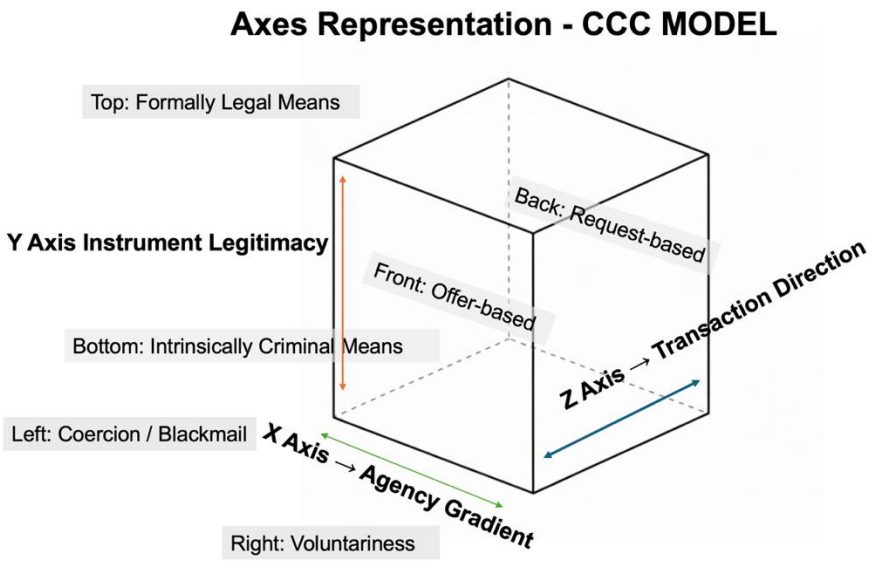
The Corruption Configuration Cube (CCC) is proposed as a multidimensional analytical framework designed to conceptualize corruption as a configurational governance phenomenon rather than as a singular behavioural deviation or isolated compliance failure. Unlike traditional corruption models, which typically explain corruption through linear causal variables such as opportunity, incentive, rationalization, or institutional weakness, the CCC adopts a configurational perspective in which corruption emerges through the interaction of multiple organizational, relational, and governance dimensions.



The framework is grounded in the assumption that contemporary corruption cannot always be adequately interpreted through binary distinctions such as legal/illegal or ethical/unethical behaviour. In increasingly complex governance environments characterized by institutional fragmentation, algorithmic mediation, ESG pressures, asymmetrical power relations, and distributed decision systems, corruption often develops through hybrid and dynamic configurations involving coercion, strategic adaptation, moral distancing, and governance-induced (Misangyi et al., The Role of Power in Organizational Corruption).

The CCC conceptualizes corruption as a multidimensional governance configuration generated by the interaction of three analytical dimensions:

1. Agency structure;
2. Legitimacy of instruments;
3. Transactional directionality.

These dimensions are represented as orthogonal analytical axes within a three-dimensional conceptual cube. Their interaction generates different corruption configurations characterized by distinct governance logics, organizational dynamics, ethical implications, and sustainability risks.

Figure 1. The Corruption Configuration Cube (CCC)

Core Dimensions

- X-Axis | Agency Structure: Evaluates the degree of autonomy and volitional capacity of the actors, mapping the spectrum from external coercion to proactive engagement.
- Y-Axis | Legitimacy of Instruments: Assesses the normative standing of the methods employed, distinguishing between formally regulated legal mechanisms and illicit or extra-legal means.
- Z-Axis | Transactional Directionality: Identifies the point of origin and the flow of the interaction, differentiating between offer-based initiatives and request-driven responses.

Research Utility

By replacing qualitative abstractions with defined structural vectors, the model enables a systematic diagnostic of transaction integrity. This framework allows researchers and managers to visualize complex power dynamics and compliance risks within a standardized geometric space, facilitating comparative analysis across diverse institutional contexts.

The configurational structure of the framework reflects two core assumptions.

First, corruption is not homogeneous. Different corruption phenomena may emerge through substantially different combinations of coercion, legitimacy, and transactional asymmetry. Consequently, anti-corruption governance mechanisms cannot be uniformly designed, since different corruption configurations require different forms of organizational intervention, accountability structures, and governance responses.

Second, corruption must be understood not only as an issue of individual misconduct, but also as a governance pathology embedded within organizational systems, power structures, and decision architectures. In this sense, the CCC shifts the analytical focus from isolated corrupt actors toward the broader governance conditions that enable, normalize, or impose corrupt conduct.

The framework should be interpreted primarily as an analytical and diagnostic tool rather than as a predictive model. Its purpose is to support a more nuanced interpretation of corruption dynamics within contemporary organizations by integrating structural, relational, cognitive, and coercive dimensions within a unified governance perspective.

4.2 The Three Dimensions of the CCC

4.2.1 Agency Structure: Voluntariness and Coercion

The first dimension concerns the structure of agency underlying corrupt conduct. Existing corruption literature has traditionally interpreted corruption as a predominantly voluntary and opportunistic behaviour driven by incentives, rationalization, or strategic gain. However, contemporary governance environments increasingly reveal forms of corruption characterized by coercion, fear, dependency, intimidation, and asymmetrical power relations.

The agency axis ranges from voluntary corruption to coercive corruption. At the voluntary end of the spectrum, actors actively engage in corrupt practices in pursuit of economic advantage, strategic benefit, reputational gain, or organizational competitiveness. These forms typically correspond to classical bribery, collusive agreements, preferential treatment, or strategic influence exchanges. At the coercive end, corruption emerges through domination, blackmail, retaliation threats, organizational intimidation, or forced compliance. In such contexts, actors may participate in corrupt conduct not because they seek illicit benefit, but because they perceive non-compliance as threatening to professional survival, organizational belonging, personal security, or economic stability.

This distinction is particularly relevant within contemporary organizations characterized by strong performance pressures, precarious governance systems, concentrated authority structures, and weak whistleblower protections. Under these conditions, corruption may progressively become a defensive adaptation mechanism rather than a purely opportunistic choice.

The agency dimension introduces moral agency conditions into corruption analysis. It highlights how governance systems themselves may weaken ethical autonomy by generating fear, dependency, moral distancing, or constrained capacity for dissent.

