the company.

Moreover, it is interesting to investigate whether a deep involvement with nonprofit issues and sectors as well as previous donation and volunteer experience changes the perspective of the employees. Employees with high commitment to social causes may react more favorably to Transformational/Narrative condition (Condition B) and especially Participatory condition (Condition C), since these approaches resonate with their personalities and motivations. Nonetheless, a more profound familiarity with humanitarian dynamics may make these employees more aware of potential "social washing" and opportunistic behavior of humanitarian causes and increase the risk of skepticism and lack of trust.

In conclusion, the impact of the professional role in the company is difficult to be determined. Employees working in marketing and communication may question the authenticity of the partnerships because they are more aware of the strategic advantages that these types of sponsorships provide. Conversely, their deeper understanding of brand positioning

may convince them to perceive these partnerships as legitimate contributions to the broader social role of the company. In this perspective, these collaborations may be viewed as opportunities to achieve relevant marketing objectives while contributing to important social causes. In this way, marketing objectives can be reached benefitting external communities rather than spending marketing budgets in different communication strategies.

Research limitations. The main limitation of the study lies in the possibility that employees may feel pressured to report higher levels of compliance and support to the partnerships with the nonprofits. Before the survey, participants were assured that the responses would remain completely anonymous and would be processed exclusively by an external university researcher with no ties to the company. However, some employees may still have been skeptical and perceive their negative evaluations as a form of dissent toward top management's strategic decisions, potentially exposing them to criticism and not being viewed as team players.

Moreover, all respondents work within the coffee industry, whose brands may have distinctive brand personalities and unique marketing strategies. Hence, findings may be difficult to generalize, as companies in other sectors may operate under different strategic, cultural, and competitive priorities. A similar issue applies to the nonprofit organizations considered in this investigation, as only two causes were examined. Other typologies of humanitarian causes may generate completely different effects on corporate brand personality perceptions and employee preferences. Some nonprofits may work on more local initiatives or adopt more adversarial and controversial approaches, thus generating significant different reactions from respondents.

Another limitation of this research is that it evaluates employees' identification with the corporate brand at only one point of time. This does not consider that the corporate brands may evolve significantly if companies modify their business models, because of, for example, an adoption of a diversification strategy, or a merger and acquisition. In this case, the brand modifications may completely reshape the meaning of and the consistency with the nonprofit partnerships. A similar consideration applies to the nonprofit organizations involved. Nonprofits can also evolve their projects, strategic priorities, or communication over time, which can redesign the core nature of their mission. As their focus changes, the degree of compatibility or perceived authenticity in the partnership may also shift. As a consequence, respondents' reactions and identification levels may vary if the research was accomplished at a different stage in the lifecycle of either organization.

A further relevant limitation concerns the sample. The vast majority of respondents are Italian nationals and Italian speakers, as the survey was administered entirely in Italian. Social Identity Theory functions differently across cultural contexts, particularly for individualistic versus collectivistic cultures. Thus, findings based on an Italian sample may not perfectly reflect dynamics in countries with more collectivistic approaches or dissimilar social reference points, such as the Northern European countries or Eastern Asian societies. The application of these results to other cultural contexts may therefore be limited, and further research may consider diverse national samples.

In conclusion, this study is subject to the methodological limitations of the scenario-based experimental design. Indeed, participants respond to hypothetical situations that may lack the complexity, emotional depth, or social pressures of real-world decision-making. As a result, their reported intentions or attitudes may differ from actual behavior, reducing the validity and generalizability of the findings. Additionally, the relatively small sample size further restricts the generalizability of the research results beyond the study's specific context.

Managerial implications. The findings offer several actionable insights for organizational practitioners. First, internal communication strategies should switch from transactional, metric-reporting style to narrative-based communication. Rather than emphasizing the economic aspects of corporate donations, human resources and marketing managers should adopt a storytelling approach that highlights the specific mission and operations of nonprofit beneficiaries and the tangible social impact that these contributions created. Nonprofit field experts should be employed as the primary communicators through internal webinars or presentations to further enhance authenticity and employee engagement.

Secondly, companies should carefully develop opportunities for employees to actively engage with nonprofit partners. Companies may plan volunteering activities that are fully integrated into the standard work schedule, allocating for example 10 or 20% of professional time to provide support to a nonprofit's internal departments, or introduce donation matching programs for employee individual contributions, or redirecting the budget reserved for customary holiday gifts toward the partner organization. In addition, organizations should approach nonprofit collaborations with the framework of co-branding strategy, treating the nonprofit organization as a legitimate brand partner rather than a peripheral beneficiary. Internally distributed co-branded materials can serve as symbolic markers of identity that reinforce employees' sense of belonging to the internal brand equity.

Third, communication initiative should involve all the organizational levels. Companies should avoid restricting the perceived value of the nonprofit partnership to executive leadership and should design initiatives and messaging that reach the entire workforce, including those in operational or administrative roles. Expanding the internal audience ensures that the identity benefits of the partnership spread more evenly throughout the organization.

Nonprofit organizations can also obtain strategic insights from these findings. When negotiating with potential corporate sponsors, nonprofits should consider reframing their value proposition shifting the focus from external social impact toward internal brand benefits. If nonprofits show how sponsorships and partnerships can contribute to improved employee attitudes, stronger organizational identification, and even lower turnover outcome, they may increase the

perceived strategic significance of these collaborations for companies. In addition, nonprofits should emphasize that when employees choose to volunteer with nonprofits, they can achieve meaningful and productive experiences that can help them develop new expertise and professional skills which can then be brought back and internalized into the company.

Moreover, nonprofits should assist corporate sponsors by offering internal communication toolkits. In addition to logo or basic visual material, nonprofits should provide ready-to-use video content, internal personnel narratives and case studies, and tailored templates for internal communication channels. These resources can help firms communicate the partnership more effectively and strengthen the employee engagement and the perceived legitimacy of the collaboration.

Originality of the paper. This study offers several original contributions to the fields of CSR, internal marketing, and nonprofit–business relationships. Previous research has primarily investigated nonprofit affiliations as mechanisms for generating external halo effects, specifically, improvements in consumer perceptions, brand value, and market reputation. Conversely, this study focuses on the internal marketing benefits of these collaborations. It examines how employees process and internalize nonprofit associations, and challenges the established assumption that external CSR strategies naturally translate into internal organizational advantages. Therefore, this research introduces the concept of an internal brand equity lift, and frames nonprofit collaborations as potential agents of employees' organizational identification.

Second, the paper innovatively employs Social Identity Theory (SIT) and Self-Categorization Theory (SCT) within the specific framework of corporate–nonprofit partnerships. SIT and SCT are well-established in nonprofit research, in areas such as in volunteer management or stakeholder responses, however, they lack systematic integration into the study of internal marketing or employee perceptions and reactions to CSR partnerships. This new theoretical application shows how employees assess the consistency between corporate identity and nonprofit's missions and how this evaluative process shapes their perceived sense of belonging within the organization.

Third, the study offers interesting insights on the under-examined role of brand personality consistency between firms and nonprofit organizations. The empirical investigation on high-fit and low-fit partnerships demonstrates how the perceived consistency, or lack of, determines employee interpretations of authenticity, strategic motivation, and organizational sincerity.

Finally, this paper advances the corporate fundraising literature by suggesting that nonprofits can strategically position themselves not only as instruments of external social impact but also as contributors to firms' internal cultural connection. Nonprofit partnerships may reinforce employee morale and identification, hence, this study reshapes the value proposition of nonprofit organizations for internal marketing purposes in addition to external reputational strategies.

Tourism pressure and gastronomy: A comparison between Italy and Croatia[1]

FRANCESCA CHECCHINATO[2], VLADI FINOTTO[2],
CHRISTINE MAURACHER[2], ANICA DOBRAN ČERNJUL[3]

Abstract. *Gastronomy is widely recognized as a strategic resource in destination branding and tourism marketing. While existing research has mainly focused on how food influences tourists' motivations and experience, less attention has been paid to how tourism, in turn, reshapes local culinary systems and destination identities. This paper explores how tourism pressure affects gastronomic identity and the projected destination image from the perspective of local hosts.*

The study adopts a qualitative comparative approach, analyzing through 24 semi-structured interviews with chefs and restaurant owners, two Adriatic destinations characterized by different forms of tourism pressure: Venice (Italy), affected by overtourism, and Istria Region (Croatia), marked by strong seasonality and peak demand.

Findings reveal that tourism acts as both a direct and indirect driver of transformation. Directly, tourists' demand for standardized or iconic national dishes encourages menu homogenization and deviations from local traditions. Indirectly, structural constraints, such as limited availability of local ingredients, workforce erosion, and rising costs, further reshape restaurateurs' practices and identities. Nonetheless, some actors adopt resistance strategies, including market-based daily menus and collaborative networks promoting local sourcing or take the opportunity to innovate traditional dishes.

The study contributes to debates on destination identity and brand co-creation by highlighting tourists' ambivalent role in transforming local gastronomic identities.

Keywords: *tourism marketing; destination image; destination projected image; overtourism*

Framing of the research. *Gastronomy can contribute to the attractiveness of a destination, often captures tourists' attention, and diversifies tourism offerings. Thanks to its interaction with the tourism sector, it might help in the promotion of sustainable local economic development by mobilizing different professional communities and industries.*

Many Destination Management Organizations (DMOs) have increasingly positioned local food as a strategic destination attribute and a distinctive tourism resource (Dixit, 2020). However, tourists' perceptions and overall satisfaction are strongly influenced by how DMOs construct, communicate, and reinforce the culinary image of a place. Such an image is not shaped solely through promotional narratives, but also through actions and initiatives, including the organization of food-related festivals and events, and, more critically, through the everyday gastronomic offerings delivered by local operators, such as cafes, restaurants, and catering services. In this stance, these actors may be considered internal stakeholders whose offerings and communicative practices directly contribute to the projection and co-construction of destination image (Stoica et al., 2022).

Most of the research on food tourism investigates how traditional food and gastronomy influence tourists' motivation and destination experience (Su et al., 2020), consistently finding that food exerts a positive effect on both. Furthermore, positive gastronomic experiences have been shown to enhance tourists' intentions to revisit a destination (Choe & Kim, 2018; Gupta & Sajnani, 2019). A further strand of research examines the relationship between food tourism and destination image by exploring the gap between projected and perceived image, generally revealing a lack of alignment between the two: the image intentionally communicated by DMOs and stakeholders (projected image) tends to diverge from the image tourists actually form (perceived image) (Wacker & Groth, 2020).

Unlike other travel activities and attractions, gastronomy is available year-round. Gastronomy can contribute to a destination's positioning and can also be conceived as a driving force behind the revival of tourism in destinations that are struggling at a critical stage of the tourist-product life cycle (Kivela & Crotts, 2006). Traditional food and cuisine have been conceptualized as one of the elements contributing to destination brand image, which is the perception of a destination in terms of its qualities and associations, usually organized by tourists in meaningful ways and held in memory (Lai et al., 2019). In recent years, especially in localities pressed by overtourism, scholars have begun to investigate the topic by inverting the perspective and considering the impact of tourism on the development, preservation, or restructuring of cities' and regions' cultural heritage and its influence on specific cultural domains such as gastronomy (Ganzaroli, 2017). This argument stems from the fact that tourist hotspots are characterized by large numbers of culturally diverse visitors, who often prefer local dishes modified to suit their foreign tastes (Freire Varela, 2025; Şengül et al., 2024). At the same time, although tourists often dine out in search of new tastes and culinary experiences, they may

[3] Faculty of economics and tourism "Dr. Mijo Mirković", Pula University, Croatia

also encounter disappointment because some offerings are a parody of the culinary destination image, or what Finkelstein (1989) calls "manufactured images".

From a consumer perspective, food experience in a destination is composed of "what is served, where it is served, and how it is served" (Björk and Kauppinen-Räisänen, 2014), thus the role of restaurants and how they craft their offering are pivotal in affecting tourists' perceptions and satisfaction. When a restaurant operates in a tourist context, it potentially addresses a wide range of target segments, including residents, domestic visitors, international tourists, and tourists with specific needs or preferences. As highlighted by Ganzaroli et al., (2017; 2021) analyzing restaurants' reviews, products and services' quality tend to decline over time because of the standardization of the culinary offering and the fact that most tourists are not foodies.

Various streams of literature emphasized the self-reinforcing mechanism triggered by the touristification of cities: as an effect of increasing tourist flows, they witness the crowding out of non-touristic economic activities and gentrification. Gentrification and the general redefinition of the urban fabric of the city (e.g. residential buildings devoted to short-term rentals) to fit the archetype of the contemporary global tourist "magnet" are sustained by the parallel spread of restaurants and places devoted to food preparation and consumption. Some researchers explicitly designate such a phenomenon with the term "foodification" (e.g.: Bourlessas et al., 2022; Varela, 2025). Food and beverage activities and the surrounding public spaces become stages where food cultures are represented. Such representations entail complex interactions between authentic local food experiences, revisited and adapted ones, and globalised standards (e.g. food chains and local variants of hegemonic food formats). Moreover, a destination's foodification influences the surrounding food producing sectors: what a city or an area reclaims in turns of supply will channel the production choices of neighboring enterprises and value chains.

Thus, the impact of tourist pressure on the cities and restaurants' offering is already confirmed by the literature, but despite the relevance that food plays in travel-related decisions (European Travel Commission, 2024) and in shaping a destination's image (Gupta et al., 2024), little is known about how restaurants maintain their authenticity and adhere to local culinary traditions, contributing to the projected image of the destination, especially in destinations primarily known for other attractions and push factors (Antara & Prameswari, 2018).

The aim of this paper is to capture these interplays in destinations affected by (over)tourism and document how they unfold, with a particular focus on how the structure of global tourism induces transformations and evolutions of local food systems (distribution, retail and restaurants, production of food) and how these evolutions affect the local actors' self-perceived identity and thus the projected destination image.

Purpose of the paper. *Instead of analysing how food and gastronomy affect tourism perception and experience, the research presented in this paper moves from the opposite direction and delves into the role of tourism in affecting, shaping, and transforming a destination's culinary culture and identity, adopting the perspective of the host (Lai et al., 2019). In particular, our analysis considers how foodscapes –the physical, sociocultural and economic space in which people encounter meals and food–, culinary culture, identity, and gastronomy are more or less induced to transform as a result of tourists' requests and expectations. Much literature on the intersection between tourism and destinations' foodscapes (Björk & Kauppinen-Räisänen, 2019) has delved into the mechanisms according to which local food systems characterize destinations and contribute to their differentiation. Mass tourism, nonetheless, shows signs of reversal in the direction of such influence: the global structural characteristics of tourism address and influence the agency, and thus the identity, of destinations and their economic actors, including food producers and distributors. Touristification, in other words, might erode and transform local cultures, including those providing the frameworks on how specific economic activities (e.g. food production, restaurants) are interpreted and performed, transforming their nature and redefining professional identities, material and entrepreneurial cultures (Cheer et al., 2019). In this paper's parlance, thus, we are interested in shedding light on an under-investigated topic in previous research: are chefs, food retailers, and ultimately local foodscapes influenced by the pressures and forces of global tourism? And despite the different conditions, what are the main challenges for restaurants in enhancing and protecting their gastronomy identity?*

Methodology. *Our selection of the field for the empirical work was guided by the search for theoretically significant contexts. First, we aimed at identifying critical case studies of destinations targeted by high touristic pressure. To be significant, each context had to be home for elaborate, history-laden, and widely recognized food traditions, cultures, and gastronomic identities. Thus, we searched for locales hosting thick culinary cultures, rich in gastronomic heritage, and distinguished by the production of various and heterogeneous typical products used in a variety of traditional dishes and recipes. Our search took into consideration the existence of codified or consolidated cooking techniques and cultures of eating. To grasp the main foundational elements of each region's culinary and food traditions' culture, we resorted to desk research on extant literature, books, and historical accounts. Then we turned to semi-structured interviews with chefs and restaurant owners to capture if and how they were aligned with these traditions and the underlying professional identities, if and how they detached themselves from "authentic" and orthodox interpretations of these traditions, and whether such deviations were due to factors we could connect with tourism. To compare different yet culturally related national contexts, we considered two contexts that are geographically close yet interested by tourism flows of different sizes, even if both remarkable: Venice in Italy and the Istria Region, in Croatia. The two areas have distinctive food cultures but their histories present some overlaps as the result of past political contingencies. Italy represents a particularly relevant context for the topics of this paper. Its strengths in the culinary field are widely acknowledged: in*

2025, Italian cuisine was recognized by UNESCO as Intangible Cultural Heritage, further legitimizing the country's traditional food culture and reinforcing its gastronomic image. Italy is celebrated for its diverse regional cuisines, high-quality wines, and artisanal products, supported by robust local supply chains that keep high-quality ingredients at the core of culinary practices. Despite these advantages, the sector also faces important challenges, particularly in highly touristic areas. Like Italy, each region of Croatia has its own special culinary recipes, ingredients and personality. In particular, Croatia is rich in natural, cultural, and historical heritage, and it represents a cross-cultural meeting place that has also been shaped by numerous nations that have left their mark on its culinary heritage.

Among these countries, we focus on destinations (a city and a region) where gastronomy is just one of the push factors contributing to the overall destination image, rather than the most important one. Within the Croatian tourism industry, Istria Region represents one of the most important tourist destinations (Krajnović et al. 2013), playing a strategic role in the national tourism economy and in the promotion of local cuisine. Venice, likewise, is a globally renowned tourist city with a strong but often not well-renowned culinary tradition. The two destinations share flavors, recipes, and food cultures shaped by a common Adriatic history.

The elaboration of the answers to our research questions relies on 24 semi-structured interviews conducted between July and December 2024 with chefs and restaurateurs from the selected areas. Specifically, 12 interviews were carried out in 9 different towns of the Istria Region and 12 in the city of Venice (Table 1). The restaurants and taverns included in the study were selected with reference to the leading restaurant guides and rankings featured on official tourism websites for both destinations. This sampling approach was complemented by the analysis of secondary sources, including social media pages and websites of additional establishments cited in such guides and rankings but not directly interviewed, to broaden the contextual understanding of each destination's food scene.

Results. *The findings confirm that touristic pressure has significantly influenced the gastronomic offering and, consequently, the image projected by local restaurants. In particular, this pressure has made it increasingly challenging for them to preserve a clear and coherent culinary identity. One of the main reasons lies in the multiplicity of tourists and culinary cultures converging in the destination. On the one hand, such diversity generates demand for simpler, more international and standardized dishes; on the other, it makes it more difficult to identify and attract those visitors who might be genuinely interested in discovering the local cuisine. Several Venetian restaurateurs emphasized that customers' requests are often oriented towards the most famous dishes of national Italian cuisine rather than local Venetian staples, without considering seasonality, nor considering the origin of ingredients: "They ask us caprese, in January". Even those who initially sought to avoid offering the most iconic dishes of Italian cuisine, reported having gradually given in to market pressure. Some restaurateurs justify this choice as a matter of customer service "if they ask me for an Italian dish and I can prepare it, I satisfy the request". The posture that emerges is one where this concession is framed as an additional service rather than a deliberate shift away from culinary identity. Others acknowledge having made compromises due to the overwhelming frequency of such requests, not to provide a service but to follow the (mass)demand. At the same time, another attitude emerging from the fields is one where actors adopt a more resistant*

stance aimed at preserving a clear culinary identity. This second group of operators asserts that "if customers are not interested in the local cuisine, they are free to dine elsewhere". This attitude is more evident in Venice than in the Istria Region, where foreign requests represent an opportunity too. In fact, a further strategy observed among restaurateurs involves adapting the culinary offer to meet the evolving expectations of tourists from different cultural backgrounds. Rather than preserving tradition in a static form, some operators embrace innovation as a means of broadening their appeal, introducing, as one Istrian restaurateur described it, "modern twists on traditional dishes for new audiences". This approach reflects a deliberate balance between cultural authenticity and contemporary relevance, allowing establishments to remain competitive without renouncing their gastronomic identity.

The evolution and transformation of local cultures and identities might not just be dictated by framings of different actors, but also by structural characteristics of the local foodscape and mismatches between the size of touristic demand and the local endowment of food and availability of products. When it comes to tourism, the issue becomes particularly relevant. While some actors aim to promote local cuisine, the limited availability of certain local ingredients—especially during peak tourist season in Istria and, more persistently, in Venice—leads them to deviate from a commitment to local authenticity. Although the two geographical areas are characterized by different conditions (overtourism versus strong seasonality and peak demand), the lack of ingredients affects the culinary identity, even if some restaurants try to resist. In Venice, some restaurants seek to preserve local culinary traditions by focusing on a "menu of the day," offering dishes based on what is available at the fish and vegetable markets each morning. Similarly, one of the observed restaurants in Istria has adopted a "from the sea to the table" approach as its core strategy. In this case, the menu is created daily according to what fishermen bring in with their nets that very morning. Rather than providing a printed menu, the staff presents the evening's selection of dishes orally, as the catch of the day determines each course. A challenge for these restaurants lies in differentiating themselves within a highly competitive and crowded hospitality landscape. One strategy through which restaurateurs simultaneously embody and communicate authenticity involves the development of labels and brands explicitly linked to local ingredients and traditional food practices. Such initiatives are perceived as opportunities to reinforce the authenticity of the offer while enhancing the visibility of local products. In Venice, for instance, a notable example is the network Osti in Orto, a farm-to-table initiative established by 13 restaurateurs, whose logo appears on the menus, signaling their shared commitment to locally sourced ingredients and seasonal produce.

Both in Venice and Istria, some restaurateurs reported that they are not sufficiently supported by DMOs in promoting traditional and local dishes, nor are they adequately protected from mass, low-quality foodservice, which often relies on pre-cooked meals and appears indistinguishable from the outside creating a"mismatch between quality and price" as some interviewees in Istria highlighted. There is a need for stronger coordination between local hosts, who concretely shape the destination experience through their activities and culinary practices, and DMOs, which are responsible for ensuring coherence, strategic direction, and visibility. One interviewee in the Istria Region pointed to the limited international recognition of the destination, suggesting that greater visibility could support the development of its gastronomic heritage. At the same time, another one stated that he benefited from operating in a place "positioning also as a gastronomic destination". By contrast, several Venetian interviewees described tourism as a potential threat to local gastronomy, as visitors are more likely to request generic "Italian" dishes rather than traditional Venetian cuisine that are not promoted by the DMO. From these emerging findings, we can conclude that destination international recognition is not enough to help develop the gastronomic heritage if there is no support from the DMO.

An additional critical aspect concerns the erosion of the professional workforce in both the kitchen and the dining room. Rising living costs driven by tourism make it difficult for qualified workers to afford to live in the city, and for those who can, their quality of life is reduced. As a result, non-professional staff is increasingly employed in both back and front-desk roles. This leads to a loss of storytelling and advisory competencies that are crucial to enhancing the dining experience. The findings are particularly relevant when considering the established role of sales personnel in shaping customer decisions. Retail salespeople, as the final point of contact before a purchase decision, play a crucial role in linking the store with customers by providing information and services that support customers' problem-solving processes (Ma & Kim, 2022). This dynamic is highly transferable to the restaurant context. Moreover, compared to home consumption, restaurant settings foster greater openness to wine exploration, with variety-seeking behavior being more likely to emerge when waitstaff are able to effectively guide consumers' choices (Dodd et al., 2005). It follows that a decline in professional service competencies deprives the establishment of a key mechanism through which it can influence decision-making, enhance perceived value, and differentiate the overall dining experience. This challenge is not yet solved by any of the interviews.

To conclude, our findings shed light on the intersection between how tourists develop the image of local food (Björk & Kauppinen-Räisänen, 2014; Aaltojärvi et al., 2018) and how restaurateurs craft their identity which is not only a matter of food, but a combination of tradition, place, and people. Based on these preliminary data, we can confirm that global tourism induces transformations and evolutions of local actors' self-perceived identity and thus the projected destination image. Although the two contexts present different structural conditions, several challenges are shared. In particular, the intense inflow of tourists can exert both economic and cultural pressure on the local culinary supply, prompting operators to adapt their offerings to the predominant tastes of tourists and thus changing the projected image of the gastronomy associations in the destination. Moreover, findings confirm that the true meaning of local gastronomy quality is embedded in subtle differences that are hardly visible to visitors and tourists, but self-evident to locals and hosts (Russo, 2001; Checchinato et al., 2025). In a city like Venice, where tourists constitute the primary target for a large share of bars and restaurants, operators may reduce the quality of their products while maintaining market share

(Russo, 2001), as visiting consumers lack the familiarity required to detect such deterioration. In the absence of coordinated action by restaurants, agrifood firms and DMOs to preserve local ingredients, recipes, and culinary traditions — and to communicate their value effectively — opportunistic behaviors are likely to prevail. This is particularly critical given that the destination's gastronomic image is not an intrinsic property of the place, but a socially constructed outcome of its operators' choices: as the composition and orientation of the local food supply changes, so too does the projected image of the destination. Crucially, individual operators cannot be assumed to be inherently committed to safeguarding culinary heritage, especially when short-term market incentives point in the opposite direction.

Research limitations. *An important limitation of this research concerns its generalizability. The findings are based on only two specific contexts and therefore reflect the socio-cultural and culinary characteristics of these settings. The results cannot be readily extended to other countries, particularly those with very different culinary traditions and restaurant cultures. Further studies in more diverse contexts — encompassing both high tourism pressure cities and micro-destinations such as mountain areas — are needed to assess the transferability of these findings and identify potential differences. In addition, it would be useful to address this topic using alternative methods, such as network analysis, or adopting a different level of analysis, for example, that of DMOs, to better understand the relationships among local actors and how the issue is being tackled at a central level.*

Managerial implications. *While restaurateurs and other local actors actively produce and embody the gastronomic culture of a place, their efforts risk remaining fragmented if not supported by a broader destination strategy. From a marketing perspective, this challenge calls for strong and coordinated communication, both at the level of the individual restaurant and at the collective level of destination branding. In particular, collaborations among restaurant owners, chefs, and gastronomy professionals — together with local institutions — could lay the groundwork for a shared positioning strategy, identifying the recipes, ingredients, and elements of gastronomic hospitality around which the destination seeks to be recognised. Only once such a positioning is collectively defined, targeted communication efforts can be developed, aimed at educating international tourists and introducing them to the specificities of the local cuisine and foodscapes.*

In destinations where food is not the primary reason to visit, tourists are often less interested in traditional gastronomy and more attracted to standardized or "safe" consumption options (e.g., tourist menus or generic dishes rather than local specialties). The high tourist demand may therefore encourage processes of homogenization in the gastronomic offer, rather than preserving local cultural and culinary specificity. This homogenization can be further exacerbated by structural factors such as the limited availability of typical products in the local market, rising procurement and commercial costs, and competition for scarce resources (e.g., seasonal ingredients and skilled labor). In this context, standardization becomes a strategic response to market logics rather than the outcome of a shared choice.

From this perspective, several strategies emerge as potential solutions to mitigate these dynamics. First, organizing gastronomic events during the low season could help attract tourist segments that are more oriented towards cultural experiences, and strengthen the link between local products and territorial identity. Second, the creation of structured networks among producers, restaurateurs, and tourism operators can foster collaborative relationships that support the supply of typical products, facilitate knowledge sharing, and promote offerings that are more consistent with local traditions. Finally, the development of consumer education or tasting initiatives and gastronomic storytelling - that is, narrating the cultural, historical, and productive context behind each dish - can enhance perceptions of authenticity and valorize the specific identity of destinations, moving beyond the mere satisfaction of functional needs.

Originality of the paper. *This research aims at analysing how the gastronomy destination identity is constructed and then projected, taking the perspective of the host (Lai et al., 2019) and considering the role of tourists as one of the stakeholders involved in the creation of the destination identity. Our paper contributes to the debate about the meanings associated with stakeholders' involvement, brand co-creation and its benefits in the destination identity (Stoica et al. 2022) not only considering the restaurant's point of view, but analyzing how other external stakeholders - tourists - affect a destination's offering and its projected image.*

Our findings depict a situation in which, under conditions of high tourism pressure, tourists become co-creators of gastronomic identity in both direct and indirect ways. Directly, their demands contribute to reshaping local restaurants' strategies — in terms of menu composition and differentiation — and the products they offer, most notably through the progressive standardization of dishes. Indirectly, tourism pressure reduces the availability of local ingredients, thereby undermining the authenticity of the gastronomic offer, while simultaneously generating bottlenecks in the skilled workforce and accelerating residential displacement. This last dynamic is particularly consequential: residents are not passive bystanders in this process, but active bearers of culinary memory and practice whose continued presence would sustain local food culture, anchor local demand, and exert an implicit pressure on restaurateurs to maintain authentic offerings and practices. When tourism pressure displaces them, it does not merely alter the social fabric of the destination, it systematically erodes the very custodians of gastronomic identity, accelerating an irreversible drift toward cultural homogenisation and the loss of the culinary traditions that once defined the place.

When Gender Meets Super-Expertise: Perceptual Bias and Behavioral Effects in AI–Human Hybrid Recommendations

MARCO FRANCESCO MAZZÙ[1], LORENZO RICCIARDI[1], MATTEO DE ANGELIS[1]

Abstract. *Consumers increasingly rely on algorithmic and human recommendations to navigate complex purchase decisions, yet research has predominantly examined either human or AI recommendation sources in isolation. This study focuses on AI–human hybrid recommendation systems, in which algorithmic outputs are combined with human expertise. Specifically, it examines whether recommender gender and expertise level jointly shape consumer perceptions and behavioral responses. Using a 2 × 2 between-subjects experiment (N = 169), participants evaluated an AI–human hybrid recommendation for a virtual reality headset. Gender was treated as a social cue and expertise as a boundary condition. Results show a differentiated pattern across expertise conditions. When the recommender is described as an expert, perceived transparency does not differ significantly between male and female recommenders. When the recommender is described as a super-expert, the female recommender is perceived as more transparent than the male recommender. In addition, perceived transparency was negatively associated with purchase intention, indicating that greater informational openness may activate caution rather than commitment in high-technology experience contexts. The paper provides preliminary evidence relevant to the debate on AI–human hybrid systems, suggesting that gender and expertise may function as joint determinants of perceived transparency, and offering initial insights into the conditions under which social identity cues shape consumer responses within algorithmic recommendation environments.*
Keywords: *Product recommendations; Artificial Intelligence; AI–human hybrid systems; Expertise signaling; Gender bias; Experience goods; Behavioral decision-making.*

Framing of the research.

AI-assisted recommendations in experience-based, high-technology contexts. *AI-assisted recommendation systems are increasingly designed as hybrid configurations, in which algorithmic outputs are combined with human expertise to guide consumer decisions (Puntoni et al., 2021; Mazzù et al., 2025). Examples of these configurations include e-commerce platforms that combine algorithmic product recommendations with advice from certified specialists, or retail interfaces that integrate AI-generated suggestions with human advisors presented as industry experts. This design logic rests on the assumption that human cues — such as credentialed expertise and recognizable identity — can enhance the legitimacy of algorithmic advice and reduce the uncertainty consumers face when evaluating complex or unfamiliar products. Yet the conditions under which human source characteristics shape how hybrid recommendations are perceived and acted upon remain poorly understood.*

Existing research has primarily compared human and AI recommendation sources, while largely overlooking how identity cues embedded in the human component of hybrid systems influence consumer evaluations. Do social identity cues such as gender influence how transparent an AI–human recommendation system is perceived to be? Does this effect depend on the level of expertise attributed to the human recommender? And does any perceptual influence translate into purchase intention? These questions are especially relevant for experience-based, high-technology products, where objective pre-purchase evaluation is limited and consumers must rely heavily on external signals to guide economically consequential decisions.

In hybrid environments, the distinction between AI-generated and human-provided advice is increasingly blurred. Algorithmic systems supply analytical depth and scale; human experts provide contextual framing, legitimacy, and socio-emotional resonance (Puntoni et al., 2021; De Cicco et al., 2025). Prior work has established that recommendation source type shapes consumer reactions (Mazzù et al., 2024), but substantially less attention has been devoted to the identity characteristics of the human component embedded within hybrid systems. In high-technology experience contexts, where product quality cannot be fully assessed before purchase (Nelson, 1970) and financial stakes are salient, the characteristics of the human source — including their perceived expertise and their gender — may function as diagnostic cues that shape how the entire recommendation system is evaluated. Specifically, such cues may influence perceived transparency (Mazzù et al., 2023), defined here as perceived informational openness — the extent to which the recommendation is seen as providing clear, accessible, and candid product information — rather than algorithmic transparency concerning how the AI system operates.

This paper examines precisely this question. Focusing on gender as a social cue and expertise level as a boundary condition, we test whether their interaction shapes perceived transparency of an AI-human hybrid recommendation and whether perceived transparency, in turn, predicts purchase intention. The study extends prior work on source effects in recommendation systems (Baccelloni et al., 2025a) by moving beyond binary human-vs-AI comparisons to examine how the identity characteristics of the human component moderate perceptual evaluations within a constant AI-supported framework. By doing so, it addresses a gap in research that has predominantly focused on attitudinal outcomes while

[1] LUISS Business School, Via Nomentana 216, 00162 Roma, LUISS Guido Carli University, Department of Business and Management, Viale Romania 32, 00197 Roma, Italia

leaving the process mechanisms and behavioral consequences of human source cues in hybrid AI environments underexplored.

Gender and perceptual legitimacy in AI-assisted high-technology contexts. *Gender is among the most pervasive social categorization cues in interpersonal and mediated communication (Eagly & Karau, 2002). In source evaluation contexts, gender operates not as an explicit evaluative criterion but as an implicit heuristic that activates gender-role expectations and stereotypic associations. In domains stereotypically linked to technical authority — such as engineering, computing, and high-technology consumption — these associations often favor male sources. When a recommendation is presented by a male versus female expert, consumers may draw on gendered competence schemas to interpret the information (Kim et al., 2024; Calluso et al., 2025).*

Research on gender and expertise evaluations consistently shows that the influence of gender depends on contextual moderators, including task type and perceived congruence between the domain and gender-role expectations (Calluso et al., 2025; Eagly & Karau, 2002). In technology-related contexts, male sources are generally perceived as more congruent with the domain, which may lead female sources — particularly those positioned at high levels of authority — to face evaluative penalties linked to expectancy violation (Rudman & Glick, 2001). Importantly, this effect is most likely to emerge when the recommender's identity is made salient — as occurs when expertise is strongly signaled. At the same time, expectancy violations may also produce the opposite effect. When individuals occupy positions that contradict stereotypical expectations, their behavior and communication style may be evaluated more carefully and perceived as more deliberate and informative. In such cases, a female recommender presented as a super-expert may be perceived as providing more transparent and detailed information precisely because her authority signals exceptional competence within a domain where expectations are typically male-oriented. In conditions of lower expertise, when identity cues are less diagnostic, gender effects on perceptual evaluations may be suppressed or absent.

While prior work has examined gender effects on trust and credibility perceptions in advisory contexts, less attention has been devoted to how gender shapes perceived transparency — an evaluative dimension particularly relevant to AI-assisted settings, where consumers assess the extent to which the recommendation provides clear guidance. Perceived transparency in hybrid recommendation systems is not simply a property of the algorithmic component; it is also colored by the identity of the human source through whom the recommendation is communicated. If a female super-expert is perceived as occupying a role at odds with domain expectations, the informational openness of the entire recommendation may be interpreted more carefully, even when the content of the advice is identical.

A further consideration concerns the link between perceived transparency and purchase behavior. In high-technology, experience-based contexts, greater informational openness does not necessarily translate into greater commitment. On the contrary, detailed disclosure of product complexity and limitations may increase consumers' awareness of risk and uncertainty, leading to more cautious allocation decisions (Schilke & Reimann, 2025). This "transparency caution" mechanism provides an important theoretical complement to the perceptual effects of source cues: even if gender and expertise shape how transparent the recommendation is perceived to be, the downstream behavioral consequence of transparency may reflect risk activation rather than trust formation.

Expertise as a legitimacy cue and boundary condition under uncertainty. *A foundational insight from source credibility research is that, when consumers cannot directly evaluate the quality of information, they rely on source characteristics as proxies for reliability and relevance (Hovland et al., 1953; Chaiken, 1980; Pornpitakpan, 2004). Expertise — the degree of domain-relevant knowledge and experience attributed to a source — is among the most consistently studied of these cues. In complex, technically sophisticated product categories, high expertise is generally associated with greater persuasiveness and stronger recommendation uptake (Donovan et al., 2024). Expertise signals not only technical competence but also normative authority, indicating that the recommender is institutionally qualified to guide decisions under uncertainty (Wiener & Mowen, 1986; Pornpitakpan, 2004).*

In AI-assisted recommendation environments, the authority function of expertise becomes particularly salient. When consumers encounter an AI-human hybrid system, the presence of a credentialed human expert may serve as a signal of informational legitimacy — not merely of the human's personal knowledge, but of the entire recommendation configuration. This is consistent with dual-process accounts, which suggest that source cues become especially influential under conditions of uncertainty or when cognitive elaboration is constrained, leading consumers to rely on heuristic processing rather than systematic evaluation (Petty & Cacioppo, 1986). Empirical research in AI-assisted retail contexts extends this principle, showing that expertise-related cues modulate how recommendation systems are evaluated as a whole, with higher expertise signals increasing the perceived authority of the overall human-algorithm configuration (Chinchanachokchai et al., 2021). For high-technology experience products, where most consumers lack the domain expertise to independently assess recommendation quality, the perceived authority of the human source may thus shape how the system as a whole is evaluated.

Importantly, elevated expertise may also amplify the diagnostic value of other source characteristics. When a recommender is perceived as a routine expert, consumers may focus primarily on the informational content of the recommendation. When the recommender is positioned as an outstanding authority — for instance, through extensive experience, certifications, and institutional recognition — the identity of the source itself becomes more salient. Under these conditions, expertise functions not only as a direct credibility cue but as a boundary condition that modulates how additional characteristics, including gender, are interpreted and weighed. This amplification logic suggests that the effect

of gender on perceptual evaluations may emerge specifically in high-expertise conditions, where the recommender's identity is most foregrounded.

This perspective treats expertise level as a structural feature of the recommendation environment rather than a simple additive predictor. Its relevance lies not in whether more expertise leads to better outcomes, but in whether it changes the interpretive context within which other cues — such as gender — operate. We accordingly treat expertise as a boundary condition in the analytical model.

Purpose of the paper. *This paper examines how human source cues embedded in AI-assisted recommendation systems shape consumer perceptions and purchase intention. Specifically, it investigates (i) whether recommender gender and expertise jointly influence perceived transparency in an AI–human hybrid recommendation, and (ii) whether perceived transparency, in turn, predicts purchase intention in a high-technology experience context. Gender is treated as a social cue, expertise as a boundary condition, perceived transparency as the focal perceptual outcome, and purchase intention as the downstream behavioral response. Rather than assuming a fully supported mediation chain, the study assesses whether social identity cues operate primarily at the perceptual stage and whether their effects extend downstream to behavioral outcomes. Based on the foregoing theoretical arguments, the following hypotheses are advanced:*

H1. The effect of recommender gender on perceived transparency of an AI-human hybrid recommendation is moderated by expertise level, such that gender differences in transparency perceptions are more pronounced when the recommender is described as a super-expert than when described as an expert.

H2. Perceived transparency of an AI-human hybrid recommendation negatively predicts purchase intention, such that higher levels of perceived transparency are associated with lower purchase intention toward the recommended product.

RQ (Exploratory). As an exploratory question, this study examines whether the indirect effect of recommender gender on purchase intention through perceived transparency differs as a function of expertise level (i.e., whether the conditional indirect effect is consistent with a moderated mediation pattern). Given the partial and marginal nature of the first-stage interaction (H1), no directional hypothesis is advanced regarding the full indirect path.

Methodology. *The study employed a 2 (human recommender gender: Female = 0 vs. Male = 1) × 2 (expertise level: expert = 0 vs. super-expert = 1) between-subjects experimental design within an AI-assisted recommendation context. Participants were randomly assigned to one of four conditions and exposed to an online shopping scenario involving a virtual reality (VR) headset, selected as a high-technology experience product characterized by high ex ante uncertainty. Across conditions, recommendations were consistently presented as AI-assisted, with an identifiable human expert integrated into the system; only the recommender's gender and level of expertise were manipulated. Expertise was manipulated by describing the recommender either as an industry expert or as a highly credentialed authority with over 30 years of experience, while all other elements of the stimulus (product information, layout, and wording) were held constant. As intended, the expertise manipulation was successful: participants in the super-expert condition perceived the recommender as significantly more expert than those in the expert condition, confirming the effectiveness of the manipulation (see Appendix).*

Descriptive statistics indicated that perceived transparency averaged 4.34 (SD = 1.36), and purchase intention equaled 2.01 (SD = .46). Recommender gender was approximately balanced across conditions (M = 0.51, SD = 0.50), as was expertise level (M = 0.51, SD = 0.50). Bivariate correlations revealed a negative association between perceived transparency and purchase intention (r = −.378). Gender and expertise level showed negligible correlations with purchase intention (r = .153 and r = −.001, respectively) and with each other (r = .065).

After exposure to the recommendation scenario, participants completed a behavioral allocation task in which they were asked to distribute a hypothetical budget of $499 — matching the price of the VR headset — across three mutually exclusive options: purchase the recommended product (fully following the recommendation), seek additional information (partial deferral), or retain the budget (full rejection of the recommendation). This three-option forced allocation design, scored on a 1–3 scale, was chosen as the primary dependent variable because it captures financial commitment as a consequential and mutually exclusive decision rather than as a self-reported attitude. Unlike intention scales, the budget allocation task imposes a concrete trade-off and thereby introduces behavioral realism into an experimental setting (Chandon et al., 2005). The task is particularly appropriate for experience products involving financial risk, where the willingness to allocate real resources constitutes a meaningful proxy for downstream purchase behavior. Response distributions indicated that 10.1% of participants chose to purchase (option 1), 78.7% opted to seek additional information (option 2), and 11.2% retained the budget (option 3), confirming that the distribution across response categories, while concentrated on option 2, reflects a behaviorally coherent pattern in a high-uncertainty, high-involvement product context. While the compressed 1–3 range may reduce statistical sensitivity relative to continuous scales — a limitation acknowledged in the Research Limitations section — the forced-choice structure is theoretically justified by the discrete and mutually exclusive nature of the financial commitment it represents. Although the budget was hypothetical, prior research has shown that incentive-compatible framing of trade-off tasks elicits behaviorally consistent responses in experimental consumer research. Participants also completed self-reported measures of intention to follow the recommendation; results on this variable have been reported elsewhere (Mazzù et al., 2025) and serve here as a reference for situating the behavioral findings.

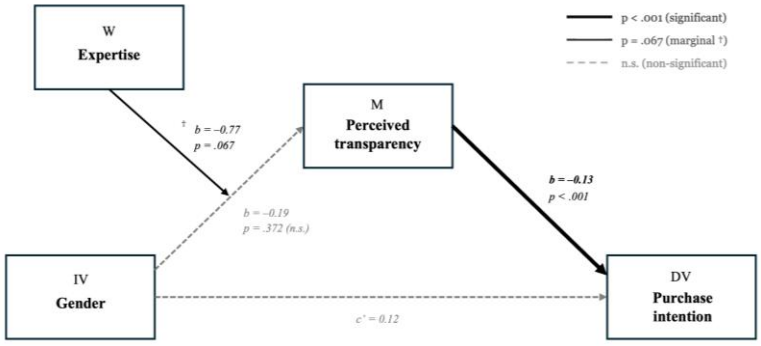
Additional perceptual measures assessed perceived transparency, credibility, warmth, competence, and gender fit using validated multi-item 7-point Likert-type scales adapted from prior research. Perceived transparency (5 items; e.g.,

"I believe the recommendation source will provide me with transparent product information") was operationalized as perceived informational openness — the extent to which the recommendation source was seen as providing clear, accessible, and in-depth product information — rather than procedural or algorithmic transparency per se, following Mazzù et al. (2023). Credibility was measured with 10 items assessing both trustworthiness (e.g., dependable, honest, reliable) and expertise (e.g., expert, knowledgeable, qualified) dimensions, adapted from Hovland et al. (1953) and Pornpitakpan (2004). Warmth and competence were each assessed with 3-item scales following established social perception research. Gender fit was assessed through two complementary 6-item scales capturing both general domain-gender congruence beliefs and the perceived suitability of the specific recommender for the product category. All scales were drawn from validated instruments. These measures were included to support the interpretation of behavioral outcomes; however, in line with the conditional process framework, perceived transparency was specified as the focal mediator in the analytical model.

*Data were collected via Prolific from a European sample. Of 224 initial respondents, 169 participants (aged 18–65) passed attention checks and were retained for analysis, yielding approximately 42 participants per cell. Participants were randomly assigned to one of the four experimental conditions. A post-hoc power analysis using G*Power (Faul et al., 2007) for a multiple regression model with three predictors and a medium effect size ($f^2 = .15$, $\alpha = .05$) indicated that a sample of 169 provides statistical power of approximately .90. For the moderated mediation pathway, in which effect sizes tend to be smaller, the present sample provides sufficient power for an initial test of the proposed framework, though future studies should employ larger samples to detect more distal conditional indirect effects with greater precision.*

Effects of the experimental manipulations were examined using Hayes' (2022) PROCESS macro for SPSS (Model 7), testing a first-stage moderated mediation model in which recommender gender predicted purchase intention indirectly through perceived transparency, conditional on expertise level. Interaction terms were computed directly from these coded variables. Indirect effects were estimated using 5,000 bootstrapped samples with 95% confidence intervals. All analyses were conducted using SPSS.

Results.



Interaction effects on perceived transparency. *The regression model predicting perceived transparency explained a modest portion of variance ($R^2 = .026$, $F(3,165) = 1.48$, $p = .221$). Neither the main effect of recommender gender ($b = -0.19$, $p = .372$) nor the main effect of expertise ($b = 0.12$, $p = .571$) was statistically significant. However, the interaction between gender and expertise was marginally significant ($b = -0.77$, $SE = .42$, $p = .067$), indicating that the effect of gender on perceived transparency depends on the level of expertise attributed to the recommender.*

Conditional effects analysis showed that when the recommender was portrayed as a super-expert, gender negatively predicted perceived transparency ($b = -0.56$, $p = .056$), whereas no significant gender effect emerged in the expert condition ($b = 0.21$, $p = .486$). This pattern indicates that gender differences in perceived transparency arise only when expertise is framed as particularly high. Specifically, in the expert condition male recommenders were perceived as slightly more transparent than female recommenders, whereas in the super-expert condition the opposite pattern emerged. Figure 1 illustrates this interaction.

The indirect effect of gender on purchase intention through perceived transparency was not statistically significant at either level of expertise. In the expert condition, the indirect effect was small and non-significant, and in the super-expert condition it was larger in magnitude but also non-significant (both 95% CIs included zero). Consistent with these results, the index of moderated mediation was not statistically significant (index = .097, 95% CI [−.008, .212]).

Overall, the results indicate that gender and expertise jointly influence early perceptual evaluations of transparency, but these perceptual differences do not translate into statistically reliable conditional indirect effects on purchase intention. The findings therefore provide partial support for the proposed interaction hypothesis, suggesting that expertise acts as a boundary condition shaping how gender cues are interpreted at the perceptual stage.

Figure 1. Moderated mediation model – estimated coefficients

Summary of results. *Overall, the results provide partial support for the proposed model. The interaction between gender and expertise on perceived transparency was marginally significant, with gender differences emerging only in the super-expert condition. Perceived transparency negatively predicted purchase intention, suggesting that greater informational openness may activate caution rather than commitment in a high-uncertainty technology context. The conditional indirect effects of gender on purchase intention through transparency were not statistically significant at either level of expertise, and the index of moderated mediation was likewise non-significant. Taken together, these findings suggest that human source cues in AI-assisted recommendation environments operate primarily at the early perceptual stage, with limited downstream effects on behavioral outcomes.*

Research limitations. *This study has several limitations that suggest directions for future research. First, the analysis focuses on a single high-technology, experience-based product category. Although a virtual reality headset is well suited to examining decision-making under uncertainty, future research should assess whether similar dynamics emerge across other experience goods and in mixed search–experience contexts. Second, the sample size is sufficient for detecting the focal direct effects but remains relatively limited for moderated mediation analysis, where interaction-based indirect effects tend to be small in magnitude and require larger samples to achieve adequate statistical power. The marginal significance of the first-stage interaction (p = .067) and the non-significant indirect effects may in part reflect this power constraint rather than a true absence of the hypothesized processes. Future research should therefore employ larger samples specifically designed to provide adequate power for detecting conditional indirect effects of the expected magnitude. Third, the study concentrates on gender and expertise as the focal human cues embedded within AI-assisted recommendations. Other characteristics—such as age, communication style, perceived similarity, or visual presentation—may shape consumer responses in different ways. Future studies should investigate how broader combinations of human attributes influence perceptual mechanisms in hybrid AI–human systems. Fourth, the dependent variable — a three-option forced allocation task scored on a 1–3 ordinal scale — while theoretically grounded in behavioral realism, imposes constraints on statistical sensitivity. The compressed response range may reduce variance and limit power to detect small conditional effects, particularly in the moderated mediation pathway. Future research might explore continuous allocation formats (e.g., percentage-based budget distribution from 0 to 100%) or multi-item behavioral indices to improve measurement resolution. Fifth, although the budget allocation task required participants to make a concrete and mutually exclusive monetary trade-off, it remained hypothetical. Research on hypothetical bias suggests that stated willingness to pay or act may diverge from actual behavior, particularly when financial stakes are salient (Chandon et al., 2005). Future research might employ incentive-compatible designs — such as bonus-conditional choice tasks on crowdsourcing platforms — or field experiments in partnership with retail operators. Finally, further theoretical work is needed to clarify the role of perceived transparency in high-uncertainty contexts. The present findings suggest that informational openness may not always facilitate commitment and, under some conditions, may instead activate caution. Future studies should examine more closely when transparency enhances trust and when it heightens perceived complexity or risk, thereby refining its role in AI-assisted decision environments.*

Managerial implications. *For managers, the findings suggest that evaluating AI-assisted recommendation systems solely through attitudinal metrics may provide an incomplete picture of system performance. Although the direct behavioral effects of recommender gender were limited, the results indicate that human cues can shape perceptual interpretations of transparency under specific expertise conditions. This highlights the importance of complementing attitudinal indicators with behavioral metrics when assessing the effectiveness of hybrid AI–human recommendation systems. The findings also indicate that integrating highly credentialed human experts into AI-supported interfaces is not a neutral design choice. Elevated expertise increases the salience of the recommender's identity, which may activate gender-related interpretive biases in technology-related contexts. Managers should therefore consider not only the credentials they communicate, but also how the identity of the human recommender interacts with expertise framing in shaping users' early evaluations of the system.*

In addition, the negative association between perceived transparency and purchase intention suggests that informational openness does not always function as a straightforward conversion mechanism. In high-technology, experience-based contexts, detailed disclosure may increase awareness of product complexity and uncertainty. Managers should therefore carefully consider how and when transparency-related information is presented along the customer journey.

For platform designers, the way human experts are visually and descriptively integrated into AI-supported interfaces may influence how the recommendation system as a whole is interpreted by users. Interface elements such as displayed credentials, biographies, or authority signals can increase the salience of identity cues and shape how recommendations are evaluated.

Finally, the results highlight the importance of the moment of financial commitment within AI-assisted customer journeys. Interface design efforts aimed at supporting clarity, reducing cognitive overload, and managing perceived uncertainty at the point of action may be more consequential than further optimizing upstream trust perceptions alone.

Originality of the paper. *This study contributes to research on AI-human hybrid recommendation systems by examining whether social identity cues embedded in the human component of such systems influence early-stage perceptual evaluations and whether these evaluations relate to purchase intention. The results provide partial evidence that gender*

differences in perceived transparency emerge when the human recommender holds a very high level of signaled expertise — a finding consistent with the view that elevated authority amplifies the salience of identity-related cues in uncertain, high-technology evaluation contexts. Theoretically, the study contributes at the intersection of expectancy violation theory (Rudman & Glick, 2001) and source credibility research (Hovland et al., 1953; Pornpitakpan, 2004) by showing that the evaluative consequences of role-incongruent identity cues are not uniform but are contingent on the intensity of authority signaling. In particular, the finding that a female super-expert — rather than a standard expert — elicits higher perceived transparency aligns with expectancy violation accounts: when a communicator occupies a role that defies stereotypical expectations and does so at an especially high level of authority, the resulting incongruence may focus evaluative attention on the informational content rather than activating backlash. This mechanism extends prior work by specifying expertise level as the structural condition under which gender-based expectancy violations shift from producing evaluative penalties to producing perceptual amplification. Furthermore, by connecting this perceptual amplification to a "transparency caution" effect on purchase behavior — consistent with Schilke and Reimann's (2025) transparency dilemma framework — the paper integrates source credibility, social identity, and behavioral decision-making literatures within a unified process model of hybrid AI–human recommendation influence.

Perceived transparency negatively predicted purchase intention, suggesting that informational openness may activate risk awareness rather than facilitate commitment in technology-uncertainty contexts — a finding that qualifies commonly held assumptions about transparency as a uniformly trust-enhancing mechanism. The conditional indirect effects linking gender to purchase intention through transparency were not statistically significant, which the study interprets as evidence of attenuation along the causal chain rather than as disconfirmation of the perceptual-stage effects.

More broadly, the study contributes to a process-oriented understanding of AI-human hybrid influence in digital retail by clarifying the scope and limits of human source cues within recommendation environments. The results indicate that social identity signals may shape perceptual stage evaluations even within algorithmic systems, but that their downstream behavioral consequences are more limited and context-dependent than prior attitudinal research might suggest. This boundary-condition perspective offers a grounded basis for further research on when and how hybrid AI-human designs translate source characteristics into consumer behavior.

In sum, the paper offers a calibrated account of hybrid recommendation influence: human source characteristics can shape how algorithmic advice is perceptually interpreted, but this influence may attenuate before reaching economically consequential outcomes. Transparently reporting where the evidence is strong and where it remains partial represents, in itself, a contribution to the growing body of research seeking to understand the conditions under which hybrid AI-human systems exert behavioral effects on consumers.

When the Community Speaks: Generational Differences in the Effectiveness of Brand versus User-Generated Content in the Digital Beauty Market

ANNUNZIATA TARULLI[1], DOMENICO MORRONE[2], MIRIAM MASELLIS[3]

Abstract. *The growing diffusion of social media has profoundly reshaped brand communication, shifting the creation of brand meaning from firm-controlled messages to participatory digital environments in which consumers actively contribute to brand narratives. In this context, User-Generated Content (UGC) has emerged as a powerful mechanism influencing trust formation, engagement, and purchase intention. Nevertheless, despite its increasing strategic importance, empirical evidence comparing the effectiveness of UGC and brand-generated content across generational cohorts remains limited, particularly within specific industry contexts. This study addresses this gap by examining whether UGC is more effective than brand-generated content in shaping consumer perceptions and purchase intentions in the cosmetic sector, and by analysing how these effects vary across generations. Building on community marketing and participatory brand communication theories, the research develops an empirical framework to investigate consumer responses to different forms of digital communication. Data were collected through an online survey distributed among consumers belonging to four generational cohorts: Baby Boomers, Generation X, Millennials, and Generation Z. Exploratory Factor Analysis was applied to identify latent dimensions associated with trust, engagement, and purchase intention in relation to both UGC and brand-generated content. The results indicate that UGC significantly enhances perceived credibility and engagement among younger generations, particularly Generation Z and Millennials, whereas brand-generated content maintains relatively greater influence among older cohorts. As a result, the study contributes to the literature on digital branding and community marketing by providing empirical evidence on generational differences in content effectiveness and offering managerial insights for designing generationally differentiated digital communication strategies.*

Keywords: *User-Generated Content; Community Marketing; Generational Marketing; Gen Z; Digital Branding; Cosmetic Industry*

Framing of the research. *The rapid diffusion of digital platforms and social media has profoundly transformed the dynamics of marketing communication, progressively shifting the locus of brand meaning from firm-controlled messages to participatory environments in which consumers actively create, interpret, and circulate brand-related content (Kaplan & Haenlein, 2010; Kietzmann et al., 2011). Within these digital ecosystems, marketing communication increasingly takes place through interaction, dialogue, and content co-creation rather than through traditional top-down persuasion. This transformation has altered not only the channels through which brand messages circulate but also the underlying logic of persuasion itself. Consumers are no longer passive recipients of communication; rather, they participate in the symbolic construction of brands, influence reputational dynamics, and shape product evaluation through networked interactions and social validation processes (Hollebeek et al., 2019).*

In this context, User-Generated Content (UGC) has emerged as a central mechanism through which consumers exchange experiences, opinions, and evaluations of products and brands (Dennhardt, 2014). Compared with brand-generated communication, UGC is often perceived as more authentic, socially embedded, and trustworthy because it originates from peers rather than from corporate sources. Increasingly, digital consumer journeys are influenced by algorithmically curated environments in which peer-generated narratives coexist with brand messages, creating hybrid communication spaces where credibility is negotiated through social interaction and community endorsement. In such environments, UGC functions not only as complementary communication but also as a key informational resource that helps consumers reduce uncertainty and evaluate products more confidently. Prior research has shown that such peer-generated information significantly shapes consumer attitudes, trust formation, and purchase intentions, especially in digitally mediated settings characterised by information asymmetry and strong reliance on social proof (Cheong & Morrison, 2008; Mathur et al., 2022). The growing importance of electronic word-of-mouth (eWOM) further reinforces this dynamic. Online reviews, comments, and peer recommendations function as informational cues that guide consumers' evaluation of products and services, often exerting stronger influence on purchase decisions than traditional advertising messages (Ismagilova et al., 2021). Empirical studies confirm that eWOM credibility, source trustworthiness, and message quality significantly influence consumer attitudes, brand perceptions, and behavioural intentions across different digital contexts (Filieri et al., 2018).

The persuasive influence of UGC can also be interpreted through broader behavioural and motivational perspectives. Social learning mechanisms suggest that individuals form attitudes and behavioural intentions not only through direct

[3] LUM University, e-mail: m.masellis1@studenti.lum.it

experience but through the observation of others' evaluations and actions (Bandura, 2001). In digital environments, reviews, tutorials, testimonials, and peer commentary therefore operate as cues for behavioural modelling and risk reduction. In parallel, self-determination arguments explain why users actively produce and share content within digital communities when these environments enable them to express themselves, gain recognition, and relatedness (Deci & Ryan, 2000). In this sense, rather than being merely promotional artefacts, consumer-generated contents become a meaningful social signal that shape interpretation, trust, and participation.

These dynamics are closely related to the rise of community marketing. In contrast with traditional approaches centred on control and broadcasting, community marketing emphasises relational engagement, brand-consumer dialogue, and the co-creation of value inside online communities. In this perspective, brands act less as unilateral senders and more as facilitators of interaction, conversation, and shared meaning-making (Matute et al., 2021; Brand et al., 2025; Srivardhana & Boonchoo, 2025). Research on virtual brand communities shows that participation in these communities fosters consumer engagement, brand attachment, and advocacy behaviours, reinforcing the strategic relevance of community-based communication (Gilal et al., 2023).

Alongside peer-generated content, influencer marketing has also emerged as a key mechanism shaping contemporary digital communication strategies. Influencers act as intermediary communicators who combine elements of traditional endorsement and peer-to-peer communication, often enhancing message credibility through perceived authenticity and relational proximity with followers (Lou & Yuan, 2019). Recent research suggests that influencer credibility, perceived authenticity, and parasocial interaction significantly affect consumer trust, brand attitudes, and purchase intentions, particularly among younger audiences (Schouten et al., 2020; Ki et al., 2023). Influencer-generated content therefore represents a hybrid form of communication situated between brand-controlled and consumer-generated narratives, further blurring the boundaries between advertising and peer communication.

Consumer responses to these communication mechanisms, however, are not homogeneous. Generational differences significantly shape how individuals use platforms, evaluate information sources, and respond to brand communication. Generation Z (Gen Z), in particular, represents the first cohort fully socialised in highly digital environments where social media interactions play a fundamental role in identity formation, recognition, and consumption practices (Benavides et al., 2023). As a consequence, younger consumers tend to attribute greater importance to authenticity, interaction, transparency, and peer-generated narratives than older cohorts do (Hermanda et al., 2019; Tirocchi, 2024). Studies on Gen Z consumer behaviour indicate that authenticity, relatability, and value alignment strongly influence brand perceptions and engagement in digital contexts (Djafarova & Bowes, 2021). Moreover, research suggests that younger consumers rely more heavily on peer evaluations, influencer recommendations, and social media communities when forming purchase intentions compared with older generations (Casaló et al., 2020).

These dynamics are particularly relevant in the cosmetic industry. The Italian cosmetics market remains economically strong and highly dynamic, while simultaneously being shaped by digitalisation, omnichannel consumption, sustainability concerns, and the growing relevance of clean beauty among younger consumers. Cosmetica Italia reports that the domestic cosmetics market in Italy reached almost €13.4 billion at the end of 2024, with continued growth expectations for 2025, confirming the economic relevance of this sector and its strong digital orientation (Cosmetica Italia, 2025). At the same time, recent research also shows that safety, ethicality, and sustainability attributes are increasingly salient among Millennial and Gen Z cosmetics consumers, making the beauty sector an appropriate empirical setting for examining differences in digital content effectiveness (Shim et al., 2024).

Despite the increasing relevance of these phenomena, empirical studies comparing the effectiveness of UGC versus brand-generated content across generational cohorts remain relatively limited, particularly in the European context and within the cosmetic industry. Therefore, this research addresses this gap and attempts to compare, under controlled conditions, the relative effectiveness of the "voice of the community" and the "voice of the brand" across generational cohorts in the Italian beauty market.

Purpose of the paper. *The purpose of this study is to investigate the relative effectiveness of User-Generated Content and brand-generated content in shaping consumer perceptions and purchase intentions in the cosmetic sector. Specifically, the study examines whether consumer-created communication generates higher levels of trust, engagement, and behavioural intention than traditional brand communication, while also analysing whether User-Generated Content exerts a stronger influence than brand-generated content and how this effect varies across generational cohorts.*

A second objective is to explore the role of digital socialisation in explaining such differences. In this sense, the study contributes to the understanding of how participatory communication mechanisms operate in contemporary digital markets and how brands may design more effective communication strategies by accounting for generational differences in media use, platform familiarity, and trust formation. Recent literature supports the relevance of this focus, showing that younger audiences, and especially Gen Z, are more responsive to participatory and peer-centred forms of communication than to purely institutional messaging (Shim et al., 2024).

To address these objectives, the research is guided by three specific research questions.

RQ1: How does User-Generated Content influence consumer perceptions of credibility, engagement, and purchase intention, compared with brand-generated content in the cosmetic sector?

RQ2: What differences emerge across generational cohorts in the way consumers interpret and respond to User-Generated Content and brand-generated communication?

RQ3: How does digital socialisation shape the relative effectiveness of community-driven versus brand-driven communication in influencing consumer behaviour?

In addition, the study seeks to explore the behavioural mechanisms through which participatory digital communication influences consumer decision-making, by examining the role of credibility, engagement, and social validation as potential pathways linking exposure to User-Generated Content with purchase intention.

By addressing these questions, the study aims to provide a more nuanced understanding of the mechanisms through which participatory communication influences consumer decision-making in digital environments. At the same time, it seeks to offer insights into how firms operating in highly digitalised industries such as cosmetics can adapt their communication strategies to better align with evolving patterns of media consumption, peer influence, and trust formation across generational segments.

Methodology. *Data were collected using a structured questionnaire distributed via online channels. It consisted of 58 items organised into 28 questions and was designed to measure consumer perceptions of both User-Generated Content and brand-generated content. Following previous research, several constructs were widely examined, including perceived content credibility, consumer engagement with digital content, brand trust, and purchase intention. These constructs were selected in order to capture the main behavioural mechanisms through which User-Generated Content may influence consumer decision-making processes in online environments. All constructs were operationalised using Likert scales adapted from previous literature to capture respondents' agreement with statements related to digital marketing communication.*

The final sample consisted of 285 respondents across three generational cohorts – i.e., Generation X, Millennials, and Generation Z – enabling us to examine how digital communication effectiveness varies across consumer groups characterised by different levels of digital familiarity and social media usage.

To identify the latent dimensions underlying consumer perceptions of digital content, an Exploratory Factor Analysis (EFA) was conducted. After confirming the suitability of the dataset through the Kaiser–Meyer–Olkin measure of sampling adequacy and Bartlett's test of sphericity, factors were extracted using principal component analysis with varimax rotation. This procedure enabled the identification of the underlying constructs associated with the evaluation of User-Generated Content and brand-generated communication. The use of EFA is consistent with the exploratory nature of the study, which aims to examine how key variables such as trust, engagement, and purchase intention cluster across the two communication conditions.

Results. *The results reveal a clear generational gradient in the evaluation of digital marketing content. In general, User-Generated Content demonstrates a stronger impact on perceived credibility and consumer engagement among younger cohorts, particularly Millennials and Generation Z. In particular, the "point of overtaking" appears among Millennials and becomes markedly stronger among Generation Z across trust, engagement, and purchase intention. These consumers tend to interpret peer-generated information as more authentic and trustworthy, reflecting their higher familiarity with participatory digital environments and social media communication dynamics (Mathur et al., 2022). In contrast, Generation X consumers appear to attribute greater authority to official brand communication. For these consumers, brand-generated content still plays a relatively stronger role in shaping brand trust and influencing purchase decisions.*

Overall, the empirical findings suggest that the effectiveness of digital marketing communication depends not only on the type of content but also on the generational background of the audience. These results are consistent with prior research showing that attitudes towards UGC mediate online purchase intention and that content credibility is one of the strongest drivers of this mechanism. They also align with recent work on younger cosmetics consumers, which highlights the growing importance of authenticity, sustainability, and socially validated information in beauty-related decisions.

A more detailed examination of the factor structure emerging from the Exploratory Factor Analysis provides further insight into these generational dynamics. The analysis reveals that trust, engagement, and purchase intention tend to cluster more strongly around UGC-related variables for Millennials and Generation Z respondents. For these cohorts, the perception of authenticity appears to operate as a central mechanism linking exposure to peer-generated content with behavioural intention. Consumers in these groups often interpret reviews, tutorials, testimonials, and other forms of experiential storytelling as credible signals of product performance and brand reliability. This effect is particularly visible in digital contexts where consumers rely heavily on visual demonstrations, social validation, and peer endorsement when evaluating products.

For Generation Z, the relationship between UGC and engagement appears particularly pronounced. Respondents belonging to this cohort report higher levels of interaction with peer-generated content, including liking, commenting, and sharing content related to beauty products. This behavioural engagement reflects a broader pattern of digital participation that characterises younger consumers, who are accustomed to navigating interactive online environments where brand meanings are continuously negotiated through social interaction. In such contexts, content created by other users is often perceived as more relatable and transparent than official brand communication. Consequently, exposure to UGC tends to reinforce trust formation and increase the likelihood of purchase consideration.

Millennials show a similar, though slightly less pronounced, pattern. While they also demonstrate strong responsiveness to UGC, they appear to maintain a somewhat more balanced evaluation between peer-generated and

brand-generated content. Although UGC exerts a strong influence on credibility and engagement, brand-generated communication still retains a meaningful role in providing product information and reinforcing brand positioning.

The generational contrast becomes more evident when analysing the responses of Generation X consumers. In this group, brand-generated communication retains a higher level of perceived authority. Official brand messages, including promotional campaigns and corporate communication, continue to play an important role in shaping brand trust and purchase decisions. While Generation X respondents do not reject peer-generated information, they tend to interpret it as complementary rather than primary information.

Table 1 highlights the different ways in which generational cohorts interpret the credibility, engagement potential, and behavioural influence of digital content.

Table 1: Generational interpretation of digital content effectiveness

Dimension	*Generation X*	*Millennials*	*Generation Z*	*Interpretation*
Perceived credibility of UGC	*Moderate*	*High*	*Very high*	*Credibility of peer-generated information increases across younger cohorts, reflecting greater familiarity with participatory digital environments.*
Perceived credibility of brand-generated content	*High*	*Moderate*	*Lower*	*Older consumers continue to attribute authority to official brand communication, while younger audiences rely more strongly on peer validation.*
Engagement with UGC	*Moderate*	*High*	*Very high*	*Interactive behaviours such as commenting, sharing, and reacting to content are significantly more frequent among Millennials and Gen Z.*
Engagement with brand-generated content	*Moderate*	*Moderate*	*Lower*	*Brand content generates lower levels of interaction compared with UGC among younger audiences.*
Role of authenticity	*Moderate*	*High*	*Very high*	*Authenticity becomes a central evaluation criterion for younger consumers, strongly influencing trust formation and engagement.*
Influence on purchase intention	*Moderate*	*High*	*Very high*	*UGC significantly influences purchase intention among Millennials and Gen Z, particularly when perceived as credible and relatable.*
Role of brand authority	*High*	*Moderate*	*Lower*	*Generation X consumers rely more strongly on brand expertise and official messaging when evaluating products.*
Importance of social validation	*Moderate*	*High*	*Very high*	*Younger consumers rely more heavily on peer opinions, reviews, and community interaction when making purchase decisions.*

Source: Authors' elaboration.

These generational differences can be interpreted through the lens of digital socialisation. Younger cohorts have grown up in highly interactive online environments where social media participation, peer communication, and user-generated narratives constitute central elements of everyday digital behaviour. As a result, credibility tends to emerge through collective validation and relational interaction rather than through institutional authority.

The results also highlight the role of engagement as a mediating mechanism linking content exposure to behavioural intention. Among Millennials and Generation Z, higher levels of interaction with peer-generated content contribute to reinforcing emotional connection with the brand and strengthening perceived product relevance. Engagement with UGC often involves both passive consumption and active participation in digital conversations surrounding the brand, thereby reinforcing relational bonds between consumers and brands.

These behavioural mechanisms are synthesised in Table 2, which illustrates the pathways through which exposure to User-Generated Content translates into consumer behavioural outcomes.

Table 2: Mechanisms linking UGC to consumer behavioural outcomes

Mechanism	*Role in digital communication*	*Empirical pattern emerging from the analysis*	*Generational relevance*	*Implications for consumer behaviour*
Content authenticity	*Perception that information is genuine and experiential*	*UGC perceived as more authentic than brand-generated content*	*Strong among Millennials and Gen Z*	*Authenticity strengthens credibility and brand evaluation*
Trust formation	*Confidence in reliability of information source*	*Peer-generated content increases perceived trustworthiness*	*Stronger among Millennials and Gen Z*	*Trust mediates the effect of content on behavioural intention*
Consumer engagement	*Interactive participation with digital content*	*UGC stimulates higher levels of interaction*	*Highest among Gen Z*	*Engagement reinforces emotional connection with brands*
Social validation	*Influence of peer opinions and community endorsement*	*Consumers rely on reviews and testimonials*	*Stronger among Millennials and Gen Z*	*Reduces perceived risk in product evaluation*
Purchase intention	*Willingness to consider or buy the product*	*Higher purchase intention associated with credible UGC*	*Particularly strong among Millennials and Gen Z*	*UGC influences behavioural intention through trust and engagement*

Brand authority	*Perceived expertise of official brand communication*	*Brand content remains influential among Gen X*	*Stronger among Gen X*	*Institutional credibility still influences purchase decisions*

Source: Authors' elaboration.

Taken together, the findings suggest that contemporary digital marketing effectiveness emerges from the interaction between content type, perceived authenticity, and generational patterns of media use. While User-Generated Content represents a particularly powerful driver of trust, engagement, and purchase intention among younger consumers, brand-generated communication continues to retain strategic relevance for older cohorts. Consequently, effective digital marketing strategies should combine community-driven communication with credible brand messaging, adapting content strategies to the media habits and credibility expectations of different generational audiences.

Research limitations. *Although the study provides relevant insights into digital marketing communication, several limitations should be acknowledged. First, the sample is geographically concentrated and not fully balanced across generational groups, which may limit the generalisability of the results. Second, the research focuses exclusively on the cosmetic industry, a sector characterised by strong social media engagement and high levels of consumer interaction. The observed dynamics may therefore differ in industries where digital community participation is less central. Finally, the analytical approach remains exploratory. While Exploratory Factor Analysis is appropriate for uncovering latent dimensions, future research could adopt more advanced analytical techniques – such as Confirmatory Factor Analysis (CFA) or Structural Equation Modelling (SEM) – in order to test causal relationships among variables.*

Managerial implications. *From a managerial perspective, the findings suggest that firms should abandon one-size-fits-all communication logics and adopt differentiated content strategies based on generational and usage profiles. Younger and highly socialised audiences are more responsive to peer-generated narratives and brand community participation, whereas Generation X consumers still rely on official brand communication. The results therefore suggest that companies should adopt hybrid communication strategies that combine brand-generated messaging with consumer-driven narratives. While peer-generated content appears particularly effective in stimulating trust and engagement among younger audiences, official brand communication continues to play an important role for older consumers. Integrating both communication sources may therefore allow firms to maximise credibility while maintaining strategic brand control. Furthermore, a more participatory approach to communication strategy was also supported. Therefore, rather than treating consumers merely as message receivers, brands should facilitate the creation, circulation, and amplification of testimonials, reviews, and peer narratives, especially in digitally native segments. In categories such as beauty, where symbolic meaning, trust, and identification are especially important, the ability to foster authentic interactions between the brand and its community may represent a key source of competitive advantage.*

Originality of the paper. *While previous research has examined the persuasive role of UGC, relatively few studies have analysed how generational differences influence the effectiveness of digital marketing communication in specific industry contexts. This study contributes to the literature debate by identifying the behavioural mechanisms through which User-Generated Content influences consumer decision-making, highlighting the role of credibility, engagement, and social validation as key drivers, linking participatory communication to purchase intention. It provides a comprehensive framework for understanding how participatory communication mechanisms influence consumer behaviour by integrating insights from digital marketing, community marketing, electronic word-of-mouth, and generational consumer research. Moreover, by focusing on the Italian beauty market, the research offers context-specific empirical evidence that contributes to both academic research and managerial practice.*

A compass or merely a caption?
Corporate Purpose Language in Italian Benefit Companies

JORDANA RECH GRACIANO DOS SANTOS, ELISA FIORE, GABRIELE GALLI

Abstract. *The concept of corporate purpose has moved to the centre of management scholarship and business practice, yet a fundamental tension persists between purpose as genuine organizational commitment and purpose as rhetorical or legal gesture. The emergence of hybrid corporate legal forms, most notably the società benefit in Italy, the benefit corporation in the United States, and the société à mission in France, represents an attempt to institutionalize purpose beyond voluntary declaration, embedding social and environmental obligations directly into corporate statutes. Yet whether legal mandates for purpose produce substantive organizational reorientation or merely a new register of compliance remains an open and empirically underexplored question.*

This paper presents an ongoing research project that addresses this question through a systematic thematic analysis of statutory purpose declarations in a sample of 295 Italian società benefit. Drawing on corporate object clauses (oggetto sociale) retrieved from the AIDA database, the study maps the thematic landscape of declared corporate purpose across the population and assesses the depth of purpose articulation by examining the linguistic specificity and structural integration of benefit language, distinguishing between companies that engage with purpose substantively and those that reproduce generic or boilerplate formulations drawn directly from the founding legislation.

Preliminary inspection of the data reveals three dominant thematic clusters and considerable variation in how benefit companies' structure and articulate their statutory purpose, from richly specific and operationally grounded declarations to near-verbatim reproductions of statutory language that carry little organizational content.

Corporate purpose, as the theoretical framing makes clear, is not a static declaration but a dynamic organizational process, one that must be continuously enacted, negotiated, and translated into concrete practices, metrics, and outcomes. The statutory document is only the beginning of that journey, but it is also, in a meaningful sense, its foundation: the moment at which an organization is asked to articulate, publicly and legally, not only what it does, but why it exists and for whom. By examining how organizations respond to that moment, with specificity or vagueness, integration or isolation, ambition or mere compliance, this study contributes empirical grounding to debates at the intersection of corporate law, institutional theory, and sustainable governance, with implications for scholars, policymakers, and practitioners navigating the boundary between genuine purpose commitment and purpose washing.
Keywords: *corporate purpose; benefit; hybrid corporate forms; thematic analysis*

Framing the research. *Defining and enacting corporate purpose has become integral to the corporate governance process, increasingly shaped by multistakeholder approaches that extend organizational accountability beyond shareholders to encompass a broader constellation of interests (Aguilera, 2023). A clearly articulated corporate purpose provides executives with a guiding compass, enabling them to maintain a broader strategic perspective and steer the organization through periods of instability and uncertainty (Lee et al., 2023). In this way, purpose should work not only as a rhetorical device but as an organizational anchor that shapes how firms set priorities, distribute resources, and respond to external pressures.*

The concept of purpose is increasingly recognized as a pivotal driver of both sustainable and financial performance, gaining attention in both academic literature and business practice (Gartenberg et al., 2019; Jones-Khosla and Gomes, 2023). Influential practice-oriented thinkers, most notably Sinek (2009), have popularized the foundational question "Why do we exist?", prompting organizations across sectors to reflect on what it means to remain relevant and valuable to society over the long term. This has contributed to a growing wave of firms presenting themselves as purpose-led corporations, committed to reconciling the pursuit of financial value with the fulfillment of broader societal goals (Walls et al., 2021). In this context, results from the literature indicate that purpose-driven companies are often better positioned to align with societal expectations and stakeholder interests, leading to enhanced performance and the creation of sustainable value (Edmans, 2021; Gartenberg, 2023).

Central to this discussion is the relationship between an organization's goal system and its overarching purpose. Organizational goals are typically aligned with, and derive legitimacy from, the organization's mission or purpose (Aguilera, 2023), and this alignment plays a pivotal role in shaping how organizations navigate crises and become genuinely purposeful over time (Hollensbe et al., 2014). Understanding the determinants, processes, and outcomes of this goal-purpose relationship remains an evolving area of inquiry, with many facets still insufficiently understood (Aguilera et al., 2024).

Yet, despite this proliferation, significant gaps remain in our understanding of how purpose is effectively enacted and sustained in practice. While the benefits of corporate purpose for organizational performance are widely acknowledged by both scholars and practitioners (Davis, 2021; Mayer, 2021; Gartenberg et al., 2019; Gartenberg, 2023; Hollensbe et al., 2014), there is limited empirical evidence on the factors that influence organizations' decisions to adopt specific objectives (Aguilera et al., 2024), on how purpose is communicated across the organization and among stakeholders, and on how it is ultimately translated into tangible impact (George et al., 2023). This gap is further compounded when purpose

is connected to the outcomes of innovative activity, that is, to impact in the fullest sense of the term (Smith et al., 2010; Busco, 2022).

Achieving meaningful impact requires deliberate strategic action and comprehensive programs operating across multiple timeframes, all guided by long-term goals and communicated in ways that genuinely involve corporations, their employees, and their broader stakeholder ecosystems (Schultz, 2022). In this sense, purpose is not a static declaration, but a dynamic organizational process: it must be continuously enacted, negotiated, and translated into concrete practices, metrics, and outcomes. Most contemporary organizations have thus embarked on an ambitious journey to connect their enduring reason for being with their strategy, business models, and performance systems , attempting to reconcile traditional financial imperatives with emerging societal values (Walls et al., 2021; George et al., 2023).

It is precisely this tension between what organizations are and what they aspire to become that places corporate purpose at the center of contemporary governance, strategy, and accountability debates. In 2019, the Business Roundtable announced a landmark redefinition of corporate purpose, committing its members to lead their companies for the benefit of all stakeholders, employees, customers, suppliers, communities, and shareholders alike (Business Roundtable, 2019). The announcement marked a decisive break from its own 1997 statement, which had embraced shareholder primacy as the organizing principle of corporate life, with profit maximization as the corporation's paramount obligation. This shift from shareholder value to stakeholder value rapidly diffused through the global business community, echoed by major trade associations, leading consulting organizations, and business schools. Yet the announcement also prompted an uncomfortable question: how dramatic a change in corporate purpose does all this represent?

It is against this backdrop that a parallel and more structurally ambitious development has appeared: the proliferation of corporate legal forms designed to institutionalize purpose beyond voluntary declaration. Referred to generically as "profit-with-purpose corporations", these new hybrid forms embed social and environmental considerations directly into corporate bylaws, alongside, and in tension the traditional objective of generating profit. Unlike classic CSR approaches or soft law instruments, which rely on voluntary commitment and reputational incentives, these legal forms propose frameworks with more clear-cut legal implications (Levillain and Segrestin, 2019; Bandini et al., 2022). The benefit corporation in the United States, the società benefit in Italy, and the société à mission in France are among the most prominent examples.

According to this, società benefit are grounded in the idea that an enterprise is not only an economic organization for producing goods and services; it is also an organization of "collective creation" that invents new technologies and develops new knowledge and expertise. It consequently has a much more radical impact, negative or positive, on society and the environment.

This growing variety of purpose-embedded corporate forms is not incidental. It reflects a broader recognition that voluntary commitments are insufficient to address the scale and urgency of contemporary grand challenges, climate change, social inequality, biodiversity loss, and that corporate governance and corporate law must become active instruments of sustainable transformation, particularly at the European level. Alongside traditional environmental policy tools, legal scholars and policymakers have increasingly turned their attention to how corporate law can propel change not only by preventing corporations from causing social or environmental harm, but by actively orienting them toward public policy goals (Sjåfjell et al., 2020; Segrestin et al., 2021; Mayer, 2021).

Italy occupies a particularly significant position in this landscape. Introduced with Law 208/2015, the società benefit was among the earliest European experiments with a legally mandated hybrid corporate form, requiring companies that adopt the status to pursue common benefit alongside profit and to operate in a responsible, sustainable and transparent manner toward a broad range of stakeholders. Nearly a decade later, the number of Italian benefit companies has grown substantially, making Italy one of the most important national laboratories for understanding whether purpose-embedded legal forms can deliver on their promise.

Yet a fundamental question remains underexplored. While scholars have examined the legal architecture, the governance implications, and the comparative landscape of profit-with-purpose corporations, far less attention has been paid to what these companies actually say when they articulate their purpose, and whether what they say constitutes genuine organizational commitment or a sophisticated form of legal compliance. The statutory document is the primary site where a benefit company is required to define its reason for existing beyond profit.

This study addresses that gap directly. Drawing on a sample of 295 Italian società benefit, we conduct a systematic thematic analysis of statutory purpose declarations to map the thematic landscape of corporate purpose in this population and to assess the depth and authenticity of purpose articulation. In doing so, we contribute empirical grounding to a debate that has so far been dominated by normative argument and legal analysis, asking not whether benefit companies should pursue purpose, but what pursuing purpose looks like when companies are required to put it in writing.

Purpose of the paper. *This paper investigates how Italian società benefit articulate corporate purpose in their statutory documents, with the aim of mapping the thematic landscape of purpose declarations and assessing whether such articulations reflect genuine organizational commitment or merely fulfil a formal legal requirement. This study pursues two interrelated objectives.*

The first is descriptive and empirical: to provide a systematic mapping of the thematic content of corporate purpose as declared in the statutory documents of Italian società benefit. By identifying dominant themes, thematic clusters, and patterns of variation across a population of 295 companies, the study establishes what Italian benefit companies actually

say when required by law to articulate their reason for existing beyond profit, responding directly to a gap in the literature, which has engaged extensively with the legal architecture of profit-with-purpose corporate forms while paying considerably less attention to the substantive content of purpose declarations themselves.

The second objective is evaluative and analytical: to assess the depth and authenticity of these declarations by examining the structural integration and linguistic specificity of benefit language across statutory documents. Together, these aims move the analysis beyond the question of how many benefit companies exist, toward the more fundamental question of what the benefit company form means in practice. They are translated into the following research questions: How do Italian benefit companies articulate corporate purpose in their statutory documents, and to what extent does the language of purpose reflect substantive organizational commitment rather than mere legal compliance? What thematic patterns characterize the declared purposes of Italian società benefit, and how do variations in purpose statements reveal meaningful differences in how companies conceptualize and communicate their broader social and environmental ambitions?

Methodology. *The dataset was constructed from two publicly available lists of Italian società benefit. Following deduplication, 18 duplicate entries were removed, yielding a final sample of 295 unique companies. Combining two independent lists rather than relying on a single registry reduces the risk of systematic omission, while acknowledging that, in the absence of an official national registry of benefit companies, complete population coverage cannot be guaranteed. Each company was matched to the AIDA database (Bureau van Dijk) to retrieve the full text of the statutory corporate object clause (oggetto sociale), which constitutes the primary unit of analysis.*

The year of benefit status adoption was identified through a triangulated approach: corporate websites and public documents were consulted first; where unavailable, AIDA records were checked for the year in which the company name was formally modified to include "S.B." or "Società Benefit"; where neither source yielded reliable information, the value was coded as missing.

The primary unit of analysis is the corporate object clause as recorded in AIDA. Under L. 208/2015, benefit companies are required to specify their common benefit purposes within their corporate statute, making this document the legally mandated and publicly accessible site of purpose articulation. Unlike voluntary disclosures such as sustainability reports or mission statements, the statutory clause is legally binding and structurally comparable across companies, making it particularly suitable for systematic thematic analysis. The data will be analyzed using thematic analysis (Braun and Clarke, 2006), implemented through Atlas.ti. The analysis will happen in two sequential phases. The first phase applied an inductive open coding process to map the thematic content of purpose declarations across the corpus, allowing dominant themes, thematic clusters and patterns of variation to emerge from the data without a predetermined framework.

Results. *This research is ongoing, and the findings reported here reflect preliminary inspection of the corpus rather than completed analysis. Nevertheless, the material already reveals patterns of sufficient clarity to warrant structured presentation. The results are organized in two parts, corresponding to the study's two sequential objectives.*

The most prevalent concerns sustainability and social responsibility. Declarations within this cluster reference environmental care, responsible resource use, community engagement, and transparent conduct toward a broad range of stakeholders. A second cluster foregrounds innovation, particularly technological innovation, framed explicitly as a means of serving social or environmental ends. Companies in this cluster articulate their benefit purpose through the development of new solutions, tools, or services whose value is defined not only in commercial terms but in terms of broader societal impact, safer digital environments, more accessible services, or more sustainable production processes. The coherence of this framing varies: in some cases, the social dimension is genuinely integrated into the innovation logic; in others it reads as a secondary justification appended to what is essentially a commercial activity description.

The third cluster centers on stakeholder welfare, with declarations extending organizational commitment beyond shareholders to encompass employees, clients, communities, and territories. This cluster is the most heterogeneous of the three. Some declarations within it articulate a clear and specific account of how different stakeholder groups are considered in decision-making and resource allocation; others rely on generic language of care and excellence that could apply to any commercial enterprise and carries little distinctive benefit content.

Taken together, these three clusters account for the large majority of purpose content in the corpus, though the degree of specificity, integration, and organizational grounding varies considerably both across and within each theme.

Research limitations. *Several limitations should be acknowledged. First, the sample of 295 società benefit was drawn from two independent lists rather than an official national registry, since no such registry exists in Italy, which means complete population coverage cannot be guaranteed, and some selection bias may be present. Second, the analysis is restricted to the statutory corporate object clause (oggetto sociale), which, while legally mandated and systematically comparable, represents only one moment in what is ultimately a dynamic and ongoing organizational process. As the theoretical framing suggests, purpose must be continuously enacted and translated into practices and outcomes that extend well beyond the founding document; what companies write in their statutes and what they do in practice may diverge in ways this study cannot capture. Third, thematic analysis, even when rigorously applied through a combined inductive-deductive approach, involves interpretive judgment; coding decisions, carry a degree of subjectivity that cannot be fully eliminated.*

Managerial implications. *The study contributes empirical grounding to a debate that has so far been dominated by normative argument and legal analysis, shifting the focus from whether benefit companies should pursue purpose to what pursuing purpose actually looks like when organizations are required to put it in writing. In doing so, it also speaks to the broader conversation about the conditions under which corporate purpose moves from declaration to commitment, and from commitment to consequential action.*

The implications of this inquiry extend beyond academic debate. For managers and executives, the findings offer a reflective mirror: a systematic account of how peer organizations across the Italian benefit company landscape have chosen to define, frame, and communicate their broader social and environmental ambitions. In a context where the articulation of purpose is not merely a strategic choice but a legal obligation, the quality, specificity, and integration of purpose language becomes a meaningful signal, both internally, as a driver of organizational alignment and employee engagement, and externally, as a marker of credibility and accountability toward stakeholders, investors, and regulators.

For boards and governance practitioners, the study highlights the risk of what might be termed purpose inflation: the proliferation of purpose declarations that are sufficiently broad to satisfy legal requirements while remaining too generic to guide strategic decision-making or to differentiate one organization from another. Understanding where this risk is most acute and what substantive purpose articulation looks like in practice equips governance actors with a more refined set of criteria for evaluating and strengthening their own purpose statements.

For policymakers and regulators, the findings carry implications for the design and enforcement of purpose-embedded legal frameworks. If a significant share of benefit companies reproduces boilerplate formulations without meaningful specificity, this raises questions about whether the current regulatory architecture provides sufficient incentives or obligations to ensure that legal form translates into genuine organizational transformation. The Italian experience, as one of Europe's earliest and most developed experiments with the benefit company model, offers valuable lessons for jurisdictions currently considering or refining analogous frameworks, including at the European level in the context of ongoing debates around sustainable corporate governance.

For investors and capital allocators increasingly attentive to ESG considerations and impact measurement, the study provides a framework for distinguishing between organizations that have substantively embedded purpose into their foundational documents and those that have adopted the benefit company status primarily as a reputational or marketing instrument. As impact investing matures and demands greater rigor in the assessment of organizational intent, the ability to read and interpret statutory purpose language becomes a relevant due diligence competence.

Finally, and perhaps most fundamentally, the study speaks to the conditions under which purpose-driven organizational models can deliver their transformative potential. Corporate purpose, as the theoretical framing makes clear, is not a static declaration but a dynamic organizational process, one that must be continuously enacted, negotiated, and translated into concrete practices, metrics, and outcomes. The statutory document is only the beginning of that journey. But it is also, in a meaningful sense, its foundation: the moment at which an organization is asked to articulate, publicly and legally, not only what it does, but why it exists and for whom. How organizations respond to that moment, with specificity or vagueness, with integration or isolation, with ambition or compliance, tells us a great deal about whether purpose, in their hands, is a compass or merely a caption.

Originality of the paper. *This study makes contributions to emerging literature on hybrid corporate forms and corporate purposes. Empirically, it offers a systematic analysis of statutory purpose declarations in Italian società benefit, moving beyond the legal and normative debates that have dominated scholarship in this area to interrogate what benefit companies say when they must articulate their reason for existing. The use of thematic analysis provides a methodological approach that is both rigorous and replicable, and which can serve as a template for comparative studies across national contexts. Finally, the paper speaks to policy-relevant debates about the effectiveness of purpose-embedded corporate law: by examining the extent to which legal mandates for purpose produce genuine organizational reorientation versus a new register of compliance, it offers empirical grounding for policymakers and regulators assessing hybrid corporate forms at the national and European levels, as well as for managers seeking to translate purpose commitments into coherent organizational goals and everyday practices.*

Does sustainability pay off? Evidence from a staggered DID analysis on Italian BCorps

ALESSANDRA COSTA [*], ANTONIO CRUPI[†], TINDARA ABBATE[‡]

Abstract. *In recent years, sustainability has become a strategic lever for firms seeking to remain competitive while handling multiple interests and responding to growing external and internal social and environmental stimuli. Within this context, and considering the heterogenous hybrid organizational structure, BCorp has emerged as the prominent one, allowing to balance economic viability with social and environmental goals. Moreover, BCorp certification itself has gained prominence in the economic and managerial debate related to its usefulness for achieving some measurable economic benefits. Against this backdrop, this study aims at investigating the effect of B Corp certification on firms' economic performance, evaluated through two complementary, yet related, performance measures: operating profitability, measured by return on assets (ROA), and operational efficiency, measured by the ratio of sales revenues to total assets.*

We focus on a sample of 101 Italian BCorps, certified in the period 2018-2022, and using a 1:1 nearest neighbor approach, we identify a control group of 101 non-certified matching firms. On the final sample of 202 Ital firms, we employ a staggered difference-in-differences design. Our results suggest that embarking on a certification path does not guarantee short-term gains, as it does not have a statistically significant effect on both profitability and operational efficiency. Overall, our findings suggest that B Corp certification should not be interpreted as a short-term driver of financial returns, but rather as a strategic investment in organizational alignment, sustainability integration, and long-term capability building. In doing so, our study contributes to the broad literature on sustainability certification and economic performance, while providing some evaluable insights for firms seeking to approach sustainability through a certification path.

Keywords: *BCorp; sustainability certification; performance; difference-in-differences*

Framing of the research. *In recent years, sustainability has become a strategic lever for firms willing to remain competitive in global markets, while responding to both internal and external stimuli and innovating their business models (Moroz et al., 2021). As a consequence, firms are compelled to overcome the classical profit-maximization paradigm in order to better anchor sustainability in their business model, through social and environmental value creation (Costa et al., 2025; Carvalho et al., 2022). This shift has fostered the emergence of new hybrid organizational forms, attempting to embed purpose into firms' structure, thereby resulting in new sustainable practices (Asselle & Piccaluga, 2019; Stubbs, 2017). Within this evolving landscape, BCorp has gained prominence as one of the most visible and structured business models of hybrid organizations (Moroz et al., 2021), aiming at combining a market-based logic with explicit social and environmental purposes. Through a voluntary third-party certification process, firms are required to adopt a multidimensional assessment of performance across governance, workers, community, environment, and customers (Krist et al., 2021), thereby moving beyond a classical stakeholder-oriented logic toward a systemic perspective of value creation (Poponi et al. 2019). In this regard, BCorp can be understood not only as a signal of commitment, but also as an organizational device through which firms formalize and operationalize the management of multiple competing objectives (Pollmeier et al., 2025; She & Michelon, 2023).*

Yet, whether this formalization generates economic benefits remains theoretically ambiguous (e.g., Patel et al., 2022; Parker et al., 2019). On one hand, previous literature suggest that business can "do well by doing good" (Richardson & O'Higgins, 2019), that implies that certification and corporate financial and nonfinancial performance are closely linked. Along this perspective, BCorp certification has been found to have the power of increasing legitimacy and strengthen stakeholder relationships (Vilella et al., 2021), while also increasing productivity and maximizing revenues (Chen et al.,2015). On the other hand, others show negative effects of the certification on firm performance, not only as the certification standards require more demanding and costly governance and accountability structures, but also because of additional burdens associated with the sustainable transition undertaken by the firms, that can outweigh economic benefit, especially in the short term (e.g., Bringas-Fernández et al., 2024;Parker et al.,2019) .

Additionally, from a competitive advantage perspective, sustainability certification such as BCorp are often considered as a lever for differentiation rather than mechanisms consistent with a cost-leadership logic (Lee & Jay, 2015), suggesting that the need of reorganizing downstream value chain activities – such as branding, communication, customer engagement – add costs and organization complexity to effectively signal a credible commitment to social and environmental goals (Colamartino et al., 2025). In the same line, from the demand side the market does not slways immediately recognize the value associated with the transition toward a purpose-driven model (Narayanan & Singh, 2023). This implies that consumers' willingness to pay may not evolve at the same pace as the certification process,

[‡] University of Messina, e-mail: tindara.abbate@unime.it

especially when consumers base their evaluations on more tangible product- or firm-level attributes.

Consequently, the certification effects are considered highly context-dependent, varying according to firms' capabilities, strategic positioning, and ability to convert sustainability commitments into competitive outcomes. Moreover, as firms do not enter the certification process randomly (Chen & Kelly, 2015): financially sound firms are more likely to undertake certification, while less resource-endowed firms may be less able to do so. This obviously makes it difficult to establish whether post-certification performance differences are driven by the certification itself or rather reflect ex-ante firms' heterogeneity.

Against this backdrop, BCorp certification represents an ideal empirical setting in which to examine whether the formal adoption of a purpose-driven organizational model translates into measurable performance effects, and their dynamic effects.

Purpose of the paper. *This paper aims to investigate the effect of BCorp certification on firms' economic performance. In particular, we focus on two related dimensions of BCorp performance (Richardson & O'Higgins, 2019; Chen & Kelly, 2015): operating profitability – captured by ROA – and operating efficiency in the use and organization of assets – measured by the ratio between sales revenues and total assets. Cupertino et al. (2021) show that best sustainable companies usually improve future profitability, by means of eco-innovation and sustainability commitment that compensate for losses of sustainable strategy execution and chain management. This is in line with the logic of the certification itself, often imposing firms to simultaneously intervene across multiple impact areas to align internal structures and routines with a broader purpose, thereby increasing the likelihood of developing product, organizational and societal-level innovative solutions (Attanasio et al., 2025). This increase in profitability has been found to be more pronounced for firms operating under stronger market logic (Kirca et al., 2005), as such firms are better positioned to sense customer expectations and easily translate these sustainability-related changes into measurable value for the market. In this sense, firms are able to strength trust and customer loyalty, as well as to maximize value of relational capital. This, in turn, enhances firms' resilience and adaptive capacity in periods of uncertainty, ultimately increasing their survival through sustained stakeholders (Stubbs, 2017)*

However, these positive effects are unlikely to be uniform across firm. This is in part explained by the long-term perspective associated with sustainable certifications (Childress & Jones, 2025). Although explicitly designed to be applicable across industries, firms entering the certification process differ in terms organizational complexity and resource availability, meaning that the certification process may require some prior costly adjustments. Rosca & Taylor (2022), for instance, specifically refer to supply chain design as one of the most important adjustments required by BCorp certification, in terms of supplier selection criteria, localization choices, reverse supply chains and monitoring mechanisms that usually entail substantial costs prior to the certification. Similarly, Lepkowska-White et asl. (2023) draw on signaling theory to stress the importance of strengthening community engagement, in order to fully externalize the internal values embedded in such sustainable certification – through reputational benefits. Given these premises, the following hypothesis is proposed:

***H_1:** In the short term, BCorp certification does not have a significant effect on firms' operating profitability.*

Moving beyond profitability, certification may affect how efficiently firms organize and deploy their resources. As stated by Pedrecca et al. (2025), BCorp certification helps firm optimize resource allocation while safeguarding operational efficiency, though the development of new internal capabilities. This aligns with the well-established research on management standards and voluntary certification, emphasizing the ability of such certification to foster process formalization, clearer routines and stronger coordination structures (Pagell et al., 2015). In addition, sustainability-oriented certifications may foster both process and product innovation when firms are able to manage complementarities across inputs and activities (Blasi et al., 2024). Accordingly, BCorp certification is expected to have a positive effect on firms' efficiency in the use of assets. Formally:

***H_2:** BCorp certification has a positive effect on firms' efficiency in the use of assets.*

Methodology. *To test the above-mentioned hypotheses***,** *this research uses a difference-in-differences (DiD) approach, that allows to empirically verify the effect of a treatment on an outcome variable, by comparing the evolution over time with that of a control group.*

Accordingly, our treated group consists of all the Italian firms that obtain the BCorp certification, extracted from Data.World[4]- that lists all firms obtained the certification from 2014 to 2025. Following previous research (e.g., Bringas-Fernández et al., 2024; Callaway & Sant'Anna, 2021), we start from our initial sample of 222 firms and restricted the sample to all certified Italian BCorps in the period 2018-2022 to ensure an homogeneous observation windows across treatment cohorts (a three-year pre-treatment window and at least two-year post-treatment window), resulting into 128 firms. We further restricted our sample to firms with minimum financial information data required for matching and subsequence analysis – by excluding firms with completely missing information on pre-treatment variables – resulting into a final treated sample of 101 BCorps.

To address non-random self-selection into certification, we adopt a structured matching algorithm to define a balance control group (Rosembaum, 2020). We first restrict the AIDA population to active Italian limited liability and joint-stock companies operating in the same 2-digit NACE industries as treated firms and with financial statements available over

[4] *https://data.world/blab/b-corp-impact-data*

the study period. Matching was then performed separately by treatment cohort, on the basis of a 1:1 nearest neighbor algorithm, based on the pre-treatment firm size (log of the average total assets over the three years pre-certification) and firm age (numbers of year since incorporation in the year before certification). This leads to a final matched sample of 101 treated firms and 101 never-treated controls

The matched sample was then used in the staggered DiD analysis, that allows to account for the heterogeneous timing of BCorp certification across firms (Freedman et al., 2023), that is firms contribute to the comparison group as long as they have not yet been exposed to certification; accordingly, the control group includes both never-treated firms and future-treated firms prior to their own treatment year.

Let G_i denote the first treatment year of firm i, defined as the first fully post-certification fiscal year. Firms that are never treated during the observation window are assigned to $G_i = 0$, whereas treated firms belong to certification cohorts $G_i \in \{2018,2019,2020,2021,2022\}$. Let Y_{it} denote the outcome of interest for firm i in year t. We estimate group-time average treatment effects:

$$ATT(g,t) = E[Y_t(1) - Y_t(0) \mid G_i = g]$$

where $ATT(g,t)$ measures the average treatment effect for firms first treated in year g at calendar time t.

$ATT(g,t) = E[Y_t(1) - Y_t(0)|G_i = g]$, which was subsequently aggregated into dynamic event-time effects.

As a further validation exercise, we complement the baseline staggered DiD estimates with a set of placebo tests.

Results. *Results of the staggered DiD analysis are reported in Table 1.*

To test H1, in order to assess the impact of BCorp certification on firms' profitability, we use ROA (defined as the ratio between net income and total asset). Results show a positive treatment effect (0.162), even if not statistically significant, implying that even if the BCorp certification may be associated with a modest improvement in firms' profitability, it is not possible to draw any conclusion about a causal effect. Additionally, placebo tests provide support for the validity of the identification strategy: none of the placebo estimates are statistically significant at the 5% level, ultimately supporting the parallel trend assumption for ROA. However, when looking at the dynamic estimates, some heterogeneity over time emerges: despite the positive, yet non-significance, of the estimated coefficients after certification, five years after the certification, the coefficient turns negative and statistically significant, thereby pointing to a possible decrease in profitability and emphasizing more uncertain longer-term implications of the certification itself.

Moving to the operational efficiency effect (hypothesis H2), we operationalize operational efficiency as the ratio between sales revenues and total assets.

The estimated treatment effect is negative but very close to zero (-0.0106) and not statistically significant (95% CI [-0.1187; 0.0975]), suggesting that BCorp certification does not produce a meaningful change in firms' operational efficiency. Contrary to our expectation, this implies that BCorp certification does not generate a substantial improvement in firms' resource allocation, process formalization and stronger internal coordination mechanisms. This result is also confirmed by the results of all placebo tests. Overall, the evidence does not support H2. Although BCorp certification may foster internal capability development and process formalization, these benefits do not appear to translate into a significant improvement in the short-term.

Table 1. Results of staggered DiD on firms' profitability (ROA) and operational efficiency (sales revenues/total assets)

		Profitability			***Operational Efficiency***	
	Estimate	***SE***	***95% CI***	***Estimate***	***SE***	***95% CI***
Treatment effect	*0.162*	*1.488*	*[-2.7545 3.0785]*	*-0.0106*	*0.0552*	*[-0.1187 0.0975]*
Placebo1	*-0.0142*	*0.744*	*[-1.47 1.44]*	*-0.0216*	*0.0243*	*[-0.813 0.0382]*

Placebo 3	*1.47*	*1.3*	*[-1.08 4.02]*	*0.0230*	*0.0144*	*[-0.0124 0.0584]*

Research limitations. *Despite the novel approach adopted to study the impact of a holistic sustainable certification, we are aware that this study presents some limitations. First, the analysis is limited to Italian BCorps: even if this choice ensures institutional comparability across firms, it can limit the external validity of our results. Second, the empirical setting is based on a small sample of certified BCorps, that have achieved the certification in the period 2018-2022- Also in this case, even if the choice ensures a comparable pre- and post-treatment effect, the final sample size may reduce the statistical power of the analysis. Third, the selected time-horizon may capture only short-term and medium-term effect, thereby potentially undermining the long-term implications of this certification scheme. Fourth, it is important to remember that our study only estimates the impact of BCorp certification, which is only a proxy for the adoption of sustainable production behavior. Finally, we limit the measure of performance to financial ones – through profitability and operational efficiency- but this does not allow us to fully capture broader value creation processes associated with certification.*

Moreover, even if we account for potential self-selection bias through a matched control group, the possibility of residual endogeneity cannot be excluded. Finally, additional controls should be added.

Managerial implications. *This research offers several managerial implications for managers and firms considering BCorp certification as a potential innovation pathway for their business models. In particular, the non-significance of short-term effects on profitability and operational efficiency suggest that certification must be interpreted as a strategic investment aimed at anchoring sustainability into the firm's business model, without expecting immediate financial benefits. Second, managers should be aware that the certification process itself may require some internal adjustments before the achievement of economic returns. This also suggests managers allocate specific financial resources to the sustainable transition, thereby lowering the expectations of rapid payoffs.*

Third, given the voluntary nature of the BCorp certification, in order to maximize its value, our results suggest firms to complement the sustainability transition with coherent upstream and downstream strategies, so that the purpose driven orientation become easier and more visible for the entire value chain. More generally, our results indicate that BCorp certification may be better considered as an instrument for organizational alignment and long-term capability building than as a concrete short-term lever.

Originality of the paper. *This study contributes to the growing literature on hybrid organizations and sustainability certifications, by providing empirical evidence on the economic impact of BCorp certification.*

While prior research has mainly focused on the normative, reputational, and organizational dimensions of BCorps, primarily based on single case studies and comparative analysis, this paper specifically examines whether certification translates into measurable changes in firms' economic performance. In this sense, the study helps bridge the gap between the literature on purpose-driven business models and the performances of sustainability-oriented organizational forms. Additionally, the adoption of a staggered DiD design allows to minimize the self-selection effect of firms entering the certification process, while also accounting for the heterogeneous timing in treatment adoption.

Future managers confront ethical dilemmas: Insights from mediated interaction with students in economics and innovation

LAMBERTO ZOLLO[1], CLAUDIA SARTIRANA[2]

Abstract. *Business ethics, corporate social responsibility (CSR), and sustainability are increasingly central topics in management education, yet teaching them effectively remains challenging. Students often perceive these subjects as abstract, distant from real business practices, or disconnected from their future professional roles. At the same time, younger generations tend to approach companies with skepticism, particularly regarding corporate communication around sustainability. This paper explores whether more participatory teaching methods can increase student engagement and provide deeper insights into how new generations perceive ethical issues in contemporary economic systems. A group of students participated in a session based on the Attentive Teaching methodology. In this setting, students were invited to actively interpret ethical concepts by creating visual representations of how they perceive business ethics and sustainability in today's economy. These drawings then became the starting point for discussion, allowing students to explain their ideas, compare perspectives, and reflect collectively on ethical dilemmas. The results show high levels of participation and engagement in the Attentive Teaching session. Students were willing to share their perspectives, debate interpretations, and express the emotions associated with ethical tensions in business contexts. The activity also revealed recurring perceptions among students, including skepticism toward corporate communication and a tendency to distinguish between themselves and companies as ethical actors. By combining insights from management, business ethics, education, and psychology, this study highlights the potential of participatory and emotionally aware teaching approaches to improve ethics education and to better understand how future managers perceive corporate responsibility and sustainability.*
Keywords: *business ethics; CSR; SDGs; attentive teaching; mediated interaction*

Framing of the research. *Business ethics (BE), Corporate Social Responsibility (CSR), and Sustainable Development (SD) in contemporary management education increasingly function as overlapping dimensions of responsible management and responsible leadership. Many of the most salient dilemmas in contemporary business (e.g. climate-risk disclosure, supply-chain labor rights, algorithmic bias) are simultaneously BE, CSR, and SD dilemmas, which make rigid curricular boundaries pedagogically artificial. The integration of BE/CSR/SD has been accelerated by legitimacy crises and by global governance frameworks, particularly SDG-oriented guidance. At the same time, integration can drift into superficial "coverage" when it becomes a bolt-on addendum rather than a coherent learning trajectory with assessment, faculty support, and institutional incentives aligned with stated values (Weybrecht, 2022). Similarly, too often the importance and impact of the individual decision maker is minimized even though at the end of the day it is individuals who stand behind any action of the business entity, whether it be expressed through the actions of individuals, corporate policy or technological mechanizations such as AI or algorithms (Kay, 2019).*

A complementary strand of scholarship reframes the aims of ethics education through the behavioral ethics turn. Ethical failure is often generated less by explicit endorsement of wrongdoing than by cognitive and social processes that reduce moral awareness and enable rationalization: ethical fading, motivated blindness, incrementalism, and moral disengagement (Bandura, 1999; Moore et al., 2012). As a result, learning outcomes extend beyond "knowing" ethical principles. Jeong et al. (2020) stressed the importance of emotions in ethical decision-making among business students, noting that that moral emotions can enhance ethical decision-making.