4.2.2 Legitimacy of Instruments

The second dimension concerns the legitimacy of the instruments through which corruption is enacted. Traditional corruption models frequently treat corruption as inherently illegal or explicitly criminal. However, contemporary governance environments increasingly reveal ambiguous situations in which formally legitimate instruments may be strategically manipulated to generate unethical or corrupt outcomes without necessarily violating explicit legal boundaries.

The legitimacy axis ranges from formally legitimate instruments to intrinsically illegitimate instruments. At the illegitimate extreme, corruption relies on explicitly unlawful or fraudulent

mechanisms such as bribery, extortion, falsification, embezzlement, coercive payments, or criminal collusion. At the formally legitimate end, corruption may operate through legal but ethically problematic instruments including lobbying abuse, revolving-door dynamics, selective information asymmetries, strategic consulting arrangements, political influence networks, or governance structures designed to privilege specific actors while preserving formal legal compliance.

This dimension reflects an important transformation in contemporary governance systems. Increasing regulatory sophistication and institutional complexity often encourage the migration of corruption from overt illegality toward legally ambiguous forms of influence embedded within organizational routines, governance structures, and institutional arrangements.

The legitimacy dimension expands corruption analysis beyond purely criminal perspectives by emphasizing the distinction between legal validity and ethical legitimacy. This distinction becomes particularly important within ESG governance environments, where formally compliant organizational practices may nevertheless undermine transparency, accountability, stakeholder trust, or sustainability objectives.

4.2.3 Transactional Directionality

The third dimension concerns the directional structure of corruption transactions.

Most corruption models implicitly assume symmetrical exchange relationships in which corrupt transactions emerge through mutually beneficial arrangements between actors. However, corruption dynamics often differ substantially depending on whether corrupt conduct originates primarily from the offering side or from the requesting side of the transaction.

The transactional directionality axis ranges from offer-based corruption to request-based corruption. Offer-based corruption occurs when the initiating actor proactively proposes corrupt exchanges in pursuit of strategic advantage, preferential treatment, competitive gain, or accelerated access to resources. These forms typically correspond to proactive bribery, influence purchasing, strategic collusion, or opportunistic corruption. Request-based corruption, by contrast, emerges when actors are pressured or required to provide benefits, payments, favours, or concessions in response to explicit or implicit demands imposed by individuals or institutions controlling access to resources, approvals, protection, or organizational opportunities.

This distinction is analytically significant because offer-based and request-based corruption generate different governance implications.

Offer-based corruption tends to reflect strategic opportunism and competitive advantage-seeking behaviour, whereas request-based corruption more frequently reflects asymmetrical power structures, institutional vulnerability, dependency relations, and coercive governance conditions.

Expanding upon this framework, the transactional directionality axis corresponds to the disparate power endowments and strategic objectives of the participants. Offer-based dynamics frequently reflect the proactive deployment of capital by high-resource non-state actors, such as Multinational Enterprises (MNEs), seeking to secure institutional capture or favourable regulatory shifts within asymmetrical economic environments; in these instances, corruption functions as an informal extension of strategic lobbying. Conversely, request-based corruption is fundamentally rooted in the extractive agency of public officials, where the solicitation of rents is facilitated by institutional gatekeeping. This latter modality manifests either as systemic petty corruption or as grand-scale political extortion, whereby the locus of initiation shifts from the private pursuit of advantage to the institutional exploitation of authority.

The transactional directionality dimension enables corruption analysis to move beyond static exchange models by incorporating power asymmetries, initiation structures, and relational dependency into the interpretation of corrupt behaviour.

4.3 Corruption Configurations and Interaction Effects

The analytical value of the CCC emerges not from the isolated dimensions themselves, but from their interaction. Different combinations of agency structure, legitimacy of instruments, and

transactional directionality generate qualitatively distinct corruption configurations characterized by different organizational dynamics, governance failures, sustainability implications, and ethical risks.

For example, a corruption configuration characterized by voluntary agency, illegitimate instruments, and offer-based directionality may correspond to classical competitive bribery, where actors proactively engage in illegal transactions to secure strategic advantage.

By contrast, a configuration characterized by coercive agency, illegitimate instruments, and request-based directionality may correspond to extortionary corruption regimes in which actors comply with corrupt demands due to fear, retaliation risk, or asymmetrical dependence.

Similarly, configurations involving voluntary agency, formally legitimate instruments, and offer-based dynamics may correspond to ethically ambiguous influence systems operating through legal but strategically distortive governance arrangements, such as lobbying capture or revolving-door influence structures.

The configurational perspective allows corruption phenomena that appear superficially similar to be analytically differentiated according to their governance logic and organizational implications.

Importantly, the framework also recognizes that the three dimensions may interact dynamically rather than remaining fully independent in practice. For instance, coercive conditions may progressively alter the perceived legitimacy of instruments, while request-based corruption may generate normalization processes that transform defensive adaptation into routine organizational behaviour. The CCC conceptualizes corruption configurations as dynamic governance patterns rather than static categories.

4.4 Illustrative Corruption Configurations

To clarify the analytical applicability of the framework, Table 3 presents illustrative examples of corruption configurations generated through different combinations of the three dimensions.

Table 3. Illustrative Corruption Configurations within the CCC

Agency Structure	Legitimacy of Instruments	Transactional Directionality	Illustrative Configuration	Governance Logic
Voluntary	Illegitimate	Offer-based	Competitive bribery	Strategic advantage seeking
Voluntary	Legitimate/formally compliant	Offer-based	Lobbying capture	Institutional influence distortion
Coercive	Illegitimate	Request-based	Extortionary corruption	Domination and forced compliance
Coercive	Legitimate/formally compliant	Request-based	Organizational intimidation	Governance-induced fear
Voluntary	Legitimate/formally compliant	Request-based	Network dependency corruption	Relational asymmetry
Coercive	Illegitimate	Offer-based	Survival corruption	Defensive organizational adaptation

The examples of *possible corruption configurations* presented in Table 3 are illustrative rather than exhaustive. Their purpose is not to rigidly classify all corruption phenomena, but to demonstrate how the CCC can support a more differentiated analysis of corruption dynamics across organizational and institutional contexts.

The framework enables corruption to be interpreted not simply according to legal status, but according to governance structure, agency conditions, relational asymmetry, and ethical configuration.

4.5 Governance and Sustainability Implications of the CCC

The CCC framework carries important implications for governance design and sustainability management because it reframes corruption as a multidimensional organizational and sustainability challenge rather than merely as a problem of legal compliance or individual misconduct. By integrating coercion, legitimacy structures, and transactional asymmetries within a unified analytical

architecture, the framework suggests that corruption risks are deeply connected to the design of organizational decision systems, accountability mechanisms, and governance environments.