Considering the educational perspective, the concern with Business Ethics education is as old as the existence of professional and academic training in business (Abend, 2014). Recently, researchers have moved from asking whether Business Ethics can be taught (e.g. Park, 1998) to asking how best to teach Business Ethics (Martini et al., 2025). Specifically, cooperative learning designs and immersive simulations, including VR-based flipped learning, can support repeated practice in ethical implementation skills raising concerns, documenting risks, and negotiating tradeoffs, provided that debriefing, feedback, and assessment are rigorous (Martini et al., 2025). Contemporary business ethics education has moved substantially beyond traditional lecture-based approaches toward more interactive and experiential methods that engage students with realistic scenarios and authentic problems. Bibliometric and systematic reviews document the field's broad variety of methods most studied (Jaganjac et al., 2023; Liu et al., 2018; Calabretta et al., 2011)

Purpose of the paper. *New generations have a unique view on social and environmental challenges, since they grew up with constant exposure to such topics. Moreover, they are the businesspeople and entrepreneurship of the future, therefore their concerns, expectations and standards are of the utmost importance. While studying in universities, they are exposed*

[1] *Department of Economics, Management and Quantitative Methods, University of Milan, Milan, Italy; lamberto.zollo@unimi.it*
[2] *B-ASC Bicocca Applied Statistics Centre, University of Milan-Bicocca, Milan, Italy; c.sartirana@campus.unimib.it*

to theories and frameworks about such topics, but they often show disengagement and disinterest, but they also lack opportunities to share and discuss their thoughts in a structured, guided way. In our work, we use an interactive, mediated approach to discuss business ethics, CSR ad SDGs with students, with the aim on the one hand to identify if the disengagement shown is related to real disinterest rather than the disillusion and negativity, and on the other hand to understand the students' views on such important topics before they enter the world of work. The primary aim of our approach is to develop and incorporate fresh, innovative teaching materials and methods into the professional education of business students who will become the leaders of tomorrow. Results can motivate students in caring about ethical issues and can help companies understand what new generations are looking for, and their point of view can help companies remaining forward-thinking and adapt to a new vision, that is brought by the managers of the future.

Methodology. *Ethical breakdowns are often driven less by the deliberate approval of misconduct than by cognitive and social dynamics that diminish moral awareness and facilitate rationalization such as ethical fading, motivated blindness, and moral disengagement. (1999). For this reason, we aim to test new engaging pedagogical tools, like Attentive Teaching. Attentive Teaching (AT) is a student-centered approach based on dialogue and interaction between teacher and learners. It uses visual representations drawn by the students and recognizes that each student brings different prior knowledge, experiences, and learning processes, which teachers should actively explore and address in an open-minded way. Rather than transmitting concepts in a purely top-down manner, the teacher acts as a facilitator who listens, observes, and builds the discussion starting from the students' own interpretations. The teacher listens carefully to each learner's perspective and acts as a mediator, offering supportive feedback that helps clarify and connect ideas. In doing so, the teacher builds on students' contributions to deepen understanding at both the individual and group levels. While subject-matter expertise is essential, it should not be used to impose a particular viewpoint. Instead, the teacher encourages dialogue, welcomes diverse perspectives, and creates space for new ideas and questions to emerge. Familiarity with the basic principles and steps of Attentive Teaching is important, though a formal pedagogical background is not required. Above all, the environment must remain non-judgmental, ensuring that students feel heard and free to express their views openly. By introducing new concepts through the ideas and reactions that emerge from the group, the method encourages students to express their viewpoints, doubts, and emotions, fostering greater involvement and engagement with the topics (Gal et al., 2023; Schur, 2025). The visual component plays a central role in this process, as drawings help externalize thoughts that might otherwise remain implicit, allowing students to reflect on their assumptions and communicate them to others in the classroom. In our work, we selected 14 students and used this methodology to obtain both visual representations of their perceptions and an interactive discussion based on the Attentive Teaching approach. The students were drawn from the second year of a master's degree program for several reasons. First, we assume that those approaching the end of their academic journey and preparing to enter the job market are more mature in addressing issues they are likely to encounter soon, requiring less theoretical instruction and benefiting more from practical learning. In addition, we expect these students to be more receptive to novel and varied teaching approaches compared to those at earlier stages of their studies. Finally, their level of experience allows for more open interaction, enabling us to gather feedback and evaluate their perceptions of the approach. This does not imply that the methodology cannot be applied to other student levels; its suitability depends on the topic and the instructor's objectives. The objective was to better understand students' priorities, levels of engagement, and possible feelings of disillusion toward topics such as business ethics, corporate responsibility, and sustainability. The session began with a brief introduction of the key concepts of Business Ethics (BE), Corporate Social Responsibility (CSR), and the Sustainable Development Goals (SDGs), presented mainly as evocative themes rather than as a traditional lecture. Students were then asked to interpret these topics by creating visual representations of how they perceive ethical issues in the contemporary economic system. Participants were given approximately 20–30 minutes to produce their drawings. They could choose to draw manually or use artificial intelligence tools, such as ChatGPT, to support the creative process, provided that they shared the prompts used. Interestingly, around half of the students decided to draw by hand despite the availability of digital tools. This phase was designed to allow students to reflect individually and translate their perceptions into visual form, without strong guidance from the instructors. Once the drawings were completed, each student presented their work to the class and explained the ideas behind it. This moment becomes the starting point for a collective discussion, where students compare interpretations, question one another's viewpoints, and connect their ideas with broader ethical themes related to business practices and sustainability. The mediation was managed by two professors, the authors of the article, with background in economics and business ethics. The discussion was intentionally open and exploratory, allowing different perspectives to emerge and evolve through dialogue. Attention was also given to the emotions that surfaced during the activity, since the Attentive Teaching methodology recognizes that ethical reflection often involves not only rational arguments but also feelings such as uncertainty, frustration, or hope. Through this process, the classroom becomes a shared space of interpretation and reflection, where students could explore ethical dilemmas, discuss the role of companies in society, and critically examine their own assumptions about business practices. The combination of visual expression, peer interaction, and facilitated discussion allows to collect qualitative insights about how students perceive ethical challenges in contemporary economic systems and how they emotionally and cognitively relate to these issues. To collect data, we relied on written notes taken during the discussion, including detailed summaries of each student's contribution and selected direct quotes. When possible, recording the session can also be useful for revisiting and analyzing the discussion. Additionally, after some time to have an objective view, we reached out to seven students who had attended the session and invited them to provide honest feedback on their experience.*

Results. *The activity produced a high level of engagement, with almost all students actively participating in the discussion and defending or revising their ideas in response to peers' comments. Compared to traditional lecture dynamics, the atmosphere was more interactive and collaborative, and students appeared more willing to share their personal interpretations and doubts. Even those who initially seemed less confident eventually contributed to the discussion by reacting to the ideas presented by their classmates. The session also revealed a strong emotional dimension: students openly expressed feelings such as anxiety, frustration, and uncertainty when confronting ethical tensions or conflicting perspectives. In several moments of the discussion, emotions such as anger toward perceived unfair economic dynamics or distrust toward corporate communication clearly emerged. Rather than being treated as distractions, these emotions were incorporated into the discussion to explore how feelings interact with rational reasoning in ethical decision-making. In many cases, the discussion moved naturally between emotional reactions and attempts to rationalize or justify certain positions, showing how ethical reflection often involves both dimensions. The drawings themselves often reflected contrasting attitudes toward the contemporary economic system. Some representations conveyed negative perceptions, such as depictions of ethical dilemmas as traps or references to manipulative practices like greenwashing or "marketing of guilt." Other drawings suggested more hopeful interpretations, using symbols such as trees, green landscapes, compasses, or lighthouses to represent guidance, sustainability, and the possibility of responsible economic behavior. These visual contrasts highlighted how students can simultaneously hold critical and optimistic views about the role of business in society. Interestingly, while emotions were strongly expressed during the discussion, they were rarely depicted explicitly in the drawings. Instead, several visualizations emphasized cognitive processes, including symbols such as brains, crossroads, or decision pathways. About a quarter of the drawings included a brain as a central element. This suggests that students often associate ethical judgment primarily with rational thinking even when emotional reactions are present and explicitly acknowledged during discussion. During the exchange of ideas, students reflected on the complexity of ethical decision-making and recognized that choices may be influenced not only by rational evaluation but also by intuition and emotional responses. This idea emerged clearly when students debated how individuals make moral decisions: some emphasized conscious reasoning and fairness as the main drivers of ethical choices, while others highlighted empathy, communication, or instinct as equally important elements. These discussions suggested a growing awareness among students that ethical decision-making is rarely a purely rational process. The activity also revealed a high degree of polarization in students' perceptions of contemporary economic actors. Many participants expressed strong criticism toward large corporations and economic practices perceived as unsustainable or manipulative, frequently mentioning examples such as greenwashing, over-capitalization, or aggressive commercial strategies. At the same time, several students framed ethical responsibility through a clear distinction between "us," representing individuals with moral values and ideals, and "them," referring to companies, politicians, or other powerful actors often perceived as unethical. This narrative appeared repeatedly throughout the discussion and reflects a broader generational tension in the way economic institutions are perceived. While this perspective demonstrates a strong ethical sensitivity, it also reveals a certain distance between students and the economic systems in which they will eventually participate. This tension became particularly visible when students acknowledged that, despite their skepticism toward corporate behavior, they would likely accept employment in such organizations if given the opportunity. Their justifications often referred to practical considerations, such as the need to work, build a career, or gain professional experience. In some cases, students did not perceive this separation between personal ideals and professional choices as contradictory, suggesting that ethical reflection may coexist with pragmatic decision-making. Another theme that emerged spontaneously was the ethical dimension of artificial intelligence and data privacy. One student, for example, initially planned to use ChatGPT only to generate ideas for her drawing but eventually relied on it to complete the image. Reflecting on this experience, she commented that in doing so she had "lost her dilemma," illustrating how easily practical convenience can override initial ethical intentions. This example sparked a broader discussion about the difficulty of maintaining ethical coherence when technological tools offer efficient but potentially problematic solutions. More generally, students showed awareness that digital platforms and AI systems create ethical dilemmas related to privacy, transparency, and responsibility, even when users willingly accept the trade-offs involved. Finally, the session also highlighted how students' apparent indifference toward ethical topics in traditional settings may sometimes hide deeper emotions or concerns. When given the opportunity to express themselves creatively and discuss their ideas openly, many students moved beyond passive attitudes and engaged with the ethical implications of contemporary economic practices in a more personal and reflective way.*

Overall, the AT session demonstrated that when students are invited to actively interpret ethical issues rather than passively receive information, they engage more deeply with the subject matter and express a wider range of reflections, emotions, and perspectives. The combination of visual expression, peer discussion, and emotional awareness allowed students to explore ethical dilemmas in a more personal and reflective way, highlighting not only their cognitive understanding of business ethics but also the underlying values, uncertainties, and tensions that shape their views of contemporary economic life.

In their subsequent oral feedback, all seven students emphasized the very positive impact this methodology had on their academic experience. They highlighted the value of being able to express their opinions without fear of judgment, which significantly increased their engagement. Some noted that they retained concepts from this session more effectively than from entire courses delivered through traditional lectures. One student pointed out that not knowing in advance how the session would unfold helped them feel more at ease and express themselves freely. While this initial uncertainty might seem like a limitation in repeated sessions, it is likely that, once students understand the non-judgmental nature of the

approach, any initial hesitation would diminish. Moreover, most students found that listening to their peers' perspectives and approaches to problem-solving greatly enriched their learning. Finally, they stressed the importance of the teacher's role as a mediator, appreciating how instructors positioned themselves on the same level as students, without imposing their views or dismissing alternative perspectives.

Research limitations. *The Attentive Teaching approach is not without limitations. First, it becomes more challenging as the number of students increases, particularly in relation to interaction, active listening, and the tracking of notes. Although the method has been shown to provide strong benefits, instructors who wish to adopt it should have some prior experience with the approach, to ensure that their facilitation does not unintentionally bias students' impressions or influence the topics discussed in class. To mitigate this risk, dedicated materials such as practical operational guidelines and suggested starting topics, which means prompt for what students can be asked to draw, could help ensure a smooth and meaningful learning experience. Moreover, the limited number of students and sessions makes this study only a first step in a broader experiment that is needed to identify common patterns among students. In fact, it is part of a project that aims to apply this approach across different countries and universities, collecting both qualitative data, as in this case, and quantitative results through dedicated surveys.*

Managerial implications. *From a company perspective, students frequently perceive firms as distant or morally problematic actors, and they tend to have a negative view of corporate communication, often associating it with greenwashing or overly polished narratives that do not reflect reality. Companies should therefore find ways to close this perception gap with younger generations, so that organizations are no longer perceived as distant or inherently unethical, but rather as a natural part of their future professional lives and, above all, as entities made up of human beings who are capable of making good decisions, behaving ethically, and sometimes making honest mistakes. Managers should break this perceived "wall of invincibility" and begin sharing their decision-making processes more openly, including the difficulties, emotions, and trade-offs involved in real business situations. Showing how decisions are made and acknowledging that ethical dilemmas often involve uncertainty and imperfect choices, could help make companies appear more credible and relatable.*

Moreover, marketing and communication strategies should consider how younger generations approach these messages: they tend to be skeptical, they question companies and focus on profit as the sole priority, they are more aware of social and environmental issues, and they have grown up with technology and social media, which they navigate naturally. As a result, traditional corporate communication that focuses only on positive narratives may be perceived as inauthentic or manipulative. Companies should therefore adopt more transparent and dialogic forms of communication, where stakeholders, especially younger audiences, can see not only the achievements but also the challenges and limitations organizations face. Creating spaces for dialogue with students and young professionals could also help companies better understand their expectations and concerns, turning this critical attitude into an opportunity for constructive engagement rather than mistrust.

Considering the pedagogical side, this project views the individual, the student in this case, as the focus of ethical business-related activities and aims to create new pedagogical materials and methods to optimally engage the student in education that might positively impact future professional ethical behavior, using novel approaches that have a positive effect on the students interaction, improving critical thinking and giving different perspectives on the topic. Considering the issue of moral disengagement (Bandura, 1999), we show that innovative teaching methods can positively influence student interaction and help reduce disengagement.

Originality of the paper. *Our work combines perspectives from management, business ethics, education, and psychology to identify effective ways to teach and engage future managers and workers. This multidisciplinary approach is distinctive, as it considers both the economic relevance and content of these topics and the ways in which students can be more effectively engaged with them. Our study does not focus only on what should be taught in business ethics and sustainability education, but also on how these topics can be experienced by students in a meaningful way. The added value of Attentive Teaching is that it works by emphasizing the teacher's role as a mediator while keeping learners actively engaged. The teacher listens to students' ideas and responds with feedback, often through individual contributions shared in whole-class discussions, allowing peers to learn from one another. Through this ongoing dialogic process, understanding is gradually developed, both individually and collectively among students. The initial visual representation allows the teacher to observe the learner's thinking process with no preconcepts or influence and their level of understanding: learners develop their own outputs to express their unique perspectives on the given topic, and this becomes the input level to develop the discussion. In our work, we show how this methodology could be applied in business ethics courses and shows that with this method there is a positive effect on the reduction of the moral disengagement theorized by Bandera (1999), and that this learning approach is positively welcomed by the students.*

Integrating participatory teaching methods and addressing emotions is crucial in ethics education, since ethical decision-making is rarely based only on rational reasoning but also involves feelings, values, and personal experiences. By encouraging students to express their ideas through drawings, discussion, and reflection, the Attentive Teaching approach allows deeper reactions, doubts, and expectations to emerge. At the same time, this approach provides companies with a way to receive direct, structured feedback from younger generations through creative and interactive activities. In this sense, the classroom can become not only a learning environment but also a space where organizations

can better understand how future employees and consumers perceive business practices, communication strategies, and ethical responsibilities.

Il purpose dell'impresa come frame interpretativo della resilienza d'impresa

MARTINA TAFURO[1], VALENTINA CUCINO[2], ANDREA PICCALUGA[3]

Abstract. *Negli ultimi anni il corporate purpose ha acquisito crescente rilevanza nel dibattito accademico e manageriale come elemento fondativo per la creazione di valore di lungo periodo e per l'impatto sociale delle imprese. Tuttavia, le evidenze empiriche sui suoi effetti organizzativi restano ancora limitate. Questo studio analizza la relazione tra corporate purpose e resilienza dell'impresa, intesa come la capacità di assorbire shock, riconfigurare le proprie pratiche e mantenere la performance in condizioni di incertezza.*

L'analisi si basa su dati raccolti tramite survey su un campione di 268 imprese italiane. Attraverso modelli di regressione OLS viene testata l'esistenza di una relazione non lineare tra purpose e resilienza. I primi risultati evidenziano una relazione asimmetrica a forma di U: la resilienza tende a diminuire a livelli bassi o intermedi di purpose, ma aumenta significativamente quando il purpose è chiaramente definito e profondamente integrato nelle pratiche organizzative.

Lo studio analizza inoltre il ruolo moderatore di alcune caratteristiche organizzative, in particolare lo status giuridico di Società Benefit e la presenza di proprietà familiare. I risultati suggeriscono che, sebbene il purpose possa rafforzare la resilienza, la sua efficacia dipende dal modo in cui viene implementato e dal contesto organizzativo in cui opera.

Nel complesso, lo studio contribuisce alla letteratura fornendo evidenze empiriche sulla natura non lineare e contingente della relazione tra corporate purpose e resilienza organizzativa, evidenziando come il purpose possa agire come cornice interpretativa capace di sostenere le dimensioni cognitive ed emotive della resilienza.
Keywords: *Corporate purpose; resilienza organizzativa; sensemaking; Società Benefit;*

Framing of the research. Negli ultimi anni il concetto di corporate purpose ha acquisito crescente centralità nel dibattito accademico e manageriale, emergendo come uno dei principali riferimenti teorici per comprendere il ruolo contemporaneo delle imprese nella società (Chua et al., 2024; George et al., 2023; Mayer, 2023). La letteratura manageriale ha progressivamente superato una visione dell'impresa esclusivamente orientata alla massimizzazione del profitto, riconoscendo l'importanza di integrare obiettivi economici con finalità sociali e ambientali più ampie (Cucino et al., 2025; George et al., 2023; Mayer, 2023; Tafuro & Piccaluga, 2025). In questo contesto, il corporate purpose è stato interpretato come la ragione fondamentale dell'esistenza di un'organizzazione, ossia il principio guida che orienta le scelte strategiche e definisce il contributo che l'impresa intende apportare alla società (Mayer, 2023).

Questo cambiamento di prospettiva riflette l'emergere di un contesto economico caratterizzato da crescente complessità e da sfide globali di natura sistemica (Cucino et al., 2026; Gerorge et al., 2023). Fenomeni quali il cambiamento climatico (Di Minin et al., 2023), l'instabilità geopolitica, le crisi sanitarie (Cucino et al., 2026) e l'aumento delle disuguaglianze sociali legate a fenomeni di fragilità umana (Cucino et al., 2025) hanno infatti messo in discussione modelli tradizionali di gestione dell'impresa, evidenziando la necessità di sviluppare nuove capacità organizzative orientate alla resilienza e all'adattamento (Tafuro & Piccaluga, 2025). In tali contesti, le imprese sono chiamate non soltanto a reagire agli shock esterni, ma anche a sviluppare forme di adattamento dinamico che consentano loro di riorganizzare le proprie risorse e continuare a operare efficacemente nel lungo periodo (Crane et al., 2015; Cucino, 2023)

All'interno di questo quadro teorico, il concetto di resilienza organizzativa ha acquisito crescente rilevanza. La resilienza viene generalmente definita come la capacità delle organizzazioni di assorbire perturbazioni, adattarsi ai cambiamenti e continuare a perseguire i propri obiettivi anche in condizioni di forte incertezza (Burnard & Bhamra, 2011; Duchek, 2020). Tuttavia, la resilienza non dipende esclusivamente da fattori strutturali o operativi. Numerosi studi hanno evidenziato come essa sia profondamente radicata nei processi cognitivi ed emotivi che caratterizzano le organizzazioni, ossia nei modi attraverso cui gli attori interpretano gli eventi, attribuiscono significato alle situazioni e coordinano le proprie azioni.

In questa prospettiva, la teoria del sensemaking offre un quadro interpretativo particolarmente utile per comprendere il ruolo del corporate purpose nello sviluppo della resilienza organizzativa. Secondo Weick (1995), il sensemaking rappresenta il processo attraverso il quale gli individui costruiscono significati condivisi che consentono loro di interpretare eventi ambigui e orientare l'azione collettiva. Nei momenti di crisi o di cambiamento, gli attori organizzativi si trovano infatti a dover interpretare segnali spesso incompleti o contraddittori, cercando di costruire narrazioni coerenti che permettano di comprendere ciò che sta accadendo e di definire possibili risposte organizzative.

In tale contesto, il corporate purpose può essere interpretato come un vero e proprio frame interpretativo che orienta i processi di sensemaking all'interno delle organizzazioni. Il purpose fornisce infatti una cornice di significato attraverso

[1] San'Anna School of Advanced Studies, e-mail: martina.tafuro@santannapisa.it
[2] LUMSA University, e-mail: v.cucino@lumsa.it
[3] Sant'Anna School of Advanced Studies,e-mail: andrea.piccaluga@santannapisa.it

la quale gli attori organizzativi interpretano gli eventi, attribuiscono priorità alle azioni e coordinano le proprie decisioni strategiche. Quando il purpose è chiaramente definito e condiviso, esso può contribuire a ridurre l'ambiguità interpretativa e favorire l'allineamento tra i diversi membri dell'organizzazione.

Nonostante queste potenzialità teoriche, la relazione tra corporate purpose e resilienza organizzativa rimane ancora relativamente poco esplorata dal punto di vista empirico. Gran parte della letteratura esistente si concentra infatti su analisi concettuali o su studi qualitativi, mentre risultano ancora limitate le ricerche empiriche che analizzano in modo sistematico gli effetti del purpose sulle performance organizzative o sulle capacità adattive delle imprese. Inoltre, alcuni studi recenti hanno iniziato a evidenziare possibili ambivalenze associate all'adozione del corporate purpose (Tafuro & Piccaluga, 2025). In particolare, è stato osservato che molte organizzazioni tendono ad adottare dichiarazioni di purpose principalmente per finalità reputazionali o comunicative, senza che queste siano realmente integrate nelle pratiche organizzative. Questo fenomeno, spesso definito purpose-washing, può generare disallineamenti interni e ridurre la credibilità delle iniziative aziendali orientate al purpose (Aguilera, 2023; Findlay, & Moran, 2019; Gulati & Wohlgezogen, 2023).

Alla luce di queste considerazioni, appare plausibile ipotizzare che la relazione tra corporate purpose e resilienza organizzativa non sia necessariamente lineare. In alcuni casi, livelli intermedi o superficiali di purpose potrebbero addirittura generare effetti negativi, soprattutto quando le dichiarazioni di purpose non sono accompagnate da cambiamenti concreti nelle pratiche organizzative. Al contrario, quando il purpose è profondamente radicato nelle strutture decisionali e nei processi organizzativi, esso può diventare un potente fattore di coordinamento e di interpretazione, contribuendo a rafforzare le capacità adattive delle imprese.

Purpose of the paper. Alla luce delle lacune presenti nella letteratura, il presente studio si propone di analizzare la relazione tra corporate purpose e resilienza organizzativa, con l'obiettivo di comprendere se e in quale misura il purpose possa contribuire allo sviluppo di capacità adattive nelle imprese.

In particolare, la ricerca intende indagare due questioni principali. La prima riguarda l'esistenza di una relazione tra corporate purpose e resilienza organizzativa. Più concretamente, si intende verificare se il corporate purpose contribuisca a rafforzare la resilienza delle imprese in contesti caratterizzati da elevata incertezza. Sebbene numerosi studi abbiano suggerito che le organizzazioni guidate da un forte purpose possano sviluppare maggiori capacità di adattamento, mancano ancora evidenze empiriche robuste che confermino tale relazione.

La seconda questione riguarda la natura di questa relazione. Come evidenziato in precedenza, alcune evidenze teoriche suggeriscono che l'impatto del purpose sulle dinamiche organizzative possa essere non lineare. In particolare, livelli iniziali di purpose potrebbero non essere sufficienti a generare benefici significativi, mentre livelli più elevati, caratterizzati da una forte integrazione del purpose nelle pratiche organizzative, potrebbero produrre effetti più marcati sulla resilienza.

Partendo dalla prospettiva del sensemaking (Weick, 1995; Maitlis & Christianson, 2014), il corporate purpose viene interpretato come una cornice interpretativa che consente ai membri dell'organizzazione di comprendere ambienti complessi, coordinare le proprie azioni e mobilitare risorse cognitive ed emotive in risposta alle avversità. Studi precedenti suggeriscono infatti che il purpose possa favorire l'allineamento interno e la costruzione di significati condivisi, elementi fondamentali per la capacità adattiva delle organizzazioni (Lengnick-Hall et al., 2011; George et al., 2023).

Lo studio analizza inoltre il ruolo moderatore di alcune caratteristiche organizzative. In particolare, viene esaminato l'effetto dello status giuridico di Società Benefit e della proprietà familiare sulla relazione tra corporate purpose e resilienza. Le Società Benefit incorporano formalmente obiettivi sociali e ambientali nelle proprie strutture di governance (Rawhouser et al., 2015), mentre le imprese familiari presentano spesso orientamenti valoriali e prospettive di lungo periodo che influenzano i processi decisionali (De Massis & Rondi, 2020).

Attraverso questa analisi, il paper contribuisce alla letteratura sul corporate purpose offrendo evidenze empiriche sul suo ruolo nel rafforzare la resilienza organizzativa.

Methodology. L'analisi empirica si basa su una survey condotta su un campione di imprese italiane. Il questionario è stato sviluppato utilizzando scale validate presenti nella letteratura.I dati sono stati raccolti attraverso interviste telefoniche assistite da computer tra settembre e dicembre 2024. Il dataset finale include 268 imprese operanti in diversi settori economici e distribuite su tutto il territorio italiano.

Particolare attenzione è stata dedicata alla costruzione del campione, al fine di garantire la comparabilità tra imprese con diverse caratteristiche organizzative. A tal fine è stata adottata una procedura di matched sampling che ha consentito di selezionare imprese simili in termini di dimensione, settore e localizzazione geografica.

La resilienza organizzativa è stata misurata utilizzando la scala sviluppata da Richtnér e Löfsten (2014), che consente di catturare sia la dimensione cognitiva sia quella emotiva della resilienza. Il corporate purpose è stato invece misurato utilizzando la Perceived Organizational Purpose Scale sviluppata da Jasinenko e Steuber (2022), che considera diverse dimensioni del purpose, tra cui contributo sociale, autenticità, capacità di orientamento e capacità ispirazionale.

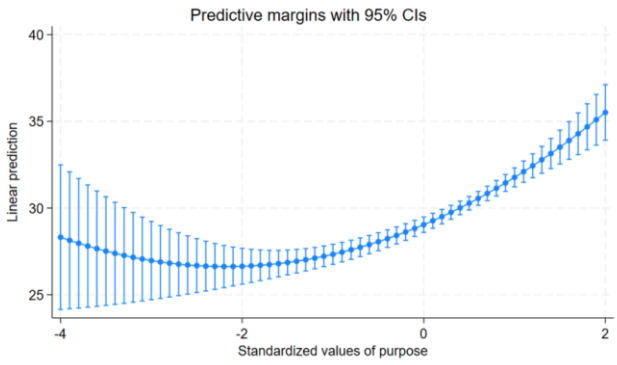
Il campione comprende sia Società Benefit sia imprese tradizionali, oltre a imprese familiari e non familiari. Questa configurazione consente di analizzare come diverse forme organizzative possano influenzare la relazione tra corporate purpose e resilienza.

Tabella 1 - Distribuzione del campione

Caratteristica	Numero imprese	Percentuale
Società Benefit	134	50%
Imprese non Benefit	134	50%
Imprese familiari	120	44.8%
Imprese non familiari	148	55.2%
Totale	268	100%

Tabella 2 - Principali variabili analizzate nello studio

Variabile	Tipo	Descrizione
Resilience	Dipendente	Capacità organizzativa di adattamento
Corporate Purpose	Indipendente	Percezione del purpose organizzativo
Benefit status	Moderatore	Società Benefit vs imprese tradizionali
Family ownership	Moderatore	Imprese familiari vs non familiari



Per testare le ipotesi sono stati utilizzati modelli di regressione OLS. Per analizzare la possibile relazione non lineare tra corporate purpose e resilienza sono stati inclusi nei modelli sia il termine lineare sia il termine quadratico del corporate purpose (Ye & Zhang, 2011). Sono stati inoltre introdotti termini di interazione per analizzare gli effetti moderatori dello status di Società Benefit e della proprietà familiare. Infine, sono state incluse alcune variabili di controllo relative alla dimensione dell'impresa, all'età dell'organizzazione, al settore di attività, alla regione geografica e alla redditività.

Results. L'analisi empirica è stata condotta utilizzando modelli di regressione OLS, in linea con studi precedenti che analizzano relazioni tra corporate purpose e performance organizzative (Gartenberg et al., 2019; Gartenberg & Serafeim, 2023). L'obiettivo principale dell'analisi è stato verificare l'esistenza e la natura della relazione tra corporate purpose e resilienza organizzativa, nonché il ruolo moderatore di alcune caratteristiche delle imprese.

I primi risultati evidenziano un andamento a U asimmetrica: ai livelli iniziali di corporate purpose la resilienza tende a diminuire leggermente, mentre oltre una certa soglia essa cresce in maniera significativa. Questo andamento suggerisce che l'introduzione del purpose all'interno delle organizzazioni può inizialmente generare dinamiche di disallineamento o ambiguità interpretativa. Quando il purpose non è ancora pienamente integrato nei processi decisionali o nelle pratiche organizzative, esso può essere percepito come una dichiarazione retorica o come un elemento estraneo alla cultura aziendale.

Al contrario, quando il corporate purpose diventa progressivamente più chiaro, condiviso e integrato nelle routine organizzative, esso inizia a svolgere una funzione di orientamento strategico e interpretativo che rafforza le capacità adattive dell'organizzazione. Questo andamento è rappresentato graficamente nella Figura 1, che illustra la relazione quadratica tra corporate purpose e resilienza.

Figura 1 Predictive margins of corporate purpose on firm's resilience

La figura mostra come la resilienza diminuisca leggermente nella fase iniziale di sviluppo del purpose, per poi aumentare rapidamente quando il purpose diventa più profondamente radicato nell'organizzazione. Questo risultato conferma empiricamente quanto suggerito dalla letteratura sul sensemaking, secondo cui la presenza di un frame interpretativo condiviso consente agli attori organizzativi di coordinare le proprie azioni e interpretare in modo più efficace situazioni ambigue o incerte.

Oltre alla relazione principale tra corporate purpose e resilienza, l'analisi ha esaminato il ruolo moderatore di alcune caratteristiche organizzative, in particolare lo status di Società Benefit e la proprietà familiare dell'impresa.

Per quanto riguarda lo status di Società Benefit, i risultati mostrano che il suo effetto diretto sulla resilienza non è statisticamente significativo. Tuttavia, l'interazione tra corporate purpose e status di Società Benefit evidenzia un pattern più articolato. In particolare, il coefficiente associato al termine quadratico dell'interazione risulta negativo e debolmente significativo, suggerendo che nelle Società Benefit l'effetto positivo del purpose sulla resilienza tende ad attenuarsi ai livelli più elevati di purpose. In particolare, nelle imprese che hanno adottato lo status giuridico di Società Benefit, la relazione tra purpose e resilienza assuma un andamento leggermente diverso rispetto alle imprese tradizionali. Sebbene queste imprese presentino livelli medi di resilienza relativamente elevati, l'effetto marginale del purpose tende a ridursi ai livelli più alti. Questo risultato può essere interpretato considerando il fatto che nelle Società Benefit il purpose è spesso formalizzato nello statuto aziendale e integrato nei meccanismi di governance, il che può ridurre la variabilità dell'effetto del purpose sulla resilienza.

L'analisi ha inoltre esaminato il ruolo della proprietà familiare. I risultati indicano che le imprese familiari presentano livelli medi di resilienza più elevati rispetto alle imprese non familiari. Questo risultato è coerente con la letteratura sulle imprese familiari, che evidenzia come queste organizzazioni siano spesso caratterizzate da una forte identità organizzativa, da relazioni di fiducia consolidate e da una visione di lungo periodo.

Tuttavia, l'interazione tra corporate purpose e proprietà familiare mostra un effetto negativo significativo per il termine lineare dell'interazione. Ciò suggerisce che nelle imprese familiari livelli molto elevati di corporate purpose potrebbero generare tensioni o rigidità organizzative che limitano l'effetto positivo del purpose sulla resilienza.

Infine, il modello esplora anche l'effetto congiunto della combinazione tra status di Società Benefit e proprietà familiare. I risultati suggeriscono che le imprese che presentano entrambe queste caratteristiche tendono a mostrare livelli relativamente elevati di resilienza, ma l'effetto marginale del corporate purpose appare più limitato.

Nel complesso, i risultati confermano che il corporate purpose può rappresentare un importante fattore di resilienza organizzativa, ma evidenziano anche che la relazione tra queste due variabili è complessa e dipende da diverse condizioni organizzative.

Research limitations. Questo studio presenta alcuni limiti che aprono possibili direzioni per ricerche future. In primo luogo, l'analisi si basa su dati cross-sectional, il che limita la possibilità di stabilire relazioni causali tra corporate purpose e resilienza. Studi longitudinali potrebbero offrire una comprensione più approfondita dell'evoluzione del purpose nel tempo e del suo impatto sulla capacità adattiva delle imprese.

In secondo luogo, le misure utilizzate si basano su percezioni auto-riportate dai manager. Sebbene questo approccio sia utile per analizzare i processi di sensemaking all'interno delle organizzazioni (Weick et al., 2005), esso può essere soggetto a bias percettivi.

Infine, lo studio analizza solo due variabili moderatrici. Ricerche future potrebbero esplorare il ruolo di ulteriori fattori organizzativi, come gli stili di leadership, le strutture di governance o i processi di coinvolgimento degli stakeholder.

Managerial implications. I risultati dello studio offrono alcune importanti implicazioni per i manager.

In primo luogo, l'adozione di un corporate purpose superficiale o puramente simbolico può risultare controproducente. Quando il purpose non è integrato nelle pratiche organizzative, esso può generare scetticismo o confusione tra i membri dell'organizzazione, indebolendo la resilienza. Questo risultato evidenzia un aspetto spesso trascurato nel dibattito manageriale: adottare dichiarazioni di purpose senza un reale cambiamento nelle pratiche organizzative può generare ambiguità interpretativa, disallineamento interno e perdita di credibilità tra i membri dell'organizzazione. In altre parole, un purpose debole o puramente simbolico non rappresenta una condizione neutrale, ma può compromettere la capacità dell'organizzazione di interpretare correttamente le situazioni di crisi e di coordinare le proprie risposte.

Per i manager ciò implica che l'introduzione del corporate purpose richiede un processo di trasformazione organizzativa più ampio. Il purpose deve essere tradotto in criteri concreti di decisione strategica, integrato nei sistemi di governance e incorporato nei processi quotidiani dell'organizzazione. Ciò significa, ad esempio, che le decisioni di investimento, le politiche di gestione delle risorse umane e le strategie di innovazione dovrebbero essere coerenti con il purpose dichiarato. Solo quando il purpose diventa parte integrante delle pratiche organizzative esso può funzionare come un vero e proprio "frame interpretativo" che aiuta l'organizzazione a interpretare segnali complessi e a coordinare azioni collettive nei momenti di incertezza.

In secondo luogo, i risultati mostrano che il corporate purpose può diventare una leva importante per rafforzare la resilienza organizzativa quando è chiaramente articolato e profondamente radicato nella cultura aziendale. In queste condizioni, il purpose contribuisce a rafforzare sia la dimensione cognitiva sia quella emotiva della resilienza. Dal punto di vista cognitivo, esso fornisce una direzione chiara che aiuta i membri dell'organizzazione a interpretare eventi ambigui e a identificare priorità strategiche. Dal punto di vista emotivo, il purpose contribuisce a creare un senso di significato condiviso che può rafforzare motivazione, fiducia e coesione organizzativa nei momenti di crisi.

Per i leader organizzativi ciò implica che il purpose dovrebbe essere comunicato e coltivato non solo attraverso dichiarazioni formali, ma anche attraverso narrazioni organizzative, pratiche simboliche e comportamenti di leadership coerenti. Storytelling organizzativo, rituali aziendali e sistemi di riconoscimento dei comportamenti coerenti con il purpose possono contribuire a rafforzare la sua credibilità e a favorire la costruzione di significati condivisi all'interno dell'organizzazione.

Una terza implicazione riguarda il ruolo delle caratteristiche organizzative nel modulare l'effetto del corporate purpose. I risultati mostrano infatti che lo status di Società Benefit e la proprietà familiare influenzano il modo in cui il

purpose si traduce in resilienza organizzativa. Nel caso delle Società Benefit, la formalizzazione del purpose nello statuto aziendale e nei meccanismi di governance può contribuire a rafforzare la credibilità del purpose e a favorire l'allineamento tra gli stakeholder. Tuttavia, questa formalizzazione può anche introdurre elementi di rigidità procedurale che riducono la flessibilità organizzativa in alcune situazioni.

Per i manager delle Società Benefit ciò implica la necessità di trovare un equilibrio tra formalizzazione e flessibilità. Da un lato, è importante mantenere meccanismi di accountability e trasparenza che garantiscano la coerenza tra purpose dichiarato e azioni concrete. Dall'altro, è fondamentale preservare spazi di sperimentazione e apprendimento che consentano all'organizzazione di adattarsi rapidamente ai cambiamenti dell'ambiente esterno.

Nel caso delle imprese familiari, i risultati suggeriscono che la resilienza organizzativa tende a essere relativamente elevata grazie alla presenza di valori condivisi, relazioni di fiducia e orientamento di lungo periodo. Tuttavia, l'introduzione di un corporate purpose formalizzato può talvolta entrare in tensione con l'identità storica o con la legacy familiare dell'impresa. In questi casi, il purpose rischia di essere percepito come un elemento esterno piuttosto che come un'estensione naturale dei valori dell'impresa.

Per le imprese familiari diventa quindi cruciale sviluppare un purpose che sia coerente con la storia e con l'identità della famiglia imprenditoriale. Integrare il purpose con la narrativa familiare e con i valori fondanti dell'impresa può facilitare la sua accettazione da parte dei membri dell'organizzazione e rafforzare la sua capacità di orientare le decisioni strategiche.

Infine, i risultati di questo studio suggeriscono che lo sviluppo di un'organizzazione realmente purpose-driven rappresenta un processo graduale che richiede tempo, coerenza e impegno da parte del top management. I manager dovrebbero essere consapevoli che l'introduzione del purpose può inizialmente generare resistenze o scetticismo, soprattutto se i membri dell'organizzazione percepiscono un divario tra dichiarazioni e pratiche concrete. Superare questa fase iniziale richiede un forte impegno di leadership e una comunicazione trasparente sulle motivazioni e sugli obiettivi del purpose.

In questo senso, il messaggio principale che emerge da questa ricerca può essere riassunto in modo semplice: se un'organizzazione decide di adottare un corporate purpose come guida strategica, è fondamentale portare questo processo fino in fondo. Fermarsi a metà strada, limitandosi a dichiarazioni simboliche o a iniziative isolate, rischia di compromettere i benefici potenziali del purpose e di indebolire la resilienza dell'organizzazione stessa.

Originality of the paper. Questo studio contribuisce alla letteratura sul corporate purpose e sulla resilienza organizzativa in diversi modi.

In primo luogo, il paper contribuisce al crescente dibattito accademico sul corporate purpose fornendo evidenze empiriche sui suoi effetti organizzativi. Sebbene il concetto di purpose abbia ricevuto crescente attenzione negli ultimi anni, gran parte della letteratura si è concentrata su discussioni concettuali e normative piuttosto che su analisi empiriche sistematiche (George et al., 2023; Mayer, 2023). In questo senso, il presente studio risponde alla crescente richiesta di ricerche empiriche che analizzino come il purpose influenzi concretamente i risultati organizzativi.

In secondo luogo, lo studio contribuisce alla letteratura sulla resilienza organizzativa, introducendo il corporate purpose come possibile antecedente della resilienza. La ricerca esistente ha prevalentemente analizzato la resilienza in relazione a fattori strutturali, operativi o strategici, come le capacità organizzative, le risorse disponibili o i sistemi di gestione delle crisi (Burnard & Bhamra, 2011; Duchek, 2020). Questo lavoro amplia tale prospettiva mostrando come elementi simbolici e valoriali, quali il corporate purpose, possano influenzare la capacità delle organizzazioni di affrontare situazioni di incertezza.

In terzo luogo, il paper offre un contributo teorico alla letteratura sul sensemaking organizzativo interpretando il corporate purpose come una cornice interpretativa che guida i processi di costruzione di significato all'interno delle organizzazioni. In linea con la prospettiva del sensemaking (Weick, 1995; Maitlis & Christianson, 2014), il purpose può aiutare i membri dell'organizzazione a interpretare segnali provenienti dall'ambiente esterno, coordinare le proprie azioni e sviluppare risposte adattive in contesti complessi e incerti. In questo senso, lo studio evidenzia come il purpose possa sostenere sia la dimensione cognitiva sia quella emotiva della resilienza organizzativa (Lengnick-Hall et al., 2011).

In quarto luogo, lo studio mostra che la relazione tra corporate purpose e resilienza non è lineare ma segue una dinamica a forma di U. Questo risultato suggerisce che livelli intermedi di purpose possano generare ambiguità organizzativa o disallineamenti tra valori dichiarati e pratiche effettive, mentre livelli elevati di purpose, quando realmente integrati nelle pratiche organizzative, possano rafforzare la capacità adattiva dell'impresa. Tale evidenza contribuisce al dibattito recente sull'ambivalenza del corporate purpose, che evidenzia come un purpose superficiale o simbolico possa risultare inefficace o addirittura controproducente (Aguilera, 2023; Gulati & Wohlgezogen, 2023).

Infine, il paper contribuisce alla letteratura evidenziando il ruolo contingente delle caratteristiche organizzative. In particolare, l'analisi mostra come lo status di Società Benefit e la proprietà familiare possano influenzare la relazione tra purpose e resilienza. Studi precedenti hanno suggerito che le imprese familiari possano sviluppare forme specifiche di resilienza legate a relazioni di fiducia e orientamenti di lungo periodo (De Massis & Rondi, 2020), mentre le Società Benefit incorporano formalmente obiettivi sociali e ambientali nelle proprie strutture di governance (Rawhouser et al., 2015). Integrando queste prospettive, il presente studio evidenzia come il corporate purpose interagisca con tali caratteristiche organizzative, influenzando in modo diverso la capacità adattiva delle imprese.

Nel complesso, questo lavoro contribuisce alla letteratura mostrando che il corporate purpose può rappresentare una risorsa strategica per rafforzare la resilienza organizzativa, ma che la sua efficacia dipende dal grado di integrazione nelle pratiche organizzative e dal contesto istituzionale e organizzativo in cui l'impresa opera.

Shared Dynamic Capabilities for Circular Economy in the Olive Oil Supply Chain: Evidence from an Italian Benefit Corporation

LORENZO TURRIZIANI, PAOLA CASTELLANI, ANNA PRISCO

Abstract. *Implementing circular economy (CE) practices in the olive oil industry is a supply-chain challenge, as circularity depends on coordinating multiple actors to redesign material flows, valorise by-products, and align quality and sustainability requirements. Yet, CE research still offers limited insight into how firms build the organisational and inter-organisational capabilities needed to scale circular initiatives beyond isolated projects, especially in Benefit Corporations. This short paper addresses this gap by adopting a dynamic capabilities lens and focusing on the development of shared (inter-organizational) capabilities enabled by boundary-spanning mechanisms. Drawing on an in-depth qualitative case study of Olio Carli, an Italian Benefit Corporation, we investigate how intra-organisational coordination and supply-chain relationships jointly support (i) sensing circular opportunities and constraints, (ii) seizing them through collaborative experimentation and partner engagement, and (iii) reconfiguring routines, standards, and governance arrangements to institutionalize circular practices. The analysis highlights boundary spanning as a key micro-foundation of shared dynamic capabilities, enacted through cross-functional integration, boundary objects, and relational governance with supply-chain partners. The paper contributes by conceptualizing CE scaling as a capability-building process across organizational boundaries and by clarifying how purpose-oriented governance can shape coordination choices and trade-off management in circular supply networks.*
Keywords: *Dynamic capabilities; hybrid organizations; boundary spanning; circular economy; olive oil supply chain; Benefit Corporations*

Framing of the research. CE is increasingly central to debates on how firms respond to resource scarcity, stakeholder pressure and regulatory demands. However, implementation remains far from straightforward. In many sectors, circularity cannot be achieved through isolated initiatives at the individual-firm level. Rather, it requires reconfiguring material flows, waste management and value recovery across a broader network of interconnected actors (Geissdoerfer et al., 2017; Kirchherr et al., 2017; Korhonen et al., 2018). This is particularly evident in agri-food supply chains, where circular solutions must be developed without compromising traceability, food safety and product quality. In these contexts, circularity is not only a technical issue, but also an organisational and relational one, as it depends on aligning routines, standards and decision criteria across suppliers, focal firms, logistics operators, packaging partners and downstream recovery or valorisation actors (Genovese et al., 2017; Farooque et al., 2019).

The olive oil supply chain provides a suitable context for examining these dynamics. On the one hand, upstream production is often fragmented and geographically dispersed. On the other hand, decisions regarding processing, packaging and distribution are highly sensitive to product quality and compliance requirements. The sector also generates by-products and waste streams whose circular recovery often depends on specialised infrastructure and collaborative arrangements beyond the control of a single organisation. This context is particularly relevant because it brings together priorities that do not always align easily. Companies must ensure reliability, consistency and cost control whilst also meeting traceability and certification requirements and responding to expectations on waste reduction, packaging redesign and resource efficiency. For this reason, the olive oil supply chain offers a useful context for studying how circularity is organised and scaled through coordination mechanisms extending beyond the focal firm.

Although the literature on the CE has expanded significantly in recent years, some key aspects remain only partially explored. A substantial part of this literature has focused on identifying circular practices, such as reuse, recycling, reverse logistics and waste recovery, as well as on classifying business model archetypes associated with circular strategies (Bocken et al., 2016; Lieder & Rashid, 2016). These contributions have clarified the forms that circularity can take at the operational and strategic levels. However, they often say less about the organisational conditions that enable such initiatives to become stable, repeatable and scalable. Similarly, the role of supply chain relationships is widely recognised in CE studies, but often in general terms. Collaboration is often presented as necessary, whilst less attention is paid to how it is built, governed and maintained when change involves different functions, knowledge bases and organisational interests (Korhonen et al., 2018; Murray et al., 2017). Consequently, CE is still rarely analysed as a capacity-building process through which firms and partners identify circular opportunities, mobilise resources, and progressively reshape routines and relationships.

To address this issue, this study adopts the perspective of dynamic capabilities. This line of research explains how organisations respond to changing contexts by sensing opportunities and threats, seizing them through strategic action, and reconfiguring resources and routines over time (Teece et al., 1997; Teece, 2007). Such a perspective appears particularly well-suited to the study of the CE. Circular transitions are, in fact, typically characterised by uncertainty, interdependence and path dependence. Firms often make decisions under incomplete knowledge about technologies, regulation and partner availability; they operate in systems where one actor's choices influence others; and they must contend with established infrastructures and routines that may hinder change. From this perspective, circularity should

not be interpreted simply as the introduction of a predefined set of practices. Rather, it can be understood as a continuous process of learning, experimentation and organisational adaptation (Eisenhardt & Martin, 2000; Helfat et al., 2007; Winter, 2003).

At the same time, an understanding of dynamic capabilities limited to the level of the individual firm is insufficient when the achievement of circular outcomes depends on supply chain partners. Many CE initiatives in supply chains cannot be implemented by the focal firm alone. This is the case, for example, with packaging redesign aligned with recycling systems, by-product valorisation through specialised external actors, or the creation of reverse flows requiring joint investment and operational synchronisation. In situations of this kind, knowledge, relevant assets and decision-making rights are distributed beyond organisational boundaries. This suggests the need to extend the analysis towards shared or relational forms of capacity development, in which adaptation and value creation become possible thanks to the quality of inter-organisational relationships (Dyer & Singh, 1998; Lavie, 2006). Previous research has shown how firms can generate relational rents through specific investments in the relationship, knowledge-sharing routines, complementary resources and appropriate governance mechanisms (Dyer & Singh, 1998). Applied to CE transitions, this implies that sensing, seizing and reconfiguring may need to take place not only within the focal firm, but also across the wider network of actors involved. In other words, the CE may depend on the development of shared dynamic capabilities, through which opportunities and constraints are jointly identified, responses are implemented collaboratively, and new routines or governance arrangements are progressively institutionalised along the supply chain.

Once CE is understood in these terms, the question becomes more specific: how are these shared capabilities actually developed in practice? The literature on boundary spanning offers a useful starting point for exploring this issue. Boundary spanning refers to the activities, roles and routines through which organisations connect internal domains and engage with external environments by crossing functional, cognitive and organisational boundaries (Aldrich & Herker, 1977; Tushman & Scanlan, 1981). Boundary spanners do not merely transfer information from one unit to another; they interpret, translate and mediate between actors with different skills and priorities. This aspect becomes particularly important when coordination requires interaction between groups that do not necessarily share the same language, assumptions or criteria for judgement. In such situations, coordination is often supported not only by individuals and teams, but also by boundary objects—that is, artefacts such as standards, templates, metrics, prototypes or dashboards that enable different communities to work together without requiring complete consensus or identical interpretations (Star & Griesemer, 1989; Carlile, 2002; Carlile, 2004). CE initiatives within supply chains are likely to be particularly boundary-intensive for this very reason. They typically involve procurement, quality and compliance experts, operations and sustainability managers, and logistics or recovery partners whose perspectives only partially converge.

Building on these contributions, this paper considers boundary spanning as a micro-foundation of shared dynamic capabilities in the circular transformation of the supply chain. More specifically, boundary spanning can support shared sensing by helping actors collectively identify and interpret circular opportunities and constraints. This can occur through material-flow mapping, the identification of waste hotspots, and the interpretation of regulatory developments and stakeholder expectations. These activities are not purely technical, as they also require negotiation regarding what should be considered a relevant problem and which circular options are feasible in light of cost, quality and compliance constraints. Boundary spanning can also support shared seizing, as opportunities must be translated into coordinated action through pilot projects, co-design initiatives and other forms of collaborative experimentation. At this stage, it becomes important to select partners, define responsibilities, align expectations and establish governance structures able to sustain cooperation under uncertainty. Finally, boundary spanning can contribute to shared reconfiguring when circular initiatives begin to impact routines, standards, metrics and governance criteria across the network. This is the stage at which circularity begins to transcend the scope of the isolated project and become embedded in the operational logic of the supply chain.

Crucially, the governance structure is not merely contextual but theoretically salient for CE implementation. As a Benefit Corporation, Olio Carli legally integrates common good and stakeholder considerations into its governance. While existing literature links hybrid organizations to long-term sustainability orientations (Battilana & Lee, 2014; Ebrahim et al., 2014; Haigh et al., 2015), the specific nexus between purpose-driven governance and shared dynamic capabilities remains underexplored. We argue that a B-Corp's legal mandate to engage external stakeholders structurally institutionalizes boundary-spanning mechanisms, directly enabling the sensing, seizing, and reconfiguring of circular practices. In this sense, purpose-oriented governance can create conditions conducive to building capacity for CE, legitimising investments whose short-term returns are uncertain, strengthening internal alignment around sustainability priorities, and supporting more enduring relational commitments with supply chain partners. At the same time, it can increase scrutiny and accountability pressures, making trade-offs more visible and heightening the need for robust measurement and governance systems.

Taken together, these arguments suggest that the relevant question is not simply whether firms adopt CE initiatives, but how they build the organisational and relational conditions that enable such initiatives to become scalable. The framework proposed in this paper is based on the idea that the scaling of CE in the olive oil supply chain depends both on the dynamic capabilities of the focal firm and on the emergence of shared dynamic capabilities among partners, with boundary spanning acting as a connecting mechanism between these two dimensions. From this perspective, boundary spanning is not a peripheral condition. It is central to the way in which internal coordination links to network orchestration through cross-functional alignment, inter-organisational governance practices and co-development, and the use of boundary objects and shared metrics that help stabilise action in conditions of heterogeneity and uncertainty. This

approach responds to the need, identified in the literature, to better clarify the organisational and inter-organisational foundations of circular transitions and to theorise how circularity is actually implemented under real constraints of compliance, quality and supply chain interdependence (Korhonen et al., 2018; Genovese et al., 2017; Farooque et al., 2019).

On this basis, the paper develops a qualitative case study aimed at investigating how dynamic capabilities are constructed and activated to pursue CE practices in the olive oil supply chain, which boundary-spanning mechanisms support the development of shared capabilities with partners, and how governance benefits influence coordination choices and the management of trade-offs in the pursuit of circular outcomes.

Purpose of the paper. This short paper aims to explain how CE initiatives are organised and progressively scaled up along the olive oil supply chain, focusing on capacity-building processes that link intra-organisational coordination with inter-organisational collaboration. Rather than viewing circularity as a set of practices or a sequence of distinct projects, this study interprets the scaling of CE as a dynamic and relational transformation, which requires, on the one hand, the development of dynamic capabilities at the firm level — that is, the ability to sense, seize and reconfigure in response to sustainability challenges — and, on the other, the emergence of shared inter-organisational capabilities, distributed amongst the various actors in the supply chain. Within this perspective, particular attention is paid to boundary-spanning mechanisms — roles, routines and boundary objects — understood as micro-foundations through which shared sensing, shared seizing and shared reconfiguring become possible in a context characterised by heterogeneous actors, stringent quality and safety constraints, and non-trivial trade-offs.

Empirically, the paper analyses these mechanisms through an in-depth qualitative case study of Olio Carli, an Italian company established as a Benefit Corporation. As a Benefit Corporation, Olio Carli operates within a purpose-oriented governance framework that formally incorporates public-benefit objectives and stakeholder accountability into the company's strategic orientation, potentially influencing how circular initiatives are prioritised, legitimised, measured, and coordinated across the supply network. The case therefore offers a useful setting not only for observing whether circular initiatives are pursued, but above all for understanding how they are translated into coordinated action through internal alignment and the orchestration of supply chain partners.

The analysis is guided by three research questions:

RQ1: How does a Benefit Corporation develop and activate dynamic capabilities to implement and scale up circular economy practices within the olive oil supply chain?

RQ2: What boundary-spanning mechanisms enable the development of shared dynamic capabilities with supply chain partners (e.g. suppliers, packaging and logistics operators, partners involved in recovery or valorisation)?

RQ3: How does purpose-oriented governance influence coordination choices and the management of key trade-offs (e.g. cost, quality/compliance, reliability, sustainability outcomes) within the context of supply chain circularity?

By addressing these questions, the paper aims to make three main contributions. Firstly, it contributes to the literature on the CE and supply chains by shifting the explanatory focus from 'which circular practices' to 'how circularity is scaled through capability development processes that span organisational boundaries'. Secondly, it contributes to studies on dynamic capabilities by clarifying the role of boundary spanning in enabling processes of shared sensing, shared seizing and shared reconfiguring, thereby extending theoretical reflection beyond the level of the individual firm and situating it within a supply chain context. Thirdly, the work offers empirically grounded insights into how a form of purpose-oriented governance, such as the Benefit Corporation, can influence circular transformation processes, affecting the legitimacy of choices, accountability mechanisms and the coordination and measurement architecture among partners.

Methodology. We adopt a qualitative research design based on an in-depth single case study, with the aim of explaining how CE initiatives are organised and progressively scaled up along the olive oil supply chain through the development of shared dynamic capabilities enabled by boundary-spanning mechanisms. The adoption of a case-based strategy is appropriate because the phenomenon under investigation is processual and relational in nature, and because research questions focused on 'how' require close attention to the context, the interdependencies between actors, and the sequence of decisions and instances of coordination. The focal case is Olio Carli, an Italian company established as a Benefit Corporation, selected via theoretical sampling as it combines, on the one hand, a supply chain context in which circularity depends on the coordination of multiple actors and, on the other, a form of governance that formally incorporates commitments to stakeholders and objectives of common benefit, with possible implications for accountability structures and the management of trade-offs. The empirical focus is therefore not limited to the focal firm in the strict sense; rather, the case is treated as an embedded context, in which intra-organisational interfaces and inter-organisational relationships jointly contribute to defining the unit of analysis through which to interpret the scaling mechanisms of the CE (Yin, 2018).

Data collection is based on a triangulation approach combining semi-structured interviews, documentary evidence and, where possible, observational data. The interviews aim to reconstruct the emergence and evolution of CE initiatives, the decision-making episodes through which circular options were evaluated and selected, the trade-offs encountered during the process — for example, in relation to quality and compliance constraints, operational reliability and cost implications — as well as the concrete mechanisms used to coordinate action across organisational boundaries. Documentary sources, such as benefit and sustainability materials, policies, project documentation, and technical and governance artefacts, support the chronological reconstruction of processes and provide useful elements for analysing

formal commitments, adopted standards, and the evolution of metrics and responsibilities. Observational materials, where accessible, are instead used to capture coordination practices as they unfold in practice and to document the boundary objects through which diverse actors align interpretations and actions, such as shared evaluation templates, performance indicators, technical prototypes or artefacts related to traceability.

Data analysis follows an abductive logic, based on a continuous dialogue between the empirical material and the theoretical lenses adopted in the paper. In an initial phase, the analysis identifies recurring episodes of coordination associated with CE initiatives and reconstructs the actors involved, the artefacts mobilised, and the rationales underpinning decisions. In a second phase, the mechanisms of boundary spanning — understood as roles, routines and boundary objects — that link internal alignment with external orchestration are conceptualised, relating them to the processes of shared sensing, shared seizing and shared reconfiguring. Third, emerging interpretations are refined through the comparison of accounts across informants and data types, the search for disconfirming evidence, and the construction of a transparent chain of evidence linking empirical materials to second-order themes and theoretical claims.

Results. Given that the empirical analysis is still ongoing, the results are presented as preliminary and aimed at identifying explanatory mechanisms. The case study is designed to show how CE initiatives in the olive oil supply chain become scalable when interpreted as a process of capability building that extends beyond the boundaries of the focal firm. More specifically, the analysis highlights how CE scaling depends on shared dynamic capabilities — distributed processes of sensing, seizing and reconfiguring — enabled by boundary-spanning mechanisms connecting internal functions and external partners in workable configurations of coordination and accountability (Teece, 2007).

A first emerging finding concerns shared sensing. In the olive oil supply chain, the identification of circular opportunities and constraints appears less as a unilateral ‘scanning’ activity and more as a collective problem-definition process spanning technical, operational and governance dimensions. The analysis should show that what can be considered a genuinely viable path to CE is negotiated at interfaces where diverse actors introduce different evaluation criteria, for example relating to quality and compliance, operational reliability, costs, reputational implications and environmental performance. At this stage, boundary spanning appears to operate through cross-functional routines and via the production and circulation of boundary objects — such as shared templates, artefacts related to traceability and compliance, or representations of material flows — which enable the establishment of a sufficiently common understanding to make action possible, without requiring full consensus. In other words, circularity becomes actionable when it is translated into a defined set of priorities, constraints and evaluation metrics that both internal units and partners can recognise as legitimate bases for decision-making (Carlile, 2004).

A second emerging finding concerns shared seizing, understood as coordinated mobilisation around pilot projects, co-development initiatives and partner engagement. The case is designed to capture how circular options are transformed into implementable initiatives through decision-making sequences that integrate multiple functions — such as procurement, quality, operations, logistics and sustainability — alongside selected external actors. Rather than assuming that ‘collaboration’ is spontaneously available, the analysis expects to show that seizing depends on an intentional orchestration of roles, responsibilities and expectations across different organisations. For this reason, the expected boundary-spanning mechanisms include not only forms of interpersonal brokerage—such as individuals or teams capable of translating between different domains—but also governance arrangements and boundary objects capable of reducing ambiguity and supporting coordinated commitments under conditions of uncertainty. In particular, we expect to observe how pilot-based experimentation is used to contain risk and to generate credible learning even in the eyes of stakeholders strongly focused on quality and compliance, thereby enabling circular initiatives to move from aspirational commitments to operationally viable solutions. This ability to seize circular opportunities is ‘shared’ insofar as it requires complementary assets and knowledge distributed among partners and insofar as the focal firm’s choices must align with their incentives and constraints.

A third emerging finding concerns ‘shared reconfiguring’, that is, the institutionalisation of circular practices through changes to the routines, standards and governance structures of the focal firm and its network. The analysis is designed to show that circularity only becomes truly scalable when it is embedded within the supply chain’s operating system: in procurement and supplier evaluation criteria, in performance indicators, in quality and compliance routines, in packaging and logistics specifications, as well as in stable agreements relating to valorisation or recovery. Reconfiguring should become evident when the lessons learnt from pilot projects are codified into revised standards and routines, when responsibilities are redistributed across different organisational interfaces, and when data-sharing practices become sufficiently routine to support ongoing coordination, rather than merely the resolution of isolated problems. The reconfiguring phase should also clarify that scaling does not amount to simple replication: it often requires redesigned interfaces and governance mechanisms so that circular practices remain robust under variability and the compliance constraints typical of food supply chains.

Across the three capability processes, a further emerging finding concerns the centrality of trade-off management. In the olive oil sector, CE initiatives appear set to grapple with persistent tensions between sustainability objectives, requirements for consistent quality, traceability and regulatory compliance, as well as operational and cost constraints. The analysis suggests that boundary-spanning mechanisms are crucial not only for enabling coordination, but also for ensuring that such trade-offs become explicit and manageable. From this perspective, boundary objects — shared metrics, assessment templates, standards — can function as genuine negotiating tools, enabling actors to clarify where compromises are acceptable and where they are not, as well as to define the conditions under which circular alternatives

can be adopted without compromising performance requirements deemed essential. In other words, the study aims to demonstrate that shared capabilities are not built by eliminating trade-offs, but by developing governance and coordination frameworks that make them manageable over time.

Finally, the Benefit Corporation status is not simply a contextual feature of the case, but a theoretically relevant condition that shapes inter-organisational capabilities. By legally mandating stakeholder accountability, it structurally forces boundary-spanning dynamics in at least two ways. On the one hand, purpose-driven governance can provide legitimacy and strategic clarity, supporting a long-term orientation, experimentation and stakeholder engagement, and thus strengthening the willingness to invest in capability-building processes whose returns are uncertain in the short term. On the other hand, the same governance context may accentuate accountability pressures and make the availability of credible measurement systems more relevant, increasing the importance of shared metrics and robust boundary objects. Overall, the findings offer a mechanism-based explanation of CE scaling, in which boundary spanning enables shared sensing, shared seizing and shared reconfiguring among supply chain partners, whilst purpose-oriented governance influences how coordination choices and trade-offs are interpreted and stabilised over time (Teece, 2007; Carlile, 2004).

Research limitations. This study is based on a single case study and therefore aims at analytical rather than statistical generalisation. Such a design is particularly appropriate for exploring the mechanisms through which boundary spanning and shared capability development support circular economy implementation in a complex supply chain setting. At the same time, the findings are necessarily grounded in the specific institutional, organizational, and sectoral context of the focal case, and should be interpreted considering the characteristics of the olive oil supply chain.

To strengthen the robustness of the analysis, the study relies on the triangulation of interviews, documentary sources, and, where possible, observational data. While this approach supports an in-depth understanding of the processes under investigation, future research could extend these insights through comparative multi-case studies, including other organizational forms or positions within the value chain, or through longitudinal analyses examining how shared dynamic capabilities evolve as circular initiatives mature across broader networks of partners.

Managerial implications. For managers keen to scale up the CE beyond the scope of isolated pilot projects, the analysis suggests viewing circularity first and foremost as a challenge of capability building and coordination. This implies investing in a boundary-spanning infrastructure linking sustainability ambitions to day-to-day operational decisions: cross-functional routines integrating procurement, quality/compliance, operations and sustainability criteria, as well as roles able to translate between technical, regulatory and commercial languages. In quality-sensitive supply chains, such as that of olive oil, circular initiatives tend to take root when they are transformed into credible operational specifications, defined responsibilities and clear decision-making rules, rather than remaining largely aspirational objectives.

A second implication concerns the coordination of partners. Scaling the CE requires the deliberate development of shared capabilities with supply chain actors possessing complementary assets and knowledge. Managers can facilitate this process by designing collaborative pathways capable of managing uncertainty: structured pilots with explicit evaluation criteria, iterative co-design practices with selected partners, and governance structures capable of balancing collaboration and accountability. At the operational level, boundary objects — shared metrics, templates, standards, traceability artefacts and performance indicators — can help reduce ambiguity and make trade-offs the subject of discussion and governance, allowing a variety of actors to coordinate without requiring full alignment of motivations or priorities.

Finally, for Benefit Corporations, legal governance commitments represent more than a strategic orientation; they act as a structural enabler for shared dynamic capabilities. By mandating stakeholder accountability, purpose-oriented governance institutionalizes the boundary-spanning practices required to negotiate trade-offs and build trust across the supply chain, provided they are supported by credible shared metrics. Managers should therefore ensure that the purpose is translated into shared objectives, monitoring routines and expectations of partners that are consistent from an incentive perspective, so that circularity can be incorporated into procurement criteria, supplier evaluation systems, operational routines and reporting mechanisms. When these elements are effectively in place, circular initiatives are more likely to withstand organisational turnover and network variability and to evolve into scalable practices, rather than remaining one-off interventions.

Originality of the paper. This paper is original in three main respects. Conceptually, it proposes interpreting the scaling of the CE within the olive oil supply chain as a process of capability building, rather than simply as the adoption of discrete circular practices or specific business model configurations. By combining the lens of dynamic capabilities with an inter-organisational perspective, the study develops the idea of shared dynamic capabilities, highlighting how sensing, seizing and reconfiguring are often distributed amongst multiple supply chain partners rather than confined within a single firm.

Secondly, the paper identifies boundary spanning as a central micro-foundation capable of linking intra-organisational alignment with inter-organisational orchestration. In this sense, it clarifies how roles, routines and boundary objects — such as shared metrics, standards and evaluation artefacts — can enable the collective framing of the problem, coordinated experimentation and the institutionalisation of circular practices in the presence of constraints typical of food supply chains, such as quality, traceability and compliance.

Empirically, the study provides evidence relating to an Italian Benefit Corporation operating in the olive oil sector, a context in which purpose-oriented governance and accountability to stakeholders can significantly influence coordination choices and the management of trade-offs. The combination of, on the one hand, a form of governance that incorporates objectives of common benefit and, on the other, a supply chain context in which circularity is highly interdependent, offers a distinctive basis for theorising how circular transformations can be made concretely scalable.

The Micro-Foundations of Humane Entrepreneurship: Individual Configurations and Opportunity Recognition

CHIARA CRUDELE[1], ROSANGELA FEOLA[2], RICKY CELENTA[3], MASSIMILIANO VESCI[4], ANTONIO BOTTI[5]

Abstract. *This paper explores the micro-foundations of Humane Entrepreneurship building on the idea that entrepreneurial, sustainability, and human orientations may combine into distinct individual configurations. The study investigates whether different profiles of nascent entrepreneurs can be identified through the joint configuration of Individual Entrepreneurial Orientation, Individual Sustainability Orientation, and Individual Human Orientation, and whether such profiles differ in the way they recognize external enablers as sources of entrepreneurial opportunities. The analysis draws on the Italian GUESSS 2023 dataset and focuses on 651 nascent entrepreneurs. A two-step clustering procedure combining hierarchical and k-means analysis was employed. The results identify four distinct profiles: Humane Entrepreneurial Mindset, Humane Mindset, Conservative Mindset, and In Transition Mindset. The findings further show that these profiles differ significantly in opportunity recognition across seven types of external enablers, including technological, demographic, regulatory, sociocultural, crisis-related, and sustainability-related changes. In particular, the Humane Entrepreneurial Mindset profile systematically reports the highest sensitivity to external change as a source of entrepreneurial opportunities. The study contributes to Humane Entrepreneurship research by extending it to the individual level and showing that humane-entrepreneurial configurations shape how nascent entrepreneurs interpret the external environment. It also contributes to opportunity recognition research by highlighting the role of multidimensional value-based profiles in filtering the entrepreneurial relevance of external change.*
Keywords: *humane entrepreneurship; entrepreneurial mindset; opportunity recognition; external enablers; nascent entrepreneurship; GUESSS project*

Framing of the research. Entrepreneurship research has increasingly moved beyond narrow interpretations of entrepreneurial action grounded solely in economic rationality and market logics. Within this broader shift, the Humane Entrepreneurship (HumEnt) perspective has emphasized that entrepreneurship should be understood as a multidimensional orientation integrating entrepreneurial posture, attention to people, and sensitivity to social and environmental concerns (Parente et al., 2018; Kim et al., 2018; Parente et al., 2021; Vesci et al., 2023). While this perspective has enriched entrepreneurship theory by offering a more inclusive and value-based understanding of entrepreneurial behaviour, it has been developed predominantly at the organizational level. As a result, its micro-foundations remain underexplored, especially with regard to nascent entrepreneurs.

This gap is theoretically relevant because entrepreneurial action is ultimately enacted by individuals whose orientations may combine in different ways. Recent research has provided strong support for studying entrepreneurial orientation (EO) at the individual level, showing that it can be meaningfully examined not only as a firm-level strategic posture but also as a multidimensional individual disposition (Bolton & Lane, 2012; Clark et al., 2024). At the same time, sustainability-related and human-centered orientations have also been recognized as relevant for explaining how individuals approach entrepreneurship, particularly when entrepreneurial action unfolds in contexts characterized by broader social and environmental transformation (Kuckertz & Wagner, 2010; Patzelt & Shepherd, 2011). Yet these dimensions have mostly been examined as separate variables. To the best of our knowledge, the HumEnt literature has not yet explored how individual entrepreneurial orientation (IEO), individual sustainability orientation (ISO), and individual human orientation (IHO) combine into distinct configurations through a person-centered approach.

A configurational perspective is especially appropriate in this context because it makes it possible to move beyond the assumption that entrepreneurial, sustainability, and human orientations vary only along isolated linear continua. Instead, individuals may embody different combinations of these orientations, and such combinations may correspond to qualitatively distinct entrepreneurial mindsets. In this sense, examining nascent entrepreneurs through the joint configuration of IEO, ISO, and IHO offers a concrete way to advance the micro-foundations of HumEnt and to capture forms of heterogeneity that variable-centered approaches are less able to detect (Martínez-Martínez & Ventura, 2020; Jebsen et al., 2023).

Once this configurational heterogeneity is acknowledged, a second question becomes relevant: do different HumEnt configurations shape the way nascent entrepreneurs interpret the external environment? Research on sustainability and sustainable entrepreneurship suggests that individual values and sensitivity to societal and environmental challenges

influence opportunity recognition, particularly in the early stages of venture creation (Kuckertz & Wagner, 2010; Patzelt & Shepherd, 2011). At the same time, the entrepreneurship literature has increasingly clarified that external change should not be treated as "opportunity" in itself. Rather, as Davidsson (2015) argues, it is important to distinguish between external conditions, venture ideas, and actors' subjective assessments. From this perspective, external enablers are actor-independent changes (such as technological developments, climate change, demographic shifts, regulatory change, sociocultural trends, crises, or other major societal developments) that may facilitate entrepreneurial endeavors across multiple possible ventures (Davidsson, 2015; Davidsson et al., 2020; Kimjeon & Davidsson, 2022). Their entrepreneurial relevance, however, is neither automatic nor uniform, but depends on how such changes are interpreted by different actors.

Against this background, the present study argues that advancing HumEnt theory requires not only identifying distinct individual-level configurations of entrepreneurial, sustainability, and human orientations, but also examining whether these configurations are associated with different ways of reading the environment as a source of entrepreneurial opportunity.

Theoretical background. Although HumEnt and Humane Entrepreneurial Orientation (HEO) have been predominantly conceptualized as an organizational-level strategic posture, HumEnt logic implies that such a posture is also rooted in individual values, beliefs, and orientations (Parente et al., 2018; Vesci et al., 2022; Vesci et al., 2026), particularly in the early stages of entrepreneurial action, when the venture is still under construction and largely depends on the founder's and team's personal dispositions. In line with scholarship calling for EO to be considered at the individual level as well (Robinson & Stubberud, 2014; Koe, 2016; Clark et al., 2024), and with increasing attention to individual-level conceptualizations of sustainability (Parente et al., 2020), it becomes theoretically and methodologically relevant to translate HEO's three components into a micro-level framework. In other words, understanding how much and how an individual incorporates entrepreneurial orientation, sustainability, and human-centered principles into their mindset and behavioral tendencies makes it possible to capture the micro-foundations of the HumEnt approach and to observe early signals of humane-oriented strategic postures even before they crystallize into organizational practices and structures. For these reasons, the next section discusses HumEnt's three dimensions at the individual level, Individual Entrepreneurial Orientation (IEO), Individual Sustainability Orientation (ISO), and Individual Human Orientation (IHO), which constitute the conceptual basis for the Individual Humane Entrepreneurial Orientation (IHEO) dimension.

Individual Entrepreneurial Orientation. EO, originally introduced by Miller (1983) and later popularized by Covin and Slevin (1989), is traditionally understood as a firm-level construct composed of innovativeness, proactiveness, and risk-taking. More recent studies, however, have argued that EO can also be meaningfully examined at the individual level (Bolton & Lane, 2012; Robinson & Stubberud, 2014). In this perspective, IEO captures the extent to which individuals display innovative, proactive, and risk-taking tendencies in the process of entrepreneurial action. As a multidimensional disposition, IEO reflects an individual's willingness and capability to engage in entrepreneurship and is particularly relevant in the nascent stage, when personal orientations strongly shape venture development.

Individual Sustainability Orientation. Sustainability Orientation has been developed within the sustainable entrepreneurship literature, although its conceptualization remains fragmented. Existing studies differ in whether they emphasize environmental sustainability alone or include social sustainability as well, and whether SO is interpreted as an attitude, a strategic posture, or a motivation toward action. In line with the HumEnt perspective, this study conceptualizes ISO as an individual-level orientation reflecting commitment to both environmental and social sustainability, encompassing both attitudinal and behavioral aspects. Accordingly, ISO captures the extent to which individuals value and act upon sustainability-related concerns in ways that may inform their entrepreneurial thinking and behavior.

Individual Human Orientation. Within HumEnt, Human Resource Orientation is based on the assumption that respecting and engaging employees is a successful strategy to achieve organizational results (Parente et al. 2022). It refers to the strategic relevance of practices aimed at respecting, involving, and developing people, although its operationalization remains underdeveloped. Translating this logic to the individual level, we define IHO as the extent to which individuals express a human-centered orientation in their interactions with others. Drawing on Kim et al. (2018), IHO is articulated through four core dimensions: (a) empathy as the extent to which an individual shares emotions and information with others; (b) equity as the extent to which an individual treats others in a fair and equal manner; (c) enablement as the extent to which an individual provide others individual what everything they needs to develop their (life) projects to the best of their abilities; and (d) empowerment as the extent to which an individual shares information and resources with another individual in developing a particular task offering him to participate in the decision-making process. Together, these dimensions capture an individual's tendency to relate to others in fair, supportive, and participatory ways, consistently with the human-centered pillar of HumEnt.

Purpose of the paper. The paper aims is to identify and interpret distinct profiles of nascent entrepreneurs based on the joint configuration of IEO, ISO and IHO, and to examine whether these profiles differ in the extent to which they recognize external enablers as sources of entrepreneurial opportunities. More specifically, the paper investigates whether clusters grounded in entrepreneurial, sustainability, and human orientations are associated with systematically different patterns of opportunity recognition with respect to new technologies, climate change and sustainability, demographic

change, regulatory change, sociocultural trends, societal crises, and other major societal developments. In doing so, the study aims to show that opportunity recognition among nascent entrepreneurs is associated with multidimensional value-based profiles rather than with isolated traits alone.

Methodology. The data were drawn from the Italian national GUESSS dataset (October–December 2023 survey wave), coordinated by the GUESSS Board Italy with the support of participating universities. Overall, the survey collected 4,374 questionnaires from 26 Italian universities, involving young people from different disciplinary backgrounds and levels of study. For the purposes of this study, we used a subset of the variables available in the GUESSS Italy dataset, selected because they were consistent with the operationalization of IHEO's three dimensions. In addition, the analysis focused on a subsample of nascent entrepreneurs, defined as individuals who, alone or with others, are actively trying to start a new entrepreneurial initiative, expect to become its owner (or co-owner), and have undertaken concrete start-up activities within the past 12 months (GEM Report, 2023; Reynolds, 2005).

IEO was measured through the 10-item, seven-point Likert scale developed by Bolton and Lane (2012), capturing nascent entrepreneurs' innovativeness, proactiveness, and risk-taking. ISO was operationalized through four items adapted from Muñoz and Dimov (2015), combining both attitudinal and behavioral aspects of sustainability in line with the HumEnt perspective. Specifically, the selected items cover the two core dimensions of sustainability/environmental and social and reflect both sustainability-related orientations and sustainability-oriented actions. All items were adapted from the organizational to the individual level to ensure consistency with the measurement of IEO. Finally, IHO was measured through four items, one for each core HumEnt dimension identified by Kim et al. (2018), empathy, equity, enablement, and empowerment. Since the original scale was developed at the firm level and conceived as a behavioral expression of human resource orientation, the selected items were similarly adapted to the individual level in order to align the measurement of IHO with the individual-level logic of the study. External enablers in opportunity recognition were measured through a seven-item, seven-point Likert scale (1 = strongly disagree; 7 = strongly agree), adapted from Davidsson (2015). Respondents were asked to indicate the extent to which the idea behind their planned business was driven by different sources of external change, namely new technologies, climate change and/or the quest for sustainability, demographic change, changed laws and/or regulations, sociocultural trends, societal crises, and other major societal developments. The psychometric properties of the focal individual-level orientation measures were assessed through exploratory factor analysis (EFA) using Principal Axis Factoring. Given the expected correlations among the dimensions, an oblique Oblimin rotation was adopted. The adequacy of the factor solutions was evaluated through the Kaiser-Meyer-Olkin (KMO) measure and Bartlett's test of sphericity, while item retention was based on the combined assessment of factor loadings, cross-loadings, and communalities. Internal consistency was then assessed through Cronbach's alpha. Based on the retained items, composite scores were computed as the mean of the items for each dimension and were subsequently standardized (z-scores) in order to ensure equal weighting in the clustering procedure.

As a first step in the clustering procedure, a hierarchical cluster analysis was conducted on the standardized composite scores of the four retained dimensions (IEO_1, IEO_2, ISO and IHO). The hierarchical procedure was carried out using Ward's method and squared Euclidean distance, a combination widely adopted in profile-oriented research because it tends to generate relatively homogeneous and well-separated clusters by minimizing within-cluster variance at each aggregation step (Ward, 1963; Murtagh & Legendre, 2014). This combination is also frequently recommended in two-step clustering procedures aimed at identifying a preliminary cluster structure before refinement through non-hierarchical methods (Punj & Stewart, 1983; Ketchen & Shook, 1996). The analysis was based on 651 complete cases with no missing values on the clustering variables. To determine the most plausible number of clusters, the hierarchical solution was examined through the dendrogram and the agglomeration schedule. Particular attention was paid to changes in the agglomeration coefficients across the final stages of the clustering process, as larger jumps indicate that relatively dissimilar clusters are being merged and therefore signal potentially meaningful cluster boundaries.

In the second step, the candidate solutions were refined through k-means cluster analysis. Comparison of the alternative solutions showed that the two-cluster solution performed slightly better in terms of statistical compactness and separation, as indicated by average silhouette width and pseudo-F statistics. However, the four-cluster solution was retained as the main solution because it provided a more fine-grained and theoretically meaningful representation of heterogeneity within the sample, produced groups of adequate size, and allowed the identification of not only extreme but also intermediate and unbalanced profiles. After the cluster solution had been established, the four groups were first described through one-way ANOVA on the clustering dimensions. Additional between-cluster comparisons were then carried out on descriptive variables and on the seven external enablers of opportunity recognition. In the ANOVA analyses, Bonferroni post hoc tests were interpreted when homogeneity of variances was met, whereas Games-Howell post hoc tests were used when Levene's test was significant. Data analysis was conducted in IBM SPSS Statistics.

Results. The analysis identified four distinct profiles. Cluster I, labelled Humane Entrepreneurial Mindset (n = 233), displayed the highest scores across all four dimensions and therefore represented the most integrated profile in the sample. Cluster II, labelled Humane Mindset (n = 186), was characterized by relatively stronger individual human and sustainability orientations than entrepreneurial ones. Cluster III, labelled Conservative Mindset (n = 94), reported the lowest scores across all four dimensions and represented the least developed configuration. Finally, Cluster IV, labelled

In Transition Mindset (n = 138), occupied a more intermediate and mixed position on the overall four dimensions. Between-cluster differences were statistically significant for all four clustering variables.

The second step of the analysis examined whether these profiles differed in the way they interpreted the external environment. Results show that the four clusters differ significantly across all seven external enablers considered in opportunity recognition, with significant F-values. A clear and consistent pattern emerges: Cluster I reports the highest mean score on every external enabler, indicating that nascent entrepreneurs in this profile is the most sensitive to external change as a source of entrepreneurial opportunities. By contrast, the remaining clusters display lower and generally more compressed scores, although the lowest value is not always associated with the same group. More specifically, Cluster III records the lowest mean on new technologies, climate change/sustainability, sociocultural trends, and other major societal developments; Cluster IV shows the lowest score on demographic change and shares the lowest level on changed laws and/or regulations with Cluster III; whereas Cluster II reports the lowest value on societal crises.

The post-hoc tests further clarify this pattern. For climate change/sustainability, demographic change, changed laws and/or regulations, societal crises, and other major societal developments, the significant differences are driven primarily by Cluster I, which scores significantly higher than the other clusters, while Clusters II, III, and IV do not differ significantly from one another. This indicates that Cluster I is not only higher in absolute terms, but also clearly distinct from the rest of the sample in the way it interprets major external changes as opportunity-generating conditions. A partially different pattern emerges for sociocultural trends and new technologies. In the case of sociocultural trends, Cluster I scores significantly higher than Clusters III and IV, but not than Cluster II, suggesting that Cluster II is relatively closer to Cluster I in recognizing sociocultural change as entrepreneurially relevant. For new technologies, the overall differentiation is weaker: the only significant pairwise contrasts are Cluster I vs. Cluster III and Cluster II vs. Cluster III, while the other comparisons are not significant. This suggests that technological change is recognized quite broadly across the sample and is less discriminating among profiles than broader societal and sustainability-related changes. Overall, the results indicate that the most distinctive feature of Cluster I lies in its systematically stronger orientation toward reading the external environment as a source of entrepreneurial opportunities, especially when such opportunities stem from climate-related, demographic, regulatory, crisis-related, and broader societal transformations. Conversely, Clusters II, III, and IV appear more similar to one another and display a comparatively weaker or less differentiated recognition of external enablers.

Research limitations. This study presents some limitations that should be acknowledged. First, its cross-sectional design does not allow causal inferences regarding the relationship between humane entrepreneurship configurations and the recognition of external enablers. The findings show systematic associations between individual configurations and opportunity recognition, but they do not establish whether specific configurations shape the interpretation of external change or whether repeated exposure to certain entrepreneurial contexts contributes to reinforcing those configurations. Second, the empirical setting is limited to nascent entrepreneurs in a university-based context, which reduces the generalizability of the findings beyond the pre-entry stage and calls for caution in extending the results to more experienced entrepreneurial populations. Third, the configurational solution itself should be interpreted with due caution. Although the four-cluster solution was retained because it was theoretically more informative and more consistent with the person-centered aim of the study, alternative solutions also showed acceptable statistical properties. This suggests that the retained solution should be understood as one theoretically meaningful representation of heterogeneity in the sample rather than as a definitive classification. Future research could address these limitations by testing the stability of the configurations through latent profile analysis, replicating the study in other institutional and national contexts, and adopting longitudinal designs to examine whether these configurations are associated with subsequent entrepreneurial behavior.

Managerial implications. The study offers a first contribution to HumEnt theory by shifting attention from the organizational to the individual level. Existing HumEnt scholarship has convincingly argued that entrepreneurial, human, and sustainability dimensions should be integrated, but it has rarely explored how these dimensions combine within individuals. By identifying four distinct profiles, the paper provides a configurational micro-level extension of HumEnt and shows that the theory can be meaningfully mobilized not only to describe firms, but also to understand heterogeneity among nascent entrepreneurs (Kim et al., 2018; Parente et al., 2021; Vesci et al., 2023).

A second contribution concerns the role of external enablers in opportunity recognition. Drawing on Davidsson (2015) and Davidsson et al. (2020), the paper shows that environmental change is not interpreted uniformly across individuals. Instead, its entrepreneurial relevance varies systematically depending on the profile through which it is filtered. In this respect, the study contributes to opportunity recognition research by showing that different humane-entrepreneurial configurations shape different ways of reading the environment. The key point is not merely that some individuals are more opportunity-oriented than others, but that distinct profiles attach different entrepreneurial significance to climate change, regulation, demographic transformation, crises, and broader societal developments. Taken together, these findings suggest that HumEnt is relevant not only as a normative or strategic framework, but also as a cognitive lens that influences how external change becomes salient as a potential source of entrepreneurial action.

From a practical standpoint, the findings suggest that universities, incubators, and entrepreneurship support actors should avoid treating nascent entrepreneurs as a homogeneous category. Individuals with a Humane Entrepreneurial Mindset appear more capable of connecting broad societal and environmental transformations to entrepreneurial ideas

and may therefore be especially suited to advanced programmes focused on impact entrepreneurship, sustainability transitions, and challenge-driven innovation. By contrast, more conservative or in transition profiles may require stronger support in scanning the external environment, interpreting contextual shifts, and translating them into entrepreneurial possibilities. This implies that support programmes should be differentiated not only by venture stage, but also by the underlying orientation profile of the entrepreneur.

Originality of the paper. The paper advances HumEnt theory by adopting an individual-level, configurational perspective. To the best of our knowledge, previous research has not examined HumEnt through configurations of individual entrepreneurial orientation, individual sustainability orientation, and individual human orientation among nascent entrepreneurs. The study therefore offers a novel micro-level extension of HumEnt, showing that its core dimensions can combine into distinct entrepreneurial configurations rather than being treated as isolated traits. A second element of originality lies in demonstrating the relevance of these configurations for opportunity recognition. Rather than stopping at their identification, the paper shows that different HumEnt configurations are associated with different ways of interpreting the external environment. In particular, they vary in the extent to which external enablers are recognized as sources of entrepreneurial opportunities. In doing so, the study connects HumEnt with opportunity recognition research and provides a more nuanced explanation of how external change becomes entrepreneurially meaningful.

Understanding purpose-driven businesses (PDBs): Insights from a systematic literature review

MARIA CRISTINA DARDANO[1], MONIA MELIA[2]

Abstract. *Research on purpose-driven businesses (PDBs) has grown significantly in recent years, yet the field remains fragmented across multiple labels and research streams. This study addresses such fragmentation through a systematic literature review (PRISMA 2020) that brings together diverse contributions related to purpose-driven approaches within the broader scholarship on corporate purpose. By synthesizing 63 articles, the study develops a multilevel framework that conceptualizes PDBs as configurations emerging from the alignment of three dimensions: internal organizational mechanisms, market-facing dynamics and institutional contexts. In doing so, the study offers a clearer conceptual organization of the field and proposes a research agenda aimed at supporting more cumulative and comparative future research.*
Keywords: *purpose-driven businesses; corporate purpose; systematic literature review*

Framing of the research. *Major global challenges, including climate change, social inequality and growing expectations for responsible business conduct, are reshaping the role of firms in society. Increasingly, companies are expected not only to generate economic value but also to contribute to addressing complex social and environmental problems (Henderson, 2021; Vredenburg et al., 2021; Kapitan et al., 2022; Dhanesh., 2020). Within this evolving landscape, the debate on corporate purpose has gained renewed prominence. Originally interpreted as the firm's raison d'être, corporate purpose is now increasingly conceptualized as a multidimensional construct linking firm identity, strategic direction and broader societal value creation (Brosch, 2023). The growing attention reflects a broader reconsideration of the role of firms in addressing complex societal challenges and contributing to long-term value creation beyond purely economic outcomes (Porter & Kramer, 2011; Quinn & Thakor, 2018; Craig & Snook, 2014).*

As the understanding of corporate purpose has expanded beyond a purely declarative notion, increasing attention has been devoted to firms that integrate purpose directly into their strategic and operational choices (Rey et al., 2019; von Ahsen & Gauch, 2021; Gartenberg, 2022; George et al., 2023). These firms are often described as PDBs. Although the label itself is relatively recent, its intellectual roots can be traced back to earlier reflections on the role of purpose in organizations and leadership (Bartlett & Ghoshal, 1994; Wilson, 2004; Ready & Truelove, 2011; Hollensbe et al., 2014). Despite the increasing scholarly attention, the literature on PDBs remains conceptually fragmented. Studies employ heterogeneous labels, such as purpose-driven, purpose-led or purpose-oriented firms and tend to focus on specific dimensions of the phenomenon, including leadership, governance, branding or institutional dynamics.

While these contributions offer valuable insights, the field still lacks a structured synthesis that connects these fragmented research streams and provides a systematic understanding of the phenomenon. Specifically, existing studies rarely integrate these contributions within a coherent framework capable of explaining how PDBs are configured across different levels of analysis.

Purpose of the paper. *To address this gap, the study aims to conduct a systematic literature review on PDBs, linking this emerging stream of research to the broader scholarship on corporate purpose and organizing scattered contributions within a coherent multilevel analytical architecture. In this work, PDBs are conceptualized as firms in which corporate purpose systematically guides strategic decision-making, shapes managerial practices and informs interactions with stakeholders and broader institutional environments.*

The study clarifies how PDBs have been conceptualized across the literature, structures the field across multiple dimensions and develops a research agenda aimed at supporting more cumulative and comparable future research. In doing so, it proposes a theoretical framework explaining how purpose-driven configurations emerge through the interaction of micro, meso and macro dimensions.

Therefore, the study is guided by the following research questions:

(RQ1). How can the existing literature on PDBs be synthesized and integrated with the broader corporate purpose scholarship to develop a coherent theoretical framework?

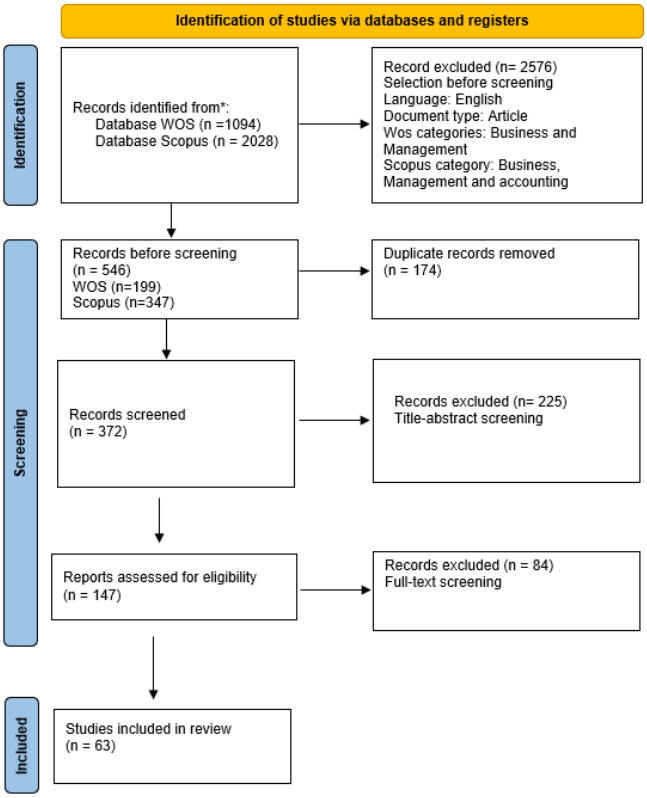
(RQ2). What key themes and underexplored areas emerge from the literature and what directions do they suggest for future research?

[1] University of Catanzaro "Magna Græcia", mariacristina.dardano@studenti.unicz.it
[2] University of Catanzaro "Magna Græcia", monia.melia@unicz.it

Methodology. *Given the heterogeneity of existing contributions, the study draws on a systematic literature review (SLR) grounded in a structured, transparent and replicable research process (Linnenluecke et al. 2019). Data collection, screening and eligibility were conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (Prisma) 2020 statement (Page et al., 2021) and shown in the PRISMA flow diagram (Figure 1).*

Data collection. As a first step we structured a research query to address the terminological and conceptual complexity of the field:

> *"purpose-driven" OR "purpose-led" OR "purpose driven" OR "purpose led" OR "purpose-oriented" OR "purpose oriented" OR "purposeful brand*" OR "purposeful business*" OR "purposeful firm*" OR "purposeful organization*" OR "purposeful corpor*" OR "purposeful compan*" OR "purposeful leadership*" OR "corporate purpose"*



Because the label "purpose-driven business" is conceptually rooted in the broader debate on corporate purpose, the search query was intentionally broadened to include related conceptualizations of corporate purpose and purposeful organizations. This approach allowed us to capture the diverse terminologies through which purpose-oriented business is discussed across management research. In addition, the terms associated with PDBs remain inconsistent across the literature. Many relevant studies discuss corporate purpose, leadership or branding without explicitly adopting the label "purpose-driven business". For this reason, the review adopts a broader analytical lens and considers these streams as complementary perspectives through which purpose-driven configurations can be examined.

In October 2025, the search query was conducted in both the Web of Science and Scopus databases, to avoid overlooking potentially relevant contributions. The search was performed using the TS field in Web of Science and the TITLE-ABS-KEY operator in Scopus. The initial search yielded 3122 documents, 1094 Wos and 2028 from Scopus. For both databases the results were refined by limiting the sample to journal articles published in English and classified within management-related subject areas. This refinement resulted in 546 articles (347 from Scopus and 199 from Wos). Subsequently, 174 duplicates were removed using Bibliometrix (Aria & Cuccurullo, 2017), leading to a consolidated dataset of 372 documents.

Data screening. The 372 documents were screened based on titles and abstracts to assess their conceptual relevance to the research objectives. During this phase, 225 articles were excluded.

Data eligibility. The remaining 147 articles were subjected to full-text assessment. Following the process, a final sample of 63 articles was retained for SLR. The analysis followed an inductive-deductive coding process. Each article was systematically examined to identify its main conceptual focus, level of analysis and the mechanisms through which corporate purpose was conceptualized and operationalized. The coding process was conducted independently by the authors and subsequently discussed to reach a shared interpretation. Through an iterative comparison of the coded studies, recurrent themes and patterns were identified and progressively grouped into higher-order analytical categories, which informed the development of the theoretical framework presented in the results section.

Figure 1. PRISMA statement

Source: authors' elaboration based on Page et al. (2021)

The coding process revealed three broad thematic clusters through which contributions are focused: internal organizational mechanisms, market and ecosystem dynamics and institutional embedding (Table 1).

Table 1 – Main themes emerging from the systematic literature review

Thematic cluster	***Main themes identified in the literature***	***Representative studies***
Internal organizational mechanisms	*Leadership and purpose articulation; governance structures; organizational identity and culture; employee engagement and meaningful work; performance management and accountability systems*	*Gartenberg et al. (2019); Quinn & Thakor (2018); Kempster et al. (2011); Busco et al. (2024); Pratt & Hedden (2023); von Ahsen & Gauch (2021)*
Market and ecosystem dynamics	*Brand purpose and purpose-driven branding; stakeholder communication; certification schemes (e.g., B Corp); purpose ecosystems and stakeholder collaboration; legitimacy and authenticity*	*Lyon et al. (2025); Walter et al. (2024); Baker et al. (2022); Villela et al. (2021)*
Institutional and societal context	*Institutional frameworks and regulation; stakeholder capitalism debate; corporate governance systems; public-private collaboration; societal expectations toward firms*	*Mayer (2021); Patriotta (2021); Aguilera (2023); Mahoney (2023)*

Source: authors' elaboration

Results: Multilevel configurations of PDBs

The thematic clusters correspond to three interrelated levels of analysis - micro, meso and macro - which capture how corporate purpose is internally embedded within firms, articulated in market interactions and shaped by broader institutional contexts.

Taken together, the literature suggests that PDBs do not simply emerge from the presence of a declared corporate purpose. Rather, they arise from the alignment of multiple organizational, market and institutional mechanisms. In this perspective, PDBs reflect a multilevel configuration in which corporate purpose operates both as a guiding compass and as a unifying element across different dimensions of firm activity.

PDBs may be founded with a clearly articulated purpose or develop it progressively over time. They are typically guided by social values, translating this orientation into strategic and operational initiatives that place individuals at the center of firm activities. In many cases, firms pursuing purpose-driven strategies engage in domain-specific initiatives or offerings that address societal challenges while ensuring environmental responsibility, product quality and employee well-being, sometimes supported by certifications or formal standards (Cucino et al.,2025).

Internal organizational mechanisms (Micro-Level). Corporate purpose is increasingly conceptualized as a hybrid objective alongside profit and as a catalyst for broader societal change (Besharov & Mitzinneck, 2023), reflecting firm-specific commitments anchored in values and societal goals that strategists translate into future-oriented strategies and forms of moral leadership (Rindova & Martins, 2023). Its strategic relevance depends on the capacity to balance inside-out and outside-in perspectives (Almandoz, 2023). At the organizational level, the literature highlights how corporate purpose becomes anchored within governance structures, leadership practices and organizational identity, orienting strategic decisions and everyday managerial practices toward long-term value creation.

Several studies advocate a redefinition of corporate purpose (Wilson,2004), embedding it at the core of organizational design. When purpose aligns vision, strategic priorities, brand promise, organizational values and leadership behaviour, it fosters coherence and resilience (Ready & Truelove, 2011). Purpose-driven transformation requires coordinated changes across strategy, structure, culture and capabilities (Carballo, 2023), enabling firms to generate value for stakeholders and the broader systems in which they operate (Glauner, 2019). Research suggests that long-term-oriented ownership reinforces purpose adoption (Gartenberg & Serafeim, 2023) and purpose-oriented entrepreneurship can shape innovation and new technologies implementation (Fernandez, 2025). Purpose-driven leadership becomes operational when leaders clarify their purpose and translate it into concrete strategic and managerial actions (Craig et al., 2014). Its effectiveness also depends on communicating purpose and engaging middle managers in reinforcing it (Quinn & Thakor, 2018). Leadership also functions as a sensemaking process that orients firms toward socially relevant purposes (Kempster et al., 2011). In doing so, leadership can reshape organizational power relations (Fujimoto et al., 2024) and is increasingly expected to be moral (Springett, 2004) and responsible (Enslin et al., 2023).

Governance arrangements influence how corporate purpose is integrated within firms, often involving trade-offs between managerial independence, shareholder control and responsiveness to societal interests (Claassen, 2025), while a strong understanding of purpose among middle managers can enhance organizational performance (Gartenberg et al., 2019). Board characteristics (Collevecchio & Gionfriddo,2023) and dedicated roles such as chief purpose officers (Steller & Björck, 2025) may favor purpose adoption, although governance systems may also foster symbolic decoupling between external claims and internal practices (Westphal, 2023). Overall, strategic corporate governance seeks to ensure long-term stakeholder value creation (Goranova & Ryan, 2022).

Employee engagement is strengthened when leader-member dialogue around purpose is actively cultivated (Durand & Asmar, 2025).

Ultimately, corporate purpose becomes relevant through processes of justification, implementation and evaluation (Durand, 2023). Coherence between declared purpose and organizational practices is critical, as misalignments risk the instrumental use of purpose (Kaplan, 2023).

Evaluation criteria are progressively shifting from legitimacy based on external conformity toward authenticity grounded in internal coherence and alignment (Suddaby et al., 2023). Accountability and measurement systems (Pratt & Hedden, 2023), stakeholder-oriented value frameworks (Jones-Khosla & Gomes, 2023) and performance management systems (Busco et al., 2024) may support this coherence, together with learning processes and market-facing mechanisms that connect internal priorities with stakeholder expectations (Menon, 2022; Blocker et al., 2025).

Market and ecosystem dynamics (Meso-Level). Purpose is externally articulated through market positioning, brand articulation and participation in purpose ecosystems, translating internal commitments into stakeholder-facing practices and legitimacy-building processes.

Purpose implementation is supported by purpose-ecosystems that enable firms to pursue broader sustainability goals (Dahlmann et al., 2020; Stubbs et al., 2022; Lyon et al., 2025) and by institutional mechanisms such as B Corp certification. Certification motivation ranges between intrinsic moral commitments to strategic legitimation (Harjoto et al., 2019). Muñoz et al. (2018) show that ventures follow different developmental paths, depending on purpose breadth, certification timing and feedback sources, while certification may enhance reputation without strengthening internal practices (Villela et al., 2021).

At the market level, PDBs effectiveness depends on stakeholders' consensus and legitimacy. Consumers and investors increasingly value PDBs, making purpose a strategic communication resource (Peters, 2024). Emerging consumer segments, such as hypermodern individuals, are particularly receptive to purpose-oriented strategies that contribute to identity construction and emotional engagement (Dhanesh, 2020). Credible and legitimate metrics for evaluating purpose and preventing washing are essential (Rennollet et al., 2020). The purpose-driven approach also requires a coherent brand identity aligned with organizational values, commonly referred to as brand purpose. Social purpose branding integrates social and environmental concerns into brand identity while promoting stakeholder engagement (Gray et al., 2024). When communicated consistently, purpose can attract public attention, stimulate community engagement and strengthen market positioning (Mirzaei et al., 2021).

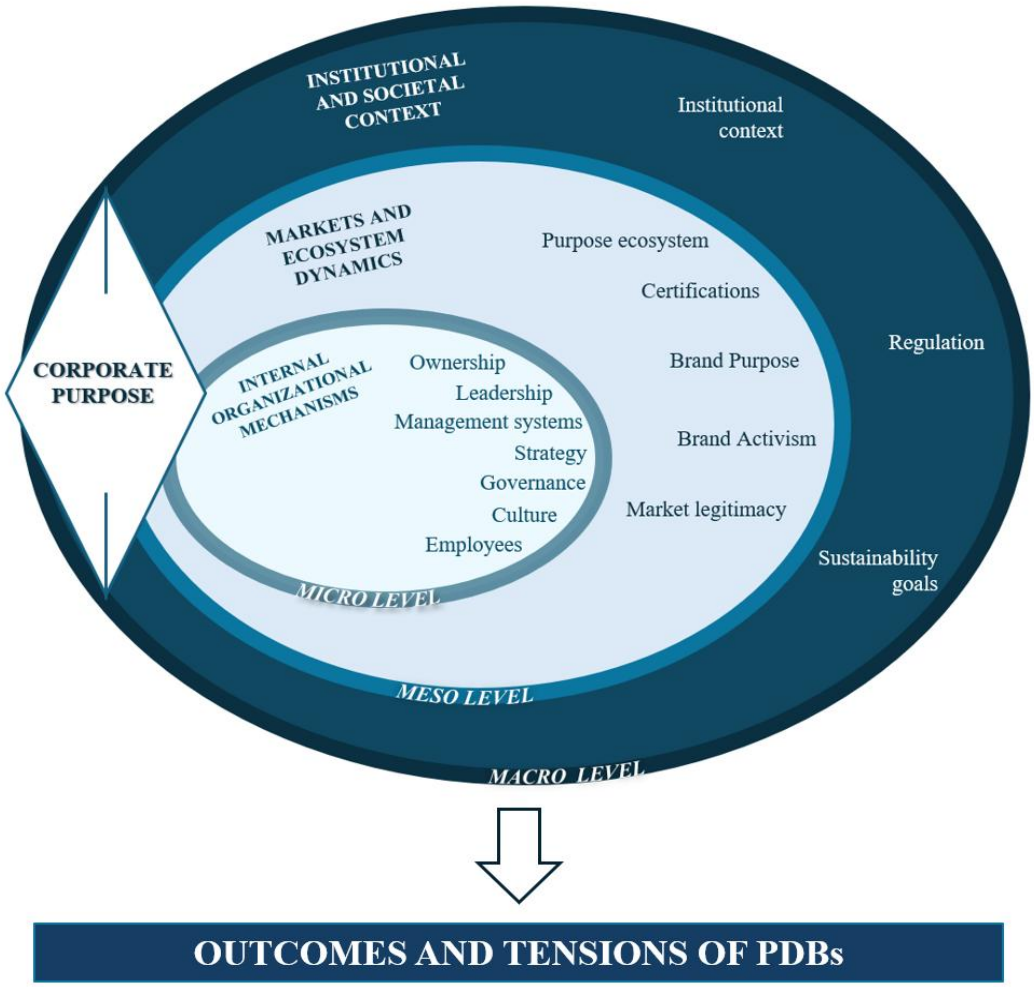
Authenticity emerges as a pivotal construct in this literature. Defined as consistency between declared purpose and actual practices, authenticity - together with congruence between cause and brand, brand and consumer and consumer and cause - shapes corporate image and consumer behavior. Evidence suggests that authenticity exerts a stronger direct effect on brand image and identity-based consumer-brand relationships than congruence alone (Fernandes et al., 2024). Stakeholder-perceived credibility is highest under conditions of authenticity and significantly reduced in cases of woke washing (Walter et al.,2024). Authenticity also extends brand activism, a strategy based on a brand's purpose and fundamental values, through which companies publicly communicate their stance on sociopolitical issues (Vredenburg et al., 2020). In B2B context, brand activism can strengthen reputation, reduce perceived customer risk and support stable supply chain relationships (Kapitan et al., 2022).

Finally, some contributions conceptualize purpose as a transformative force capable of reshaping cultural structures and enabling new social practices (Hajdas & Kłeczek., 2021). Within service ecosystems, brand meaning emerges through co-creation processes among multiple actors operating across institutional arrangements (Baker et al., 2022).

Institutional context (Macro-Level). Purpose is institutionally embedded within broader regulatory, legal and cultural environments that enable, constrain and stabilize purpose-driven configurations over time. Mayer (2021;2023) challenges traditional capitalist models, arguing that markets and regulation often fail to ensure that profits derive from solving rather than generating social and environmental problems. In this view, a clear and credible purpose strengthens trust among customers and employees and fosters stronger relationships with communities and suppliers. Achieving shared and sustainable prosperity requires effective public policies and public-private collaborations. Similarly, complex institutional and regulatory environments both enable and constrain corporate action. As business models evolve, inequalities increase, forms of corporate and social involvement evolve and new institutional partnerships emerge, supportive institutional frameworks and public policies are essential to ensure the accountability of purpose (Patriotta,2021). Furthermore, legal personhood can transform firms into durable institutions responsible for stakeholder value creation, supported by governance mechanisms and fiduciary duties (Mahoney, 2023). Finally, the relevance of corporate purpose also varies across institutional and cultural contexts, which shape how firms interpret and operationalize their societal roles (Aguilera, 2023).

PDBs outcomes and tensions.

Beyond the structural dimensions of the framework, the literature also highlights a set of outcomes and tensions associated with the adoption of purpose-driven configurations. These outcomes illustrate how the adoption of a purpose-driven approach may generate multidimensional value while simultaneously creating strategic and organizational tensions.



PDBs are often associated with improved financial performance (Wilson, 2004; Von Ahsen & Gauch, 2022). Research on purpose suggests that these effects may be stronger when mid-level employees have a strong understanding of the firm's purpose (Gartenberg et al., 2019) and when within firms there are high levels of intangible capital, innovation and long-term investors (Gartenberg, 2023). Purpose also enhances employee engagement (Bhattacharya et al., 2023; Von Ahsen & Gauch, 2022) and strengthens firms' ability to respond to environmental volatility and uncertainty (Lee et al., 2023). When stakeholders perceive credibility, through transparent communication and collaborative adaptation of

purpose, PDBs may foster stronger customer loyalty (Von Ahsen & Gauch, 2022; Ibn-Mohammed et al., 2024). The integration of the SDGs at normative, strategic and operational levels offers a framework for vision-setting and strategic alignment (Sasaki et al., 2023). Their influence on corporate purpose is stronger when embedded normatively rather than confined to strategic or operational practices (Sasaki et al.,2024). Moreover, a hybrid outside-in and inside-out approach further supports SDGs implementation (Sasaki & Stubbs,2025).

However, these outcomes are linked to significant tensions. PDBs may encounter investor disagreements, internal conflicts and difficulties in measuring performance (Von Ahsen & Gauch, 2022). Moreover, the attractiveness of PDBs may legitimize long work hours (Brosch, 2025) and intensification, obscuring stress and negative emotions. A sustainable purpose is essential to recognize workers as valuable resources (Dupret & Pultz, 2021).

Overall, the defining characteristic of PDBs is not merely the presence of a declared corporate purpose, but the consistency with which purpose is anchored internally, articulated in market-facing practices and institutionally embedded across micro, meso and macro levels. Becoming a PDB therefore requires a deeply integrated configuration in which purpose coherently guides structures, market positioning and institutional engagement. Figure 2 illustrates this multilevel analytical architecture.