A first implication concerns the limitations of compliance-centered governance approaches. Traditional anti-corruption systems have historically emphasized compliance monitoring, auditing, formal controls, legal and regulatory enforcement. While these mechanisms remain essential, the CCC suggests that they may be insufficient in organizational environments where corruption emerges through coercion, fear, governance-induced pressures and moral distancing, or normalized dependency relations rather than through explicit opportunistic intent alone.

In such contexts, organizations ought to move beyond traditional reactive compliance architectures, towards mechanisms capable of protecting and encouraging autonomous moral agency. This requires governance systems that reduce asymmetrical dependence, encourage ethical dissent, and strengthen individuals' capacity to resist coercive or ethically ambiguous pressures. Protected whistleblowing channels, independent reporting structures, anti-retaliation safeguards, and distributed accountability systems thus become central governance tools rather than peripheral compliance instruments.

Second, the CCC framework highlights the importance of governance transparency within digitally mediated organizational systems with important implications for board governance and organizational oversight. As algorithmic management and AI-assisted decision-making increasingly influence organizational processes, corruption risks may become embedded within opaque decision architectures characterized by distributed accountability and reduced human oversight. Emerging governance research suggests that technologically mediated systems may unintentionally intensify accountability diffusion, moral distancing, and opacity in organizational decision processes. Under such conditions, corruption risks may become embedded not only in individual actions, but also within the architecture of automated or semi-automated governance systems themselves.

Consequently, organizations adopting AI-supported governance mechanisms should complement technological efficiency with ethical oversight structures capable of preserving transparency, traceability, and human accountability. Governance safeguards may include explainability mechanisms, ethical escalation procedures, algorithmic audit systems, and human review structures designed to reduce the risk of ethically opaque or coercively normalized decision processes.

Corruption risks should not be evaluated exclusively through legal exposure or financial misconduct indicators, but through broader governance configurations involving power concentration, decision opacity, dependency structures, and accountability fragmentation. Boards and senior governance actors should assess corruption risk not only by asking whether illegal conduct exists, but also whether organizational conditions may progressively normalize coercion, silence, strategic ambiguity, or ethical disengagement.

From this perspective, governance quality depends not only on control intensity, but also on the capacity of organizational systems to preserve ethical reflexivity and moral agency under conditions of strategic pressure. This issue becomes particularly relevant in highly competitive sectors, politically exposed industries, and transnational organizational environments characterized by institutional fragmentation and regulatory asymmetries.

A further implication concerns the relationship between corruption and sustainability governance. The framework supports a broader interpretation of ESG governance in which integrity, accountability, transparency, and ethical decision architectures become central dimensions of sustainable organizational performance. In this sense, corruption risks should not be confined to legal compliance departments alone, but integrated into enterprise governance, sustainability oversight, and strategic risk management systems.

The CCC reinforces the idea that corruption should be interpreted as a sustainability failure capable of undermining long-term organizational resilience, stakeholder trust, institutional legitimacy and ESG credibility even in the absence of overt illegality. Configurations involving formally legitimate but ethically distortive practices - such as influence capture, governance opacity, selective information control, or structurally asymmetrical access to decision-making processes - may remain

formally compliant while nevertheless eroding institutional trust and sustainable governance outcomes.

Finally, the framework supports the development of more differentiated anti-corruption strategies. For example:

- voluntary and offer-based corruption configurations may require stronger monitoring systems, transparency measures, and incentive realignment mechanisms;
- coercive and request-based corruption configurations may instead require whistleblower protection, anti-retaliation safeguards, organizational decentralization, and reductions in dependency asymmetries;
- corruption configurations relying on formally legitimate instruments may require enhanced governance transparency, conflict-of-interest regulation, and ethical oversight beyond strict legal compliance.

The framework additionally highlights the importance of differentiating governance responses according to the specific corruption configuration involved. Different corruption configurations generate different organizational dynamics and therefore require different governance interventions. Organizations may require tailored interventions involving whistleblower protection systems, governance transparency mechanisms, ethical escalation channels, accountability redistribution, and AI governance safeguards.

The CCC therefore contributes to reframing corruption not merely as a legal compliance issue, but as a multidimensional governance and sustainability challenge embedded within contemporary organizational systems.

7. Conclusion

This paper proposed the Corruption Configuration Cube (CCC) as a multidimensional conceptual framework aimed at reconceptualizing corruption as a governance and sustainability phenomenon rather than merely as an issue of legal non-compliance or individual misconduct. Building upon and extending classical corruption models, the framework integrates three analytical dimensions - agency structure, legitimacy of instruments, and transactional directionality - in order to capture the configurational complexity of corruption within contemporary organizational environments.

The study contributes to corruption and governance research in several ways. First, it advances existing literature by explicitly incorporating coercion, fear-based compliance, and moral agency erosion into corruption analysis. While traditional models have primarily interpreted corruption through opportunity structures, incentives, and rationalization mechanisms, the CCC highlights how corruption may also emerge through asymmetrical dependence, governance-induced vulnerability, and organizational pressure systems. In doing so, the framework shifts attention from corruption as isolated opportunistic behaviour toward corruption as a systemic governance configuration embedded within organizational architectures and power relations.

Second, the paper contributes to contemporary governance and sustainability debates by emphasizing the relationship between corruption, organizational legitimacy, and governance design. The framework suggests that corruption risks increasingly arise not only through overt illegality, but also through ethically ambiguous governance arrangements, accountability fragmentation, and technologically mediated decision systems capable of weakening ethical reflexivity and diffusing responsibility. This perspective becomes particularly relevant within emerging AI-supported and algorithmically mediated organizational environments characterized by increasing opacity and distributed agency structures.

Third, the CCC contributes methodologically by adopting a configurational perspective capable of integrating organizational, relational, cognitive, and institutional dimensions within a unified analytical architecture. Rather than proposing a linear explanatory model, the framework provides an interpretive structure capable of differentiating corruption configurations according to their

governance dynamics, sustainability implications, and ethical characteristics. This multidimensional approach may support future comparative analyses, organizational diagnostics, governance risk assessments, and empirical operationalization efforts.