Figure 2. Multilevel configuration of PDBs

Source: authors' elaboration.

Research agenda. Building on the multilevel framework developed in this review, future research can further explore how PDBs emerge, evolve and consolidate across different dimensions (table 2).

Table 2. Future research directions

Dimension	***Topics for future research***	***Related literature***
Internal organizational mechanisms (Micro-level)	● *What managerial processes enable firms to embed corporate purpose into strategic decision-making and managerial practices?* ● *How do entrepreneur characteristics and firm features (such as size, ownership structure etc.) shape firms' propensity to adopt a PDB configuration across different industries?* ● *How do PDBs sustain internal alignment as tensions emerge between purpose commitments, performance pressures and accountability demands?*	*Carballo (2023)* *Blocker et al. (2025)* *Von Ahsen et al. (2021)* *Cucino et al. (2025)*
Market and ecosystem dynamics (Meso-level)	● *How do purpose-ecosystems enable firms to transition toward PDBs?* ● *How do purpose-driven initiatives shape brand reputation and consumer perceptions and how do digital communication infrastructures mediate the co-creation of brand meaning, authenticity and legitimacy in PDBs?* ● *How do certification schemes shape accountability and enhance comparability, scalability and credibility of PDBs?*	*Baker et al.(2022)* *Lyon et al. (2025)* *Stubbs et al. (2022)* *Walter et al. (2021)* *Blocker et al. (2025)* *Cucino et al. (2025)*
Institutional context (Macro-level)	● *How do heterogeneous institutional contexts influence the consolidation and stability of PDBs?* ● *Under what conditions do PDBs contribute to public-private governance collaborations within institutional frameworks?* ● *How do institutional and cultural heterogeneity shape legitimacy and long-term sustainability outcomes?*	*Aguilera (2023)* *Jones-Khosla & Gomes (2023)*
Outcomes and tensions	● *Do PDBs exhibit greater resilience in contexts of environmental and market turbulence and through which mechanisms do multidimensional purpose contribute to (or hinder) such resilience?* ● *How do internal conflicts between profitability, stakeholder expectations and operational constraints affect the long-term viability of PDBs?* ● *Under what competitive conditions do PDBs generate distinctive strategic advantages compared to traditional profit-oriented firms?*	*Von Ahsen & Gauch, (2022)* *Ibn-Mohammed et al. (2024)* *Blocker et al. (2025)*

Source: authors' elaboration

Research limitations. *The SLR was limited to peer-reviewed journal articles in management, potentially excluding books, book chapters, institutional reports and grey literature, which have significantly contributed to the broader debate on corporate purpose and the emergence of PDBs. Given the field's terminological fragmentation, relevant studies using alternative labels may not have been captured despite the broad search query.*

Theoretical implications. *The study advances the literature on PDBs by providing a systematic review of existing research. Specifically, by structuring dispersed contributions into three interrelated dimensions, it enhances analytical clarity and offers a common reference framework for future empirical and theoretical investigations. Conceptualizing PDBs as multilevel configurations shifts the focus from isolated purpose-related attributes to the alignment through which corporate purpose becomes internally anchored, externally articulated and institutionally embedded. This perspective contributes to the consolidation of a fragmented field and facilitates more systematic comparisons across empirical contexts and levels of analysis.*

Originality of the paper. *The originality of this study lies in providing an integrative synthesis of the fragmented literature on PDBs. While existing studies have examined specific dimensions of the phenomenon, this review brings together diverse research streams associated with purpose-driven approaches within the broader literature on corporate purpose. By structuring these contributions within a multilevel theoretical framework, the paper highlights the systemic nature of PDBs emerging from the interaction of three main dimensions. The framework highlights how PDBs emerge from the alignment of internal organizational mechanisms, market-facing dynamics and institutional contexts. In doing so, the study provides a more systematic understanding of the phenomenon and offers a foundation for more cumulative and comparable future research.*

Working with vulnerable populations

GIOVANNA BAGNATO[1], FELIPE RUIZ MORENO[2], FERNANDO CAMPAYO[3], FEDERICO BRUNETTI[4]

Abstract. *This study explores the factors influencing the job satisfaction of able-bodied employees working alongside colleagues with disabilities. The theoretical framework proposed integrates the construct of empathy, Social Exchange Theory (SET), and the Job Demand–Resources (JD-R) model to explain the factors that able-bodied employees derive from working alongside colleagues with disabilities. Empirical data were quantitatively analyzed; particularly, the hypotheses were tested using a two-stage PLS-SEM approach. Measurement reliability and validity, common method bias, and multicollinearity were first assessed, after which the structural model was estimated using bootstrapping (10,000 resamples). Expecting to support the proposed hypotheses, this short paper contributes to the business and management literature on diversity, equity, and inclusion, with a specific focus on organizational behavior and team diversity, repositioning able-bodied coworkers as active agents in workplace inclusion. By integrating empathy, SET, and the J-D-R model, it conceptualizes inclusion as a cognitive and affective process that generates benefits and shapes job satisfaction. In practice, the study equips managers and policymakers with an actionable roadmap to promote diversity management through a shared-benefit approach to workplace inclusion.*
Keywords: *organizational inclusion management; able-bodied employees; colleagues with disabilities; inclusive workgroups*

Framing of the research. *On the International Labour Organization's (ILO) Business and Persons with Disabilities webpage, Director-General Guy Ryder states: "Employing persons with disabilities is not just a good moral cause, it is also good for business." At the policy level, the Strategy for the Rights of Persons with Disabilities 2021–2030 (European Commission, 2021) highlights the growing policy commitment to enhancing employment opportunities for people with disabilities (PwDs).*

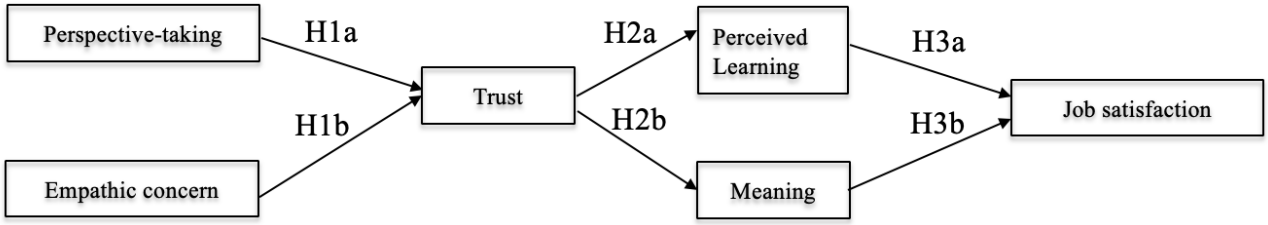
This policy attention is well supported by empirical evidence showing that employment promotes social inclusion and improves the physical and mental health of PwDs (Zappella, 2017). A systematic review by Lindsay et al. (2018) confirms that work enhances quality of life, income, self-confidence, and a sense of belonging to a community. From the firm's side, studies such as Aichner et al. (2024) and Lindsay et al. (2018) show that these outcomes are associated with higher profitability, lower turnover, greater innovation, stronger corporate reputation, and a more positive workplace climate. However, understanding how these benefits emerge requires attention to the conditions that enable successful inclusion, including corporate culture and climate, job characteristics, government support, employer attitudes, and societal attitudes (Ikutegbe et al., 2025). Extending this perspective to a specific scientific area, Dwertmann et al. (2025) in organizational behavior research show, through a large-scale field study and two experiments, that working with colleagues with disabilities enhances creativity. In the hospitality management research area, Chan and McGinley (2024) explore how hotel employees perceive working with colleagues with disabilities. They find that senior managers express positive attitudes but often lack concrete implementation strategies; middle managers show hesitation driven by operational concerns; and line-level staff in midscale hotels appear more open and supportive. From a psychology and education research perspective, Santilli et al. (2023) found that both the type of disability and its presentation influence colleagues' attitudes. Moreover, employees' gender, educational level, and prior experience working with PwDs also shape these attitudes.

Purpose of the paper. *Despite the value of the above contributions, the business and management literature still offers limited awareness into the active agency of able-bodied employees. Therefore, this study adopts a multidimensional view of empathy encompassing cognitive and affective dimensions (Kerem et al., 2001; Smith, 2006; Wieseke et al., 2012) and integrates Social Exchange Theory (SET; Blau, 1964; Homans, 1958) to capture the factors that able-bodied employees derive from working alongside colleagues with disabilities. Furthermore, drawing on the Job Demand–Resource (JD-R) model (Demerouti et al., 2001), this study accounts for the conditions under which these factors translate into job satisfaction. So, these considerations call for addressing the aforementioned shortcomings by investigating the factors influencing the job satisfaction of able-bodied employees working alongside colleagues with disabilities.*

Building on this, several hypotheses are developed to investigate the above aim:

H1a. Perspective-taking positively affects trust toward working alongside colleagues with disabilities

H1b. Empathic concern positively affects trust toward working alongside colleagues with disabilities



H2a. Trust positively affects perceived learning toward working alongside colleagues with disabilities

H2b. Trust positively affects meaning toward working alongside colleagues with disabilities

Methodology. *Data will be collected through an online platform, selecting a European employee sample, aged between 18 and 60, and fluent in English. Additionally, only individuals with prior employee interaction experience were included in the sample. Following the methodological recommendations of Hair et al. (2022), a two-stage estimation procedure was applied to test hypotheses 1 to 4. In the first stage, we will evaluate the reliability and validity of the measurement instruments. In particular, we will examine reliability by calculating Cronbach's alpha, composite reliability, and Dijkstra-Henseler's rho_A. For convergent validity, we will evaluate whether the standardized loadings are high (> 0.7) and statistically significant, and whether the average extracted variance (AVE) values are greater than 0.5 for all constructs. Likewise, discriminant validity was checked using criteria widely accepted in the literature, such as the Fornell–Larcker criterion and the HTMT (Heterotrait–Monotrait). To reduce the risk of common method bias, various measures were also implemented following the methodological recommendations found in the literature (e.g., Krosnick, 1999; Kock et al., 2021). First, the questionnaire was pretested. Likewise, the questionnaire was designed to be brief and structured, seeking to reduce possible responses influenced by social desirability. In addition, the instructions provided to participants explicitly emphasized that there were no right or wrong answers. From an analytical perspective, we will also use statistical procedures to detect the presence of common method bias, specifically the latent variable correlation method (Bagozzi et al., 1991) and Harman's single factor test (Podsakoff et al., 2003), which creates a model with a single latent variable (where all the indicators studied are included in an exploratory factor analysis without rotation) to check whether the first factor explains less than 50% of the variance of its indicators. Multicollinearity will also be detected by checking that the variance inflation factors (VIFs) (Hair et al., 2022). In the second stage, we will estimate the structural model described in Figure 1 using a partial least squares structural equation model (PLS-SEM). The choice of PLS-SEM over covariance-based structural equation models (CB-SEM) is justified for several methodological reasons. First, PLS-SEM does not require the assumption of multivariate normality, as it is a nonparametric method, which makes it particularly suitable when data have non-normal distributions or small sample sizes. Second, this approach allows for the modeling of higher-order constructs (whether reflective or formative) and the handling of complex conceptual structures with multiple simultaneous relationships. To assess the statistical significance of the hypothesized relationships, we will use a bootstrapping procedure with 10,000 resamples, which will allow us to obtain robust estimates of the standard errors, confidence intervals, and t-values associated with each coefficient of the structural model. In addition, we will analyze the goodness of fit and the explanatory and predictive power of the model using coefficients of determination (R^2), effect sizes (f^2), and predictive relevance values (Q^2).*

Results. *We expect that the results of the structural model will support the hypothesized relationships in this short paper.*

Research limitations. *Despite the preliminary nature of this short paper, we attempt to identify the study's potential limitations and future research avenues. First, it is necessary to consider that the current short paper is work-in-progress research.*

Second, the analysis will focus exclusively on able-bodied employees. While this choice will be consistent with the study's exploratory aim and contemporary, advanced understanding in an underexplored research area, it will limit comparisons from a disabled employee's perspective. Future research can incorporate the perspectives of employees with disabilities to provide a comparative understanding of inclusive work experiences.

Third, the study will adopt a cross-country European perspective, which, while offering valuable comparative insights, may mask contextual differences at the national or regional level. Future research will therefore focus on specific European countries or regions to better capture institutional, cultural, and organizational variations, and then will proceed to a cross-country comparison. Alternatively, subsequent studies will extend the analysis beyond Europe to assess whether the observed patterns will hold in non-European contexts.

Managerial implications. *Although the empirical results of this study are still under analysis, the proposed theoretical framework and the expected results already suggest several practical implications for organizations seeking to strengthen inclusive workplaces. In particular, the model highlights how everyday interactions between able-bodied employees and colleagues with disabilities may shape trust, learning, and job satisfaction within inclusive teams. First, hypotheses H1a and H1b suggest that perspective-taking and empathic concern may play an important role in fostering trust toward colleagues with disabilities. From a managerial standpoint, this implies that inclusion strategies should extend beyond formal diversity policies and address interpersonal understanding within teams. Organizations may therefore benefit from training programs that promote perspective-taking, empathy development, and inclusive communication practices. Prior research shows that perspective-taking and empathic concern are associated with supportive and cooperative behaviors in workplace relationships (Longmire and Harrison, 2018). In addition, interventions encouraging employees to adopt others' perspectives have been shown to improve attitudes toward dissimilar coworkers and facilitate more positive interactions (Madera et al., 2011). In inclusive work settings, such initiatives may help employees better understand the experiences and challenges of colleagues with disabilities, thereby strengthening trust and cooperation in daily work.*

Second, H2a and H2b propose that trust may function as a relational mechanism enabling positive outcomes in inclusive work settings. If supported empirically, these relationships would suggest that trust toward colleagues with disabilities can create conditions that facilitate learning and enhance the meaning of work. Research in organizational behavior consistently shows that trust plays a central role in promoting cooperation, knowledge sharing, and positive workplace outcomes (Dirks and Ferrin, 2001). Moreover, in team contexts characterized by mutual task dependence, trust has been shown to support collaborative learning processes among coworkers (de Jong et al., 2007). Managers may therefore consider designing collaborative tasks and team structures that encourage mutual reliance and open communication among employees. Strengthening trust within inclusive teams may help create environments in which employees experience their work as more meaningful and developmentally enriching.

Finally, H3a and H3b indicate that inclusive work experiences may generate value not only for employees with disabilities but also for their coworkers. When employees perceive that collaboration with colleagues with disabilities contributes to their own learning or professional development, they may report higher levels of job satisfaction. Likewise, when work is experienced as meaningful within an inclusive environment, employees may feel more positively connected to their roles and to the organization. Recent research suggests that inclusive leadership and supportive team climates can enhance employees' sense of meaningful work by fostering psychological safety and opportunities for learning (Shafaei and Netaji, 2023). For managers, this implies that workplace inclusion should not be framed solely as a social responsibility initiative, but also as an opportunity to strengthen employees' developmental experiences and work meaningfulness.

Originality of the paper. *By investigating how able-bodied employees interpret their work experience alongside colleagues with disabilities and the factors influencing their job satisfaction, our research makes multiple contributions to the business and management literature on diversity, equity, and inclusion, with a specific focus on organizational behavior and team diversity. First, it extends empathy research (Longmire & Harrison, 2018; Madera et al., 2011; Weißhaar & Huber, 2016), by showing that perspective-taking and empathic concern foster trust among able-bodied employees toward colleagues with disabilities.*

Second, this study extends the application of SET to inclusive work environments. While prior research has focused on both vertical and, more recently, horizontal exchanges (Cropanzano & Mitchell, 2005; Eisenberger et al., 2004; Rhoades & Eisenberger, 2002; Elamin et al., 2024; Darke et al., 2024; Zhang et al., 2025), the role of social exchange processes in inclusive work environments—where employees with and without disabilities interact—remains underexplored. Addressing this gap (Ahmad et al., 2023), the study shows that exchanges between able-bodied employees and colleagues with disabilities generate psychological benefits such as perceived learning and meaning, highlighting the importance of non-material outcomes in social exchange processes.

Third, this study contributes to the JD-R model by extending its application to inclusive coworker relationships. Building on prior research on job resources and demands (Bakker et al., 2005; Schaufeli & Bakker, 2004; Maslach et al., 2001; Zeshan et al., 2025), our findings show that perceived learning and meaning—interpreted as psychological benefits arising from empathic and trust-based exchanges—act as relational job resources that foster job satisfaction (Bakker & Demerouti, 2007; Bakker et al., 2005).

Fourth, the study shifts attention from disability as an individual condition to the relational nature of workplace inclusion, conceptualizing inclusion as a social process emerging from everyday interactions and highlighting the active role of able-bodied employees in shaping inclusive workplaces (Chan & McGinley, 2024; Dwertmann et al., 2025; Santilli et al., 2023).

Finally, this study contributes to the "Purpose-driven Businesses" track of the Sinergie-SIMA 2026 conference by showing how workplace inclusion of colleagues with disabilities aligns with a core organizational purpose that extends beyond economic goals. It demonstrates how inclusion-driven values, enacted through everyday interactions among all employees, foster a positive organizational climate. In this way, the study highlights how organizational purpose can also be understood through an inclusive lens, emerging from the collective contribution of all organizational members—

starting from employees, as evidenced in this research—and suggests future research to further explore the broader system of stakeholders involved in shaping such purpose.

A Quantitative Assessment of Consumers' Reactions to "Clean" Labels•

GIOVANNI PINO*, STEFANIA VITIELLO♣, JASON K. SIT♠, SHYNAR DYUSSEMBAYEVA♦

Abstract. *Across three quantitative studies, this research investigates consumer reaction to "clean" labels, a broad label category identifying products obtained through production processes aimed at minimally affecting consumer health and the natural environment as well as "free from" products, namely products devoid of potentially harmful substances. Study 1 focuses on sales data regarding three European countries (Italy, Spain, and France) and a three-year period (2020-2022). It shows that the sales of clean labelled hedonic products (e.g., snacks) are substantially equivalent to those of products displaying other labels, here referred to as "descriptive". However, with respect to more utilitarian (hereafter, "functional") foods (e.g., cooking ingredients), the sales of clean labeled products are significantly lower than those of products with descriptive labels. Study 2 focuses on an example of functional foods and using an experimental approach confirms that consumers exhibit more favorable reactions to functional products with descriptive rather than clean labels. Study 3 also uses an experimental approach and confirms that employing clean versus descriptive labels does not significantly influence consumers' intentions toward hedonic products. Overall, the results suggest that, compared to clean labels, descriptive labels favorably influence the decision to purchase functional products. However, for hedonic products, descriptive and clean labels exert an equivalent influence on consumers' choices.*
Keywords: *clean labels*; *product sales*; *hedonic food*; *functional food*

"Clean" labels as drivers of food consumption decisions. *Consumers are increasingly attentive to food healthiness because the outbreak of global health problems and the greater availability of health-related information have determined a progressive shift toward preventive nutrition and healthy eating (Mintel, 2025). This trend has led to the rise of negative dispositions toward ultra-processed foods, which, however, offers food manufacturers the opportunity to improve the quality and healthiness of such products, in order to meet consumers' desires for healthy food (Soininen, 2025). In this context, marketing communication plays a crucial role: front-of-package labels, in particular, have become a key information source that helps consumers evaluate food products and make their purchase decisions (De Marchi et al., 2016; Kunz et al., 2021).*

In many cases, food labels incorporate claims concerning relatively unobservable features (e.g., "organic" origin) which may be certified by third-party organizations (e.g., the European Union), by product makers, or food retailers. For this reason, many consumers consider product labels as quality and safety cues and credence attributes that guide their purchasing decisions. However, other consumers question their truthfulness and are unwilling to pay higher prices for certified products (Lee et al., 2020), especially when certifications are ambiguous or when their limited understandability raises skepticism about the real characteristics of food products (Rossi and Rivetti, 2023).

Among the various labels, the so-called "clean" labels (e.g., "no preservatives", "pesticide free") identify products devoid of substances that could harm both consumers or the environment (Lin and Wang, 2023; Sirieix et al., 2012) as well as products obtained through relatively simple production processes that do not involve harmful substances (e.g., artificial dyeing, genetic modification, etc.; Asioli, 2017; Grappe et al., 2022). Clean labels include "free from" labels (e.g., "gluten-free", "sugar-free") which certify that the product does not contain any allergens or chemical substances that could have adverse effects on consumer health. Some studies maintain that consumers generally have favorable opinions about clean labeled products and consider them to be healthier than comparable products (Priven et al., 2015). As a consequence, the perceived healthiness and quality of clean labeled products are the main drivers of consumers' intentions toward such products (Castellini et al., 2023). However, other scholars have noted that these positive effects might be context-specific: for instance, consumers might prefer clean labeled products to comparable products when they aim to avoid some specific health risks (e.g., allergic reactions) or when clean labels are accompanied by information about ingredients or production processes (Liaukonyte et al., 2013).

Purpose of the paper. *Consumer reaction to clean labels might differ significantly from their reaction to other widespread labels – hereafter "descriptive" labels (e.g., "locally sourced", "free range", "rich in Omega 3"). However,*

still little is known about the impact of clean labels on consumers' attitudes and intentions. Considering that, for food producers and retailers it is important to be aware of such differences in order to effectively market their products, this research aims at: a) exploring said differences by focusing on the sales value of products featuring "clean" and "descriptive" labels; a) understanding how these two label categories influence consumers' purchase decisions. To achieve these objectives, we ran three empirical studies. In Study 1, we analyzed data concerning the sales of products carrying clean and descriptive labels in three European countries (Italy, Spain, and France) sharing some cultural characteristics and consumption habits. The study aimed at establishing whether one of the two label categories is associated with higher sales. Then, to validate Study 1 results, we ran two between subjects online experiments. The first experiment (Study 2) assessed consumer reactions to comparable clean and descriptive labels (i.e., "No Chemicals" versus "100% Natural") focusing on an example of functional food. The second experiment (Study 3) assessed consumer reactions to analogous labels (i.e., "No Chemical Additives" versus "100% Natural Ingredients") applied to hedonic food products.

Study 1: Methods. *We used Euromonitor's Passport sales data (https://www.euromonitor.com/passport) regarding two product categories – snacks and cooking ingredients – as examples of hedonic and functional food products, respectively. Particularly, we analyzed data concerning the sales of products displaying 21 different labels (7 clean labels; 14 descriptive labels) occurred in Italy, Spain, and France over a three-year period (2020-2022). We focused on these countries because they are located in a continuous geographical space and share similarities in terms of food consumption. Two independent coders analyzed the label text in order to distinguish clean labels from other label categories (here referred to as "descriptive"; Tables 1 and 2). Because for each label and for each product category, Euromonitor provides sales and average price data (in USD), we divided the sales data by the corresponding price in order to control for possible effects related to product prices. Hence, for each country and for the two label / product categories, we obtained "sales per price unit" indicators (i.e., sales quantity indicators).*

Study 1: Comparative analysis. *For all countries, we assessed whether sales quantities vary based on the label type by running a series of ANOVA (Table 3). We ran this analysis for both hedonic (i.e., snacks) and functional products (i.e., cooking ingredients). For hedonic products, the results suggest that sales are unrelated to the type of labels as the analysis did not return significant differences. Instead, for functional products, and for Italy and Spain, we found that descriptive labels are associated with significantly higher sales quantities than clean labels.*

Study 1: Moderation analysis. *Based on the results illustrated above, we assessed a possible interaction effect of label type and product category by running a moderation analysis trough Hayes' (2022) PROCESS macro (model 1). Specifically, we ran a linear regression analysis that assessed a possible influence of label type (a variable coded as -1 = Clean label; 1 = Descriptive label), product category (a variable coded as -1 = Hedonic products; 1 = Functional products), and the interaction between these two variables (Label type × Product category) on product sales. For Italy and Spain, the analysis returned significant positive effects of label type on product sales, signaling that descriptive labels are associated with greater sales quantities than clean labels (Table 4). For Italy, the analysis also returned a negative effect of product category, signaling that, compared to hedonic products, functional products are associated with lower sales quantities. Importantly, in all cases, the analysis returned a significant interaction effect of label type and product category. In line with our previous considerations, we found that the conditional effect of label type on product sales is positive and significant for functional products; however, it is non-significant for hedonic products.*

Overall, the results suggest that consumers tend to prefer functional products labelled with descriptive labels, whereas, when it comes to hedonic products, descriptive and clean labels seem to exert an equivalent influence on consumers' purchase decision. Accordingly, in the specific case of Italy and Spain, we found that, for functional products, descriptive labels are associated with significantly greater sales quantities compared to clean labels. This effect does not extend to hedonic products.

Study 2: Methods. *To further investigate whether consumers tend to prefer descriptive labels when their purchase decisions concern functional products, we ran a two-cells between subjects' online experiment with 225 Canadian consumers (mean age = 39; 54% female) recruited through Prolific.com. We presented all participants with a picture of a functional food product (i.e., a package of dried beans). We prepared two versions of this picture: one included a clean label ("No Chemicals"), the other included a descriptive label ("100% Natural"). After checking this picture, participants rated the intentions toward the product using a mono-item scale ("How likely is that you look for further information about that product?"; 1 = Not at all likely, 7 = Very likely). Participants also rated the perceived healthfulness of the product using a mono-item semantic differential scale (1 = Not healthy at all, 7 = Very healthy). Finally, they completed the survey by providing their demographic data.*

Study 2: Results. *Participants' ratings of the perceived healthfulness of the test product did not change across the two experimental conditions ($p = 0.873$; Table 5). However, those participants who were exposed to the picture that featured a descriptive label expressed marginally significant stronger intentions toward the product ($M = 4.80$, $SD = 1.75$) than their counterparts who were exposed to the picture with a clean label ($M = 4.37$, $SD = 1.81$, $F(1, 223) = 3.34$, $p = .069$).*

These findings appear relatively consistent with the results of Study 1 because they indicate that, specifically for functional products, consumers tend to exhibit better reactions to descriptive labels rather than clean labels.

Study 3: Methods. *To assess whether consumers are relatively indifferent to clean and descriptive labels when their purchase decisions concern hedonic products, we ran a two-cells between subjects' online experiment with 384 US consumers (mean age = 47; 61% female) recruited through Prolific.com. We used a mock-up online food store displaying some hedonic food products (biscuits and wafers). The store featured "add to cart" buttons, which allowed participants to simulate an online shopping experience. It was designed to display either a clean label ("No Chemical Additives") or a descriptive label ("100% Natural Ingredients") below each product. Participants accessed the store through a link embedded in an online questionnaire. Half of them saw the version of the store with "clean" labels below the products; the other half saw the version with "descriptive" labels below the same products. After visiting the store, participants completed the questionnaire used a mono-item scale (1 = Not healthy at all, 7 = Very healthy) to rate the perceived healthfulness of the products available in the store and provided their demographic data.*

Study 3. Results. *Participants' ratings of the perceived healthfulness of the products available in the store did not change across the two experimental conditions (p = 0.180; Table 6). Similarly, both their overall expenditure (p = 0.976) and the number of products that they added to their carts (p = 0.450) did not change across the two conditions. These findings confirm that, specifically for hedonic products, the adoption of clean versus descriptive labels does not affect consumers' perceptions and behavioral intentions.*

Research limitations. *While a strength of this research is the adoption of a mixed method combining archival and experimental data, it is important to acknowledge that our research did not assess the factors underlying consumers' decision to purchase (or not) products featuring clean labels. Therefore, to fully understand why the influence of such labels on consumers' decisions varies across different product categories, future studies should investigate potential factors responsible for such differences: for example, consumers might find descriptive labels more understandable than clean labels. Furthermore, although we observed the purchase behavior of consumers living in different countries, it is important to acknowledge that the preference for clean or descriptive labels may significantly vary within each national consumer group. Future research is, therefore, recommended to investigate characteristics such as a consumer age and cultural factors because they might significantly influence consumers' reaction to clean and descriptive labels.*

Managerial implications. *The studies illustrated above yield two main results that are relevant to food producers and retailers: a) clean labels are less effective than descriptive labels when they are applied to functional products; b) clean labels are as effective as descriptive labels when they are applied to hedonic products. Managerially, these results advise manufactures and retailers to use clean labels only for hedonic products because the application of these labels to functional products may lead to sub-optimal economic results. Instead, they could use descriptive labels for functional products. Such conclusions likely apply to the other forms of communication (e.g., website information, etc.). Therefore, marketers should maintain information consistency across different communication channels.*

Originality of the paper. *The food market is characterized by a growing use of labels which compete to attract consumers' attention and influence their purchasing decisions. As a meaningful category of labels that reassure consumers about the absence of potentially harmful substances, clean labels have progressively captured the interest of food marketing scholars (e.g., Asioli et al., 2017; Grappe et al., 2022). However, it is still unclear whether their ability to influence consumers' decisions significantly varies across consumption contexts. The present research addresses this gap and establishes that functional products do not benefit from the adoption of these labels. The results also indicate that cultural factors may affect consumer reaction to these labels as we detected the same results in countries that share similarities in their food consumption patterns (Italy and Spain). Thus, from a global perspective, the findings of this study suggest that consumer responses to clean labels vary across product categories and are further shaped by the specific characteristics of the target market.*

Breaking the shelf blindness: how dynamic social norms-based communication increases visual attention toward high-fiber breakfast products

SOFIA LAUDANI[1], SUSANNA GRAZIANO[2], MARIA GRAZIA CARDINALI[3]

Abstract. *Questo studio indaga il ruolo delle norme sociali descrittive dinamiche come strumento di Nutrition Shopper Marketing per promuovere l'acquisto di prodotti dal miglior indice nutrizionale. Nonostante l'efficacia delle norme sociali sia nota, la letteratura riporta risultati contrastanti; secondo gli studi precedenti, una delle principali ragioni di insuccesso potrebbe essere la scarsa visibilità delle iniziative stesse da parte dei consumatori. Al fine di comprendere questo aspetto, è stato condotto un esperimento sfruttando la tecnologia dell'eye-tracking in due punti vendita della Grande Distribuzione italiana su un campione di 52 partecipanti. Nel punto vendita sperimentale è stata installata una comunicazione basata su norme dinamiche applicata a cereali, biscotti e merendine per la promozione dei prodotti che offrissero un maggior apporto di fibre. L'utilizzo dell'eye-tracking ha permesso di misurare i processi di scelta. I risultati evidenziano come la comunicazione abbia aumentato significativamente il numero di fissazioni e il dwell time sui prodotti target, specialmente per biscotti e merendine. Inoltre, solo nel punto vendita sperimentale sono state osservate una maggiore facilità di ricerca e una superiore soddisfazione per l'esperienza d'acquisto, oltre che scelte più corrette dei partecipanti rispetto al gruppo di controllo. La ricerca dimostra come il ricorso a una strategia di comunicazione basata sulle norme sociali abbia migliorato la visibilità dei prodotti ricchi in fibre e orientato i consumatori nella scelta dei prodotti.*

Keywords: *norme sociali dinamiche; marketing nutrizionale; in-store communication; eye-tracking; fibre; prima colazione*

Framing of the research. *Il panorama epidemiologico attuale è fortemente condizionato dall'aumento delle malattie croniche non trasmissibili legate all'alimentazione. Infatti, l'eccessiva disponibilità di alimenti ad alta densità energetica ha contribuito alla diffusione del fenomeno dell'obesità, un disturbo multifattoriale che provoca l'insorgenza di gravi comorbilità, come malattie del sistema circolatorio e metabolico e che può portare allo sviluppo di diverse forme tumorali (Mahony, 2025; WHO, 2022). In particolare, la letteratura evidenzia come l'abuso di sodio, grassi trans e bevande zuccherate, unito a un consumo insufficiente di fibre, frutta e vegetali freschi, rappresentino i principali fattori di rischio per lo sviluppo di una condizione di obesità e delle relative comorbilità (Afshin, 2019).*

É importante notare come l'obesità sia provocata da una combinazione di variabili, tra cui emerge con forza il ruolo determinante dell'ambiente. Nello specifico, le strategie di marketing attuate dalle imprese industriali e distributive rappresentano un fattore rilevante nell'influenzare le preferenze e i pattern di acquisto e consumo della popolazione rinforzando le abitudini alimentari e comportamentali che non promuovono l'equilibrio energetico positivo (Farzand et al., 2025). L'architettura delle scelte nei punti vendita può influenzare profondamente le decisioni d'acquisto. Spesso, infatti, i prodotti ricchi di zuccheri, grassi saturi e sale vengono valorizzati all'interno dei punti vendita grocery attraverso strategie di posizionamento, l'aumento dell'ampiezza e della profondità assortimentale e l'uso di comunicazioni aggressive (Thorndike et al., 2020). Tuttavia, i distributori hanno l'opportunità di agire come attori del cambiamento, attraverso l'applicazione di strategie di "Nutrition Shopper Marketing" per influenzare positivamente le abitudini di acquisto (Grandi & Cardinali, 2021). Infatti, secondo l'approccio del Nutrition Shopper Marketing, il punto vendita non rappresenta un luogo in cui avvengono scelte puramente razionali. In quest'ottica, le leve del marketing in-store possono essere declinate strategicamente per incoraggiare l'acquisto di referenze dal miglior profilo nutrizionale (Grandi & Cardinali, 2021). Nonostante l'ampia letteratura sui driver che incoraggerebbero l'adozione di regimi alimentari orientati alla salute, il contributo strategico dei retailer nella promozione di scelte sane, rimangono molte domande senza risposta sulle migliori pratiche per l'implementazione di interventi efficaci nei punti vendita (Karpin et al., 2020). Inoltre, gran parte degli approcci esistenti tende a sovrastimare la componente razionale del consumatore e attribuisce scarsa rilevanza alle strategie di condizionamento ambientale e ai messaggi basati sulle norme sociali, in grado di attivare euristiche che permettono di modellare i comportamenti (Slapø et al., 2021; Glanz et al., 2012).

Le norme sociali possono essere intese come l'insieme di regole implicite, non scritte e legate al contesto che guidano e vincolano il comportamento umano (Gelfand et al., 2024). Coerentemente con la Focus Theory of Normative Conduct (Cialdini et al., 1990) è possibile distinguere tra norme descrittive (descrivono il comportamento altrui all'interno di uno specifico gruppo di riferimento) e norme ingiuntive (prescrivono ciò che è considerato appropriato dal gruppo di riferimento). Si parla di "social norm nudges" per descrivere l'esplicitazione delle norme sociali attraverso l'utilizzo di

comunicazione testuale (Wolfswinkel et al., 2025). L'efficacia di interventi volti a incoraggiare l'acquisto o il consumo di prodotti dal miglior contenuto nutrizionale attraverso il ricorso alla comunicazione basata sulle norme sociali descrittive è stata ampiamente riconosciuta in letteratura (Melnyk et al., 2022; De Groot, 2022; Sharps & Robinson, 2016; McGrath, 2023; Guichard et al., 2021; Higgs et al., 2019). È importante notare come le norme sociali non siano statiche ma, piuttosto, evolvano continuamente. Nuovi comportamenti possono affermarsi grazie ad una maggiore consapevolezza su costi e benefici legati alle vecchie abitudini o all'influenza degli atteggiamenti e delle convinzioni che caratterizzano il proprio gruppo di riferimento. Inoltre, l'allineamento con le tendenze sociali più ampie può favorire l'adozione di nuove norme. Infatti, le persone sono più propense a cambiare i propri comportamenti se percepiscono il cambiamento in linea con una tendenza generale. Questo avviene perché le norme dinamiche possono far credere che il cambiamento personale sia possibile, importante per gli altri e/o coerente con la propria identità sociale (Gelfand et al., 2024). Nonostante alcuni studi abbiano evidenziato come le norme sociali descrittive dinamiche siano più efficaci di quelle statiche nella promozione di comportamenti prosociali tra cui quelli alimentari (Edwards et al., 2026; Sparkman & Walton, 2017; Sparkman et al., 2020; Carfora et al., 2022); altri hanno mostrato come la comunicazione non abbia prodotto alcun effetto o generato addirittura effetti controproducenti (si parla a tal proposito di "effetto boomerang"). Spesso gli autori suggeriscono che il fallimento degli interventi normativi rivolti a modificare i comportamenti alimentari possa essere dovuto ad abitudini fortemente consolidate. Infatti, spesso i messaggi contenenti norme sociali descrittive dinamiche sono stati utilizzati non tanto per promuovere comportamenti alimentari orientati alla salute ma alla sostenibilità ambientale e, nello specifico, la riduzione del consumo di carne a fronte di un aumento del consumo di alimenti a base vegetale (Aldoh et al., 2021; Çoker et al., 2022). Inoltre, alcuni esperimenti condotti in ambiente reale (nei ristoranti, nelle mense o all'interno dei punti vendita grocery) potrebbero non aver prodotto gli effetti desiderati a causa del forte rumore visivo legato alla presenza di molteplici stimoli (Patel et al., 2024; Çoker et al., 2022). Infatti, affinché un'iniziativa di comunicazione in-store possa funzionare, è necessario che le persone la notino e la comprendono davvero (Bartels et al., 2018). Diversi studi (Jacoby et al., 1977; Mazis & Staelin, 1982; McGuire, 1976) dimostrano che, tra leggere un'informazione e cambiare il proprio comportamento, ci sono diversi "ostacoli" da superare: bisogna esporsi al messaggio, prestargli attenzione, capirlo e, infine, ricordarlo. Se uno di questi passaggi fallisce, l'informazione diventa sterile. Inoltre, i consumatori sono esposti a un sovraccarico informativo che eccede le loro capacità di elaborazione (es. Jacoby et al., 1977; Bartels et al., 2018). Di conseguenza, l'individuo adotta dei meccanismi di attenzione selettiva, filtrando gli stimoli e concentrandosi solo su una porzione ridotta dei dati disponibili (Jacoby et al., 1977). Per questa ragione, al fine di arricchire la comprensione di come i consumatori percepiscono ed elaborano le informazioni durante l'esperienza di spesa, questa ricerca si propone di misurare l'efficacia di un'iniziativa di comunicazione in-store attraverso il ricorso allo strumento dell'eye-tracking.

Purpose of the paper. *Spesso i consumatori sfruttano euristiche per dedurre la qualità nutrizionale dei prodotti e la loro attenzione è limitata e catturata da elementi visivi salienti (Bartels et al., 2018). Di conseguenza, semplificare le informazioni relative al contenuto di fibre dei prodotti attraverso la comunicazione puntuale su reglettes e stopper potrebbe renderle più fruibili.*

Methodology. *Al fine di testare l'efficacia della comunicazione in-store basata sulle norme sociali dinamiche, è stato condotto un esperimento in ambiente reale in due punti vendita (uno sperimentale e uno di controllo) appartenenti a una catena della Grande Distribuzione italiana. L'iniziativa ha riguardato i prodotti ricchi in fibre della prima colazione, in particolare cereali, merendine e biscotti, sia della Marca del Distributore (MDD) che dell'Industria di Marca (IDM). Nel punto vendita sperimentale, è stata installata un'iniziativa di comunicazione attraverso crowner, banner, stopper, reglettes e calpestabili, che recitavano il seguente messaggio:*

"SCELGO + FIBRE. Sempre più consumatori [Retailer] scelgono prodotti ricchi di fibre. E TU COSA SCEGLI?"
"Prenditi cura del tuo benessere. Scopri i prodotti per la prima colazione con maggiore apporto di fibre."

Poiché il consumo di fibre non rappresenta ancora un'abitudine diffusa, nonostante mostri una tendenza in crescita (Tao et al., 2023; GS1 Italy, 2022; 2024; AIRC - Fondazione per la Ricerca sul Cancro, 2021), l'uso di una norma descrittiva statica rischierebbe di demotivare i destinatari, evidenziando come tale comportamento sia adottato solo dalla minoranza. Per superare questo limite, si è scelto di ricorrere a una norma descrittiva dinamica. Al fine di testare l'efficacia di tale iniziativa è stato condotto uno studio di eye-tracking con gli occhiali Tobii Glasses 3 nel punto vendita oggetto dell'esperimento e nel punto vendita di controllo. Lo strumento dell'eye-tracking permette infatti di analizzare i processi percettivi, cognitivi e decisionali (Rayner, 1998; Radach et al., 2003). Durante l'atto d'acquisto, consente di monitorare i movimenti oculari come indicatori dell'acquisizione informativa e dei meccanismi subconsci di elaborazione (Bartels et al., 2018). Nello specifico, permette di mappare la sequenza, la collocazione e la persistenza dello sguardo su determinati stimoli, identificando quali sono gli elementi che vengono effettivamente rilevati dal consumatore. Sebbene l'atto percettivo non implichi necessariamente la decodifica o l'utilizzo del dato che il consumatore raccoglie, questo rimane sempre una condizione preliminare indispensabile per la successiva comprensione e applicazione dell'informazione raccolta (Becker et al., 2015). Inoltre, l'utilizzo degli occhiali come strumento di eye-tracking ha consentito di acquisire i dati delle fissazioni e delle saccadi in condizioni ecologiche, lasciando al partecipante la totale libertà di movimento.

Prima dell'inizio della sessione, a ciascun partecipante è stato assegnato un codice per consentirne l'anonimato ed è stato sottoposto a una procedura di calibrazione standard a un punto. I dati grezzi registrati dagli occhiali sono stati

successivamente importati e analizzati tramite il software Tobii Pro Lab, che è stato utilizzato per l'analisi delle Aree di Interesse (AOI) e la realizzazione delle heatmap. Inoltre, è stato misurato il tempo che il partecipante impiegava nel trovare i prodotti ricchi di fibre ed è stato annotato se il prodotto selezionato era effettivamente ricco di fibre o meno.

A ciascun partecipante è stata fornita una lista della spesa fittizia come shopping mission, che prevedeva l'acquisto di una confezione di cereali ricchi in fibre, una confezione di biscotti ricchi in fibre e una confezione di merendine ricche in fibre. Ai partecipanti non è stato dato alcun vincolo di tempo, di ordine o di percorso. Al termine della simulazione, sono state poste loro delle domande attraverso un breve questionario. In particolare, sono state misurate la facilità di ricerca dei prodotti all'interno dello scaffale (Seiders et al., 2005; α =.961), la valorizzazione percepita dei prodotti ricchi in fibre all'interno dello scaffale e la soddisfazione dell'esperienza di acquisto simulata (Van Ittersum et al., 2013; α =.978). Inoltre, ai partecipanti è stato chiesto come hanno fatto a identificare e riconoscere il prodotto ricco in fibre.

Il campione dello studio consta di 52 partecipanti, 27 partecipanti per il punto vendita sperimentale e 25 per il punto vendita di controllo, così suddiviso:

Results. *Per quanto riguarda il punto vendita sperimentale, dal dichiarato dei partecipanti è emerso che il 48% aveva notato la comunicazione e, di questi, il 77% ha dichiarato che è risultata utile nella ricerca dei prodotti ricchi di fibre. Ai partecipanti è stato chiesto come hanno fatto a indentificare e riconoscere il prodotto ricco in fibre (Tabella 2). Il confronto tra i due punti vendita evidenzia come l'introduzione della comunicazione a scaffale nel punto sperimentale abbia parzialmente sostituito l'affidamento ad altri elementi visivi, come il packaging, le immagini e i colori del packaging. Si osserva inoltre una maggiore incidenza del fattore marca nel campione sperimentale, che potrebbe suggerire una ricerca più mirata e "programmata" rispetto al gruppo di controllo.*

Tabella 2. Driver di ricerca dei prodotti

Affermazione	***sperimentale***	***controllo***
Ho letto le informazioni presenti sul pack	*41%*	*48%*
Mi sono fatto guidare dall'immagine presente sul pack	*7%*	*21%*
Mi sono fatto guidare dal colore del pack	*12%*	*15%*
Conoscevo già il prodotto e l'ho cercato a scaffale	*11%*	*10%*
Mi sono fatto guidare dalla marca	*16%*	*6%*
Mi sono fatto guidare dalla comunicazione a scaffale	*13%*	*-*

Nel punto vendita sperimentale, il 33% del campione ha selezionato correttamente tutti i prodotti ricchi di fibre, il 56% ne ha selezionato uno errato, il 7% ne ha selezionati due errati e solo un partecipante ha sbagliato a selezionare tutti e tre i prodotti. Nel punto vendita di controllo, invece, solo il 29% del campione ha selezionato correttamente tutti i prodotti ricchi di fibre, il 48% ne ha selezionato uno errato, il 15% ne ha selezionati due errati e l'8% ha sbagliato a selezionare tutti e tre i prodotti. Attraverso un t-test a campioni indipendenti, è stata calcolato il numero di scelte corrette in entrambi i punti vendita ed è risultato che nel punto vendita con la comunicazione i partecipanti hanno effettuato più scelte corrette (Ms = 2.19, Mc = 1.76; p = .042).

Sia nel punto vendita sperimentale che di controllo, la categoria di prodotti dove i consumatori hanno riscontrato più difficoltà, ovvero dove hanno commesso più errori, è quella delle merendine, mentre quella risultata più semplice da trovare è quella dei cereali.

Attraverso l'ausilio degli occhiali eye-tracking, è stato cronometrato il tempo impiegato nell'esperienza di spesa simulata in entrambi i punti vendita (Tabella 3). Tuttavia, eseguendo un t-test a campioni indipendenti, è emerso che i tempi di spesa per ciascuna categoria di prodotto (ad eccezione dei cereali) sono inferiori nel punto vendita sperimentale, anche se non in modo significativo (p>.05).

Tabella 3. Tempo impiegato nella ricerca dei prodotti

Punto vendita	*Tempo impiegato (in secondi)*			
	Biscotti	*Cereali*	*Merendine*	*Spesa totale*
sperimentale	*69,57*	*53,14*	*42,52*	*165,23*
controllo	*57,26*	*62,84*	*43,89*	*172,08*

Per quanto riguarda i cereali, i risultati potrebbero risentire del diverso spazio espositivo; infatti, i metri lineari assegnati alla categoria nel punto vendita di controllo sono ridotti rispetto a quelli del punto vendita sperimentale. L'assenza di significatività tra le due condizioni potrebbe essere dovuta anche al modo in cui i partecipanti hanno ricercato i prodotti ricchi in fibre. Infatti, in entrambi i punti vendita, i partecipanti si sono fatti guidare in gran parte dalle informazioni presenti sul packaging (48% nel punto vendita di controllo, 41% nel punto vendita sperimentale). Questo risultato non sorprende dal momento che il packaging rappresenta spesso l'ultimo e più rilevante strumento di comunicazione capace di raggiungere il consumatore nel momento della scelta (Butkevičienė et al., 2008). Tuttavia, la facilità di ricerca nello scaffale è risultata più alta nel punto vendita con la comunicazione (Ms = 5.64, Mc = 3.86; p < .001), così come la soddisfazione dell'esperienza di acquisto (Ms = 5.50, Mc = 4.52; p =.004). Ai partecipanti è stato chiesto anche quanto, secondo loro, i prodotti ricchi in fibre fossero valorizzati a scaffale ed è risultato che nel punto vendita sperimentale la valorizzazione risulta maggiore rispetto a quello di controllo (Ms = 4.88; Mc = 3.56; p < .001).
Successivamente, è stato calcolato un t-test sulle fissazioni e il dwell time, ponendo come AOI i prodotti ricchi in fibre in entrambi i punti vendita. Dai risultati si può evincere che nel punto vendita sperimentale vi è un incremento significativo nelle fissazioni per le categorie dei biscotti (Ms = 33.37, Mc = 8.96; p = .001) e delle merendine (Ms = 22.85, Mc = 6.96; p = .004), mentre non significativo per i cereali (Ms = 42.28, Mc = 43.63; p > .05). Anche il dwell time è aumentato in modo significativo sia per i biscotti (Ms = 12.05, Mc = 3.66; p = .003) che per le merendine (Ms = 8.45, Mc = 2.83; p = .019) e in modo non significativo per i cereali (Ms = 16.39, Mc = 16.44; p > .05).
Infatti, mentre nel punto vendita di controllo i consumatori tendevano a ignorare i prodotti ricchi di fibre o a cercarli basandosi principalmente sul packaging, nel punto vendita sperimentale la comunicazione ha aiutato nella ricerca del prodotto. Questo spiega anche perché i partecipanti nel punto vendita sperimentale abbiano poi effettuato un numero significativamente maggiore di scelte corrette.
Inoltre, attraverso il software Tobii Pro Lab, sono state generate delle mappe che permettono di approfondire meglio la comprensione dei meccanismi di attenzione selettiva attivati dalla comunicazione in-store. Le heatmap evidenziano come gli stimoli abbiano guidato lo sguardo dei partecipanti verso elementi specifici della comunicazione, favorendo la decodifica del messaggio sulle norme sociali dinamiche.
Le heatmap relative ai calpestabili (Figure 1-2-3) mostrano una concentrazione di fissazioni prevalentemente sulla parte superiore, in corrispondenza del claim "SCELGO + FIBRE". In particolare, nel calpestabile dei biscotti si osserva una maggiore intensità di sguardo sul testo, che sembrerebbe aver dunque svolto una funzione di anchor visivo. La dispersione minore di fissazioni sugli altri elementi decorativi conferma che il messaggio centrale è stato il principale driver dell'attenzione. Per quanto riguarda le heatmap dei crowner (Figure 5-6-7), quello delle merendine presenta la maggiore densità di fissazioni, con attenzione sia sul messaggio testuale superiore che sulla call-to-action centrale. Nel crowner dei biscotti, la presenza di fissazioni sul volto e sul prodotto che tiene in mano il soggetto può suggerire che l'elemento umano abbia contribuito a rendere la norma sociale più tangibile e identificabile, favorendo il processo di allineamento alle tendenze del gruppo di riferimento. Infatti, la visione di individui che mangiano cibi con espressioni edoniche, rispetto a espressioni neutre, aumenta le risposte positive verso i cibi sani e può avere un impatto sulla salienza del messaggio (Samson e Buijzen, 2020). Nel crowner dei cereali non sono presenti fissazioni, probabilmente dovuto al fatto che era posizionato in un punto in cui i partecipanti transitavano solo al termine della loro esperienza di spesa. I crowner delle merendine e dei biscotti erano invece disposti all'inizio, in modo quasi speculare.

Figura 2. *Calpestabili biscotti*

Figura 3. *Calpestabili merendine*

Figura 4. *Crowner cereali*

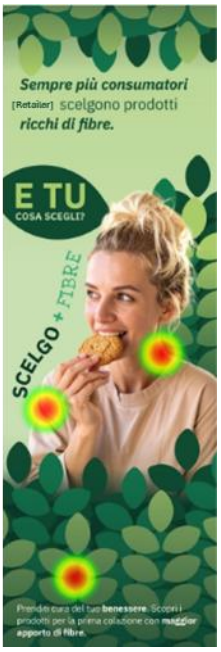

Figura 5. *Crowner biscotti*

Figura 6. *Crowner merendine*

Attraverso gli scan path (Figure 7-8) è invece possibile evincere le differenze nel percorso di scelta che i consumatori hanno adottato. Nel punto vendita di controllo, i partecipanti attuano un'esplorazione "bottom-up": lo scan path risulta fortemente guidato dalle caratteristiche visive dei packaging e da una scansione a "Z". Il percorso è caratterizzato da saccadi lunghe e frequenti incroci, segno di un processo di ricerca per tentativi ed errori in cui il consumatore deve processare singolarmente numerosi stimoli prima di identificare il prodotto target. Lo scan path nel punto vendita sperimentale mostra invece un percorso di ricerca più lineare. Lo sguardo viene "catturato" dalle reglettes e dagli stopper. Una volta agganciato il messaggio normativo, lo sguardo si muove successivamente verso i prodotti adiacenti. Le fissazioni sono più concentrate e ravvicinate, a dimostrazione del fatto che la comunicazione ha ridotto l'area di ricerca visiva, guidando il partecipante direttamente verso i prodotti corretti.

Figura 7. *Scanpath pv sperimentale*

Figura 8. *Scanpath pv controllo*

Research limitations. *Le limitazioni di questo studio risiedono innanzitutto nella numerosità campionaria di 52 partecipanti che, pur essendo adeguata a uno studio sperimentale con eye-tracking in ambiente reale, circoscrive la generalizzabilità dei risultati. Inoltre, l'utilizzo di una shopping mission simulata potrebbe aver parzialmente alterato i naturali processi decisionali, attenuando l'influenza delle abitudini di acquisto consolidate che solitamente guidano il*

consumatore nel punto vendita. Un ulteriore vincolo è rappresentato dalle differenze strutturali intrinseche dei punti vendita coinvolti; in particolare, la diversa dotazione di metri lineari nella categoria cereali potrebbe aver influenzato la visibilità dei prodotti e i tempi di ricerca indipendentemente dall'efficacia dell'intervento comunicativo. Lo studio si è inoltre focalizzato esclusivamente sui prodotti per la prima colazione e sul contenuto di fibre, non permettendo di estendere le conclusioni ad altri nutrienti o categorie merceologiche caratterizzate da driver d'acquisto differenti.