The framework also carries important implications for managerial and governance practice. The analysis suggests that anti-corruption systems focused exclusively on compliance and monitoring may be insufficient in organizational contexts characterized by coercion, fear dynamics, legitimacy ambiguity, or technologically mediated accountability diffusion. Effective anti-corruption governance increasingly requires organizational systems capable of protecting moral agency, encouraging ethical dissent, strengthening transparency, and preserving accountability within complex governance environments.

At the same time, the study presents several limitations. The CCC remains a conceptual and exploratory framework that has not yet undergone systematic empirical validation across organizational or institutional contexts. Future research could operationalize the model through qualitative case studies, comparative governance analyses, network approaches, or quantitative configurational methodologies aimed at testing the interaction among the proposed dimensions. Additional research may also explore the applicability of the framework within AI-governance environments, ESG reporting systems, transnational organizational networks, and politically exposed industries. Despite these limitations, the paper argues that understanding corruption within contemporary organizations requires moving beyond simplified distinctions between legal and illegal conduct or between ethical and unethical individuals. Corruption increasingly emerges through complex governance configurations involving power asymmetries, institutional fragmentation, coercive adaptation, and technologically mediated decision structures. By providing an integrative framework capable of analysing these dynamics, the Corruption Configuration Cube seeks to contribute to the development of more nuanced, systemic, and governance-oriented approaches to corruption research and organizational integrity.

Le emissioni che pesano in Borsa: un confronto tra Scope 1–2 e Scope 3

ANNA PRISCO[1], CHIARA LEGGERINI[2], IRENE RICCIARDI[3], MARTINA PERCUOCO[4]

Abstract

***Framing della ricerca**. Negli ultimi anni il cambiamento climatico è diventato un fattore centrale nelle decisioni strategiche delle imprese e nelle valutazioni dei mercati finanziari. Le emissioni di gas effetto serra sono sempre più interpretate come indicatori di rischio di lungo periodo; tuttavia, la letteratura si è concentrata prevalentemente sulle emissioni operative (Scope 1 e Scope 2), trascurando il ruolo delle emissioni generate lungo la catena del valore (Scope 3), che rappresentano spesso la quota maggiore dell'impronta carbonica complessiva.*
***Obiettivo della ricerca.** Il lavoro analizza se e in che misura il mercato azionario attribuisca una rilevanza differenziale alle emissioni di Scope 1, Scope 2 e Scope 3 nella determinazione del valore di mercato delle imprese.*
***Metodologia.** Lo studio adotta un approccio quantitativo basato su dati panel relativi a 1.172 imprese europee quotate nel periodo 2015–2024 (11.790 osservazioni). L'analisi empirica si fonda sul framework di valutazione di Ohlson e utilizza modelli di regressione a effetti casuali per stimare l'impatto delle diverse categorie di emissioni sul valore di mercato per azione, controllando per variabili contabili, organizzative e settoriali e conducendo test di robustezza.*
***Risultati**. I risultati mostrano che le emissioni complessive sono negativamente associate al valore di mercato. In particolare, l'effetto è guidato dalle emissioni di Scope 3, che risultano statisticamente significative, mentre le emissioni operative di Scope 1 e 2 non mostrano un impatto rilevante sulle valutazioni di mercato.*
***Limiti della ricerca.** L'analisi si basa su imprese europee quotate e su dati secondari disponibili nei database, che possono riflettere limiti di disclosure e di misurazione, soprattutto per le emissioni di Scope 3.*
***Implicazioni manageriali.** I risultati suggeriscono che le imprese dovrebbero integrare in modo più esplicito la gestione delle emissioni di filiera nelle strategie di sostenibilità, poiché tali emissioni risultano maggiormente rilevanti per gli investitori e per la creazione di valore nel lungo periodo.*
***Originalità della ricerca**. Il contributo principale consiste nell'analisi comparativa della rilevanza valutativa delle diverse categorie di emissioni, evidenziando il ruolo informativo specifico delle emissioni di Scope 3 nei mercati finanziari.*

Keywords: *Emissioni di gas a effetto serra, Scope 1, Scope 2, Scope 3, valore di mercato, regressione multipla*

1. Introduzione

Negli ultimi due decenni il cambiamento climatico è emerso come una delle principali sfide strategiche per le imprese, influenzando in modo crescente le decisioni manageriali, le politiche pubbliche e le valutazioni dei mercati finanziari. La letteratura dimostra infatti che le questioni ambientali, e in particolare le emissioni di gas a effetto serra, non rappresentano più un ambito meramente etico o reputazionale, ma costituiscono un fattore rilevante nella determinazione del valore economico delle imprese. Studi empirici mostrano che i mercati finanziari incorporano sempre più le informazioni legate alla performance ambientale nelle valutazioni azionarie, penalizzando le imprese caratterizzate da elevata intensità carbonica e premiando, al contrario, quelle che dimostrano capacità di riduzione delle emissioni e di gestione proattiva dei rischi climatici (Klassen e McLaughlin, 1996; Matsumura et al., 2014; Choi e Luo, 2021; Clarkson et al., 2015). In questo contesto, le emissioni di gas serra sono diventate un indicatore chiave non solo dell'impatto ambientale delle attività aziendali, ma anche dell'esposizione dell'impresa a rischi operativi, regolatori e reputazionali di lungo periodo. Evidenze empiriche mostrano che un'elevata impronta carbonica è associata a maggiori rischi di transizione, a una più elevata probabilità di interventi regolatori e a una crescente pressione da parte di investitori istituzionali e stakeholder finanziari, con

effetti negativi sul valore di mercato e sul costo del capitale (Chapple et al., 2013; Busch et al., 2022; Ahyan Panjwani et al., 2022).

Il Greenhouse Gas Protocol distingue le emissioni CO_2 in tre categorie: Scope 1, emissioni dirette derivanti da fonti controllate dall'impresa; Scope 2, emissioni indirette associate al consumo di energia acquistata; e Scope 3, emissioni indirette generate lungo la supply chain a monte e a valle, inclusi fornitori, trasporto, uso e fine vita dei prodotti. Sebbene Scope 1 e Scope 2 siano direttamente sotto il controllo manageriale, numerose evidenze mostrano che, in molti settori le emissioni di Scope 3 rappresentano la componente dominante dell'impronta carbonica complessiva, arrivando in diversi casi a superare la quota delle emissioni operative (Blanco, 2021; Hettler e Graf-Vlachy, 2024).

Fino ad oggi, la letteratura accademica si è concentrata prevalentemente sulle emissioni operative (Scope 1 e Scope 2), in quanto più facilmente misurabili, verificabili e direttamente gestibili attraverso interventi tecnologici o di efficienza energetica. Le emissioni di Scope 3, al contrario, presentano una maggiore complessità informativa e organizzativa, poiché dipendono da relazioni contrattuali con fornitori e clienti, da scelte di modello di business e da comportamenti di attori esterni al perimetro diretto dell'impresa (Tang e Demeritt, 2018; Butt et al., 2025). Tale complessità rende le emissioni di filiera meno controllabili dal management, ma al tempo stesso potenzialmente più informative, in quanto riflettono in misura maggiore la strategia aziendale, la configurazione della supply chain e la capacità manageriale di coordinare attori eterogenei lungo l'intera catena del valore.

Dal punto di vista dei mercati finanziari, tale distinzione è cruciale. La valutazione d'impresa non riflette soltanto la performance corrente, ma incorpora aspettative sulle prospettive future, sui rischi e sulla sostenibilità del modello di business nel lungo periodo. In questo senso, le emissioni Scope 3 potrebbero rappresentare un segnale rilevante per gli investitori, in quanto indicano l'esposizione dell'impresa a rischi climatici e regolatori che non possono essere mitigati esclusivamente attraverso interventi interni. Alti livelli di emissioni Scope 3 potrebbero infatti segnalare una forte dipendenza da fornitori carbon-intensive, una limitata flessibilità strategica o una maggiore vulnerabilità a cambiamenti normativi lungo la catena del valore, elementi che il mercato tende a interpretare come fonti di rischio sistemico (Busch et al., 2022; Blanco, 2021).

Nonostante la crescente attenzione regolatoria e mediatica verso lo Scope 3, manca ancora un'analisi sistematica e comparativa che valuti se e in che misura i mercati finanziari attribuiscano un peso differente alle diverse tipologie di emissioni nella determinazione del valore d'impresa. In particolare, la letteratura esistente tende ad aggregare le emissioni complessive o a focalizzarsi esclusivamente sulle emissioni operative, trascurando il potenziale ruolo strategico e informativo delle emissioni legate alla supply chain. Questa lacuna è particolarmente rilevante dal punto di vista manageriale, poiché può portare le imprese a concentrare risorse e investimenti su ambiti che non sono necessariamente quelli più rilevanti per la creazione di valore nel lungo periodo. Emerge, quindi, l'esigenza di chiarire se i mercati finanziari distinguano effettivamente tra le diverse componenti delle emissioni di gas a effetto serra nella valutazione delle imprese, attribuendo un peso differente alle emissioni generate all'interno dei confini operativi (Scope 1 e Scope 2) rispetto a quelle originate lungo la catena del valore (Scope 3).

Il presente lavoro nasce da questa esigenza e mira a colmare tale lacuna nella letteratura. In particolare, l'obiettivo della ricerca è duplice. Da un lato, il presente studio intende analizzare se le emissioni di Scope 3 esercitino un impatto più rilevante sul valore di mercato delle imprese rispetto alle emissioni di Scope 1 e Scope 2, riflettendo una maggiore sensibilità degli investitori verso i rischi climatici che si estendono oltre i confini organizzativi dell'impresa. Dall'altro lato, la ricerca si propone di esaminare se tale relazione vari in base al settore di attività, con particolare riferimento all'intensità carbonica del settore di appartenenza, che può amplificare o attenuare la rilevanza informativa delle diverse categorie di emissioni.

Alla luce delle evidenze discusse, la ricerca adotta un framework teorico integrato che combina la Stakeholder Theory e la Contingency Theory per interpretare il ruolo informativo delle emissioni di gas a effetto serra nella valutazione di mercato delle imprese. Dal punto di vista della Stakeholder Theory, le emissioni di gas a effetto serra rappresentano un segnale rilevante della capacità

dell'impresa di rispondere alle aspettative degli stakeholder chiave, in particolare degli investitori, sempre più attenti ai rischi climatici di lungo periodo. In questa prospettiva, la rilevanza informativa delle emissioni non dipende esclusivamente dalla loro entità quantitativa, ma dalla loro capacità di segnalare l'esposizione dell'impresa a rischi reputazionali, regolatori e strategici che possono compromettere la sostenibilità del modello di business nel tempo. Le emissioni di Scope 3, in quanto generate lungo relazioni di interdipendenza con fornitori, partner e clienti, riflettono in misura maggiore la qualità della governance delle relazioni di filiera e la capacità dell'impresa di coordinare attori esterni al proprio perimetro organizzativo, rendendole particolarmente salienti per gli stakeholder finanziari. Allo stesso modo, la Contingency Theory consente di estendere questa interpretazione, evidenziando che la rilevanza economica delle emissioni non è uniforme, ma dipende dal grado di allineamento tra la configurazione organizzativa dell'impresa e le pressioni ambientali e istituzionali del contesto in cui opera. In questa prospettiva, le emissioni di gas a effetto serra possono essere interpretate come un indicatore di misfit tra strategie operative, struttura della supply chain e richieste di decarbonizzazione imposte dal contesto competitivo e regolatorio.

Il presente studio contribuisce alla letteratura sulla valutazione d'impresa e sulla sostenibilità ambientale attraverso un'analisi empirica della rilevanza differenziale delle emissioni di Scope 1, Scope 2 e Scope 3 nella determinazione del valore di mercato delle imprese europee quotate. In tal modo, il lavoro fornisce evidenze utili sia sul piano teorico, chiarendo il ruolo informativo delle emissioni lungo la supply chain nei processi di valutazione finanziaria, sia sul piano manageriale, offrendo indicazioni su quali dimensioni della performance ambientale risultino maggiormente rilevanti per la creazione di valore nel lungo periodo.

L'articolo è strutturato come segue. Il paragrafo 2 presenta il framework teorico, il paragrafo 3 sviluppa le ipotesi di ricerca, il paragrafo 4 descrive la metodologia e il paragrafo 5 illustra dati e variabili. Il paragrafo 6 riporta i risultati empirici e i test di robustezza, mentre il paragrafo 7 discute le evidenze. Infine, il paragrafo 8 presenta implicazioni, limiti e conclusioni.