Managerial implications. *I risultati di questo studio possono offrire punti di riflessione per i retailer e i player industriali interessati a promuovere abitudini di acquisto più salutari attraverso strategie di Nutrition Shopper Marketing. In primo luogo, i risultati dimostrano che l'implementazione di iniziative di comunicazione basate su norme sociali dinamiche può essere una strategia efficace per rompere la shelf blindness e incrementare l'attenzione visiva verso prodotti dal miglior profilo nutrizionale. L'implementazione di queste strategie potrebbe migliorare la soddisfazione complessiva dell'esperienza di acquisto e la percezione di facilità nella ricerca. Inoltre, la riduzione degli errori di scelta osservata nel punto vendita sperimentale suggerisce che tali interventi semplificano il processo decisionale del consumatore, agendo come euristiche che riducono il sovraccarico informativo e contrastano l'affidamento esclusivo a elementi meno accurati come i colori o le immagini del packaging. Dal punto di vista strategico, l'utilizzo delle norme dinamiche permette di promuovere comportamenti ancora minoritari senza demotivare il consumatore, rendendo il cambiamento percepito come una tendenza socialmente approvata e in crescita.*

Originality of the paper. *Mentre numerosi studi hanno analizzato l'impatto delle norme sociali in contesti controllati o online, questa ricerca si distingue per l'applicazione di un esperimento in ambiente reale che integra la teoria delle norme dinamiche con l'analisi dei processi di scelta tramite la tecnologia dell'eye-tracking. Inoltre, a differenza di precedenti ricerche focalizzate prevalentemente sulla sostenibilità o sulla riduzione del consumo di carne, questo studio applica il framing normativo alla promozione di un nutriente specifico, la fibra, in categorie di prodotti spesso percepite come edonistiche (biscotti e merendine), offrendo nuove prospettive sulla capacità dei retailer di agire come agenti di promozione della salute delle persone. Infine, l'approccio integrato che combina dati di fissazione, performance di scelta corretta e metriche di soddisfazione del cliente fornisce una visione più completa dell'efficacia del nudge normativo.*

Can Product Aggregation Facilitate the Identification of Healthy Options? An Eye-Tracking Field Experiment on Visual Attention and Search Efficiency

SUSANNA GRAZIANO[1], MARIA GRAZIA CARDINALI[2], GUIDO CRISTINI[3]

Abstract. *L'incremento delle malattie croniche legato a regimi alimentari non salutari richiede un'urgente attenzione da parte di tutti gli attori della filiera alimentare. In particolare, il contributo dei retailers risulta prezioso, dato che la maggior parte delle decisioni d'acquisto viene presa in punto vendita. Tuttavia, l'efficacia degli interventi in store di marketing nutrizionale è spesso ostacolata dall'information overload, che compromette la capacità decisionale del consumatore davanti allo scaffale. Questo studio mira a valutare se l'aggregazione dei prodotti salutistici possa mitigare il sovraccarico informativo e facilitare la ricerca degli stessi. Attraverso un field experiment condotto in due punti vendita della Grande Distribuzione italiana, è stata testata l'efficacia dello space management e dell'in-store communication su un paniere di prodotti per la prima colazione a Marchio del Distributore (MDD). In particolare, in un punto vendita tutti i prodotti selezionati sono stati aggregati ed è stata installata un'iniziativa di comunicazione basata sul beneficio del gusto, mentre nell'altro punto vendita la stessa iniziativa di comunicazione è stata installata sui singoli prodotti, mantenuti disaggregati sul piano espositivo. La metodologia ha previsto l'impiego della tecnologia eye-tracking su un campione di 85 partecipanti per mappare i processi visivi e decisionali in condizioni ecologiche. I risultati indicano che l'aggregazione dei prodotti non solo aumenta significativamente la visibilità e l'efficacia percepita dell'iniziativa di comunicazione, ma riduce anche i tempi complessivi di ricerca e di scelta. Inoltre, l'aggregazione raddoppia l'attenzione visiva dedicata agli stimoli comunicativi e migliora sia la percezione di salubrità dello scaffale sia la soddisfazione complessiva dell'esperienza d'acquisto. Lo studio contribuisce al dibattito accademico sulla manovra delle leve di in-store nell'ambito del Nutrition Shopper Marketing, fornendo indicazioni manageriali utili per ottimizzare lo spazio di vendita in chiave salutistica, dimostrando come l'organizzazione dei prodotti possa agire da facilitatore cognitivo per il benessere del consumatore.*

Key words: *space management; nutrition marketing; in store communication; UTI; eye-tracking; field experiment.*

Framing of the research. *L'incremento delle malattie croniche osservato negli ultimi anni costituisce un tema di crescente gravità e rilevanza (GBD, 2018), alimentato in larga misura da regimi alimentari insalubri e stili di vita sedentari (GBD, 2019). Diventa dunque imprescindibile l'adozione di strategie preventive volte al miglioramento del benessere collettivo, attraverso degli interventi sull'alimentazione degli individui e sul comportamento degli stessi. Coerentemente con questa necessità, i retailer hanno adottato negli anni un ruolo attivo, implementando diverse strategie di marketing nutrizionale come, ad esempio, attraverso l'ampliamento dell'assortimento con nuove linee di MDD salutistiche o manovrando le leve di in-store marketing. Tuttavia, la comprensione dei messaggi legati alla salute che sono comunicati in punti vendita è spesso ostacolata dall'eccessiva esposizione informativa a cui è sottoposto il consumatore. Il cosiddetto "information overload" può infatti compromettere il processo decisionale (Toffler, 1970), poiché una sovrabbondanza di stimoli riduce la capacità di analisi razionale dell'individuo (es. Toffler, 1970). La letteratura evidenzia, infatti, come l'aumento delle opzioni di scelta possa generare confusione e decisioni meno soddisfacenti e subottimali (Jacoby et al., 1974; Jacoby, 1977; Iyengar & Lepper, 2000). Quando un consumatore valuta la scelta di un prodotto, deve elaborare molteplici variabili, compiendo un compito che richiede non solo tempo per il reperimento delle informazioni, ma anche uno sforzo cognitivo per sintetizzarli in un giudizio di valore (es. Russo, 1981). A tal proposito, data la scarsità di risorse temporali e cognitive durante la spesa (es. Hoyer, 1984), l'organizzazione dei prodotti a scaffale diventa essenziale nel guidare l'elaborazione delle informazioni (Lamberton & Diehl, 2013). Lo space management si configura dunque come una leva strategica (Kim & Moon, 2021) per orientare le preferenze (Pechey et al., 2020; Arno & Thomas, 2016) e stimolare gli acquisti non pianificati (Sorensen, 2003).*

Diversi autori (es. Dulsrud & Jacobsen, 2009; Chandon et al., 2009; Stilley et al., 2010) concordano sul fatto che la visibilità - intesa come quantità e qualità dello spazio espositivo assegnata ai prodotti - sia un driver fondamentale dell'acquisto (Bayley & Nancarrow, 1998; Inman et al., 2009; Muruganantham & Bhakat, 2013; Wilson et al., 2016; Cadario & Chandon, 2017). Tuttavia, l'analisi dell'efficacia delle diverse tecniche di space management nel contesto del marketing nutrizionale ha riportato risultati contrastanti. Ad esempio, sebbene Liu et al. (2018) abbiano osservato un aumento delle vendite di prodotti sani nelle testate di gondola, tale effetto svaniva se nelle vicinanze venivano collocati prodotti meno salutari. Analogamente, Young et al. (2020) non hanno riscontrato variazioni significative nelle vendite posizionando i prodotti salutari ad altezza occhi. Altri studi, come quello di Adam et al. (2017) o di de Wijk et al. (2016), hanno mostrato impatti limitati o nulli sulle vendite complessive della categoria, nonostante le manipolazioni volte a

migliorare la visibilità dei prodotti. Al contrario, sono emersi risultati positivi posizionando, ad esempio, le bevande più salutari nelle testate di gondola (Nakamura et al., 2014) o rimuovendo gli snack dolci dalle avancasse (Baird et al., 2018). Trude et al. (2018) hanno inoltre dimostrato che l'aumento dello spazio per gli snack e le bibite senza zucchero, supportato dalla sinergia di altre leve, come la comunicazione e le promozioni, può favorire la scelta di prodotti meno calorici. La letteratura suggerisce quindi che, nella promozione della corretta alimentazione in punto vendita, sia più efficace integrare diverse leve di in-store marketing in modo sinergico (es. Graziano et al., 2025). Nonostante la letteratura esistente concordi sull'importanza della leva dello space management, rimangono inesplorati i meccanismi cognitivi che guidano le scelte salutari del consumatore davanti allo scaffale. Gli studi precedenti si sono focalizzati prevalentemente sulle performance di vendita, pur riportando risultati spesso divergenti (Liu et al., 2018; Young et al., 2020). Mancano dunque delle evidenze su come il "blocking" a scaffale dei prodotti salutari possa mitigare il sovraccarico informativo e facilitare attivamente la ricerca visiva.

Per tali ragioni, questo studio intende valutare l'effetto combinato della manovra della leva dello space management e della comunicazione in store. Per farlo, è stato implementato un esperimento in ambiente reale - ancora in corso - in due ipermercati appartenenti alla stessa insegna. In un punto vendita (PV1) i prodotti MDD salutistici sono stati aggregati sul piano espositivo, mentre nell'altro (PV2) sono stati mantenuti disaggregati. In entrambi gli ipermercati è stata implementata un'iniziativa di in-store communication basata sul beneficio del gusto. Si è deciso di comunicare il beneficio del gusto perché, nelle decisioni che riguardano i prodotti alimentari, le aspettative sensoriali giocano un ruolo determinante ai fini della scelta del prodotto (Saba et al., 2019; Roininen et al., 1999). È noto, infatti, che i consumatori spesso associno il concetto di "salutare" a una minore palatabilità, secondo l'"Unhealthy = Tasty Intuition" (UTI) (Mai & Hoffmann, 2015; Raghunathan et al., 2006; Erhard et al., 2024; Piqueras-Fiszman & Spence, 2015; Saba et al., 2019; Teisl & Levy, 1997). Tuttavia, è possibile modificare tale percezione attraverso messaggi che stimolino aspettative positive sul sapore (Wansink, 2017; Steptoe et al., 1995).

Alla luce di quanto riportato sopra, si ipotizza che:

H1: *L'aggregazione dei prodotti rende più visibile l'iniziativa di comunicazione.*
H2: *L'aggregazione dei prodotti migliora l'efficacia percepita dell'iniziativa di comunicazione.*
H3*: La soddisfazione dell'esperienza di spesa è maggiore nel punto vendita con l'aggregazione.*
H4: *L'aggregazione dei prodotti genera una maggiore attenzione visiva rispetto alla disaggregazione.*
H5: *L'aggregazione dei prodotti aumenta la percezione di salubrità dello scaffale.*
H6: *L'aggregazione dei prodotti riduce i tempi di ricerca dei prodotti salutari per la prima colazione.*
H7: *L'aggregazione dei prodotti facilita la ricerca dei prodotti salutari per la prima colazione.*

Purpose of the paper. *Lo scopo di questa ricerca è quello di valutare l'impatto della gestione strategica dello spazio espositivo, in combinazione con l'iniziativa di comunicazione in-store, sull'orientamento dei consumatori verso scelte alimentari più salutari. In particolare, lo studio mira a verificare se l'aggregazione dei prodotti a scaffale sia in grado non solo di massimizzare l'efficacia della comunicazione in-store, ma anche di aumentare la visibilità dell'iniziativa stessa. Inoltre, la ricerca si propone di verificare se l'aggregazione dei prodotti salutari sia in grado di elevare la percezione di salubrità dello scaffale, di facilitare la ricerca dei prodotti salutari e di diminuire i tempi di ricerca. Questo studio intende mappare i processi visivi e decisionali dei consumatori attraverso l'impiego della tecnologia di eye-tracking, fornendo ai retailer insights per gestire lo spazio nei punti vendita in chiave di marketing nutrizionale.*

Methodology. *In due punti vendita appartenenti a una grande catena della distribuzione italiana, è stata implementata un'iniziativa di comunicazione in store basata sul gusto che ha coinvolto un paniere di prodotti salutari della prima colazione della MDD, in particolare cereali, biscotti e merendine, scelti in base ai loro valori nutrizionali. In un punto vendita (PV1) i prodotti sono stati aggregati, mentre nell'altro (PV2) sono stati mantenuti disaggregati. L'iniziativa di comunicazione ha impiegato diversi supporti di comunicazione, quali crowner, calpestabili, reglette e stopper.*

Al fine di testare l'efficacia dell'iniziativa, è stato condotto uno studio di eye-tracking con gli occhialini Tobii Pro Glasses 3. Questo strumento permette infatti di monitorare i movimenti oculari, che sono indicatori dell'acquisizione informativa e dei meccanismi di elaborazione subconscia (Bartels et al., 2018). Mappando la sequenza e la persistenza dello sguardo, è possibile infatti identificare gli stimoli effettivamente rilevati, che sono il presupposto necessario affinché l'individuo possa elaborare l'informazione (Becker et al., 2015). L'utilizzo degli occhialini ha inoltre garantito la raccolta delle fissazioni e delle saccadi in condizioni ecologiche, preservando quindi la naturalezza del comportamento d'acquisto.

A ciascun partecipante è stata data la stessa shopping mission, ovvero l'acquisto (fittizio) di: "un pacco di cereali MDD sani e gustosi", "un pacco di merendine MDD sane e gustose" e "un pacco di biscotti MDD sani e gustosi". Il campione consta di 85 partecipanti (43 nel PV1 e 42 nel PV2) ed è composto come indicato nella Tabella 1.

Al termine della simulazione di spesa, ai partecipanti è stato somministrato un breve questionario, misurando attraverso scale Likert a 7 punti la salubrità percepita dello scaffale (Van Kleef et al., 2012; $\alpha = .727$), la facilità di ricerca nello scaffale (Bauer et al., 2012 $\alpha = .879$), l'efficacia percepita della comunicazione (Kim & Lakshmanan, 2015; Lehnert et al., 2014; $\alpha = .801$) e la soddisfazione dell'esperienza d'acquisto simulata (Van Ittersum et al., 2013; dove 1 = "per niente soddisfatto" e 7 = "molto soddisfatto").

Tabella 1. Composizione del campione

Results. *I dati raccolti attraverso l'eye-tracker e il questionario post esperimento sono stati elaborati attraverso il software Tobii Pro Lab e IBM SPSS. Per testare H1, è stato chiesto ai partecipanti se avessero notato l'iniziativa di comunicazione durante la loro esperienza di spesa simulata. Conducendo un t-test a campioni indipendenti, è risultato che l'iniziativa di comunicazione non solo è stata notata maggiormente nel punto vendita con l'aggregazione (Magg = .70; Mdis = .24; p < .001), ma anche l'efficacia percepita dell'iniziativa è risultata maggiore (Magg = 6.00; Mdis = 4.80; p < .001). Sia H1 che H2 sono dunque confermate. Inoltre, seppure i partecipanti abbiano riportato un alto grado di soddisfazione per l'esperienza d'acquisto in entrambi i punti vendita, nel punto vendita con l'aggregazione è stata significativamente maggiore (Magg = 6.91, Mdis = 6.48; p = .001). H3 è quindi confermata. Per testare H4, è stato condotto un t-test a campioni indipendenti sulle fissazioni, ovvero il numero totale di volte che l'occhio si è fermato su un'area specifica (in questo caso sulla comunicazione), e sul dwell time, ovvero la somma totale del tempo passato a guardare quell'area. Attraverso le fissazioni è infatti possibile misurare il coinvolgimento e la salienza visiva del partecipante verso lo stimolo (es. Pomaranski et al., 2021), mentre attraverso il dwell time è possibile misurare l'interesse e l'elaborazione cognitiva (es. Isomoto et al., 2023). Sia per quanto riguarda il numero medio di fissazioni (Magg = 571.67, Mdis = 250.64; p = .003), sia per il dwell time medio (Magg = 179.30 Mdis = 73.86; p<.001), i valori nel punto vendita con l'aggregazione significativamente sono più alti rispetto al disaggregato. Di conseguenza, possiamo accettare H4. Per quanto riguarda H5, la percezione di salubrità dello scaffale è risultata significativamente maggiore nel punto vendita con l'aggregazione (Magg = 5.75, Mdis = 4,82; p = .002). H5 è quindi confermata. Per testare H6, è stato cronometrato, attraverso l'ausilio degli occhiali eyetracking, il tempo impiegato (in secondi) dai partecipanti dall'inizio alla fine della simulazione d'acquisto. Eseguendo un t-test a campioni indipendenti, è risultato che nel punto vendita con l'aggregazione i partecipanti hanno complessivamente speso meno tempo rispetto al punto vendita disaggregato, sia considerando il tempo speso per la scelta nelle singole categorie di prodotto, sia per il tempo complessivo. Tuttavia, a livello statistico è risultata significativa la differenza solo nel tempo complessivo (Magg = 157, 74; Mdis = 193, 01; p = .014). H6 è dunque confermata. È stato anche chiesto ai partecipanti un parere sulla facilità di ricerca dei prodotti salutari per la prima colazione nello scaffale, che è risultata maggiore nel punto vendita con l'aggregazione (Magg = 6.22, Mdis = 5,17; p <.001). Possiamo dunque accettare H7.*

Sono state anche generate delle heatmap sui materiali di comunicazione in entrambi i punti vendita (Figure 1a-6c).

Figura 1a. *Bandiera cereali*

Figura 1b. *Bandiera biscotti*

Figura 1c. *Bandiera merendine*

Figura 2a. *Calpestabile cereali*

Figura 2b. *Calpestabile biscotti*

Figura 2c. *Calpestabile merendine*

Figura 3a. *Crowner cereali*

Figura 3b. *Crowner biscotti*

Figura 3c. *Crowner merendine*

Figura 4a. *Aggregazione cereali*

Figura 4b. *Aggregazione cereali*

Figura 4c. *Aggregazione cereali*

Figura 5a. *Aggregazione biscotti*

Figura 5b. *Aggregazione biscotti*

Figura 5c. *Aggregazione biscotti*

Figura 6a. *Aggregazione merendine*

Figura 6b. *Aggregazione merendine*

Figura 6c. *Aggregazione merendine*

Nel punto vendita dove i prodotti sono disaggregati, le heatmap dei calpestabili (Figure 2a-c) mostrano una forte concentrazione visiva sull'elemento testuale centrale e sul claim legato al gusto. In particolare, l'area rossa si focalizza sulla promessa del gusto. Nei crowner (3a-c) l'attenzione è più articolata: oltre al testo, vi sono delle fissazioni sulle immagini edonistiche dei prodotti. Le heatmap relative allo scaffale aggregato (Figure 4a-c, 5a-c, 6a-c) mostrano invece un pattern di esplorazione visiva differente. Mentre per la disaggregazione l'attenzione è più focalizzata in determinati punti, nell'aggregazione l'attenzione è più distribuita.

Attraverso gli scan path della disaggregazione (Figure 8a-c) e dell'aggregazione (Figure 9a-c), è possibile notare la differenza nei percorsi di ricerca che i partecipanti hanno attuato.

Figura 8a. *Scan path cereali (disaggrezione)*

Figura 8b. *Scan path biscotti (disaggrezione)*

Figura 8c. *Scan path merendine (disaggrezione)*

Figura 9a. *Scan path biscotti (aggregazione)*

Figura 9b. *Scan path merendine (aggregazione)*

Figura 9c. *Scan path cereali (aggregazione)*

Gli scan path relativi alla disaggregazione appaiono estremamente densi, con un numero elevato di fissazioni distribuite su un'area molto vasta. Questo indica che il consumatore è costretto a un'analisi prodotto per prodotto. L'occhio deve quindi processare ogni singolo stimolo per discriminare tra prodotti sani e non sani. L'elevata numerosità delle saccadi e i frequenti cambiamenti di direzione dello sguardo indicano invece un alto sforzo visivo. Al contrario, gli scan path dell'aggregazione appaiono più lineari. La minore densità di fissazioni indica una maggiore efficienza nella ricerca: questo perché, una volta identificato la sezione dedicata ai prodotti salutari, l'area di ricerca si restringe immediatamente.

Research limitations. *Questa ricerca presenta alcune limitazioni che aprono interessanti prospettive per ricerche future. In primo luogo, la ricerca si è concentrata sui prodotti per la prima colazione (cereali, biscotti e merendine). Sarebbe dunque interessante testare la strategia di aggregazione in altre categorie merceologiche per verificarne la trasversalità. Un ulteriore spunto di indagine riguarda l'approfondimento dell'impatto emotivo e dei livelli di stress: alcuni fattori, come la presenza di altri acquirenti, potrebbero infatti alterare i processi decisionali osservati in condizioni sperimentali. Inoltre, seppur la numerica del campione raccolto sia in linea con gli studi di eye-tracking, la dimensione dello stesso limita la generalizzabilità dei risultati; studi futuri potrebbero ampliare il numero di partecipanti al fine di fornire una maggiore solidità statistica. Un altro limite risiede nel fatto che questa ricerca si è concentrata esclusivamente sui prodotti MDD; pertanto, sarebbe opportuno testare la strategia di aggregazione includendo brand industriali. Infine, la natura della "shopping mission" fittizia potrebbe aver indotto i partecipanti a una ricerca più razionale rispetto a una spesa quotidiana. I prossimi step di questo studio consisteranno nel replicare lo studio in un punto vendita di controllo, al fine di approfondire l'efficacia della comunicazione in forma disaggregata che, seppur si sia dimostrata meno efficace rispetto alla sinergia della stessa con la leva dello spazio, è possibile che risulti comunque più utile nel guidare le scelte rispetto a una condizione che non preveda alcun facilitatore di scelta.*

Managerial implications. *Le implicazioni manageriali emerse dallo studio suggeriscono che i retailer e i player dell'industria alimentare dovrebbero implementare una gestione strategica dello spazio espositivo come leva cardine del marketing nutrizionale per orientare i consumatori verso scelte alimentari più sane. L'aggregazione dei prodotti salutistici si configura come una strategia efficace per semplificare il processo di ricerca e ridurre lo sforzo cognitivo richiesto durante l'acquisto, mitigando così gli effetti negativi del sovraccarico informativo, che spesso caratterizza il punto vendita. La ricerca dimostra inoltre come la sinergia tra la manovra dello space management e la comunicazione in-store aumenti la salienza visiva e l'interesse verso l'iniziativa. Tale approccio non solo eleva la percezione di salubrità dell'intero scaffale e facilita l'identificazione delle opzioni più sane, ma ottimizza anche l'efficienza decisionale, riducendo i tempi di ricerca e incrementando la soddisfazione complessiva dell'esperienza di spesa. Dato che la maggior parte delle scelte avviene ancora all'interno del punto vendita, la manovra strategica di queste leve offre dunque ai retailer l'opportunità di assumere un ruolo attivo nella prevenzione delle malattie croniche legate a regimi alimentari insalubri. Facilitando acquisti nutrizionalmente più consapevoli, infatti, i retailer possono agire come un agente di cambiamento, migliorando il benessere dei consumatori e facilitando l'accesso a stili di vita più salutari.*

Originality of the paper. *L'originalità di questa ricerca risiede nell'approccio che integra lo space management e la comunicazione in store focalizzata sul gusto, in chiave di marketing nutrizionale. Sebbene sia noto come l'eccesso di stimoli nel punto vendita possa generare un sovraccarico informativo in grado di compromettere la capacità decisionale del consumatore (Toffler, 1970; Jacoby et al., 1974), meno indagato è il ruolo che la gestione dello spazio può avere nell'influenzare le scelte di prodotti salutari in punto vendita. Testando l'efficacia dell'aggregazione espositiva dei prodotti per la prima colazione a valenza salutistica, questo studio contribuisce al dibattito accademico, oggi caratterizzato da risultati contrastanti tra chi rileva un aumento delle vendite di prodotti sani grazie al posizionamento dei prodotti (es. Nakamura et al., 2014) e chi non riscontra impatti significativi (es. Young et al., 2020). Attraverso l'impiego dell'eye-tracking, la ricerca analizza se tale strategia, unita a una comunicazione che prova a sfidare il pregiudizio dell'UTI (Raghunathan et al., 2006; Mai & Hoffmann, 2015), possa facilitare l'identificazione dei prodotti e migliorarne la percezione di salubrità. L'impiego di questa tecnologia ha permesso di affermare che l'aggregazione riduce la complessità della ricerca dei prodotti, non solo riducendo i tempi medi dell'esperienza di spesa, ma anche raddoppiando l'attenzione visiva (fissazioni e Dwell Time) dedicata agli stimoli. Inoltre, a differenza degli studi condotti in laboratorio, questa ricerca offre un contributo attraverso un esperimento in ambiente reale, in condizioni ecologiche, dimostrando che una gestione strategica della leva dello spazio, in sinergia con la comunicazione in-store, può migliorare la soddisfazione dell'esperienza di spesa e la facilità di scelta di prodotti salutari.*

Do shopping behaviors change the importance of store attributes? Evidence from the French grocery market.

MICHELE BADOLATO[1]

Abstract. *This research examines whether behavioral shopping repertoires shape the importance that consumers assign to grocery store attributes. We propose that shopping behavior — defined by primary format destination and repertoire breadth — predicts attribute importance profiles more strongly than socio-demographic variables. The analysis draws on survey data from 725 grocery shoppers in the Alpes-Maritimes department (French Riviera). Exploratory factor analysis of 13 store attributes yields four dimensions: 'Store Experience and Service,' 'Product Quality and Assortment,' 'Convenience and Proximity,' and 'Price and Promotion Sensitivity.' Six behavioral consumer segments are identified from primary format destination and format variety. Multivariate analysis of variance confirms significant differences across all four attribute dimensions between segments, with the price-sensitivity gradient producing the largest and most consistent effect. A particularly notable finding concerns Premium Destination Shoppers, who record the lowest convenience and proximity score of all segments — a pattern that persists in the multinomial logistic regression after controlling for actual travel distance and socio-demographic variables, suggesting that reduced accessibility sensitivity in this segment reflects a structural evaluative difference rather than geographic adaptation. Overall, the results indicate that behavioral repertoire provides stronger discriminatory power over attribute importance than demographics alone.*
Keywords: *grocery retailing; store attributes; behavioral segmentation; retail format choice; multi-format markets; consumer typology; store attribute importance*

Framing of the research. One of the most prominent paradigms in understanding the decision to choose a grocery store has been based on a standard research methodology in which respondents rate the importance of store attributes when deciding where to go shopping. Woodside and Trappey (1992) point out that consumers are likely to choose a store or brand by linking the store to some attributes, while Carpenter and Moore (2006) provided the benchmark for store attribute ratings in the US by conducting a survey among 454 grocery shoppers across five different store formats. They identified cleanliness, product selection, price competitiveness, and courtesy of personnel as the attributes that were most consistently linked to store format, while socio-demographic variables were linked positively to shopping in supercenters. Pan and Zinkhan (2006) furthered the research in an international context across different decades by conducting a meta-analysis of 45 studies. They found that assortment size and quality, price, service, store atmosphere, and convenient location were the primary determinants of store patronage in different contexts. They further found that demographic variables had only a modest impact on store choice. In the European context, Nilsson et al. (2015a) conducted a survey among 1,575 Swedish consumers. They used principal component analysis on an extensive range of store attributes. They distinguished between attractiveness and accessibility attributes. They found that car accessibility was the most important attribute overall, contradicting the findings in the US that emphasized product and service dimensions, showing us that the importance of attribute categories depends also on the market context.

However, these contributions have a structural limitation in common that has not received sufficient attention. They all treat attribute importance ratings as population means or via socio-demographic groups, averaging over respondents in a way that masks the variety of consumer motivations. Such an aggregation assumption may have been justifiable in a grocery retail environment where only a limited number of competing models existed; however, in the contemporary European environment where hard discounters, regular supermarkets/hypermarkets, organic and specialty stores, open-air markets, and convenience stores all compete at the same time with strongly differing value propositions, the notion of averaging over consumer segments in terms of attribute importance starts to become problematic, especially when the grocery market is segmented along several store choice dimensions. A systematic review of the subsequent empirical literature on format competition by Bonfrer et al. (2022) reinforces this idea, finding that the drivers of format choice extend across price, location, and assortment dimensions in ways that aggregate measurement frameworks struggle to capture.

A parallel research stream has approached consumer heterogeneity from the behavioral side, constructing typologies based on where and how consumers shop. Since the foundational work of Stone (1954) we found that there exist different types of shoppers defined along social dimensions and behaviors. Fox et al. (2004) proved that the volume of consumer spending in different formats is more responsive to differences in assortment and promotional activity than to price differences. Moreover, the influence of demographic factors on the heterogeneity of spending in different formats is limited. This again emphasizes the need to consider behavioral factors to explain the differences in the spending patterns of various consumers on different formats. In the same vein, Sinha and Banerjee (2004) found that store selection behavior is a result of complex motivational factors that cannot be explained through the help of demographic factors in a changing marketplace.

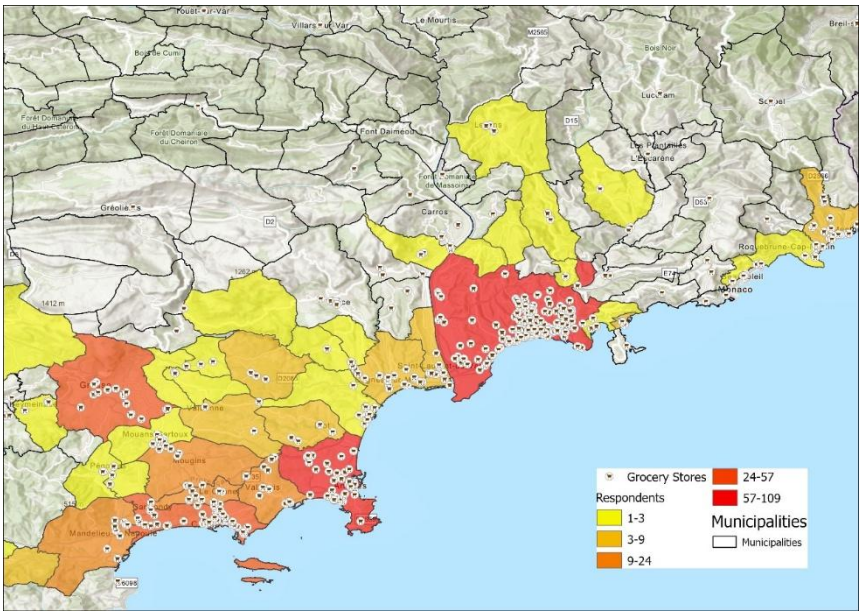
[1] University of Genova, michele.badolato@edu.unige.it

Reutterer and Teller (2009) showed that the type of trip indeed moderates the preference for the format, such that major shopping trips generate higher consumer utility for discount stores and hypermarkets, while supermarkets perform better in the case of fill-in trips. Moreover, the study by Luceri and Latusi (2012) supported the notion that repertoire breadth indeed represents a significant behavioral variable, which is mainly determined by the market structure in terms of the number of formats available and consumers' general perception of the shopping activity. Finally, Nilsson et al. (2015b), using the combination of format and trip types in the Swedish data, identified a typology of five segments: Planning Suburbans, Pedestrians, Social Shoppers, City Dwellers, and Flexibles; and showed that behavioral segments differ in socio-demographic variables. The above studies suggest that a more differentiated behavioral typology, which considers primary format orientation in more than two categories and repertoire breadth as a continuous criterion, would reveal profiles of attribute importance that remain undetected by the existing aggregate measures and by studying simply the socio-demographic characteristics of the consumers.

Purpose of the paper. What is left unexplored and what this current study address is the development of behavioral consumer typology and then an evaluation of whether these types vary in terms of their structure along a multi-dimensional attribute importance dimension. Nilsson et al. (2015a, 2015b) recognized this as an issue to be explored and proposed that research should investigate if the behavioral format orientation changes the attribute importance ratings of consumers; however, their own attempt at this issue, with a focus on a binary format taxonomy distinguishing between supermarkets and convenience stores, is not sufficient to capture the full range of formats present in modern European retail markets. So, following Nilsson et al. (2015a), our research question is the following:

RQ. Do store attribute importance ratings differ systematically across consumers who primarily shop in different grocery store formats?

A further question concerns the robustness of these differences to socio-demographic controls. Attribute importance profiles may simply reflect the demographic composition of each behavioral segment rather than representing an independent dimension of consumer heterogeneity. To address this, a multinomial logistic regression estimates the contribution of each attribute dimension to segment membership after controlling for age, income, education, household type, travel distance, and shopping time. This allows us to assess whether behavioral format orientation and attribute orientation carry independent explanatory power, or whether their observed association is fully mediated by underlying demographic variables.



Methodology. Data were collected through a structured questionnaire given to grocery shoppers in the Alpes-Maritimes department (French Riviera) from October 2025 to January 2026. The final sample included 725 respondents from 60 municipalities, collected through a combination of offline and online panels. The department can be conceived of as an ecologically valid setting for this study, with an exceptional diversity of retail formats.

The range of formats includes all the large mainstream supermarkets and hypermarkets of France (Carrefour, Casino, Leclerc, and Intermarché), hard-discount retailers (Aldi, Lidl, and Netto), specialty stores, traditional delicatessens and daily open-air markets. The heterogeneity of formats ensures that the behavioral segmentation dimensions used in this study, namely, primary format destination and repertoire breadth, will display substantial discriminatory power.

The sample used in this study is generally representative of the population of the department but slightly overrepresents the younger and better-educated population than the departmental census. More than 47% of the sample was 35 years old or younger, and 69% held a university-level educational degree. The questionnaire used for data collection consisted of three substantive sections. The first section of the questionnaire collected sociodemographic data, including nationality, age, educational level (four categories: lower than high school, high school, bachelor's degree, and master's degree or higher), household income (six income categories), household type, employment status, and car availability. The second module of the questionnaire focused on behavioral shopping habit data. Here, respondents indicated the categories of store formats and brands they normally frequent. The number of distinct store locations visited within a week was also recorded. The logistics of shopping trips, including the initiation point of the shopping trip (respondents could select multiple options; home on foot, 43%; home by car, 63%; directly from work, 19%; via Internet with home delivery, 7%; via Internet with drive-through collection, 10%), distance traveled to the store (categories for walking and driving), and time spent in the store (ranging from 0 to over 45 minutes), were also recorded.

The third module involved evaluating the relative importance of 13 attributes of stores using five-point Likert scales, with 1 indicating ‘not at all important’ and 5 indicating ‘extremely important.’ The attributes were based on benchmarks of Carpenter & Moore (2006) and Nilsson et al. (2015), which were then refined in collaboration with a leading grocery retailer to validate their business importance. The attributes include price competitiveness, promotional offers, quality of products, variety of products, private label products, proximity to home or work, hours of operation, cleanliness, helpfulness of staff, parking facilities, atmosphere of the store, speed of checkout, and convenience of the store. The relative importance of these attributes was analyzed using principal component factor analysis with orthogonal rotation (varimax) (n = 722 after listwise deletion of missing responses). The Kaiser-Meyer-Olkin measure of sampling adequacy was .81, and Bartlett’s test of sphericity was significant, indicating factorability of the data. Four factors were extracted based on the Kaiser criterion, retaining factors with eigenvalues of 1 or higher (4.73, 1.60, 1.14, 1.03), supported by inspection of the scree plot. The factors accounted for a cumulative percentage of 65.4 of the total variances.

Figure 1 - Map of Alpes Maritimes with Respondents and Store Locations

Subsequently, six segments of behavioral consumers were developed by combining two behavioral variables: variety of formats (the quantity and variety of visited stores during the week) and primary format destination. Segments were created in descending order of premium orientation, with one additional segment for online shoppers: (1) Premium Destination Shoppers (PDS): primary store is a specialty or organic store; (2) Premium Cross-Format Explorers (PCFE): primary store is not a specialty, but at least one premium format is present in repertoire, with variety of formats ≥2; (3) Supermarket Loyalists (SL): primary store is a mainstream supermarket or hypermarket, no premium formats, variety of formats =1; (4) Mainstream Value Mix (MVM): primary store is mainstream, no premium formats, variety of formats ≥2; (5) Discount-Led Value Seekers (DLVS): primary store is a hard discount; (6) Online Lovers (OL): primary shopping channel is online. Multivariate analysis of variance (MANOVA) was conducted to examine differences among segments for the four attribute factors. Subsequently, univariate ANOVAs and Bonferroni post hoc tests were conducted. Finally, a multinomial logistic regression (baseline category: Supermarket Loyalists) predicted segment membership from the four factor scores together with age, income, education, household type, travel distance, and typical shopping time, to assess the independent contribution of attribute orientation to format behavior after demographic controls.

Results. The exploratory factor analysis yields four clear and interpretable dimensions (Table 1). The first factor, Store Experience & Service, captures in-store service quality and operational efficiency, including atmosphere, staff helpfulness, checkout speed, store quickness, cleanliness, and parking facilities. Notably, parking loads within this factor rather than within accessibility, suggesting that in the local market it is perceived as a service facility rather than a pure location attribute. The second factor, Product Quality & Assortment, reflects the breadth and perceived quality of the product offering, including product variety, product quality, and private-label range. The third factor, Convenience & Proximity, captures traditional spatial and temporal accessibility attributes, primarily proximity to home/work and opening hours. Finally, the fourth factor, Price & Promotion Sensitivity, groups price competitiveness and promotional offers as a distinct dimension of store evaluation. Overall, the factor structure closely aligns with prior research on grocery store attributes while cleanly separating experiential, assortment, convenience, and price-related dimensions.

Table 1. Factor structure: rotated loadings and variance explained (varimax rotation, n = 722)

Attribute item	F1 Experience	F2 Quality	F3 Convenience	F4 Price
Store atmosphere	.78			
Staff helpfulness	.76			
Checkout speed	.72			
Store quickness	.67			
Cleanliness	.65			
Parking facilities	.61			
Product variety		.75		

Product quality		.71		
Private-label range		.64		
Proximity to home/work			.82	
Opening hours			.77	
Promotional offers				.88
Price competitiveness				.87
Variance explained (%)	**24.5**	**14.4**	**13.5**	**13.1**
Cumulative (%)	**24.5**	**38.8**	**52.3**	**65.4**

Note. Loadings < .50 hidden for clarity. Total variance explained = 65.4%. KMO = .81; Bartlett $\chi^2(78) = 3291.26$, $p < .001$.

Then, six behavioral segments are built from the behavior-based classification (Table 2). The two largest groups are Premium Cross-Format Explorers (35.3%) and Mainstream Value Mix shoppers (25.1%), together accounting for over 60% of the sample and highlighting the prevalence of multi-format grocery shopping in the Alpes-Maritimes market. Supermarket Loyalists (21.8%) represent the traditional single-format grocery shopper anchored in mainstream supermarkets. Two smaller segments occupy the extremes of the price–experience spectrum: Discount-Led Value Seekers (7.7%), strongly oriented toward price, and Premium Destination Shoppers (6.1%), whose primary destinations are specialty or organic stores. Finally, Online Lovers (4.0%) form the smallest group and rely primarily on digital grocery channels.

Socio-demographic differences across segments are generally modest. Age shows the strongest association, with Premium Destination Shoppers skewing older, while discount-oriented segments tend to be overrepresented among lower-income households. Overall, however, demographic variables explain only limited variation, reinforcing the idea that behavioral repertoires capture dimensions of consumer heterogeneity not fully reflected by demographics alone.

Table 2. Behavioral consumer segments: size, construction criteria, and key behavioral features

Segment	n (%)	Construction criteria	Key behavioral features
Premium Destination Shoppers (PDS)	44 (6.1%)	Primary: specialty/organic store	High scores in F1 (Experience) & F2 (Quality). Low scores in F3 (Convenience) & F4 (Price)
Premium Cross-Format Explorers (PCFE)	256 (35.3%)	Primary: non-specialty; ≥1 premium format in repertoire; ≥2 formats	High score in F2 (Quality). Low score in F4 (Price)
Supermarket Loyalists (SL)	158 (21.8%)	Primary: mainstream; no premium formats; 1 format only	Low Score in F2 (Quality)
Mainstream Value Mix (MVM)	182 (25.1%)	Primary: mainstream; no premium formats; ≥2 formats	Low scores in F1 (Experience) & F2 (Quality). High scores in F3 (Convenience) & F4 (Price)
Discount-Led Value Seekers (DLVS)	56 (7.7%)	Primary: discount store	Low scores in F1 (Experience) & F2 (Quality). High scores in F4 (Price)
Online Lovers (OL)	29 (4.0%)	Primary: online channel	High scores in F1 (Experience)

Note. Segment construction based on primary format destination, presence of premium formats in repertoire, and format variety (distinct format count). Chi-square tests: age $\chi^2(30) = 130.15$, $p < .001$; income $\chi^2(30) = 67.70$, $p < .001$; education $\chi^2(15) = 23.78$, $p = .069$ (ns).

The MANOVA test confirms that the six behavioral segments differ significantly across the four attribute dimensions. Univariate ANOVAs indicate significant between-group differences for all factors: Store Experience & Service, Product Quality & Assortment, Convenience & Proximity, and Price & Promotion Sensitivity. Effect sizes are modest to moderate, which is consistent with the exploratory nature of the segmentation and the expected heterogeneity within behavioral groups. Mean standardized factor scores by segment are reported in Table 3.

Price & Promotion Sensitivity (F4) follows the behavioral gradient most clearly. Premium Destination Shoppers (PDS) display the lowest price orientation, followed by Premium Cross-Format Explorers (PCFE), Supermarket Loyalists (SL), while Discount-Led Value Seekers (DLVS) and Mainstream Value Mix (MVM) shoppers show the highest score. Post-hoc comparisons confirm that PDS differ significantly from all other segments, while PCFE also differ significantly from the more price-oriented MVM and DLVS groups. This strong alignment between primary store format and price sensitivity provides a clear validation of the behavioral segmentation: price orientation emerges as the main dimension distinguishing premium-oriented shoppers from discount-driven consumers.

Store Experience & Service (F1) and Product Quality & Assortment (F2) show a largely inverse pattern. PDS record the highest scores on both dimensions, followed by PCFE, while MVM exhibit the lowest evaluations of both experience and assortment attributes. Post-hoc tests indicate that PDS differ significantly from MVM on experience and from both SL and MVM on quality, while PCFE also score significantly higher than mainstream segments on product quality. The Online Lovers (OL) segment displays a relatively high experience score, comparable to PDS; however, given the small size of this group (n = 29, 4.0% of the sample), this result should be interpreted with caution and no strong conclusions are drawn from it.

The Convenience & Proximity (F3) dimension reveals the most theoretically intriguing pattern. Premium Destination Shoppers record the lowest convenience score of all six segments (M = −0.51), significantly below Mainstream Value Mix (p = .002), Supermarket Loyalists (p = .044), and Premium Cross-Format Explorers (p = .035). This result is notable because PDS consumers have by construction selected specialty or organic stores as their primary destination — formats that typically require greater travel effort in the Alpes-Maritimes market than mainstream supermarkets. Yet they are the segment least concerned with proximity and opening hours. Distance data confirm that this is not a simple adaptation to longer travel: average travel distances for PDS (M = 3.50) are comparable to those of other segments, including Discount-Led Value Seekers (M = 3.54). The pattern suggests that for this segment, spatial and temporal accessibility are not central evaluative criteria when selecting a primary store, irrespective of the actual distance involved.

Table 3. Mean factor scores by behavioral segment (standardized, M = 0, SD = 1) and ANOVA results

Segment	F1 Experience	F2 Quality	F3 Convenience	F4 Price
PDS (n=44)	+0.36	+0.37	−0.51	−0.78
PCFE (n=256)	+0.06	+0.18	−0.01	−0.16
SL (n=158)	−0.01	−0.16	0.00	−0.02
MVM (n=182)	−0.18	−0.18	+0.13	+0.24
DLVS (n=56)	−0.13	−0.12	−0.02	+0.59
OL (n=29)	+0.31	+0.06	+0.09	+0.06
F(5,716)	3.24	5.15	2.98	13.72
p	.007	<.001	.011	<.001

Note. Bonferroni post-hoc significant pairs: F4: PDS vs all others (p ≤ .004); PCFE vs MVM (p < .001); PCFE vs DLVS (p < .001); SL vs DLVS (p < .001). F3: PDS vs MVM (p = .002); PDS vs SL (p = .044); PDS vs PCFE (p = .035). F2: PDS vs SL (p = .029); PDS vs MVM (p = .015); PCFE vs SL (p = .011); PCFE vs MVM (p = .002). F1: PDS vs MVM (p = .020).

To test whether the attribute importance differences observed in the MANOVA reflect independent consumer orientations or merely the demographic composition of each segment, a multinomial logistic regression was estimated with Supermarket Loyalists as the baseline category. The four factor scores were entered alongside age, income, education, household type, travel distance, and typical shopping time as predictors.

Product Quality & Assortment (F2) is the strongest and most consistent attribute predictor across premium-oriented segments. It positively and significantly predicts membership in Premium Destination Shoppers (β = .775, p < .01) and Premium Cross-Format Explorers (β = .394, p < .01) relative to Supermarket Loyalists, while it does not significantly predict membership in either of the two more price-oriented segments. Price & Promotion Sensitivity (F4) produces the mirror image: it is a strong positive predictor of Discount-Led Value Seekers membership (β = .649, p < .01) and a significant negative predictor of Premium Destination Shoppers membership (β = −.699, p < .01). Expressed as average marginal effects, a one-standard-deviation increase in F2 raises the predicted probability of PDS membership by 2.6 percentage points and of PCFE membership by 5.2 percentage points, while a one-standard-deviation increase in F4 reduces PDS probability by 3.1 percentage points and raises DLVS probability by 4.2 percentage points. Together, these two dimensions account for the primary discrimination between premium and discount segments independently of demographic controls.

The Convenience & Proximity dimension (F3) provides the most diagnostically important result from a segmentation standpoint. It is a significant negative predictor of Premium Destination Shoppers membership (β = −.426, p < .05), even after all demographic and locational controls are included. Expressed as an average marginal effect, a one-standard-deviation increase in F3 reduces the predicted probability of PDS membership by 2.0 percentage points (p = .014). Crucially, the actual travel distance variable is non-significant not only for PDS (β = .028, p = .829) but across all segments in the model, confirming that the convenience sensitivity differences observed are not a function of objective spatial constraints. This dissociation — lower stated importance assigned to convenience attributes in the absence of any difference in actual travel distances — indicates that differential accessibility sensitivity among PDS consumers is not an artifact of geographic adaptation. It reflects a structural difference in the evaluative role of spatial and temporal accessibility for this segment, independent of actual travel behavior.

Importantly, demographic variables provide limited explanatory power once attribute preferences are included in the model. Income and education do not reach conventional significance levels, while age remains the only consistent

predictor of premium-format membership, with older consumers more likely to belong to these segments. This pattern is broadly consistent with Kohijoki and Marjanen's (2013) finding that ageing consumers show a heightened preference for stores offering a complete and high-quality assortment, a dimension that maps directly onto our F2 factor. Overall, these findings suggest that store attribute factors and shopping behaviors provide stronger insights into consumer heterogeneity than traditional socio-demographic characteristics alone.

Research limitations. Three limitations should be acknowledged. First, the sampling approach over-represents younger and more educated respondents relative to the Alpes-Maritimes population, which may compress income variance and potentially understate price sensitivity among older consumers. A probability sample stratified by age and income would strengthen external validity. Second, the study relies on explorative cross-sectional data and therefore cannot track how behavioral segments and attribute priorities evolve over time as new retail formats enter the market. Longitudinal research would help assess the stability of behavioral repertoires and the dynamics of format competition. Third, the Alpes-Maritimes market is characterized by high format diversity and cross-border retail proximity. While this limits direct generalizability to other grocery markets, the underlying mechanisms linking behavioral repertoires and attribute priorities are likely to extend to other multi-format retail environments.

Managerial implications. The findings provide several practical insights for grocery retailers. First, the limited explanatory power of socio-demographic variables compared with behavioral indicators reinforces the value of transaction-based segmentation. This result aligns with the argument of Baltas and Papastathopoulou (2003) that combining behavioral and store-choice criteria yields more actionable segments than relying on demographics alone.

Second, the differential convenience sensitivity identified among Premium Destination Shoppers has direct implications for location and investment decisions. For this segment, improvements in accessibility — such as extended opening hours or additional parking capacity — are unlikely to significantly influence patronage, since convenience does not function as a primary evaluative criterion for store choice. Instead, product quality, assortment distinctiveness, and in-store experience are the dimensions most likely to drive destination choice in this segment. By contrast, for Supermarket Loyalists and Mainstream Value Mix consumers, convenience remains a central decision criterion, making location optimization and operating hours key competitive levers. Treating accessibility sensitivity as uniform across consumers may therefore lead to inefficient allocation of retail investment.

Third, the dominance of F2 (Product Quality & Assortment) as a predictor of both PDS and PCFE membership in the multinomial logit points to assortment differentiation as the primary competitive tool for premium and specialty formats. In a market where mainstream supermarkets are widening their organic and premium private-label ranges, specialty retailers cannot compete on breadth. The segment most likely to respond to a quality assortment positioning strategy, PCFE, is also the largest segment (35.3%) and the one with the widest format repertoire, making it the most contestable by mainstream operators attempting to upgrade their offer. For specialty retailers, the strategic imperative is curation, provenance, and the experiential dimensions of F1, dimensions that mainstream formats find hardest to replicate.

Originality of the paper. This study makes two main original contributions to the body of knowledge in retail marketing. First, it offers direct empirical support for the claim that behavioral shopping repertoires can be used as predictors of attribute importance profiles in a multi-dimensional factor structure in a market that is more complex than the binary format of most segmentation studies. While Nilsson et al. (2015) suggested in their study that future research should investigate drivers of satisfaction with stores across different segments of shoppers—implying attribute importance as a mediator—our study offers direct investigation. Our study uses a six-segment model of behavioral typology, acknowledging the complexities of European multi-format grocery competition. Our findings support the theoretical proposition that behavioral criteria hold discriminatory power over demographics in forecasting how consumers rate grocery stores.

Second, this study provides direct empirical evidence of differential convenience sensitivity across behaviorally defined consumer segments in a European multi-format grocery market. Prior research has established that proximity and accessibility are among the most consistent predictors of store patronage in aggregate studies (Pan and Zinkhan, 2006; Nilsson et al., 2015a). Our results show that this relationship is highly segment-specific: while mainstream and discount-oriented consumers assign moderate-to-high importance to Price Sensibility and Convenience & Proximity, Premium Destination Shoppers assign systematically lower importance to these dimensions, and this difference persists in the multinomial logistic regression after controlling for travel distance and all socio-demographic variables. The dissociation between actual travel behavior and convenience importance ratings is a novel empirical finding that challenges the assumption that accessibility is a universal driver of grocery store choice. The combined findings suggest that behavioral repertoire should be treated as a first-order segmentation variable in grocery retail research, with demographics playing an enrichment role and attribute importance profiles serving as the outcome variable through which the link between behavior and competitive format positioning is most clearly understood.

Mind the fit: A Framework for Virtual Reality Integration in the Online Customer Journey

GIOVANNI ROMANO[1], BEATRICE LUCERI[1], SIMONE AIOLFI[1]

Abstract. Virtual Reality (VR) offers the opportunity to reimagine digital marketing activities by extending traditional internet usage. Despite extensive efforts to identify the drivers and barriers to adoption, market perspectives on VR have fluctuated, leaving it unclear how consumers effectively integrate such tools into their online shopping journeys. As part of a broader research project investigating VR's role in consumer decision-making, the present study proposes a behavioural framework grounded in Task-Technology Fit (TTF) theory to explain the intention to use VR solutions when shopping online. Data were collected via a cross-sectional survey (N = 206) and analysed using Partial Least Squares Structural Equation Modelling (PLS-SEM). Results indicate a significant effect of technological characteristics (interactivity and vividness) on TTF, alongside an unexpected negative moderation effect of Personal Need for Structure (PNS) on usage intention. From a theoretical standpoint, this research represents an initial application of the TTF lens to VR effectiveness in online retailing while testing the moderating impact of PNS. Such findings contribute to the literature on VR as a decision-support service and provide strategic guidelines for practitioners seeking to integrate VR solutions into e-commerce journeys.
Keywords: *virtual reality; online shopping; task-technology fit; personal need for structure; PLS-SEM*

Framing of the research. Three-dimensional representations present an opportunity for digital marketing to extend how online purchasing processes happen. A significant impetus in this direction was provided by the development of Virtual Reality (VR). The B2C VR market is expected to reach revenues of over $25 billion by the end of 2030 (Statista 2025), underlining its contribution to digital innovation in the interaction between brands, retailers, and consumers.

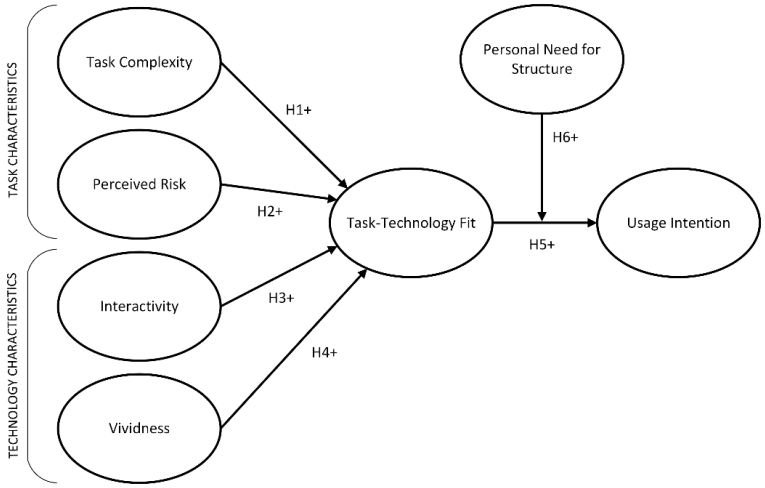
VR applications exist along a continuum of immersion (Yildiz et al., 2024), allowing them to be utilised either through screen-based devices (i.e., smartphones) or via dedicated equipment, like head-mounted displays (HMD). On the one hand, VR environments can be entirely synthetic, requiring technical expertise in "*digital product creation*" (see Hanson, 2025). On the other hand, spaces can be "*tridimensionalised*" through the spatial rendering of objects and areas; these become explorable as 360° virtual tours, the development of which has become increasingly accessible.

Concurrently, literature has shown that interacting with VR content is particularly effective in stimulating positive consumer outcomes. In destination marketing, significant results have emerged regarding its ability to induce the intention to visit places experienced virtually (Chekembayeva and Garaus, 2024). Furthermore, virtual visits to production centres in the food sector have highlighted these positive effects, encouraging both visits and product purchase intention (Peruzzini et al., 2023).

However, the development of VR-based interactions has slowed over the years, contrary to initial growth expectations (Vanian, 2026). Regarding immersive use, HMD adoption levels have remained low (Osservatori.net, 2026), suggesting that such implementations remain unattractive for direct remote consumption and are confined to "*in-place*" experiences. Therefore, from a consumer-oriented e-commerce perspective, the most significant implementation prospects remain low-immersion VR applications (e.g. screen-based virtual tours), representing a customer service component during online shopping.

Purpose of the paper. The remaining question is when screen-based VR solutions can effectively and efficiently find a place within consumer purchasing processes to convey their value proposition. Although previous studies have sought to clarify the drivers behind such solutions, this field remains underexplored, requiring further investigation into their implementation as an online service (Lee et al., 2025).

While three-dimensional visualisation has demonstrated its ability to yield better outcomes than static, two-dimensional images (Wang et al. 2019), providing benefits in terms of both micro and macro consumer conversions (Zhu and Chao, 2023), evidence also suggests that these solutions can appear of limited utility. Specifically, they may impose an excessive cognitive load during the purchasing process (e.g., Fici et al., 2024). In this context, the level of involvement emerges as a variable explaining when the utility of product virtualisation effectively surfaces; this is particularly evident in the immersive utilisation of VR (Cowan and Ketron, 2019; Zhang et al., 2024), but remains unclear regarding non-immersive solutions.



This study is part of an ongoing research project aimed at understanding how VR applications can be effectively integrated into online customer journeys, with a particular focus on their role as decision-support tools. In light of this literature gap, the study aims to provide a framework delineating how and when VR systems can enrich online retailing services, addressing the following research question: "*RQ: What is the behavioural process that drives consumers to use VR solutions during their online purchasing journey?*".