2. Framework teorico

2.1 Stakeholder theory

La stakeholder theory è un quadro centrale per comprendere la sostenibilità come leva di creazione di valore, poiché sostiene che le imprese debbano considerare non solo gli azionisti ma anche tutti gli attori che possono influenzare o essere influenzati dalle loro attività (Freeman, 2002). In questa prospettiva, l'impresa è una rete di relazioni e la performance include dimensioni sociali, ambientali ed etiche oltre ai risultati economici (Kivits e Sawang, 2021); di conseguenza, il valore sostenibile deriva dalla capacità di costruire e mantenere relazioni cooperative di lungo periodo con gli stakeholder, che i manager devono governare riconoscendo le interdipendenze tra attori e decisioni aziendali (Sciarelli, 2012;Parmar et al., 2010; Gutterman, 2023). Entro tale cornice, la riduzione delle emissioni può generare valore perché rafforza fiducia e legittimazione presso gli stakeholder e, attraverso questo canale, accresce la reputazione aziendale come asset intangibile in grado di sostenere la valutazione di mercato (Jo et al., 2016; Raithel et al., 2015). In particolare, la reputazione è interpretata come una risorsa strategica costruita nel tempo tramite relazioni con gli stakeholder, difficilmente imitabile e capace di produrre valore economico duraturo (Romenti et al., 2008). Evidenze empiriche confermano che il miglioramento delle performance ambientali, inclusa la riduzione dei costi ambientali, si associa a un rafforzamento reputazionale e a un incremento del valore aziendale, con effetti più marcati in contesti in cui l'attenzione istituzionale e sociale verso il clima è più elevata (Jo et al., 2016). Coerentemente, gli investitori possono interpretare la riduzione delle emissioni come una componente di valore intangibile, premiando le imprese che mostrano maggiore capacità di contenimento dei gas serra con valutazioni più alte (Nishitani et al., 2012). La reputazione opera quindi come meccanismo di trasmissione tra segnali ambientali e creazione di valore: è generata da segnali al mercato che vengono recepiti dagli stakeholder e trasformati in

vantaggi competitivi, e le percezioni reputazionali, soprattutto quando fondate su dimensioni non finanziarie, risultano predittive di maggiore valore per gli azionisti e di rendimenti futuri più elevati (Raithel et al., 2015;Góis et al., 2017).

2.2 Contingency Theory

La Contingency Theory, sviluppata da Donaldson nel 1995, afferma che la performance organizzativa dipende dall'allineamento (fit) tra assetti organizzativi e contingenze interne ed esterne; quando emerge un disallineamento (misfit), l'organizzazione subisce penalizzazioni di efficacia e tende ad attivare processi di aggiustamento per recuperare coerenza funzionale (Donaldson, 1995; Donaldson, 2001). In questa prospettiva non esiste una configurazione universalmente ottimale, perché la razionalità delle scelte organizzative è funzione delle condizioni contestuali che definiscono vincoli, costi e opportunità; il contesto diventa dunque parte integrante dell'interpretazione degli esiti (Van de Ven, 1984; Drazin and Van de Ven, 1984). Questa cornice è stata scelta perché permette di leggere le emissioni di gas a effetto serra non solo come un dato ambientale, ma come un indicatore di quanto l'impresa sia coerente con le richieste di decarbonizzazione provenienti dal contesto competitivo e istituzionale. In altri termini, livelli emissivi elevati possono segnalare un disallineamento tra il modo in cui l'azienda opera e le pressioni esterne verso la transizione climatica, mentre livelli più contenuti indicano una maggiore capacità di adattamento. Inoltre, la Contingency Theory chiarisce che le conseguenze economiche di questo (dis)allineamento non sono uguali per tutte le imprese, perché dipendono dalle specifiche condizioni in cui esse operano e dall'intensità delle pressioni ambientali e istituzionali cui sono sottoposte (Donaldson, 2001; Berkhout et al., 2012). L'efficacia organizzativa non deriva da soluzioni "ottimali" valide per tutti, ma dalla coerenza tra assetti, decisioni e pressioni esterne, che possono variare per intensità e natura nel tempo e tra contesti competitivi differenti (Van de Ven, 1984; Drazin and Van de Ven, 1984). Inoltre, la teoria enfatizza che le organizzazioni non sono entità statiche, ma sistemi adattivi che, di fronte a disallineamenti rilevanti, attivano processi di aggiustamento strutturale e gestionale per recuperare coerenza e performance , in linea con concezioni più dinamiche del fit (Volberda et al., 2012; Donaldson, 2001). Nel complesso, tale framework offre una lente interpretativa solida per inquadrare come specifiche pressioni ambientali e caratteristiche operative possano incidere sulla performance e sulla valutazione esterna delle imprese, evidenziando che gli effetti osservati tendono a manifestarsi in modo differenziato a seconda delle condizioni in cui le organizzazioni operano (Donaldson, 1995; Donaldson, 2001).

3. Ipotesi di Ricerca

La letteratura evidenzia in modo crescente che le imprese in grado di generare un impatto ambientale positivo tendono a ottenere anche migliori performance economico-finanziarie. Le iniziative orientate alla riduzione degli impatti ambientali contribuiscono infatti a mitigare i rischi regolatori e reputazionali e a rafforzare l'efficienza complessiva dell'impresa. Studi basati su analisi di eventi mostrano che il mercato reagisce positivamente a riconoscimenti ambientali e penalizza, invece, crisi o comportamenti ambientalmente dannosi, riflettendo tali informazioni nei rendimenti azionari (Klassen e McLaughlin, 1996; Yamashita et al., 1999). Evidenze successive confermano che livelli inferiori di emissioni e pratiche più efficaci di prevenzione dei rifiuti sono associati a migliori risultati operativi e finanziari (King e Lenox, 2002). All'interno di questo quadro, le emissioni di gas a effetto serra emergono come una dimensione centrale nella valutazione di mercato delle imprese. Numerosi studi documentano che un'elevata intensità di gas a effetto serra comporta penalizzazioni significative in termini di valore aziendale e capitalizzazione di mercato, mentre il superamento delle quote di emissione è negativamente associato al valore dell'impresa (Chapple et al., 2013; Clarkson et al., 2015). Al contrario, la riduzione delle emissioni di gas serra risulta positivamente correlata al valore di mercato, suggerendo che tali sforzi siano interpretati dagli investitori come investimenti in

risorse intangibili e nella sostenibilità futura dell'impresa (Matsumura et al., 2014; Nishitani e Kokubu, 2012; Choi e Luo, 2021). Tali evidenze possono essere lette alla luce della Stakeholder Theory, secondo cui le imprese creano valore nel lungo periodo quando riescono a soddisfare le aspettative dei diversi stakeholder. Le strategie di riduzione delle emissioni di gas a effetto serra contribuiscono a migliorare la reputazione aziendale e a segnalare un impegno credibile verso la sostenibilità, favorendo una valutazione più positiva da parte di investitori e mercati finanziari. In questo processo, non solo i risultati ambientali effettivi, ma anche la divulgazione volontaria delle strategie e degli obiettivi di riduzione delle emissioni giocano un ruolo rilevante nel rafforzare la fiducia degli stakeholder e nel sostenere la creazione di valore (Jacobs, 2014). Sulla base di tale evidenze si formula la seguente ipotesi:

H1. A parità delle altre condizioni, una riduzione delle emissioni di CO_2 è associata a un aumento del valore di mercato delle azioni.

Il valore di mercato dell'impresa riflette le aspettative informative e i rischi percepiti dagli investitori. Storicamente tali aspettative si sono concentrate prevalentemente sulle emissioni di Scope 1 e Scope 2, in quanto più facilmente misurabili e direttamente controllabili (Eccles et al., 2011; Kalesnik et al., 2021). Tuttavia, la letteratura più recente evidenzia un progressivo spostamento dell'attenzione verso le emissioni di Scope 3, poiché rappresentano la quota predominante dell'impronta carbonica delle imprese e riflettono in misura maggiore i rischi normativi, reputazionali e legati alla catena di fornitura (Blanco, 2021; Hettler e Graf-Vlachy, 2024). Le emissioni di Scope 3 sono infatti generate lungo relazioni di interdipendenza con fornitori, partner e clienti, e possono costituire emissioni di Scope 1 o 2 per altri attori economici, rendendo evidente la natura sistemica della contabilizzazione del gas a effetto serra (Butt et al., 2025). In questo contesto, gli investitori utilizzano sempre più spesso le informazioni di Scope 3 come proxy della capacità dell'impresa di gestire tali relazioni e di affrontare rischi climatici che si estendono oltre i confini organizzativi (Tang e Demeritt, 2018; Blanco, 2021). Sebbene la rendicontazione di Scope 3 sia tuttora volontaria (Blanco, 2021) e alcuni studi riportino risultati contrastanti o non significativi in termini di performance contabile (Kayser et al., 2026), la disclosure accurata di tali informazioni è associata a benefici indiretti rilevanti, quali una riduzione del costo del debito (Ahyan Panjwani et al., 2022), un miglioramento dell'efficienza operativa (Park et al., 2025) e una maggiore trasparenza informativa richiesta dagli investitori (Busch et al., 2022). Alla luce di queste evidenze si formula la seguente ipotesi:

H2. A parità delle altre condizioni, le emissioni di Scope 3 esercitano un'influenza più forte sul valore di mercato delle azioni rispetto alle emissioni di Scope 1 e Scope 2.

La letteratura suggerisce che la relazione tra la riduzione delle emissioni di CO_2 (Scope 1 e Scope 2) e il valore di mercato delle azioni sia fortemente eterogenea e dipenda in misura rilevante dal settore di appartenenza dell'impresa e dal contesto competitivo in cui essa opera. Analisi settoriali mostrano come l'impatto delle emissioni sulla performance finanziaria non sia uniforme: Gonenc e Scholtens (2017), concentrandosi sulle industrie dei combustibili fossili, evidenziano effetti differenziati tra sotto-settori, con impatti nulli nel comparto chimico, effetti negativi sui rendimenti nel settore del carbone e risultati misti nel settore petrolifero e del gas. Evidenze più recenti rafforzano l'idea che la sensibilità settoriale amplifichi l'effetto delle emissioni sulla performance di mercato. Desai et al. (2022) dimostrano che l'impatto negativo delle emissioni di gas a effetto serra sulla performance finanziaria risulta significativamente più marcato per le imprese considerate "sensibili" dal punto di vista ambientale rispetto a quelle non sensibili, suggerendo che l'esposizione settoriale al rischio climatico giochi un ruolo chiave nella valutazione da parte dei mercati. In modo coerente, Yu et al. (2021) evidenziano come i benefici finanziari derivanti dai sistemi di scambio delle emissioni siano più pronunciati per le imprese non statali e per quelle operanti in settori meno energivori. Ulteriori contributi sottolineano che l'impatto delle strategie ambientali sulla performance

economico-finanziaria non è diretto, ma mediato da meccanismi competitivi specifici del settore. López-Gamero et al. (2009) mostrano che il vantaggio competitivo di costo derivante dalle iniziative ambientali incide in modo diverso sulla performance finanziaria nei settori regolamentati rispetto a quelli dei servizi. Analogamente, van Emous et al. (2021) evidenziano che, sebbene la riduzione delle emissioni sia generalmente associata a migliori indicatori finanziari, la forza di tale relazione dipende da caratteristiche specifiche dell'impresa e dal settore in cui essa opera. Infine Le e Nguyen-Phung (2024) mostrano come la connessione tra intensità delle emissioni di gas serra e corporate financial performance vari significativamente tra settori e aree geografiche, suggerendo che le dinamiche istituzionali e di mercato locali influenzino la capacità delle imprese di tradurre le performance ambientali in valore economico. In questa prospettiva, anche la possibilità di trasferire i costi ambientali ai consumatori, approssimata dal grado di concentrazione del settore e dal posizionamento relativo dell'impresa in termini di emissioni, emerge come un ulteriore fattore chiave nel determinare l'impatto delle riduzioni di CO_2 sul valore di mercato delle azioni (Clarkson et al., 2015). Pertanto si ipotizza che:

H3. L'effetto della riduzione delle emissioni di CO_2 sul valore di mercato delle azioni varia in funzione del settore di appartenenza dell'impresa, risultando differenziato tra settori a diversa intensità di gas a effetto serra.

4. Metodologia

Per valutare le nostre ipotesi di ricerca, adottiamo un approccio quantitativo empirico basato sull'analisi di dati panel raccolti da un campione di società europee quotate (Greene, 2011; Wooldridge, 2019). La strategia empirica si basa sul framework di valutazione sviluppato da Ohlson (1995), che spiega il valore di mercato delle aziende combinando fondamentali contabili con informazioni extracontabili rilevanti per le decisioni di valutazione degli investitori. In linea con questo framework, indaghiamo se le emissioni di gas a effetto serra, in quanto dimensione non finanziaria chiave e rilevante per il valore, influenzano il valore di mercato delle aziende al di là delle tradizionali informazioni contabili.