[1] Department of Economics and Business Management, University of Parma, Italy

To achieve the study's objectives, a theoretical model is proposed based on Task-Technology Fit (TTF; Goodhue and Thompson, 1995). TTF has been applied across various fields, undergoing significant evolution over time. For instance, it was designed within Information Systems literature to move beyond the narrow focus on "*utilisation*" and "*fit*" found in earlier theories. The model rests on three propositions: first, a user's evaluation of fit is determined by both task and technology characteristics; second, system utilisation depends on this perceived fit; and finally, a positive fit evaluation not only predicts utilisation but also positively influences perceived performance (Goodhue and Thompson, 1995). Empirical evidence has confirmed the robustness of the model and its extensions across several digital contexts, such as e-commerce, online courses and mobile banking (see Marikyan and Papagiannidis 2023).

In this study, task and technology characteristics are treated as groups of variables to capture the multidimensional nature of the purchasing process, whilst the TTF construct is considered unidimensional. This approach is consistent with the "*fit-as-match*" perspective identified by Marikyan and Papagiannidis (2023) as a common practice in recent literature. Figure 1 illustrates the proposed theoretical model, with the hypotheses presented below:

Figure 1 – Proposed model

Task characteristics comprise task complexity and perceived risk. Task complexity is defined as "*the number of attributes each product has to be evaluated*" (Tang, 2020, p. 180). In online shopping environments where task complexity is high, information demands may exceed the consumer's limited working memory capacity, generating cognitive overload (Gaillard, 2000; Mikolon et al., 2015). Consequently, a mentally fatigued user tends to reduce effort by relying on simplified, less accurate decision heuristics (Hadjimarcou and Hu, 1999). According to Resource-Matching Theory (Anand and Sternthal, 1988), decision quality is maximised only when available cognitive resources match those required by the task. In this sense, a support service can act as a decision aid, potentially reducing the cognitive resources needed to filter and process information within a complex process. However, if the task is inherently simple, the same service may provide excess resources; this mismatch can induce cognitive laziness or distraction, paradoxically leading to a decline in performance (Tang, 2020). Therefore, it is hypothesised that VR generates an optimal fit only when task complexity is high, as this triggers the need for (and justifies) the advanced cognitive support provided by the technology, thereby improving decision quality.

Perceived risk is defined as "*the consumer's perception of the uncertainty and adverse consequences of buying products or services*" (Dowling and Staelin, 1994, p. 114). In online shopping, the inability to physically examine or test goods prior to a transaction intrinsically generates high perceived risk, linked to uncertainty and the possibility that the product may not meet expectations (Ariffin et al., 2018). When the risk associated with a specific choice exceeds a consumer's "*acceptable risk*" threshold, individuals actively undertake risk-handling strategies and problem-solving activities to mitigate their sense of insecurity (Dowling and Staelin, 1994). Accordingly, high-risk decision-making necessitates solutions capable of overcoming information barriers; VR services could address this need by providing simulations that emulate the physical experience. Consequently, as the uncertainty intrinsic to the choice process increases, consumers will feel a greater need for reassurance and will thus perceive a higher degree of fit for VR to resolve their decision-making task.

In light of this evidence regarding task characteristics, the following hypotheses are postulated:

H1: Task complexity positively influences TTF for VR solutions during the online purchasing process.
H2: Perceived risk positively influences TTF for VR solutions during the online purchasing process.

Technology characteristics comprise two dimensions identified as fundamental in VR literature (Steuer, 1992; Kim et al., 2021): interactivity and vividness. Vividness refers to the representational richness of the virtual environment, defined by its sensory breadth and the depth (or resolution) of the information provided (Steuer, 1992). Interactivity, meanwhile,

represents "*the extent to which users can participate in modifying the form and content of a mediated environment in real time*" (Steuer 1992, p. 14).

Vividness and interactivity are hypothesised to act as direct antecedents of TTF, as they align the capabilities of the technological system with the user's decision-making and evaluative needs (Chen et al., 2023). Specifically, interactivity supports the analytical and cognitive processing of the task: by providing functional and visual control (e.g., rotate, zoom or manipulate product properties), it allows buyers to actively explore products based on their preferences and focus on the details where they feel the greatest uncertainty (Chen et al., 2023). Simultaneously, vividness enriches the experiential aspect by offering realistic, high-resolution product visualisations within a natural three-dimensional space (Kim et al., 2021).

The synergy of these two technological stimuli maximises perceived diagnosticity, defined as the extent to which the virtual environment proves useful for accurately understanding and judging product characteristics (Chen et al., 2023). Furthermore, the integration of vivid images and realistic interactions produces a sense of telepresence (the psychological sensation of "*being there*") which increases the system's perceived utility for positive shopping outcomes (e.g., Kim et al., 2021). Since these characteristics provide consumers with the essential tools to overcome online limitations and achieve effective evaluative outcomes, it is postulated that they determine the adequacy of the technology to the task. In light of this theoretical background, the following hypotheses are formulated:

H3: Interactivity positively influences TTF for VR solutions during the online purchasing process.
H4: Vividness positively influences TTF for VR solutions during the online purchasing process.

Within information systems literature, the relationship between TTF and use intention has been a well-established principle since its original conceptualisation, although it has often produced stronger predictive outcomes when extended with other technology acceptance theories (Marikyan and Papagiannidis, 2023).

In its original form, the theory posits that regardless of a user's general attitude or curiosity towards an innovation, they are unlikely to adopt it if its functionality fails to address the practical requirements of the task (Marikyan and Papagiannidis, 2023). For example, regarding other retail technologies, a high degree of alignment between the tool and the purchasing task exerts a direct impact on consumers' usage intention (Khashan et al., 2023).

In interactive shopping environments, such as those enhanced by VR solutions that effectively support product exploration and evaluation, adoption may be stimulated by lowering psychological barriers to tools capable of better performing the shopping mission. Accordingly, it is reasonable to expect that congruence between the shopping task and the VR simulation will directly motivate users to employ the system. Consequently, the following hypothesis is proposed:

H5: TTF positively influences the behavioural intention to use VR solutions in the online shopping process.

Finally, this study examines the moderating role of Personal Need for Structure (PNS), defined as "*a chronic aversion to ill-structured situations and a longing for certainty and predictability*" (Rietzschel et al., 2007, p. 856). Previous studies have considered the influence of PNS within the decision-making process; for instance, Cutright (2012) showed that high-PNS individuals seek "*structured consumption*", manifesting in a preference for closed product forms and well-delimited environments to manage attentional overload, particularly when personal control is low.

In online shopping, where the absence of physical products leads to fewer decisional cues, VR can provide "*perimeters*" that help delimit the decision-making process through increased focus. Since high-PNS users require structured knowledge to resolve ambiguity (Thompson et al., 2001), VR may facilitate this desired cognitive state by providing clear mental starting and stopping points. Accordingly, a higher PNS will amplify the positive effects of TTF on usage intention, due to the technology's ability to provide predictability and satisfy the user's need for certainty during product evaluation.

Furthermore, recent scholarship has underscored the importance of investigating psychological variables such as PNS as moderators between consumer perceptions of new technology and the resulting outcomes (Jayawardhena et al., 2026). Hence, we propose:

H6: PNS positively moderates the relationship between the TTF and the behavioural intention to use VR solutions in the online shopping process.

Methodology. To test the proposed model and its hypotheses, and thus address the research question, this study conducted a quantitative investigation through a cross-sectional survey. The rental market for students and professionals was selected as the focal context due to three primary characteristics. First, it presents a high probability of information asymmetry, as potential tenants often face the necessity of securing a property without a prior physical viewing. Second, the search process is typically conducted exclusively through online channels (Rently, 2026). Third, the level of purchase involvement is predictably high, necessitating a rigorous evaluation of alternatives and informed decision-making. Future stages of this research will expand upon the present study by examining low-involvement purchasing contexts.

The survey was designed on the EUSurvey platform for online distribution. The access link was shared across international social media groups and pages dedicated to housing searches, facilitating a purposive sampling approach. A filter question identified respondents who had actively searched for a rental apartment for study or work purposes within

the last 24 months. Regarding the measurement of variables, task complexity was assessed using a 4-item scale (Li et al., 2011), while perceived risk was measured with a 3-item scale adapted from Laroche et al. (2004). Vividness and interactivity were measured using an 8-item scale (Babin and Burns, 1998) and a 5-item scale (Peruzzini et al., 2023), respectively. Finally, TTF was assessed with a 5-item scale adapted from Howard and Rose (2019), PNS with a 4-item scale adapted from Thompson et al. (2001), and usage intention with a 3-item scale adapted from Ramos-de-Luna et al. (2016).

To mitigate common method bias and prevent issues such as response sets, primacy and recency effects that could distort validity, the order of questions was randomised and respondents were guaranteed full anonymity (Krebs and Bachner, 2018).

During the survey, respondents were instructed to use a link to take a virtual tour of an apartment, allowing them to experience the tool first-hand and evaluate its characteristics and spaces in a simulated choice process. To ensure validity and confirm that the tour was completed, an attention-check question was included (asking for the number of windows in the bathroom). Additionally, following Hericher and Bridoux (2023), respondents with excessively short or long completion times were excluded. This criterion removed profiles characterised by potential lack of attention or interruptions, ensuring the reliability of the collected data. Table 1 presents the sample characteristics.

Table 1 – Sample characteristics

Variable	Category	Frequency (n=206)	Percentage (%)
Gender	Woman	138	67%
	Man	68	33%
Age Range	18 – 24	75	36%
	25 – 35	82	40%
	35 – 44	13	6%
	45 – 54	17	8%
	> 55	19	9%
Education	Middle School	4	2%
	High School	53	26%
	Bachelor's	53	26%
	Master's Degree	87	42%
	Doctorate	9	4%
Occupation	Student	69	34%
	Working Student	13	6%
	Employed	104	50%
	Unemployed	7	3%
	Other	13	6%

Table 2 – Means, standard deviations, internal reliability, convergent validity, and discriminant validity

	Mean	S.D.	α	rho_A	AVE	CPX	RISK	INT	VIV	TTF	NFCC
CPX	5.19	1.30	0.719	0.889	0.769

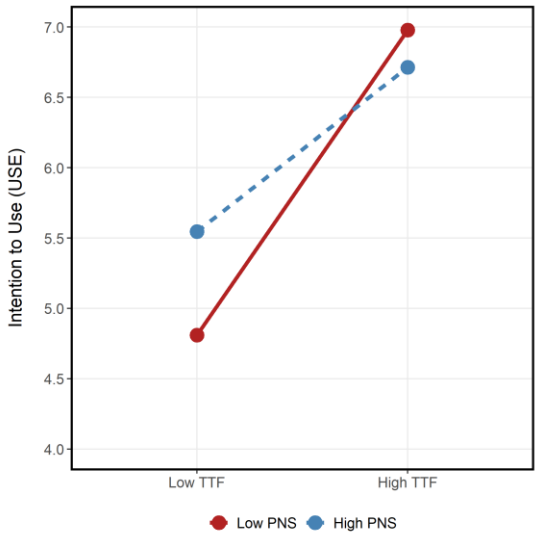
Following the data collection, the measurement model was evaluated according to established protocols (Sarstedt et al., 2022) to ensure the reliability and validity of the constructs (Table 2). Internal consistency reliability was supported by Cronbach's alpha and rho_A coefficients, which were all above the 0.70 target. Furthermore, convergent validity was established, with Average Variance Extracted (AVE) values exceeding the 0.50 benchmark. The Heterotrait-Monotrait ratio (HTMT) criterion showed values below the 0.85 threshold, confirming discriminant validity. Additionally, the Variance Inflation Factor (VIF) values ranged from 1.05 to 2.466, well below the threshold of 3.3, indicating that common method bias was not a concern in this study.

Results. For the data analysis, this study employs the Partial Least Squares Structural Equation Modelling (PLS-SEM) approach, using the SEMinR library in R (version 4.5.3) to test the hypotheses within the model (Hair et al., 2021). The selection of this methodology is motivated by the particular suitability of PLS-SEM for managing complex structural models, as well as its prediction-oriented approach (Sarstedt et al., 2022).



To test the hypothesised relationships, a bootstrapping procedure was performed with 10,000 subsamples and a 95% bias-corrected and accelerated confidence interval. Path analysis evaluated the structural coefficients and their significance levels, while age and service frequency were used as control variables. The final structural model, including path coefficients and the moderation effect, is illustrated in Figure 2.

Figure 2 – PLS-SEM results

Note(s): ***: p-value < 0.001; *: p-value < 0.05; ns: not significant

Figure 3 - Moderation plot

The findings indicate that interactivity is positively associated with TTF (β = 0.438, p < 0.001) and vividness also shows a significant positive effect on TTF (β = 0.290, p < 0.001), supporting H3 and H4. In contrast, task complexity (β = -0.148, p = 0.140) and perceived risk (β = 0.132, p = 0.144) did not significantly affect TTF. Therefore, H1 and H2 were not supported. These variables explain 50.9% of the variance in TTF ($R^2 = 0.509$). Furthermore, the analysis revealed a strong positive relationship between TTF and usage intention (β = 0.687, p < 0.001), supporting H5. Overall, 55.3% of the variance in usage intention is explained ($R^2 = 0.553$).

Surprisingly, the moderation of PNS resulted in a significant but negative effect (β = -0.112, p = 0.014), thus not supporting H6 but suggesting its role in attenuating the impact of TTF on use. As illustrated in Figure 3, the positive influence of TTF on usage intention is more pronounced for individuals with low PNS, whereas high-PNS users appear less sensitive to improvements in TTF.

Research limitations. This study is not without limitations. The specific focus on the rental market and the use of purposive sampling may limit the generalisability of the findings to other categories. In different contexts, VR usage might be driven by a strong hedonic component, a factor not measured in this study. Future research could therefore integrate variables such as perceived enjoyment and aesthetics to examine how hedonic value interacts with TTF. Nevertheless, the present results provide a robust preliminary assessment of the proposed model. Our objective was to establish its initial validity before extending its applicability through a comparative analysis with low-involvement contexts and diverse industries, such as fast-moving consumer goods. This will allow for a deeper exploration of how the role of VR as a decision-support tool varies across heterogeneous customer journeys.

Secondly, a significant limitation lies in the focus on positive fit, without empirically exploring the dynamics of mismatch. As suggested by Resource-Matching Theory, adopting advanced technologies for excessively simple tasks can generate a cognitive mismatch; future research should therefore investigate the thresholds beyond which VR complexity becomes an obstacle rather than a support. Moreover, adopting a longitudinal approach to examine how the perception of fit evolves as user familiarity with the tool increases could significantly enrich the evidence from this cross-sectional design.

Finally, participants may have viewed the virtual tour on diverse devices, such as smartphones, tablets or computers. This heterogeneity in hardware could have influenced the perception of the virtual environment. Future studies could control for this factor by requiring the use of a specific device or by analysing the potential impact of the hardware utilised.

Managerial implications. From a managerial perspective, the initial results of this study offer valuable insights for digital marketers. Contrary to expectations, the model suggests that task complexity and perceived risk do not alone determine where VR functions as a value-driven service. This suggests that non-immersive VR solutions may possess a broader applicability than previously assumed, potentially fitting product categories that do not necessarily require high consumer involvement. While this aspect can be further clarified in the next stages of this research, managers should already prioritise the strategic optimisation of the service's functional attributes. Ensuring that interactivity and sensory vividness act as indispensable tools for product diagnosticity will enable consumers to effectively evaluate items and successfully fulfil their shopping missions.

Finally, this study confirms the potential of PNS as a segmentation variable, although its impact appears more complex than previously assumed. The results suggest that structure-oriented consumers may remain cautious or resistant even when the technology is functionally adequate for the task. Marketers should, therefore, utilise this variable to personalise service offerings, recognising that high-PNS users may perceive a technology that radically alters task procedures as a source of ambiguity. Accordingly, VR services should not only ensure maximum clarity and explicit navigation paths but also reshape the online shopping journey with caution. Technical or design frictions (e.g., slow rendering times, pop-up windows, loss of primary informational references) can be perceived as threats. For high-PNS users, such disruptions can transform the VR experience into a chaotic one, acting as a significant barrier to adoption even when the system is deemed adequate for the task.

Originality of the paper. This study offers three main contributions to the literature on VR adoption in online retailing.

First, by employing a TTF lens, the research shifts the focus from general technology acceptance to the alignment between technological capabilities and the cognitive requirements of the purchasing task. This provides a clearer understanding of how VR integrates into the consumer's online journey.

Second, the current research helps clarify the boundary conditions of VR effectiveness, providing evidence for a field where the literature remains fragmented. Contrary to expectations, the findings suggest that technological "*fit*" is driven primarily by the tool's intrinsic functional attributes rather than task complexity or risk. Such results help define the applicability of non-immersive VR in online shopping by demonstrating its potential value across a broader range of product categories, regardless of the consumer's level of involvement. Building on these insights, the next stage of the study will further validate the model by extending the investigation to low-involvement purchasing contexts.

Thirdly, a further innovative element is the integration of PNS as a key individual-level moderator. Although the findings did not support the initial hypothesis, they offer significant theoretical insights by showing that individuals with high PNS levels may rely on heuristic processing to reach a decision (Rietzschel et al., 2007). In this respect, the density of information and complex interactions inherent in VR can trigger cognitive overload, acting as a barrier that leads these users to prefer faster, more familiar, or traditional decision-making processes. Overall, such an inclusion provides an original perspective on how this personality trait influences the intention to use VR solutions throughout the customer journey, illustrating how psychological alignment can ultimately enrich the service experience and facilitate conversions.

What Drives Theatre Attendance? Audiences Who Plan, Attend More Work in progress

CLEMENTINA BRUNO[•] VALERIA FARALLA[*]

Abstract. *This paper presents preliminary results from a survey-based study aimed at exploring relevant elements related to the choice of attending theatre performances. Drawing on data collected from a representative sample of participants in the United Kingdom, the analyses focus on time preferences, wellbeing indicators, and socio-demographic variables as the primary variables of interest. In particular, although the survey instrument captured multiple dimensions of theatre participation, we relate attendance frequency to the future orientation of the respondents and to their perception of the effects of attendance on their wellbeing. Results show that attendance frequency is positively and significantly related to respondents' future-orientation, as captured through their willingness to purchase a discounted seasonal subscription. We also find some evidence of the role of gender, age and education in explaining attendance frequency. In addition, a positive relationship appears between frequency of attendance and individual wellbeing, particularly when it is framed through on a health-related definition. These findings suggest that performing arts organizations may benefit from targeting forward-looking audience segments and from communicating theatre attendance as part of a healthy lifestyle. We discuss the implications of these preliminary findings and outline directions for further research.*
Key words: *performing arts; survey; future orientation; wellbeing.*

Framing of the research. *The study of the performing arts from an economic perspective is commonly traced back to the seminal work of Baumol and Bowen (1965, 1966), who focused on the issue of rising costs against essentially stagnant productivity levels, recognized as the root cause of the financial problems that often characterize the organizations active in this field.*

Although the first framework of analysis employed this supply-side perspective, the study of theatre production cannot be disentangled from its relationship with the audience, for both financial (as a source of revenues) and social reasons, since theatrical organizations' efforts, historically, have been oriented towards achieving the mission of meeting the public ("The theatre is meant to be full, not empty", in Giuseppe Verdi's opinion; Triola, 2013, p.207). In this context, we can place the broad strand of literature that adopts a demand-side perspective. Some studies focus on aggregated demand analysis, with the aim of estimating key indicators such as price and income elasticities (see, for instance, Zieba, 2009 or Laamanen, 2013). Other studies assess attendance choices at individual level, in relation to prices or personal characteristics such socio-demographic factors and education (e.g. Borgonovi, 2004). It is relevant to recall the perspective of authors highlighting the role of audience motivation, which indeed can show some degree of relationship with socio-economic factors, but is also related with the development of attendance experience, both in terms of past events and planning for future events (Swanson et al., 2008; Tröndle et al., 2025). This is consistent with the nature of the performing arts product that, as an experience, even if not customized, is perceived in a unique way by each user (Pine and Gilmore, 1998), and its impact is as well unique and audience-dependent (Walmsley, 2013).

In addition, other studies highlight patterns related to the effects of cultural consumption over time, such as habit formation, learning-by-consumption, and (rational) addiction (see, for instance, Borgonovi, 2004; Castiglione and Infante, 2016; Throsby et al., 2024; Turrini, 2006). In particular, Castiglione and Infante (2016) characterizes theatre attendance as a beneficial "habit-forming activity" in which consumers engage in a learning-by-doing process, one through which past participation in theatre increases their appreciation and desire for it in the present and future. These findings may suggest a process of taste acquisition for the arts through repeated exposure.

Cultural attendance can be then explored from a forward-looking perspective. In this sense, individual time preferences, and in particular the degree to which individuals are oriented towards the future, may play a relevant role in shaping attendance choices. Future-oriented individuals are more likely to plan cultural activities in advance, to commit to subscription schemes, and to perceive the benefits of repeated attendance as worthwhile investments in long-term personal enrichment. This perspective connects the study of arts and culture demand to the broader literature on intertemporal decision-making (Frederick et al., 2002; Loewenstein and Prelec, 1992), suggesting that the willingness to engage with theatre is not only shaped by past experience but also by individual attitudes towards future consumption and its perceived benefits.

Such future-oriented behaviour is also likely to be shaped by the perceived personal benefits of attendance, among which wellbeing plays a particularly relevant role. Relatedly, Meeks et al. (2018) discuss how theatre involvement is related to psychological benefits; in addition, Meeks et al. (2020) find evidence of positive effects for over 60 attenders. Alsop et al. (2025) document the impact of concerts on attendees' wellbeing with respect to the emotional, social, and cultural dimensions.

[•] Associate Professor of *Management* – University of Piemonte Orientale, e-mail: clementina.bruno@uniupo.it
[*] Researcher Tenure Track in *Management* – University of Piemonte Orientale, e-mail: valeria.faralla@uniupo.it

In this context, it emerges that theatre attendance involves individual choices that consider a set of element behind the traditional (although relevant) demand determinants, such as price, income or socio-demographical factors. These benefits, which unfold over time, naturally connect attendance choices to individual future orientation and perceive wellbeing, the two dimensions at the core of the present study.

Purpose of the paper. *This paper presents the preliminary results of a work in progress research that relies on a survey-based approach to explore relevant elements related to the demand of theatre performances, with a focus on two under-explored dimensions: individual future orientation and perceived wellbeing. To capture the role of time preferences, we proxied intertemporal orientation through respondents' willingness to commit to a discounted seasonal subscription, treating this as a behavioral indicator of their propensity to plan and invest in future cultural experiences. We further examine how individual future orientation relates to attendance decisions, alongside respondents' perceptions of the effects of theatre-going on their wellbeing, which we assess across multiple dimensions. We also consider the role of socio-demographic characteristics. By integrating these perspectives within a single empirical framework, the paper aims to contribute to a more comprehensive understanding of the drivers of theatre demand, while offering actionable insights for managers of performing arts organizations.*

Methodology. *The research protocol and planned analyses were specified in advance in an AsPredicted preregistration document. Participants were recruited via the Prolific online research platform, targeting a minimum of 300 completed responses from representative samples in the United Kingdom. No experimental manipulation or random assignment to conditions was implemented; however, two survey versions were administered: a full version for individuals with varying levels of theatre attendance and a shortened version for non-theatregoers to enable between-group comparisons. To this end, the primary dependent variable—attendance frequency—was measured using a six-level ordinal scale: non-attendee, sporadic (≤1/year), occasional (2-3/year), regular (4-6/year), frequent (7-10/year), and very frequent (>10/year) attendee. The first two categories were classified as non-theatregoers, whereas the remaining four were classified as theatregoers. A pilot test assessed the survey for language-related and technical issues prior to full deployment. Informed consent was obtained from all participants.*

Data were collected using a structured, self-administered questionnaire implemented in LimeSurvey. After reviewing the informed consent document, theatregoers completed questions on theatre attendance, well-being and emotional experiences, cultural and social engagement, and time preferences. In addition to our primary dependent variable, other indicators of engagement included years of theatre attendance, possession and continuity of theatre subscriptions, anticipated future attendance, and ticket-purchasing behavior. As for non-theatregoers, we asked them to identify barriers to theatre attendance and completed the time preference items administered to the theatregoer group. For both groups, educational attainment was also measured. Additional demographic data (age and gender) were instead obtained via Prolific. Although 300 participants completed the survey, 2 were excluded for failing the attention checks, resulting in a final sample of 298 participants.

In line with the aims of the present paper, although the survey instrument captured multiple dimensions of theatre participation, the analyses reported here focus on theatre attendance and socio-demographics, time preference, and well-being indicators as the primary variables of interest. Time preference was mainly assessed through participants' willingness to purchase a discounted seasonal subscription for their preferred type of event. Specifically, all participants were asked to: "Imagine you can purchase a discounted seasonal subscription for your preferred type of event today. How likely are you to accept this offer compared to buying individual tickets for events as they occur? Please rate your likelihood on a scale from 1 to 10, where 1 means "not at all likely" and 10 means "very likely" (please assume that you have the financial means and that season subscriptions/tickets do not sell out quickly)." This item reflects future orientation through engagement with a commitment device: accepting a subscription requires planning ahead and forgoing flexibility in exchange for deferred rewards—behaviours consistent with a future-oriented time preference. Although this format differs from standard monetary delay-discounting tasks (e.g., choosing between receiving 100€ today or 120€ in one month; Frederick et al., 2002), such items would have been contextually incongruous in a survey focused on theatre participation and may have reduced engagement or introduced demand effects. By embedding the intertemporal trade-off within a domain-relevant consumption decision, we preserved contextual coherence while still capturing individual differences in future orientation[1].

Moreover, to better identify whether subscription willingness genuinely reflects future orientation rather than other considerations, conditional follow-up items were employed to capture the qualitatively distinct reasons underlying low versus high subscription willingness. Participants who reported lower likelihood scores (1–5) were asked to select one reason from the following forced-choice options (with an additional open-ended "Other" option): preference for making decisions closer to the event date rather than months in advance; concern about committing to events too far in advance; difficulty predicting future schedule and availability; and concern about wasting money if unable to attend some subscription events. Participants who reported higher likelihood scores (6–10) were instead presented with a different set of forced-choice options (again including an open-ended "Other" option): enjoyment of planning cultural activities

[1] *While the survey instrument included an additional proxy of time preferences, the analyses reported in this paper concentrate on a single measure: the willingness to purchase a discounted seasonal subscription for the preferred type of event. As this research is still in progress, the role of this additional measure will be explored in subsequent stages of the work.*

well in advance and having events to look forward to; appreciation of a fixed schedule that motivates continued cultural engagement; valuing having cultural events planned and scheduled throughout the year; preference for guaranteeing access to all events to avoid missing performances. While several of these options explicitly relate to intertemporal orientation (e.g., preference for advance planning or reluctance to commit far ahead), others capture conceptually distinct considerations, such concerns about wasting money. By including both time-related and non-time-related motivations, along with the "Other" option, we aimed to untie future orientation from alternative drivers of subscription willingness, such as uncertainty about future availability or concerns about financial loss. The conditional follow-up items were included in the original survey instrument.

As for well-being measures, the variables included were: belief that theatre attendance enhances individual well-being (10-point scale); satisfaction with most recent theatre experience (10-point scale), and perceived impact of attendance interruptions on physical/psychological health (10-point scale). Data was analyzed by using Stata 16.1.

Results. *The first point our analysis focuses on is the level of theatre attendance, intended as the yearly frequence of participation to professional theatrical performances. Responses have been converted on a 6-points scale. Our first target is to investigate the determinants of the attendance level, with special focus on time preferences, assessed through the described question on the willingness to purchase a discounted seasonal subscription, and demographics variables. This analysis considers the whole sample, i.e., including both theatregoers and non-theatregoers. Average values for the whole sample are reported in table 1.*

The sample is almost evenly distributed between non-theatergoers (levels 1 and 2 of Attendance scale) and theatregoers (levels 3 to 6). Given the low numerosity of frequent and very frequent attendees, levels 5 and 6 will be merged into a single group henceforth. It is interesting to note that the mean values of the variable wtp_subscr (willingness to purchase a discounted seasonal subscription immediately) and of the demographic variables tend to increase, on average, as the level of attendance increases. In particular, female is a dummy variable that assumes value of one when the respondents are classified as female by Prolific. The variable age, as well, is reported in years by the platform. Tertiary_edu is a dummy variable equal to one if the respondent declares owning a tertiary education title.

Table 1. Attendance, time preferences and demographics, average values – whole sample. Source: our elaboration

Attendance scale	*Obs*	*wtp_subscr (scale) Average*	*female (dummy) Average*	*age (years) Average*	*tertiary_edu (dummy) Average*
1 (non-attendee)	*48*	*4,729*	*0,396*	*44,813*	*0,5*
2 (sporadic)	*99*	*5,21*	*0,404*	*47,23*	*0,7*
3 (occasional)	*88*	*6*	*0,614*	*46,4*	*0,704*
4 (regular)	*49*	*6,76*	*0,653*	*47,55*	*0,735*
5 (frequent)	*10*	*7,9*	*0,6*	*53,7*	*1*
6 (very frequent)	*4*	*5*	*1*	*57*	*0,75*

Table 2 provides models evaluating the role of willingness to purchase the subscription and of demographics as determinants of theatre attendance. The first column of coefficients refers to an ordered logistic regression run using Attendance_scale (5 levels) as dependent variable; the second column of coefficients refers to a binary logistic regression aimed at distinguishing theatregoers from non-theatregoers (by aggregating the levels of Attendance_scale as described above). We notice that, although the pseudo-R2 are not very high, in both the models the independent variables are jointly significant in explaining the response variable. All the considered variables show a positive and significant effect in explaining the level of attendance in the ordered logit, implying that female and older respondents, as well as more educated respondents attend theatre performance more frequently. In addition, and more interestingly in terms of the focus of our study, more future-oriented respondents also state significantly higher frequency, i.e. individuals who express higher willingness to purchase a subscription show a higher demand for theater performances. This result is confirmed in the binary logistic regression, as well as the role of gender, while age and education do not longer show significant coefficients.

At this point, it is relevant to deepen the nature of the relationship between frequency of attendance and future orientation by investigating the motivation underlying the willingness (or unwillingness) to purchase a discounted subscription for the preferred time of event, as described by the conditional follow-up items which, as noted earlier, were employed to capture the qualitatively distinct reasons underlying low versus high subscription willingness.
First (as expected, given the results of the logistic regressions), on average, respondents with high willingness to purchase a discounted subscription (n=172) tend to be more frequent attendees than respondents with low willingness to purchase (n=126), with an average of 2.84 vs 2.28 points, as resulting from the last row of Table 3. A Wilcoxon-Mann-Whitney test confirms that the distribution of the variable Attendance_scale significantly differs between the two groups (p-value < 0.0001). Notice, however, that not all the reasons for low or high willingness to subscribe are related to future orientation: reason identified as 4H is more related to security reasons (fear of missing out performances), while reason 4L is more related to loss aversion. These motivations, however, do not collect the majority of responses in either of the two groups. Therefore, we repeat the test by including only respondents with high or low willingness to subscribe due to time-related motivation (i.e. respondents reporting motivations 1H, 2H, 3H versus respondent reporting motivations 1L, 2L, 3L; motivations not related to future-orientation and the residual categories "other" are thus excluded).
In this case, we get an average value of Attendance_scale of 2.92 for the group with high willingness to purchase a subscription, vs an average of 2.28, for the other group, with a difference even more evident than considering the whole sample (these last average values are not displayed in the table). The distribution of Attendance_scale differs between the two groups, as confirmed by a p-value, also in this case, smaller than 0.001 for the Wilcoxon-Mann-Whitney test.

Table 3. Reasons for high and low willingness to purchase a subscription and attendance frequency

High wtp_subscr (6-10 points)	*Obs*	*Average Attendance_scale*	*Low wtp_subscr (1-5 points)*	*Obs*	*Average Attendance_scale*

Total	*172*	*2.84*		*126*	*2.28*

Source: our elaboration

Let us, now, restrict our analysis to the theatergoers subsample, in order to verify the relationship between attendance and well-being indicators (which have been collected only for the theatregoers group).
For this part of the analysis, therefore, we exclude non-attendee and sporadic attendees (n=147). Without going deeper in the analysis of non-theatregoers behavior, we just would like to notice that the main reason for non-attendance is related to the fact that theatre is considered too expensive (72 responses).
We maintain, thus, the subsample of theatregoers (151 observations). For this subsample, table 4 reports the average level of the well-being indicators, all expressed over a 10-point scale, declined for the remaining levels of Attendance_scale (notice that the number of observations is reduced for the last well-being indicator since 34 respondents state having not interrupted their attendance, except during the Covid-19 pandemics).
It is possible to notice a positive association between the average levels of the well-being indicators and the frequency of attendance. This relation is more evident for the perceived impact of interruption, although for this indicator the respondents have systematically assigned a lower score on the 10-point scale than for the other two indicators.

Table 4. Attendance levels and well-being indicators. Source: our elaboration

Well-being indicator	*Attendance_scale*	*3*	*4*	*5*
Belief that theatre attendance enhances individual well-being	*Obs*	*88*	*49*	*14*
	Average	*8.43*	*8.33*	*9.29*
Satisfaction with most recent theatre experience	*Obs*	*88*	*49*	*14*
	Average	*8.22*	*8.18*	*8.29*
Perceived impact of attendance interruptions on physical/psychological health	*Obs*	*70*	*34*	*13*
	Average	*3.37*	*4.65*	*5.15*

Table 5 deepens this analysis by reporting the correlation coefficients computed among the attendance variable and the well-being indicators. The variable willingness to purchase a subscription is also included.
As expected, the frequency of attendance shows a positive and significant correlation with the willingness to subscribe. The correlation of Attendance_scale with the belief that attendance increases well-being and with satisfaction with the last theatre experience are positive, but very small in magnitude and not significant. However, the correlation of Attendance_scale with the perceived impact of interruption on health is positive and significant. Therefore, the considered well-being determinants are likely to capture different well-being concepts, and the one more related to health seems to have a direct connection with the frequency of attendance. It is interesting, however, to notice that the belief that attendance enhances individual wellbeing show a significant positive correlation with the willingness to subscribe, i.e. is correlated with forward-looking behavior. The same holds, with a weak significance level, for the health-related indicator. Finally, the level of satisfaction with the last performance is not significantly correlated either with frequency of attendance or with the willingness to purchase a subscription. However, the correlation is positive, relatively strong and highly significant with the belief that attendance increases wellbeing, highlighting a reasonable link between perceived wellbeing and satisfaction.

Table 5. Correlation among attendance, future-orientation and wellbeing measures. Source: our elaboration

	(1)	*(2)*	*(3)*	*(4)*	*(5)*
Attendance scale (1)	*1*				
Willingness to purchase a subscription (2)	*0.1835***	*1*			
Belief that theatre attendance enhances individual well-being (3)	*0.1089*	*0.2616****	*1*		
Satisfaction with most recent theatre experience (4)	*0.0046*	*0.0963*	*0.5198****	*1*	
Perceived impact of attendance interruptions on physical/psychological health (5)	*0.2884****	*0.1738**	*-0.0764*	*-0.1269*	*1*

Research limitations. *This paper, as a work in progress, reports preliminary results of broader research that will also allow to include the role of emotion and of the individual and social benefits associated with theatre attendance. At this step of analysis, therefore, we can rely only on a partial framework for explaining individual attendance choices.*

In addition, a few methodological limitations should be acknowledged. First, the reliance on self-reported data may lead to overreporting of both attendance frequency and wellbeing effects, as theatre-going is a socially valued activity and respondents may be inclined to present themselves as more culturally engaged or to overstate the personal benefits of attendance. Second, the subscription willingness item, while contextually coherent, remains an indirect proxy for future orientation, and may not fully capture the complexity of individual time preferences. A more standard monetary measure of time preferences was also included in the survey but, being less contextually embedded in the cultural framework, its integration with the present findings will require careful interpretation and then will be explored in subsequent stages of the research.

As for future research directions, subsequent stages will explore the role of the additional time preference measure, develop the between-group comparison between theatregoers and non-theatregoers, and incorporate emotional and social dimensions of theatre attendance into the analytical framework. Extending the analysis to other national contexts beyond the UK sample would also represent a valuable step forward.

Managerial implications. *The findings of this paper carry several theoretical implications for the literature on cultural economics and the demand for performing arts. First, the positive relationship between future orientation and attendance frequency supports the need to increasingly incorporate behavioral dimensions, and in particular individual time preferences, into theoretical frameworks of cultural demand. By connecting attendance choices to future orientation, the paper contributes to bridging the performing arts literature with the broader literature on intertemporal decision-making, opening up a promising theoretical avenue for understanding cultural consumption as a forward-looking behavior, rather than merely a response to current prices and income levels. Moreover, the finding that the health-related dimension of wellbeing shows a stronger and more significant association with attendance frequency than other wellbeing dimensions contributes to the growing literature on cultural participation and individual wellbeing. It suggests that different definitions of wellbeing may capture distinct aspects of the theatre-going experience. Finally, the results are consistent with a theoretical view on performing arts as experience goods, where value accumulates over time through repeated consumption. Although this paper does not directly test this mechanism, the positive relationship between future orientation and attendance frequency, as well as the association between attendance and health-related wellbeing, suggest that individuals may perceive theatre-going as an investment in a long-term experiential and personal benefit, rather than a one-off consumption act. This interpretation is consistent with the concepts of habit formation and learning-by-consumption mentioned in the framing section, and points to a promising direction for future theoretical and empirical work.*

Beyond their theoretical relevance, these findings also suggest practical implications for managers of performing arts organizations. First, since future orientation is positively related to attendance frequency, forward-looking attenders represent a crucial target to consolidate a relationship with, for instance through early presentations of future programming, the creation of ancillary events anticipating the shows or the implementation of early bird discount policies. Second, a correlation emerges between attendance and the health-related definition of wellbeing. This suggests that the way that cultural organizations communicate their activity should not focus only on the aesthetic experience or on the role of cultural products in individual development, but also on the opportunity of their integration in a healthy lifestyle. Finally, the quality of the performance is crucial to be maintained, given the significant correlation with the perception of enhancement of individual wellbeing.

Originality of the paper. *This paper analyses the demand of theatre performance by adopting an original perspective that additional and novel behavioral and motivational factors that may influence individuals' participation in theatre activities. Particularly, on top of considering socio-demographics characteristics, it investigates the role of consumers' attitude towards time, with special focus on their future orientation. In addition, it focuses on motivational factors that may be medium or long-term, such as the impact on personal wellbeing.*

From a methodological standpoint, the study also contributes to research transparency and replicability in the performing arts field through its preregistration. Finally, the two-group survey design — administering different survey

versions to theatregoers and non-theatregoers — will enable more structured between-group comparisons in subsequent stages of the research.

Overall, the study offers new insights into the behavioral drivers of cultural participation and contributes to a better understanding of audience behavior in the performing arts sector.

B Corps: Do they signal their status? Family vs. Non-Family Owned Behaviour

REBECCA QUARANTA, CRISTINA BETTINELLI

Abstract. *This short paper describes where we are with our work in progress of our long-term investment in a research project that investigates how certified B Corporations communicate their B Corp status and sustainability commitments, and whether these communication strategies differ across ownership structures. Building on Signalling Theory and Identity Theory, we examine whether certification functions primarily as an instrumental market signal or as an expression of deeply embedded organizational identity.*
Our exploratory findings reveal significant ownership-based differences in both symbolic signalling and substantive sustainability framing.
By moving beyond a binary view of certification and examining heterogeneity within the certified population, this study aims at contributing to the literature on sustainability communication, ownership structure, and third-party certification. It offers first empirical evidence to our intuition that B Corp status is not enacted uniformly but is shaped by governance and identity dynamics, offering new insights into how organizational form influences the meaning and strategic deployment of sustainability credentials.
Keywords: *sustainability, B Corps, Signaling Theory, Identity Theory*

Framing of the research.
The current marketplace is rife with certifications and insignias; some are product- or industry-specific, such as GOTS; others certify the process, such as FSC or Green Seal; each signals to the consumer that the firm or product meets specific criteria. The B Corp certification is widely recognized and highly valued by both consumers and industry actors, in part because it is accessible to firms regardless of country of origin, size, or industry. Moreover, the certification process is generally regarded as stringent and demanding, thereby enhancing the credibility and signaling strength of the certification toward end consumers This work situates itself within Signaling Theory and Identity Theory. According to Spence (1973), a signal represents and transmits reliable information about an unobservable quality to an actor in a state of information asymmetry. This signal, to be reliable and well-received, must be costly and difficult to imitate, thus increasing receivers' trust in the signal. From a signaling perspective, B Corp certification can be understood as a strategic communication device aimed at reducing uncertainty and enhancing legitimacy among stakeholders. However, Signaling Theory also suggests that firms may differ substantially in how they deploy such signals. Some firms may adopt certification instrumentally, using it selectively or cautiously to avoid potential scrutiny or accusations of greenwashing, while others may amplify the signal through more visible and integrated communication strategies (Carlos & Lewis, 2018). Achievement of certification alone does not fully capture its strategic meaning; the *intensity and visibility* of its communication are central to understanding how the signal is used. We believe this to be significant and important as understanding this relationship could provide further insights into why some firms choose not to advertise their costly certifications, moving past issues raised by Gehman & Grimes (2017), (distinctiveness) and Carlos & Lewis (2018) (hypocrisy and reputational concerns). Furthermore, to our knowledge, few papers exist within family firm scholarship that seek to combine core identity values of a firm with the use (or lack thereof) of a costly, observable, and highly recognizable signal, as well as comparing their behaviour to other forms of ownership.
On the other hand, Identity Theory describes those core beliefs that exist within an organization, that are accepted by all members and considered as enduring, central, and distinctive (Albert & Whetten, 1985). In short, they describe the "*who we are"* and "*why we act"* of an organization. Identity Work considers the ongoing actions and processes that are undertaken by individuals or entities in order to construct, evolve and revise their identities (Burke & Stets, 2009). It encompasses the cognitive and behavioural efforts required for the creation and evolution of a sense of self (Bettinelli et al., 2022).
However, identity *work* does not translate directly into identity *communication*. The outward signaling of internal toil and identity construction is not always a clear or conscious path; in the organizational context, this translates into the adoption of symbols, practices, procedures, and certificates that are used to clearly communicate identity through explicit declaration and visible value-alignment. As pointed out by Bettinelli et al. (2022), there is a significant gap in family business literature on identity work.
Further evidence that certification can serve as an indicator of identity work is pointed out by Richards et al. (2017), as they find that the act of certification is not a passive moment, but that it leads firms through a process of questioning and managing their own legitimacy in the chosen arena. In this view, the B Corp certification, grounded in increasing social purpose and boosting responsibility, becomes instrumental in shifting organizational identity and expectations to further align them with the B Lab credo.

Purpose. With this exploratory study, we seek to deepen understanding of the relationship between a costly and observable signal, such as B Corp certification, and the underlying identity beliefs that motivate organizations to pursue and enact such certification. Specifically, we investigate whether B Corp status functions primarily as an instrumental market signal or as an authentic expression of organizational identity, and whether this distinction varies systematically across ownership structures, namely family firms, founder-controlled firms, and non-family firms.

Drawing on Signalling Theory and Identity Theory, we develop a dual theoretical lens through which certification is conceptualized not merely as a reputational device, but as an observable outcome of identity-building work. From a signaling perspective, B Corp certification represents a costly, third-party verified credential that reduces information asymmetry and communicates quality and commitment to external stakeholders. From an identity perspective, however, certification may also serve as a mechanism through which firms consolidate, formalize, and publicly affirm deeply embedded values and beliefs. In this sense, certification becomes part of the firm's identity narrative rather than a purely symbolic or market-oriented signal.

Considering these aspects, we began to notice an interesting trend: many firms we know to be B Corp certified do not "shout it from the rooftops", providing little or no visual communication of their certification. We chose to question why, after a lengthy and costly process, some firms would choose a very low-profile communication strategy. This work seeks to set the floor for a better understanding of the behavior firms exhibit towards communicating their belonging to a specific subgroup; we thus ask: *How do certified B Corps communicate their B Corp status and sustainability commitments in their mission statements, and how do these communication strategies differ between family and non-family firms?*

As we are studying a sustainability certification, this work is also adjacent to the greater topic of nonfinancial reporting and performance in family firms. Brunelli et al. (2024) show that current literature has focused heavily on how family influence can moderate nonfinancial reporting and performance. Other literature reviews such as Buchetti et al., (2025), Van Gils et al., (2014) have also focused primarily on ESG and CSR metrics, relating them to family firm performance and heterogeneity, showing that the realm of certifications, especially sustainability certifications, is as yet underrepresented in family firm scholarship.

Through this project, we aim to contribute to the family business literature by linking ownership structure to the strategic and symbolic use of sustainability certification, offering a more nuanced understanding of how identity and governance dynamics influence the meaning and enactment of third-party credentials.

Our work in progress potentially aims at making some contributions to the family business and sustainability literatures. Firstly, we move beyond a binary view of sustainability certification by considering whether the B Corp status varies meaningfully in its communicative enactment across ownership types. Secondly, by integrating Signaling Theory with Identity Theory, we explain why the same certification can function either as an instrumental market signal or as an expression of organizational identity.

Methodology. This study refers to a work in progress employing a mixed-method approach to explore how Italian certified B Corporations communicate sustainability, with particular attention to differences across ownership structures. The analysis integrates secondary data with qualitative and content-based examination of corporate communications, using established criteria to group firms into broad ownership categories.

To preserve the originality and integrity of the ongoing research, detailed specifications of the research design, data construction, and analytical procedures will be fully articulated at the end of the research process.

Preliminary findings from a sample of Italian B Corporations indicate observable variation in both sustainability framing and symbolic communication across ownership categories. Initial evidence suggests that firms tend to emphasize multiple sustainability dimensions, with indications that certain ownership types are associated with broader sustainability narratives and comparatively stronger visibility of certification-related signals. Statistical testing points to meaningful differences across groups, and supplementary analyses provide consistent directional support for these patterns. As this is an ongoing study, the results presented here should be interpreted as provisional.

Research limitations. Since we have not completed the project and are presenting the progress of our work in order to receive constructive feedback on its evolution, detailed statistical outputs, model specifications, and robustness procedures are not available at this stage. Furthermore, as this is a work in progress, our preliminary findings would benefit from ulterior quantitative testing focusing eventually on non-parametric tests, in the future we would consider widening the definition of "family firm" to be less stringent on ownership share as well as on family involvement in governance; this widening would allow for the inclusion of various firms and would therefore, we hypothesize, render the family ownership variable significant in in explaining "Pride score" and "mission emphasis". Also, while a strength of this work is the strong commitment to check the qualitative nature of mission statements, beyond mere word counts, even more could be disclosed about the reasons for such communication strategies with qualitative in-depth interviews with decision makers to reflect nuances in family and firm identity.

Managerial implications. This work-in-progress seeks to contribute to the literature on sustainability signaling by examining why some firms choose not to actively communicate certifications like the B Corp one and how this behavior may relate to ownership structure and stated organizational purpose. A suggestion from preliminary findings is that different ownership types may be associated with whether certification is seen as a tool to signal a company's identity or not.

Given the ongoing nature of the project, these interpretations should be considered provisional. A full articulation of theoretical implications, managerial contributions, and supporting evidence will be disclosed once the research project is completed.

Originality of the paper. This work-in-progress explores the intersection of ownership structure, sustainability communication, and certification. It represents a first step towards a more nuanced understanding of differences among certified B Corps. The work tentatively contributes by suggesting an approach that moves beyond distinguishing between certified and non-certified companies and by considering the communication strategies of certified companies.

The study also introduces an initial communication-based methodological approach combining visual and textual analysis as proxies for organizational positioning. As the research is ongoing, these contributions are provisional.

Dual-Speed Transformation After Succession: Why Family Business Groups Change while Staying the Same

CINZIA DESSÌ[1], ANDREA VINCIS[2], ALESSANDRO BALBINA[3], ANNALISA SUCCA[4]

Abstract. *Generational succession is central in family-controlled firms, but post-succession is often framed as producing either strategic renewal or strategic continuity. Conversely, this paper develops a theory of "dual-speed" strategic transformation in large family-controlled business groups by integrating insights from family business research, business group scholarship, and organisation theory, using the South Korean chaebols context as an extreme illustrative setting for mechanism elaboration. Drawing on socioemotional wealth theory, the attention-based view, and institutional complexity, we argue that succession triggers a successor legitimacy calculus: incoming leaders must signal competence and future orientation to external audiences while preserving family control, socioemotional wealth, and internal coalition stability. This tension leads to selective change across domains. Continuity is expected in control-critical domains, such as governance, ownership, and core affiliates, where change is politically costly. Renewal is more likely in growth-critical domains, such as technology, capability development, and international expansion, where visible change offers greater legitimacy benefits with lower risks to the control core. The paper also identifies boundary conditions that intensify this pattern, including institutional scrutiny, ownership-control complexity, predecessor imprinting, and resource slack.*
Keywords: *Generational succession, Socioemotional wealth (SEW), Strategic change, Family-controlled business groups, Chaebols, Corporate governance.*

Framing of the research. *Generational succession is widely recognised as one of the most consequential events in family-controlled firms, shaping strategic orientation, governance arrangements, and long-term survival (Gómez-Mejía et al., 2007; Miller et al., 2008). Family business research typically frames succession as a pivotal juncture that yields either strategic continuity or strategic renewal (De Massis et al., 2016), thereby polarising existing perspectives on succession. The first stream links succession to strategic inertia, grounded in families' motivations to preserve control, identity, and socioemotional wealth (SEW) and to avoid decisions that might intensify conflict or jeopardise authority (Gómez-Mejía et al., 2007; Miller & Breton-Miller, 2014; Berrone et al., 2012). The other stream positions succession as an opening for renewal, enabling next-generation leaders to pursue innovation, redirect growth, and realign the organisation with changing competitive and institutional environments (Chirico & Salvato, 2016; Kellermanns et al., 2012). Both accounts are plausible and share an implicit assumption that post-succession responses are organisation-wide and internally coherent.*

*However, emerging works suggest that succession involves multiple processes and uneven effects across strategic arenas: intergenerational dynamics redirect attention in complex ways (Magrelli et al., 2022), successor imprinting and willingness to lead can constrain some choices while enabling others (Marques et al., 2022), and transgenerational control intentions may both encourage experimentation and generate inhibiting uncertainty depending on the domain (Dorsch et al., 2023). Business-group evidence further shows that successor effects depend not only on the successor's "outsiderness" at the affiliate level, but also on embeddedness in the group's internal labour market, which shapes the capacity to override inherited commitments and networks (Kim et al., 2022). Moreover, the canonical change-versus-inertia framing is complicated by the evidence that leadership transitions can remain "shadowed" by the continued influence of departing executives, thereby narrowing successors' discretion and suppressing strategic change even after formal succession has occurred (Kim et al., 2022). Th*ese insights are *particularly salient in the chaebol domain, where research has expanded rapidly but remains fragmented and disproportionately centred on ownership and governance structures, leaving limited cumulative theorising on how dynastic transitions translate into patterned post-succession strategy within complex business groups (Tomeczek, 2025).*

While family business research still tends to treat strategic change as relatively homogeneous, organisation and strategy theory has long argued that firms respond to leadership transitions and institutional pressures through selective adaptation, preserving stability in some arenas while changing in others (Ocasio, 1997; Greenwood et al., 2011). The chaebol context amplifies the plausibility of such selectivity. Historically shifting governance-CEO models, from hierarchical owner-chairman coordination to post-1997 "global standard" reforms and later internal-market governance mechanisms, create differentiated pressures across domains, making uniform transformation unlikely (Shin & Kim, 2025). In addition, the "shadow" mechanism suggests that stability can be an outcome of inherited relational

and governance constraints, not merely a family preference, and that these constraints may operate unevenly across arenas (Kim et al., 2022).

Chaebols are a distinctive and analytically rich form of family-controlled business organisation. As large, diversified business groups, they coordinate portfolios of legally independent affiliates under a shared strategic and governance umbrella, while control is centralised through pyramidal ownership chains and cross-shareholding ties (Chang, 2003; Khanna & Yafeh, 2007). Although they differ from the archetypal small and medium-sized family firms often studied in the family business literature, chaebols embody core family-enterprise attributes: concentrated family control, transgenerational intent, and the persistent intertwining of family and business goals (Carney, 2005; Morck et al., 2005). Their theoretical importance lies less in size than in the institutionalised architecture of control, which allows controlling families to sustain stable rule despite limited direct equity. This makes protecting control a uniquely salient strategic objective (Park, 2025; Dessì & Kim, 2026).

In chaebols, dynastic control coexists with ownership complexity, professionalised management, and intense scrutiny from regulators, the media, and capital markets, making governance and control a central battleground for legitimacy (Park, 2025; Korea Fair Trade Commission, 2023). A The defining feature of chaebols is the pronounced separation between ownership and control (Park, 2025) and effective control with relatively small direct equity stakes (Chang & Hong, 2000). This wedge enables disproportionate influence over strategy with limited capital commitment, but it also creates governance vulnerabilities, coordination costs, and exposure to regulatory intervention. Succession often intensifies these pressures by inheritance-related financing and control-preserving transactions that occur under heightened scrutiny, making governance and ownership decisions politically and reputationally "high stakes" for successors (Park, 2025). From an SEW perspective, these features amplify the preservation of control as a core dimension of family value, pushing governance arrangements into a control-critical arena across generations (Berrone et al., 2012; Gómez-Mejía et al., 2007).

Historically, research on chaebol and business groups has examined succession-adjacent issues through governance and agency lenses, including tunnelling and minority shareholder expropriation in group-based control settings (Bae et al., 2002; Bertrand et al., 2002), and links to firm value and crisis-era outcomes that highlight how institutional shifts shape strategic constraints (Baek et al., 2004; Campbell II & Keys, 2002). Arguably, succession in chaebols is not merely a leadership change but a system-level reconfiguration of authority, legitimacy, and control in which business-group dynamics further complicate it by reshaping discretion. While this scholarship clarifies the "control core" aspects, it offers more limited theorisation of how successors' strategic actions are patterned across domains inside the group. Recent works show why such patterning should be expected by demonstrating that control, legitimacy, and information dynamics are tightly coupled. More broadly, governance scholarship argues that group governance and the group-level CEO/owner-chairperson role are "virtually inseparable," with real governance dynamics partly decoupled from formal charts, limiting the feasibility of rapid change in control-critical domains (Shin & Kim, 2025). At the same time, other strands indicate why renewal may be more feasible in growth-critical arenas. Yet CEO- and succession-centred mechanisms remain relatively under-integrated, leaving open the question of why post-succession change should unfold asymmetrically rather than uniformly (Tomeczek, 2025).

Purpose of the paper. *This paper aims to develop a conceptual theory of dual-speed post-succession strategic transformation in family-controlled business groups, explaining why succession generates continuity in control-critical domains and renewal in growth-critical domains. We develop a theoretical model of dual-speed strategic transformation, arguing that successors face a legitimacy calculus: they must demonstrate strategic competence and a future-oriented stance to external audiences while preserving family control and cohesion. This tension reallocates strategic attention asymmetrically. Inertia is expected to dominate control-critical domains (governance structures, ownership arrangements, control architectures, core assets), where disruption is politically costly and prone to cascades. Instead, renewal should focus on growth-critical domains (technology upgrading, new investments, emerging markets, international expansion), where visible change can build legitimacy while posing a comparatively lower threat to the control core. This persistent theoretical tension in succession research affects the design logic of this work. Rather than treating this divergence as an inconsistency to be resolved via additional contingencies, it is leveraged as a productive site for theory development. Following arguments that contradictions can generate stronger theory (Poole & Van de Ven, 1989), the article proposes a higher-order explanation in which renewal and inertia systematically coexist but are distributed across strategic domains. The rationale of the research is underpinned by several considerations.*

First, family business research offers some building blocks for a domain-differentiated view. Families evaluate strategic moves selectively, depending on whether actions threaten control, identity, or relational wealth, a pattern observed in decisions such as IPOs and acquisitions (Calabrò et al., 2024; Carbone et al., 2024). Dominant-coalition lens emphasises that control is sustained through both equity and relational coalitions, implying that successors must manage formal and informal power simultaneously (Ben-Shahar et al., 2023). These insights converge on a central problem in complex family enterprises: successors must signal capability and future orientation while operating within fragile control architectures in which destabilising moves are costly, especially when discretion is narrowed by the predecessor's "shadow" conditions and inherited networks (Kim et al., 2022; Park, 2025).

Second, succession research has long regarded leadership transitions as critical turning points that alter risk preferences and the balance between economic and non-economic goals (Berrone et al., 2012; Gómez-Mejía et al., 2007). SEW helps explain inertia when change threatens control or identity (Gómez-Mejía et al., 2007; Miller & Breton-Miller,

2014), yet recent contributions clarify that SEW is multi-dimensional, helping explain selective acceptance of change across arenas (Carbone et al., 2024). In parallel, renewal perspectives argue that successors may pursue innovation to build a distinctive legacy (Chirico & Salvato, 2016; Kellermanns et al., 2012), with successor imprinting and willingness to lead shaping behaviour unevenly (Marques et al., 2022), and pre-succession uncertainty influencing innovation incentives (Dorsch et al., 2023). However, what remains under-theorised is the structure of post-succession change in internally differentiated organisations. Outcomes are often treated as a single firm-level trajectory despite the likelihood that constraints and discretion vary across domains and layers (Kim et al., 2022).

Third, business group theory makes heterogeneity unavoidable. In family-controlled groups, these theoretical tensions intensify because dynastic power rests on control-preserving structures with limited cash-flow rights (Carney, 2005; Morck et al., 2005). Korean evidence reinforces this: governance outcomes vary with proximity to the control core and the magnitude of the wedge (Ahn et al., 2025; Kim et al., 2025), while succession effects depend on group-outsider status and the predecessor shadow, with crisis conditions moderating change (Kim et al., 2022).

These strands remain suggestive but fragmented, motivating an integrating logic of where, when, and why renewal and inertia coexist within the same group. Two broader lenses can help to clarify why such integration is needed. Institutional complexity implies competing demands that invite selective accommodation rather than a single, coherent strategy (Greenwood et al., 2011). The attention-based view depicts organisations as attention-constrained systems where leadership transitions reallocate attention and intensify selective engagement (Ocasio, 1997). Together, these perspectives imply that successors in chaebols will likely pursue visible renewal that builds legitimacy and growth, while preserving stability when change threatens control, cohesion, and the governance architecture underpinning dynastic authority. This is the theoretical space a dual-speed framework addresses, bridging SEW (Gómez-Mejía et al., 2007; Carbone et al., 2024), attention-based reasoning (Ocasio, 1997), and institutional complexity (Greenwood et al., 2011) to explain patterned, domain-differentiated post-succession transformation, and to motivate propositions and boundary conditions (e.g., ownership/control complexity, predecessor shadow, institutional scrutiny, resource slack) for future empirical research.

Methodology. *This paper adopts a conceptual research design focused on theory building rather than theory testing. The goal is to develop a parsimonious yet generative explanation that specifies focal constructs, clarifies their relationships, and delineates the boundary conditions under which the theory should apply (Whetten, 1989). Consistent with foundational views in organisation studies, theory is treated as an explanatory system that clarifies why relationships emerge, how they unfold, and under what conditions they hold, rather than as a mere catalogue of variables or empirical regularities (Sutton & Staw, 1995; Weick, 1989). To avoid ungrounded abstraction, recent empirical findings on Korean business groups are used as stylised facts that anchor theorising, such as evidence that post-transition strategic change can be selective and shaped by group-level constraints and legacy effects, and that succession dynamics may shift risk-taking incentives even before formal transfer (Kim et al., 2022; Lee et al., 2023). These findings are not retested; instead, they serve as empirical signals motivating the conceptual model.*

The theory-building design is an integrative synthesis: established perspectives are recombined to produce an explanation that no single body of literature can yield on its own (Jaakkola, 2020). In line with Weick's notion of disciplined imagination, novelty is recognised as theoretically valuable only insofar as it remains coherent and plausible (Weick, 1989). Three bodies of work are integrated: (1) SEW and family succession research, (2) attention-based and strategic change theories, and (3) business group scholarship. To sharpen microfoundations of why some arenas resist change, the model also draws on dominant-coalition theorising that links hard power (equity) and soft power (relational ties) (Ben-Shahar et al., 2023). On this basis, the contribution lies in offering an original and useful explanation, one that can redirect future research and clarify theoretical and practical implications (Corley & Gioia, 2011; Whetten, 1989). In our study, chaebols are used as an extreme, illustrative context to clarify mechanisms and boundary conditions. This aligns with the logic of extreme-case design in theorising; the setting aims to shed light on constructs and processes rather than to achieve statistical representativeness (Eisenhardt, 1989; Eisenhardt & Graebner, 2007; Siggelkow, 2007). Moreover, the Korean context amplifies the preservation–renewal tension through high ownership–control wedges, professionalised CEO models, and shifting governance expectations (Park, 2025; Shin & Kim, 2025). The aim is to analytically generalise to other complex family-controlled enterprises under close scrutiny.

Construct development proceeds iteratively. The framework specifies the successor legitimacy calculus as the central mechanism, distinguishes between control-critical and growth-critical domains, and predicts a dual-speed transformation as the post-succession pattern. Boundary conditions (e.g. institutional scrutiny, ownership/control complexity, predecessor imprinting, resource slack) are defined to avoid overgeneralisation (Corley & Gioia, 2011; Whetten, 1989), and propositions are deductively derived to guide future empirical work, especially process and longitudinal designs attentive to temporality and selective change (Langley, 1999).

Results. *In developing a dual-speed theory of post-succession strategic transformation in family-controlled business groups, this study starts from the premise that generational succession is not merely a discrete managerial turnover, but a legitimacy-challenging turning point that reconfigures strategic attention and priorities. Succession activates a successor legitimacy calculus: incoming leaders must reconcile two competing imperatives, demonstrating strategic competence and future orientation in the eyes of external audiences while simultaneously preserving family control and*

SEW. This calculus helps explain why successors are pulled toward both continuity and change immediately after succession rather than moving in a single strategic direction.

This mechanism aligns with emerging family business research that emphasises succession as historically and relationally situated, shaped by how successors negotiate inherited values and what Magrelli et al. (2022) describe as the "wisdom of the past" as they launch new initiatives. It is also consistent with Marques et al.'s (2022) research on family imprinting and successor willingness, which shows that successors' motivations and perceived fit are endogenously shaped through family influence, generating both commonalities and differences in succession-related orientations. In business groups, moreover, legitimacy-building may be proactively engineered through governance pathways: controlling families can use board appointments strategically to position next-generation members within the group's governance structure, thereby enhancing their visibility and legitimacy as potential successors (Jeong et al., 2022). Dominant-coalition perspectives further suggest that legitimacy pressures are filtered through political considerations, as coalitions interpret performance feedback not solely through efficiency criteria but also through a control calculus oriented toward preserving dominance (Lee et al., 2025). Taken together, these insights imply that the successor legitimacy calculus is not purely external but simultaneously shaped by family history, internal coalitions, and broader institutional audiences.

Crucially, this legitimacy calculus does not produce a uniform organisational response. Instead, it implies the selective deployment of change efforts across domains, depending on two dimensions: the visibility of actions to external audiences and the perceived risk they pose to family control and internal cohesion. Because succession reopens tensions between past and future while exposing successors to multiple evaluative audiences, a single coherent package of change is unlikely to emerge. This logic is consistent with institutional complexity arguments: when organisations face heterogeneous, partly incompatible demands, they often respond by adopting differentiated, compartmentalised adaptations across domains rather than a uniform shift (Greenwood et al., 2011).

This differentiated response becomes more analytically tractable when the theory distinguishes between control-critical and growth-critical domains. In the first domain, changes in governance structures, ownership and control architectures, and the core affiliates that underpin family authority are politically costly and can provoke cascading contestation; successors therefore prioritise stability, and, when change is inevitable, they tend to adopt incremental adjustments to safeguard coalition stability. The latter domain, which includes outward-facing, future-driven fields such as technological investment, capability development, and international expansion, poses less threat to the control core and, at the same time, provides greater legitimacy because visible renewal can convincingly signal competence and modernity.

Several contextual forces intensify this dual-speed logic. Institutional scrutiny from regulators, media, and capital markets operates as a dual force: it increases incentives for visible renewal in growth domains while raising the political and legal risks of altering governance and ownership arrangements, reinforcing stability in the control core. Ownership and control complexity further magnifies these dynamics by increasing coordination costs and cascading risk; in settings characterised by pyramids and cross-shareholdings, disturbances to the control architecture can produce unintended ripple effects across affiliates, making control-critical change especially hazardous. Discretion is also shaped by predecessor imprinting and internal elites: longstanding routines and elite coalitions socialised under predecessors may persist after succession, constraining what successors can credibly change and encouraging them to redirect renewal toward safer arenas. Finally, slack expands the feasible set for successors, enabling more intensive experimentation and investment in growth-facing domains while maintaining stability in areas tied to family authority; such slack can be financial, but it may also be political, reflecting the coalition's capacity to act despite constraining performance signals (Lee et al., 2025).

Research limitations. *As a conceptual article, the framework aims to generate explanatory clarity and guide empirical inquiry rather than to directly test hypotheses. This presents some limitations.*

First, the dual-speed logic is developed from a revelatory context (South Korean chaebols) in which ownership-control wedges, coalition dynamics, and external scrutiny are especially pronounced. Although this extreme-case context improves mechanism explanation, future research should assess its applicability across other forms of family capitalism and business groups, including European family firms, Latin American conglomerates, and other Asian business groups, where ownership complexity, institutional scrutiny, and coalition structures may differ in both intensity and form (Barkema et al., 2015; Khanna & Palepu, 2000).

A second limitation concerns micro-foundations. The framework would benefit from a richer empirical understanding of how successors interpret competing audiences, negotiate internal elite constraints, and identify which domains are perceived as safe arenas for renewal rather than anchors of continuity. Qualitative and mixed-method studies would be especially valuable in clarifying how legitimacy is constructed over time and how it interacts with imprinting, successor willingness, and dominant-coalition dynamics (Ben-Shahar et al., 2023; Magrelli et al., 2022; Marques et al., 2022).

Third, the theory calls for longitudinal evidence. Tracking strategic actions across domains before and after succession would allow researchers to observe not only whether dual-speed transformation emerges, but also how it evolves as successors consolidate authority and as boundary conditions shift (e.g., scrutiny levels, ownership complexity, predecessor "shadow," resource slack) (Kim et al., 2022; Lee et al., 2023).

Finally, the framework does not yet fully specify the role of exogenous shocks and major discontinuities. Legal sanctions, crises, technological disruptions, and major governance events may interact with succession in ways that alter

the relative feasibility and attractiveness of control-critical versus growth-critical change, thereby intensifying, attenuating, or reconfiguring the dual-speed pattern.

Managerial implications. *For successors, controlling families, boards, and advisors, the framework highlights why attempting to "change everything at once" is often neither feasible nor strategically optimal in complex family-controlled groups. A first practical implication is to explicitly separate domains: treat control-critical arenas as spaces where continuity and careful sequencing protect coalition stability, while positioning growth-critical arenas as domains where renewal is both safer and more effective for demonstrating competence and future orientation.*

Second, governance stability should not automatically be interpreted as rigidity. In the dual-speed view, preserving the control core can serve as a strategic buffer, creating political and organisational slack for experimentation elsewhere, particularly when external audiences expect visible modernisation. In this sense, stability and renewal can complement each other when intentionally allocated across domains.

Third, advisors and policymakers should anticipate selectivity in change. Governance interventions that overlook the domain-specific calculus of control and legitimacy may trigger resistance or unintended ripple effects, especially in tightly coupled ownership structures. A more effective approach is to recognise that change is often shaped by where it is introduced: outward-facing initiatives may build legitimacy and expand the successor's room for manoeuvre before more politically sensitive adjustments to the control core become feasible.

Originality of the paper. *The paper's originality lies in reframing post-succession outcomes away from a binary "renewal versus continuity" logic toward a domain-differentiated theory of dual-speed transformation in family-controlled business groups. Rather than treating stable governance indicators as evidence of organisational stagnation, the framework explains how governance stability can coexist with substantial strategic renewal in growth-critical domains (e.g., technology, international expansion, capability development). This challenges interpretations that infer "no change" from unchanged ownership or board structures, redirecting attention to where change occurs within groups. A second original contribution is conceptual. Institutional scrutiny is theorised as a dual force rather than a uniformly disciplining mechanism. Scrutiny can simultaneously intensify outward-facing renewal (because visible initiatives yield legitimacy returns) and reinforce conservatism in governance-related arenas (because control moves become more observable, contestable, and cascade-prone) (Greenwood et al., 2011). This opens a pathway for governance scholarship to theorise selective and compartmentalised adaptation, rather than expecting comprehensive governance reform following succession. Third, the dual-speed lens encourages more fine-grained research designs by highlighting intra-group heterogeneity across affiliates and organisational roles within business groups (Chang & Hong, 2000; Khanna & Yafeh, 2007).*

Energy Transition as an Ecosystem enabler of growth in Italian MSMEs: Preliminary evidence from a national survey

MARCO VALERIO ROSSI[1], GIANPAOLO BASILE[2], MARIA PALAZZO[3], MARIA ANTONELLA FERRI[4]

Abstract. *The energy transition represents one of the most significant structural transformations affecting contemporary business ecosystems. While large corporations have been widely investigated in relation to sustainability strategies and decarbonization pathways, far less attention has been paid to micro, small, and medium enterprises (MSMEs), particularly within national contexts characterized by structural fragmentation and financial constraints. This study explores how energy transition strategies function as enabling or constraining mechanisms of ecosystem-based growth among Italian MSMEs. Drawing on preliminary evidence from a national survey carried out by Universitas Mercatorum and Federterziaio as components of Lamp Observatory involving 139 firms with fewer than 50 employees, the paper analyzes patterns in energy awareness, strategic behavior toward energy procurement, adoption of efficiency and renewable energy investments, and access to public financing. The findings reveal a structural divide between proactive and passive firms, a significant energy literacy gap among microenterprises, and strong size-based asymmetries in financial access and strategic adaptability. While a majority of firms have undertaken some form of energy-related intervention, many initiatives remain incremental and self-financed, limiting systemic impact. The study proposes a conceptual interpretation in which energy transition acts simultaneously as a capability filter and as an ecosystem growth enabler. By integrating sustainability transition dynamics into ecosystem-based growth models for MSMEs, the paper contributes preliminary empirical evidence to debates on sustainable competitiveness and institutional support mechanisms.*

Keywords: *energy transition; MSMEs; ecosystem growth; sustainable competitiveness; renewable energy adoption; Italy*

Framing of the research. *The energy transition is increasingly recognized as a structural transformation reshaping economic systems, industrial organization, and competitive dynamics (Newell, 2019). Decarbonization pressures, volatility in energy markets, technological innovation in renewable sources, and evolving regulatory frameworks are redefining the strategic landscape within which firms operate (Laurie & Serrano-Archimi, 2025; Üstgörül et al., 2024). In this evolving context, energy transition becomes intertwined with growth trajectories, cost structures, reputational positioning, and ecosystem participation (Thomas et al., 2024).*

While much of the academic and policy discourse has focused on large corporations and energy-intensive industries, micro, small, and medium enterprises (MSMEs) represent the structural backbone of many European economies, including Italy (Faggioni & Rossi, 2025a; 2025b; Sestino et al., 2025). Italian MSMEs are characterized by high fragmentation, strong territorial embeddedness, prevalence of family ownership, and limited financial and managerial slack (Palazzo et al., 2017; Rossi et al., 2026). These structural features influence their capacity for innovation and their ability to engage in sustainability-oriented transformation processes (Basile et al., 2025).

Ecosystem theory has emphasized the importance of inter-organizational networks, institutional support, and resource complementarities in enabling firm growth and innovation (Vrontis et al., 2020). From this perspective, growth is not solely an internal process but emerges through relational and systemic dynamics (Sánchez-García et al., 2023). Business ecosystems are conceptualized as loosely coupled yet interdependent constellations of actors, firms, institutions, financial intermediaries, and knowledge providers, whose coordinated interactions generate collective value and enable capability development beyond firm-level boundaries (Tani et al., 2025). However, the integration of energy transition into ecosystem-based growth models remains underdeveloped, particularly for microenterprises (Chatzinikolaou & Vlados, 2025). Energy-related strategic decisions, such as switching suppliers, investing in renewable energy systems, or accessing public incentives, may signal broader capabilities related to strategic adaptability, financial planning, and institutional embeddedness (Prashar, 2019; Fresner et al., 2017).

In this sense, energy transition can also be understood as a dynamic capability test within the ecosystem (Pouw & Mosink, 2024). Firms capable of monitoring energy consumption, renegotiating contracts, leveraging public incentives, and integrating renewable technologies demonstrate higher levels of absorptive capacity, strategic reflexivity, and ecosystem connectivity (Dong et al., 2022). Conversely, firms displaying inertia in these domains may experience cumulative competitive disadvantages (Munguia et al., 2018).

Recent fluctuations in energy prices across Europe, including significant increases in wholesale electricity costs, have further exposed vulnerabilities within smaller firms (Martin-Valmayor et al., 2023). Energy procurement, once

considered a purely operational issue, has become a strategic variable affecting margins, investment decisions, and long-term competitiveness (Petrovich & Kubli, 2023). In such a context, the capacity to understand energy consumption patterns, evaluate contractual alternatives, and implement efficiency measures can be considered an indicator of organizational maturity (Britel & Cherkaoui, 2022).

Within Italy, the MSME sector faces additional structural constraints, including bureaucratic complexity, limited access to external capital, and uneven participation in formal networking and institutional support mechanisms (Pascucci et al., 2022). These factors may amplify asymmetries in the adoption of energy transition strategies; consequently, energy transition provides a valuable analytical lens through which to observe broader ecosystem-based growth dynamics (Thomas et al., 2024).

While recent studies have increasingly explored sustainability transitions and ecosystem dynamics, the intersection between energy transition and MSME ecosystem-based growth remains only partially developed. In particular, prior contributions have predominantly focused either on firm-level sustainability adoption or on macro-level ecosystem configurations, without explicitly conceptualizing energy-related strategic behavior as a diagnostic lens of underlying capability structures. By positioning energy transition as both a capability filter and an ecosystem enabler, this study contributes to advancing current debates by bridging sustainability transitions with capability-based and ecosystem-oriented perspectives in the specific context of MSMEs.

Considering this scenario, this study positions energy transition as a potential ecosystem enabler of growth in Italian MSMEs. Rather than treating sustainability as an isolated policy domain, the paper interprets energy-related strategic behavior as a proxy for organizational capabilities development, institutional engagement, and growth orientation. The preliminary quantitative evidence presented here aims to stimulate discussion on how energy transition interacts with structural characteristics of the Italian MSME ecosystem.

By embedding energy transition within a conceptual ecosystem-growth framework, the study contributes to emerging debates on sustainable competitiveness, arguing that energy-related strategic behavior reflects deeper patterns of resource orchestration, institutional embeddedness, and long-term strategic positioning.

Purpose of the paper. *The purpose of this study is to explore how energy transition strategies function as enabling or constraining mechanisms within ecosystem-based growth trajectories of Italian micro, small, and medium enterprises.*

Specifically, the study seeks to:

1. *Examine the level of energy awareness among Italian MSMEs and its relationship with organizational size.*
2. *Analyze strategic behaviors in energy procurement and contract management.*
3. *Investigate the adoption of energy efficiency measures and renewable energy investments.*
4. *Assess the extent to which firms access public financial support for energy-related initiatives.*
5. *Conceptually interpret these findings within an ecosystem-based growth framework.*

Rather than testing causal hypotheses, this preliminary investigation aims to identify structural patterns and asymmetries that may inform the development of an integrated conceptual framework linking energy transition and MSME growth dynamics. The study contributes early empirical evidence to ongoing discussions regarding sustainable competitiveness and institutional support systems for small firms.

Methodology. *This study adopts an exploratory empirical approach based on preliminary evidence from a national quantitative survey of Italian micro, small, and medium enterprises. The survey collected 139 valid responses from firms with fewer than 50 employees, the majority of which qualify as microenterprises.*

The participating firms are predominantly active in services, commerce, and manufacturing sectors. A significant proportion operate as family-owned businesses and exhibit entrepreneur-centered governance structures. Most firms reported having been established without public incentives and relying primarily on personal capital at start-up.

The questionnaire included sections addressing firm profile, strategic orientation, networking behavior, and energy-related practices. The firm profile section gathered detailed information on organizational characteristics including firm size, sector, age, ownership structure, and market orientation, providing essential contextual data for interpreting subsequent responses. The strategic orientation section explored managerial priorities, competitive strategies, and tendencies toward innovation, with particular attention to how firms align their long-term objectives with operational decision-making. The networking behavior section examined the extent and nature of inter-firm relationships, partnerships, and institutional linkages, capturing networking capabilities, knowledge exchange, and external support mechanisms contribute to business development and adaptation. The energy-related practices section assessed operational approaches to energy management, including monitoring systems, efficiency measures, and investment planning, offering insights into how firms balance short and long-termism approach. The energy transition component of the survey focused on four main dimensions: (i) awareness of annual energy consumption linked to specific products or services; (ii) changes in energy supply contracts within the past five years; (iii) adoption of energy efficiency and renewable energy interventions; (iv) access to public funding for energy-related investments.

Data was analyzed using descriptive statistics to identify distributional patterns and structural asymmetries, particularly in relation to firm size categories. Given the exploratory nature of this study, the analysis aims to identify trends and emerging patterns rather than establish statistical causality. Different survey items referred to partially overlapping biennial periods (2023-2024 and 2024-2025), depending on the specific intervention considered.

As this paper presents preliminary findings, the results should be interpreted as indicative of structural dynamics rather than definitive conclusions.

Results. *The analysis reveals four interconnected themes that illuminate how energy transition interacts with ecosystem-based growth dynamics among Italian MSMEs, providing a comprehensive framework for understanding the strategic, organizational, and relational mechanisms that underpin sustainable business development. These themes collectively demonstrate that energy transition is not a linear or isolated process, but rather a multidimensional transformation shaped by internal capabilities, external pressures, and network-based interactions. They capture how firms interpret environmental challenges, mobilize resources, and embed sustainability practices within their broader growth trajectories. Furthermore, the interconnections among the four themes highlight the cumulative and reinforcing nature of energy-related strategies, whereby progress in one domain facilitates advancements in others. This dynamic interplay underscores the importance of coherence between managerial awareness, operational adjustments, institutional engagement, and ecosystem participation. By revealing these linkages, the analysis provides deeper insight into how Italian MSMEs navigate structural constraints and opportunities, leverage ecosystem support, and translate energy transition initiatives into competitive advantage, organizational learning, and potential long-term resilience that is still not fully considered by the analyzed firms (see Table 1).*

Table 1. Summary of key results

Theme	***Key Findings***	***Ecosystem Interpretation***
Energy Awareness Divide	*27% lack energy-output awareness; 32% among micro firms*	*Knowledge asymmetry; limited absorptive capacity*
Strategic Inertia	*57% did not change contract in 5 years*	*Adaptive rigidity; weak institutional engagement*
Financial Asymmetry	*25% accessed public funds; lower among micro firms*	*Capability filter effect; institutional access divide*
Asset-Based Transition	*29% renewable systems; 16% EV charging*	*Strategic signaling; ecosystem embeddedness strengthening*

Source: Authors' elaboration

The four dimensions identified are not independent but can be interpreted as part of a cumulative and reinforcing process. Limited energy awareness may constrain firms' ability to actively manage energy procurement, leading to forms of strategic inertia. This, in turn, may reduce the likelihood of engaging with institutional support mechanisms, particularly in accessing public funding. The resulting financial constraints can limit the scale and scope of energy-related investments, ultimately reinforcing capability divides within the ecosystem. From this perspective, energy transition dynamics reveal a sequential and path-dependent process through which initial capability gaps translate into broader structural asymmetries.

***Energy Awareness Divide**. A significant proportion of firms exhibit limited awareness of their energy consumption in relation to specific products or services. Approximately 27% of surveyed firms report a lack of clarity regarding the relationship between energy use and output, with this percentage rising to around 32% among firms with five or fewer employees.*

This finding suggests an energy literacy gap within the microenterprise segment. From a growth perspective, the inability to monitor and analyze energy consumption may constrain strategic decision-making and limit firms' capacity to implement a systematic efficiency improvements. Energy awareness thus emerges as a foundational capability within the transition process that needs of a networking capability useful in knowledge exchanges, financial support and advisory systems that typically highlights a sustainable territorial ecosystem capable to diffuse best practices related to efficiency management producing relevant impacts on specific places.

***Strategic Inertia in Energy Procurement**. Energy contract management reveals patterns of strategic inertia. Over 40% of firms report never having changed their energy supplier, and 57% have not modified their contract within the past five years. Given the volatility of energy prices over recent years, this behavior may signal limited strategic reactivity or insufficient information-processing capacity.*

Such inertia can be interpreted as an indicator of constrained managerial bandwidth or risk aversion. From an ecosystem perspective, firms that do not actively monitor and renegotiate energy contracts may also display weaker engagement with institutional support systems and advisory networks. Strategic inertia in energy procurement therefore, becomes not only a cost-management issue, but a marker of limited adaptive capacity within turbulent institutional environments.

***Partial Activation with Limited Financial Leverage**. Despite these limitations, a substantial majority (77%) of firms report having undertaken at least one intervention to reduce energy consumption during the 2023–2024 period. When excluding minor lighting upgrades, approximately 71% still report implementing efficiency or renewable-related measures.*

However, only about 25% of firms that invested in efficiency or renewable energy accessed public funding. Among microenterprises, access rates are even lower. This rate indicates that energy transition efforts are frequently self-financed, potentially limiting scale and scope.

These findings highlight strong size-based asymmetries in access and increasing relationships with institutional financial support. Larger firms appear better positioned to navigate funding mechanisms, reinforcing structural capability divides within the MSME ecosystem. The energy transition thus operates as a capability filter, rewarding firms with stronger administrative, financial, and institutional competencies while reinforcing vulnerabilities among structurally weaker actors.

***Asset-Based Energy Transition and Ecosystem Positioning**. Approximately 29% of firms installed renewable energy systems during the 2024–2025 period, often in combination with heat pump installations or building efficiency improvements. Additionally, 16% implemented electric vehicle charging infrastructure.*

These investments reflect not only cost-saving strategies with short-term impacts but also reputational positioning and ecosystem integration dynamics. Renewable installations and charging infrastructure can expand customer bases, enhance sustainability signaling, and create new revenue streams.

From an ecosystem growth perspective, asset-based energy investments may function as anchoring mechanisms that strengthen firms' embeddedness within local sustainable value chains. Such investments can enhance relational capital, attract environmentally conscious stakeholders, and signal long-term commitment to sustainable transformation and impacts.

Research limitations. *This study presents preliminary evidence based on 139 survey responses and relies on self-reported data. As such, the findings are subject to potential response biases and may not fully capture sector-specific heterogeneity. The findings are limited to the Italian institutional and regulatory context and cannot be directly generalized to other national settings. Given the nature of the data collection process, the sample should not be considered statistically representative of the overall population of Italian MSMEs. The survey relies on voluntary participation and self-reported information, which may introduce response bias and limit generalizability. However, the dataset provides a valuable first empirical insight into underexplored dynamics, particularly at the microenterprise level.*

The cross-sectional design prevents analysis of longitudinal dynamics or causal relationships between energy transition strategies and growth outcomes. Moreover, the descriptive statistical approach does not allow for inferential generalization to the broader population of Italian MSMEs.

Future research should incorporate longitudinal designs, comparative regional analyses, and multivariate modelling to test relationships between energy transition adoption, ecosystem engagement, and firm performance indicators. Further studies may also explore how ecosystem orchestration mechanisms, such as institutional convenors, regional innovation clusters, and financial intermediaries, moderate the relationship between energy transition and growth trajectories.

Managerial implications. *The findings suggest that the energy transition should be considered a strategic dimension of firm development within broader business ecosystems, not merely a regulatory or cost-related issue. For many micro and small enterprises, the first step is not technological investment, but awareness. A clearer understanding of how energy consumption relates to specific products or services represents a foundational managerial capability, enabling more informed decisions on pricing, cost structures, and long-term competitiveness and reputational performances.*

Energy procurement practices also deserve greater strategic attention. In contexts characterized by price volatility, regularly reviewing contracts and supplier conditions can reduce exposure to external shocks and enhance managerial responsiveness. Even operational choices in energy procurement may reflect broader patterns of strategic adaptability.

Access to public fundings emerges as another critical dimension. The data suggests that many firms, particularly microenterprises, rely primarily on self-financing when implementing energy-related investments. This condition may limit the scale and transformative potential of their initiatives. Strengthening advisory support and simplifying access to incentives could therefore play a pivotal role in enhancing the systemic impact of energy transition strategies.

Having said that, investments in renewable energy systems and charging infrastructure carry implications beyond immediate cost savings. Such initiatives can reinforce firms' reputational positioning, strengthen relational capabilities with stakeholders, and increase embeddedness within emerging sustainable value chains. From this perspective, energy transition becomes part of a broader strategic narrative that connects operational efficiency with long-term sustainable ecosystem positioning. Ultimately, this suggests the need for more targeted and differentiated policy instruments, particularly aimed at supporting microenterprises through simplified procedures and ecosystem-based advisory mechanisms.

Originality of the paper. *This paper contributes to the literature by integrating energy transition dynamics into ecosystem-based growth models for Italian MSMEs. Rather than treating sustainability adoption as an isolated phenomenon, the study interprets energy-related strategic behavior as a proxy for broader relational capabilities within a sustainable ecosystem view. In doing so, it positions energy transition not merely as a compliance-driven or cost-centered decision, but as a strategic process embedded within firms' learning, innovation, and relational activities. This perspective enables a more nuanced understanding of how MSMEs develop adaptive capacities, mobilize internal and*

external resources, and align environmental objectives with short and long-term competitive and growth-oriented strategies.

By embedding energy-related practices within an ecosystem framework, the study highlights the interconnected roles of institutional support, policy incentives, market pressures, and network relationships in shaping firm-level transitions. This approach captures the dynamic interactions between MSMEs and their surrounding business environments, emphasizing how co-operative relations, knowledge exchange, and access to funding mechanisms jointly influence sustainability trajectories and performance outcomes. Consequently, the paper extends existing ecosystem-based growth models by demonstrating that energy transition strategies can serve as indicators of organizational maturity, strategic alignment, and long-term resilience, thereby offering both theoretical advancement and practical insights for policymakers and practitioners concerned with sustainable MSME development.

By providing preliminary empirical evidence from a national survey, the paper advances understanding of how structural asymmetries, energy awareness gaps, and financial access constraints shape sustainable growth trajectories within fragmented MSME ecosystems.

The proposed interpretation of energy transition as both a capability filter and an ecosystem growth enabler offers a novel analytical lens for future research on sustainable competitiveness in small-firm contexts. In particular, the study suggests that energy transition operates as a diagnostic lens through which underlying ecosystem capabilities and structural fragilities visible, thereby enriching theoretical debates on sustainable competitiveness, institutional embeddedness, and small-firm resilience.

Next-Generation Digital Leadership in Family-Owned SMEs: An Integrative Review and Research Agenda—Ongoing Study

VERA AMPADU

Abstract. *Family-owned small and medium-sized enterprises (SMEs) operate at the critical intersection of intergenerational renewal and pervasive digitalization. Contrary to the assumption that "familiness" obstructs change, recent evidence indicates that family-specific attributes condition digital transformation (DT) through unique configurations of ownership goals, governance structures, and resource trade-offs. This study provides an integrative systematic synthesis of literature published between 2016 and 2026, exploring the entry of Generation Z—digital natives with distinct value systems—into the family SME landscape. The synthesis reveals that while "familiness" (e.g., long-term orientation and emotional bonds) can catalyze digital adoption, it can also constrain openness to external knowledge. Gen Z leaders introduce digital fluency and entrepreneurial agility that align with firm longevity; however, their demand for tech-enabled, purpose-driven cultures often disrupts traditional Socioemotional Wealth (SEW) frameworks. Drawing on SEW and Upper Echelons Theory, we identify digital leadership—specifically digital innovativeness and transformational styles—as the primary mechanism for harmonizing Gen Z's potential with family legacies. We highlight inherent tensions: while strong family control ensures stability, multigenerational top management teams may inadvertently dampen risk-taking in digital initiatives. This study contributes a holistic framework for understanding how next-generation leaders navigate the "willingness/ability" paradox. We conclude with a research agenda that addresses gaps in Gen Z's role in digital succession and offers managerial recommendations to foster a digital-first organizational culture.*
Keywords: *family-owned SMEs; next generation; digital leadership; digital transformation; succession; integrative review*

Framing of the research. *Globally, family-owned SMEs (FOSMEs) contribute to both the domestic and international economies by serving as catalysts for job opportunities, continuity, local production systems, and long-term wealth creation. Compared with non-family-owned SMEs, they have distinctive organizational forms in which ownership, governance, identity, and strategic intent are deeply embedded in family influence and continuity aspirations, generating long-term commitment and orientation, as well as a traditional paradox (De Massis et al., 2016; Chirico & Nordqvist, 2010). Therefore, providing suitable settings for analyzing firms' digital transformation pathways built on existing norms and systems.*

Embracing continuous, multidimensional restructuring of organizational structures, with reliance on digital tools, has become a distinctive context for small- and medium-scale enterprises, especially family-owned ones, that must adapt to remain relevant in the market across all sectors (Bouncken et al., 2025; Ricciardi, 2024). This process, known as digital transformation, is a shift from just acquiring digital hardware to a definitive blend of business goals nurtured in a family's socioemotional wealth (SEW). With a prioritization of legacy and control over aggressive innovation and path dependencies that can hinder adaptation (Ceipek et al., 2021; Ano & Bent, 2022; De Massis et al., 2014; Soluk & Kammerlander, 2021; Teece, 2007).

FOSMEs are characterized by resource constraints and risk aversion, a common barrier to digitalization, generational issues loom large: succession dynamics and the blending of family and business systems create both barriers and catalysts for innovation. In practice, family firms' digitalization is often more reactive than that of larger organizations that place greater emphasis on maximizing shareholder dividends (Żukowska et al., 2025). In the current work environment, the incoming Gen Z cohort—digital natives born in the mid-1990s to the early 2010s—plays a transformative role (Urme et al., 2025). They bring distinct values, digital fluency, and work expectations that promote greater flexibility in the workplace and the labor market (Stevanovski et al., 2024). An avenue not fully explored by these FOSMEs due to the assumption that Gen Z's perspectives are wholly different from the existing organizational cultures.

With the growing trend in family firm research, many scholars have addressed generational succession, DT, and Gen Z's impact in the workplace. However, few studies integrate Gen Z, digital leadership, and family SMEs. Daskalopoulos and Machek's (2023) systematic review found only 30 relevant studies on family firms' digitalization (2019–2023), underscoring a very young literature. Also, the bibliometric study on family firm digital transformation shows a rapid increase in publications in China and Europe in 2023, highlighting a clear gap that warrants urgent attention (Atienza-Barba et al., 2025). With the existing growing parallel research on Gen Z, which largely appears in human resources or consulting outlets, not explicitly in family business journals, there is a clear gap: we need to understand "next-generation digital leadership"—how younger family members (and nonfamily Gen Z employees) can drive or impede digital change. In this context, emphasizing digital leadership (DL) goes beyond technical expertise or digital literacy. It can be defined as the know-how to interpret technological opportunities, mobilize support for digital change, shape strategic priorities, and align transformation with the firm's long-term direction (The Future of Digital Leadership, 2026). In the current digital age, amid significant uncertainties, traditional leadership approaches (Kane et al., 2019) are insufficient to fully explore and exploit untapped resources (Contreras et al., 2020; Tigre et al., 2024).

In the convergence of these trends, we pose the following research questions:
RQ1: *How are Generation Z characteristics and digital leadership competencies influencing digital transformation in family SMEs?*
RQ2: *What organizational factors moderate the relationship between Gen Z leadership and digital innovation?*
Drawing on the theoretical lenses of socioemotional wealth (SEW), which explains resistance to change in family firms, and upper echelon theory, highlighting how leadership traits shape strategic direction.
Our review addresses the following: What leadership dynamics emerge when Gen Z enters family SMEs, and how do these dynamics affect digital transformation outcomes? An analytical opportunity, not to reduce the discussion to a narrow cohort label, but to build an underdeveloped, coherent explanation of how next-generation actors exercise digital leadership in family-owned SMEs. How that leadership shapes the direction, pace, and depth of digital transformation.

Purpose of the paper. *This paper aims to synthesize empirical and conceptual research (2016–2026) on Generation Z's impact on family-owned SMEs undergoing digital transformation.*
More specifically, the paper seeks to

1. *Examine how the literature conceptualizes the role of the next generation in digital transformation within family-owned SMEs.*
2. *Identify the main mechanisms through which next-generation actors enable, constrain, or redirect digital change.*
3. *synthesize the principal themes linking succession, governance, digital leadership, and organizational capability;*
4. *Develop an integrative framework and research agenda for future scholarship.*

The paper contributes in three ways. First, it integrates two research domains that have often evolved in parallel: family business succession and SME digital transformation. Second, it reframes the next generation not merely as a succession outcome but as an active source of digital leadership and strategic renewal. Third, it develops a research agenda that supports more precise theorization and stronger future empirical inquiry.

Methodology. *This paper adopts an integrative review design. Such an approach is particularly well-suited because the literature on next-generation digital leadership in family-owned SMEs is conceptually dispersed and methodologically heterogeneous. Relevant evidence is spread across family business studies, entrepreneurship, strategic management, SME digitalization, innovation, and information systems research. Moreover, the direct literature on younger generations and digital transformation in family firms is still emerging, making a narrowly aggregative or meta-analytic approach less appropriate (Torraco, 2016; Whittemore & Knafl, 2005). The review was guided by two main search streams. The first focused on family firms and generational transition, using terms such as "family business," "family firm," "family-owned SME," "succession," "next generation," "generational involvement," and "intergenerational transition." The second focused on digital transformation, using terms such as "digital transformation," "digitalization," "digital innovation," "digital leadership," "technology adoption," "dynamic capabilities," and "Industry 4.0." Searches were conducted through Scopus, Web of Science, and Google Scholar, which were selected because they provide broad coverage of business and management scholarship and were also identified as core databases for your search strategy.*
Because the direct "Generation Z + family-owned SMEs + digital transformation" literature remains limited, the review deliberately included proxy concepts such as next-generation involvement, successor influence, generational dispersion, leader digital innovativeness, and intergenerational digitalization. This widened the retrieval logic without diluting the conceptual focus. Studies were retained if they directly examined digital transformation in family firms, succession-related digital change, or the role of younger family actors in strategic renewal. Where possible, we relied on evidence-based findings (e.g., statistical results) and theoretical arguments from the sources. Conflicting evidence or open issues were highlighted as research gaps. We excluded studies of SMEs that were not family-involved and work on broader generational cohorts (e.g., "Millennials") unless Gen Z-specific content was present. We applied these across titles, abstracts, and keywords. From the initial hits (140 records), we removed duplicates. Inclusion criteria were studies of family-owned SMEs (or broader family firms) that explicitly addressed digital or technological change and involved issues related to younger-generation leadership or workforce. We excluded papers on large corporations, purely technical digital systems without human factors, or non-English publications. Abstracts were assessed for alignment with our focus; about 45 articles passed this screening. We then retrieved the full texts of each and verified their relevance, narrowing to 30 core sources (including empirical studies, reviews, and theoretical pieces). Bibliographies of key papers were also hand-searched to identify any missing sources (backward snowballing). Analyses were descriptive and thematic. We charted publication counts by year and geography, identified dominant authors or clusters (e.g., family business centers or regions), and extracted recurring themes (e.g., SEW impact, innovation pathways). Any divergences or notable methodological issues (e.g., use of qualitative vs. quantitative data) were recorded. This transparent process ensures reproducibility.

Results.
Trends. *Our review confirms a recent surge in interest at the intersection of Gen Z, family firms, and digitalization. Few relevant papers appeared before 2020; interest picked up after 2021. Before the identified peak period, most papers generally focused on family firms or SMEs, whereas later pieces explicitly mentioned generational or leadership factors*

(Araya-Castillo et al., 2021). These studies originate from diverse economies, including Asia, Europe, the Middle East, and Latin America (Atienza-Barba et al., 2025). The different geographic representations underscore global recognition that family firms face similar digitalization imperatives and generational transitions.
The integrative review reveals that the impact of Generation Z on digital transformation in family-owned SMEs is shaped by interconnected organizational and socio-cultural mechanisms, not solely by generational presence. Across the literature, five recurring themes emerge: renewal, legitimacy, identity, leadership, and capabilities. These themes set the ground for explaining how next-generation actors influence digital transformation and why their impact varies significantly across family firms.

Renewal. *A major recurring theme is the next generation as a catalyst for organizational renewal, given their characteristic digital fluency, collaboration, and adaptability from formative immersion in digital environments. Across the reviews, the next generation is consistently associated with stronger digital awareness, openness to experimentation, and a greater willingness to modernize existing traditional business models. This influence often extends beyond technology adoption to broader strategic initiatives, such as process digitalization, platform-based business models, customer-oriented innovation, and data-driven decision-making (Ano & Bent, 2022; Maseda et al., 2025). Gen Z makes their digital influence felt before formal succession through project-based involvement, advisory roles, or informal participation in strategic discussions. A clear indication that digital leadership within family firms should be understood as a continuous intergenerational process rather than a single succession event (Ricciardi, 2024; Mihotić & Pfajfar, 2026). Similar observations can be identified in broader family-business research, which portrays the growing role of next-generation actors as internal entrepreneurs who introduce new capabilities and strategic directions (De Massis et al., 2013; Nordqvist & Melin, 2010). With a broader perspective, next-generation actors have greater potential for capability expansion and strategic direction (Del Vecchio et al., 2024), but effective, sustainable outcomes rely heavily on organizational acceptance and decision-making authority (Schroth, 2019; Deloitte, 2023).*

Legitimacy. *From the review, even formal succession alone doesn't grant the next generation the autonomy they need to have their influence felt. Perceived credibility largely rests with incumbents, who often retain strong informal authority even after younger family members assume visible roles (Appleton et al., 2025; Ko et al., 2025). Mostly resulting in tension and slow digital transformation across units, as senior family members typically control strategic decision-making and resource allocation. Digital transformation initiatives regularly depend on incumbents' willingness to grant younger family members decision-making rights and strategic autonomy. In situations where senior leaders support experimentation and gradually transfer authority, digital initiatives are more likely to evolve into sustainable, substantive, and entire organizational changes. Compared with when the founder's authority remains centralized or ambiguous, digital initiatives typically remain symbolic or limited to low-risk activities (Ricciardi, 2024; Ano & Bent, 2022). With older generations placing much emphasis on stability, tradition, and hierarchical decision-making, whereas younger members prioritize adaptability, digital tools, and collaborative innovation, this creates complications in the digital transition process in family-owned firms (Subhani et al., 2026). Generational involvement has both negative and positive effects: Othman (2025) finds that the active participation of younger family members increases digital tool adoption by 26.5% in Jordanian family firms, compared with 10.8% in non-family businesses. Similarly, Ko et al. (2025) show that the presence of multiple next-generation leaders can reduce resistance to digital transformation by dispersing authority and legitimizing innovation initiatives. Other studies indicate that multigenerational leadership teams may sometimes weaken the impact of proactive strategic initiatives due to conflicting perspectives and coordination challenges (Maseda et al., 2025).*

Identity. *One significant trait of family-owned SMEs is that they do not approach digitalization purely as a technical or economic process; instead, they make strategic decisions deeply rooted in family identity, reputation, and aspirations for continuity (De Massis et al., 2016; Ceipek et al., 2021). Thereby, striking a balance between continuity and modernization, as change agents must simultaneously demonstrate respect for the firm's legacy and values to maintain legitimacy within the family system. As a result, successful digital leadership in family firms rarely frames digital transformation as a radical break with the past. The concept of familiness, one of the pillars of family-owned firms, can support innovation through strong commitment and patient capital; it can also create resistance to disruptive change when family members prioritize stability and socioemotional wealth over experimentation (Berrone et al., 2012; Costa et al., 2023).*

Leadership. *Leadership functions as a central mechanism connecting generational change to digital transformation outcomes. Digital leadership is often identified as a fundamental enabler, enabling family firms to convert generational digital competencies into enhanced innovation performance. Empirical studies show that leadership that supports digital innovation and is open to experimentation positively influences digital innovation when complementary resources, such as IT infrastructure, employee training, and digital-oriented organizational cultures, are available (Żukowska et al., 2025). Urme et al. (2025) argue that leadership traits such as agility, digital fluency, and synergistic empowerment closely align with Gen Z's preferences, which value autonomy, authenticity, and flexible work structures. Consequently, adopting digital leadership practices may enhance innovation performance and improve the retention and motivation of*

younger employees. Again, the effectiveness of leadership depends on the broader governance and whether the firm operates in a centralized or decentralized system.

Capabilities. *Achieving a sustainable, digitally transformed, family-owned firm can't be done solely through tech-driven Gen Zs; it requires organizational capabilities that enable absorption and implementation. Studies in dynamic capability theory shed light on the value of absorptive capacity, IT infrastructure, employees' digital skills, and the sustaining of digital cultures in facilitating transformation (Soluk & Kammerlander, 2021; Żukowska et al., 2025). In the absence of these capabilities, the efforts of digital natives are limited to incremental improvements, such as digital marketing tools or basic internal communication technologies. With these capabilities, next-generation leaders can drive deeper organizational transformation through business model innovation, data-driven decision-making, and platform-based strategies (Maseda et al., 2025; Mihotić & Pfajfar, 2026). A clear indication that next-generation digital leadership should not be viewed as a direct cause of transformation, but rather as a catalyst whose effectiveness depends on the wider institutional ecosystem.*

Discussion. *This review probably challenges the common belief that "familiness" always blocks organizational change. Instead, it finds a more complex "ability-willingness" paradox (Chrisman et al., 2014), which is becoming more important as Generation Z joins family businesses. Traditional Socioemotional Wealth (SEW) frameworks focus on stability and identity (Gomez-Mejia et al., 2007), but Generation Z is driving digital renewal. For them, digitalization is key to keeping the family business strong over time, not just a threat to tradition.*
Gen Z's digital skills are not enough if they do not also have real authority within the company. The study indicates that the "next-gen effect" is constrained by a "legitimacy gap," in which older leaders retain informal control over key resources even after stepping down from their roles. This aligns with Upper Echelons Theory, which holds that a company's digital path depends on its most powerful people—right now, that means both cautious founders and tech-savvy successors.
Upgrading from small digital initiatives to large business innovation depends on building dynamic capabilities (Teece, 2014). Without these skills and an open digital culture, Generation Z's impact stays mostly on the surface. Digital leadership can help by connecting Generation Z's push for agility with the family's desire for stability, helping family SMEs shift from reacting to change to leading it.
While the current literature identifies the "what" and "who" of digital transformation in family SMEs, it remains thin on the "how" regarding the specific behavioral mechanisms of Gen Z. To advance the field, we propose the following four research directions: psychological ownership and digital change, the role of non-family Gen Z, longitudinal crisis adaptation, and intergenerational knowledge integration.

Research limitations. *This paper is an integrative review and therefore shares the strengths and limitations of that approach. The strength lies in its ability to consolidate a fragmented body of literature and to generate conceptual advancement. Its limitation is that the literature on next-generation digital leadership is still emergent and uneven. Papers focused on Generation Z, in particular, remain limited, stressing the need to include adjacent studies that use proxy concepts such as next-generation involvement, generational dispersion, or successor influence. Secondly, the review integrates studies that use diverse methods, operate in diverse contexts, and define digital transformation in different ways. While this is appropriate for an emerging field, it also means that conclusions should be understood as interpretive rather than statistically generalizable. Additional research could strengthen the field through longitudinal, mixed-method, and comparative designs.*

Managerial implications. *This study finds that for family-owned SMEs, bringing Gen Z into the business is less about technical onboarding and more about making structural and psychological adjustments. From the evidence, we recommend three key actions for managers:*

Understanding Psychological Ownership and Digital Responsibility. *Managers need to distinguish between Gen Z's digital projects that benefit the company as a whole and those that primarily serve personal career goals. In many family SMEs, younger members propose digital changes to develop their own areas of expertise, separate from the founder. If these projects are treated as personal rather than as part of the company's main strategy, they can become isolated and fail to support the firm's long-term socioemotional wealth (SEW). Managers should focus on connecting digital changes to the family's legacy so that the next generation's desire for recognition strengthens the company's identity rather than divides it (Pierce et al., 2001; Ceipek et al., 2021).*

Using Non-Family Gen Z Employees as Cultural Connectors. *Family firms often focus on their heirs and overlook the important role non-family Gen Z employees can play. These employees are usually just as skilled with digital tools as family members, but they do not have the family ties that can complicate decisions. Managers should see these employees as neutral connectors or cultural bridges. By involving non-family Gen Z workers in digital decision-making groups, companies can reduce emotional conflicts in multigenerational leadership teams (Maseda et al., 2025). This helps create a more objective, data-driven approach to digital change that is less affected by old family habits.*

Building Lasting Resilience Instead of Only Reacting to Change. *Recent evidence indicates that many digital changes in family SMEs occur in response to external events rather than as part of a planned strategy (Jalilvand et al., 2024). To improve, leaders need to make ongoing crisis adaptation part of the company's routine. This means moving from quick fixes to building lasting skills. For family managers, it involves working with Gen Z employees to create a cycle of continuous improvement in which digital tools are regularly updated. This helps keep the business strong through economic ups and downs and across generational changes (Soluk et al., 2021; Mihotić & Pfajfar, 2026).*

Originality of the paper. *This paper proposes a novel perspective on the next generation in family-owned small and medium-sized enterprises (SMEs). Rather than considering younger family members solely as future leaders or a demographic cohort, it positions them as central actors in digital leadership who influence both the direction and pace of organizational change. By integrating research on family business succession and SME digital transformation, the paper clarifies the connections among governance, legitimacy, digital orientation, and the cultivation of new competencies. This framework provides a more actionable and strategic lens for understanding how family-owned SMEs prepare for digital transformation.*

Productivity patterns of family *vs* non-family firms under stability and crisis

CRISTINA BETTINELLI[1], CLEMENTINA BRUNO[2], FABRIZIO ERBETTA[3], ANNA MENOZZI[4]

Abstract. *This study examines the effect of family and non-family ownership on the productivity of listed Italian firms during periods of economic crisis and stability. Using Total Factor Productivity (TFP) as a comprehensive measure of firm performance and applying unconditional quantile regression, we expect that, during periods of economic growth or stability, family firms at the higher tail of the productivity distribution perform worse than non-family firms, whereas those at the lower tail outperform their non-family counterparts. During crisis periods, however, this pattern may reverse. The findings may be interpreted in light of the property rights theory, which emphasize how the exercise of use, appropriation, and transfer rights by family owners shapes the production process and productivity outcomes. Overall, the study aims to shed light on the longstanding debate over the comparative superiority of family versus non-family firms by revealing how family firms' attitudes toward the productive use of their resources change contingently on their relative performance position and on the hardships caused by economic crises.*
Keywords: *family firms; non-family firms; productivity; property right theory; quantile regression*

Framing of the research. *Family firms represent the dominant form of business organization worldwide and are key economic players (Masulis, Pham, and Zein, 2011). In Italy, they account for approximately 85% of all companies (AIDAF, 2025), making their performance central to explaining the evolution of the national economy. Over the past two decades, Italy has recorded disappointing productivity dynamics, with an average annual productivity growth of -0.3%, compared to an OECD average of +0.3% (OECD, 2023). The weak aggregate total factor productivity (TFP) growth and subdued capital accumulation are widely regarded as principal explanations for the underperformance of the Italian economy (Giordano and Zollino, 2021), and the prevalence of family ownership is often cited among the structural factors contributing to low firm productivity (Baltrunaite et al., 2022, Andretta,Brunetti, and Rosso, 2021).*

Firm productivity is shaped by both external and internal drivers. At the system level, productivity depends on the quality of institutions, the efficiency of the legal system, the degree of market competition, and the quality of infrastructure and human capital. At the firm level, governance and ownership structures (Shleifer and Vishny, 1997) and management quality (Bartelsman and Doms, 2000) play critical roles. Within this context, the theoretical literature has long debated the relative superiority of family versus non-family firms in terms of performance. Creemers et al. (2023) offer a reconciling perspective on the contrasting arguments by employing a quantile-based regression to show that the sign of the relationship between family ownership and labor productivity changes across the productivity distribution. Aguilera et al. (2024) further enrich this picture by demonstrating that family-owned businesses tend to prioritize labor over capital in their production processes, and this distinctive decision lead to consistently lower levels of productivity compared to non-family firms; in addition, when family firms share ownership and control with non-family members, they become less labor intensive, invest more in capital, and achieve higher productivity, suggesting that specific governance configurations can mitigate the productivity gap.