Una delle principali sfide metodologiche nello studio della relazione tra performance ambientale e valutazione aziendale è il potenziale problema dell'endogeneità, derivante da causalità inversa o da bias da variabili omesse. Per mitigare questo problema, sono state ritardate tutte le variabili indipendenti di un anno, seguendo pratiche consolidate nella ricerca in materia di contabilità, corporate governance e sostenibilità (Liang et al., 2013; Ashwin et al., 2015). Questa struttura di ritardo aiuta a stabilire una relazione causale più plausibile, garantendo che le variazioni nelle emissioni e nelle caratteristiche aziendali precedano le variazioni del valore di mercato. Viene adottato un modello di regressione multipla per analizzare l'impatto di diverse misure di emissioni di gas a effetto serra sul valore di mercato delle aziende, operazionalizzato come prezzo di mercato per azione. In linea con il modello di Ohlson (1995), il valore di mercato è specificato in funzione dei fondamentali contabili, ovvero il valore contabile per azione e l'utile per azione, e di un insieme di variabili non contabili che catturano le prestazioni ambientali e le caratteristiche di governance delle aziende.

Le emissioni di gas a effetto serra sono gestite tramite specifiche alternative. In primo luogo, si considerano le emissioni totali di Scope, che aggregano tutte le fonti di emissioni di gas serra. In secondo luogo, per cogliere l'eterogeneità tra le fonti di emissione, è stata fatta una distinzione tra emissioni di Scope 1-2, che riflettono le emissioni dirette e indirette legate all'energia, ed emissioni di Scope 3, che catturano le emissioni indirette lungo la catena del valore. Inoltre, per tenere conto delle differenze strutturali tra i settori, è stato incluso un modello che identifica i settori ad alta intensità di gas a effetto serra e i termini di interazione tra emissioni e intensità di gas a effetto serra settoriale.

Data la struttura a panel del dataset, abbiamo considerato sia modelli a effetti fissi (FE) che a effetti casuali (RE) per controllare l'eterogeneità non osservata tra le imprese (Greene, 2011; Wooldridge, 2019). Per determinare lo stimatore più appropriato, abbiamo condotto il test di Hausman, che confronta la coerenza degli stimatori a effetti fissi e casuali. I risultati del test hanno favorito la specificazione a effetti casuali, indicando che gli effetti non osservati a livello di impresa non sono correlati con le variabili esplicative e consentendo una stima più efficiente (Greene, 2011). I modelli a effetti casuali sono particolarmente adatti in contesti caratterizzati da un'ampia variazione trasversale e una dimensione temporale relativamente breve (Wooldridge, 2019).
Per analizzare la relazione tra emissioni di gas a effetto serra e valutazione aziendale, sono stati stimati i seguenti modelli di regressione:

Modello 1: Valore di mercato = f(Scope totale + Variabili di controllo)

Modello 2: Valore di mercato = f(Scope totale × Settore CO_2 + Variabili di controllo)

Per distinguere ulteriormente gli effetti di valutazione delle diverse fonti di emissione, stimiamo modelli aggiuntivi che distinguono tra categorie di Scope:

Modello 3: Valore di mercato = f(Scope 1–2 + Scope 3 + Variabili di controllo)

Modello 4: Valore di mercato = f(Scope 1–2 × Settore CO_2 + Scope 3 × Settore CO_2 + Variabili di controllo)

In tutte le specifiche, le variabili di controllo includono il valore contabile per azione, l'utile per azione, l'età dell'azienda, la dimensione del consiglio di amministrazione, la diversità di genere nel consiglio, il numero di dipendenti e il ritorno sulle attività (ROA), in linea con la letteratura sulla valutazione aziendale, la governance aziendale e le performance ambientali. Tutti i modelli includono anche un termine costante e sono stimati con errori standard robusti.

5. Dati e variabili

Il campione di ricerca comprende 1.172 società europee quotate, osservate nel periodo 2015-2024, per un totale di 11.790 osservazioni aziendali-anno. Questa struttura longitudinale consente di cogliere sia le differenze trasversali tra le aziende sia le dinamiche temporali nella valutazione di mercato e nei profili delle emissioni di gas a effetto serra.
Per costruire il set di dati, abbiamo integrato informazioni provenienti da due fonti autorevoli. I dati sul valore di mercato delle aziende e sulle variabili contabili basate sulle azioni, tra cui il valore di mercato per azione, il valore contabile per azione e l'utile per azione, sono stati ottenuti da Refinitiv, un fornitore ampiamente riconosciuto di informazioni aziendali finanziarie e relative alla sostenibilità. Refinitiv è stata utilizzata anche come fonte primaria per i dati sulle emissioni di gas a effetto serra, comprese le emissioni totali di Scope, nonché le emissioni di Scope 1, Scope 2 e Scope 3, che vengono riportate utilizzando metodologie standardizzate e garantiscono la comparabilità tra paesi e settori.

Le variabili di controllo a livello aziendale sono state raccolte dal database Orbis, fornito da Bureau Van Dijk. Orbis fornisce informazioni dettagliate sulle caratteristiche strutturali e di governance delle aziende, consentendoci di controllare l'età dell'azienda, le dimensioni del consiglio di amministrazione, la composizione di genere del consiglio, il numero di dipendenti, la redditività (ROA) e la classificazione del settore. Queste variabili catturano dimensioni chiave della struttura organizzativa, della governance aziendale e della scala operativa che possono influenzare la valutazione aziendale.

L'integrazione dei dati Refinitiv e Orbis garantisce un set di dati completo e affidabile, pienamente coerente con il quadro di valutazione di Ohlson (1995), consentendo una valutazione solida per stabilire se le emissioni di gas a effetto serra rappresentino informazioni non contabili rilevanti per il valore, valutate dai mercati finanziari.

La **Tabella 1** riporta le fonti e le definizioni delle variabili dipendenti, indipendenti e di controllo utilizzate nell'analisi empirica.

Tab. 1: Variabili

Variabile	Definizione	Fonte
Variabili dipendenti		
Valore di mercato	Variazione percentuale del valore di mercato per azione alla fine dell'anno di riferimento.	Thomson Reuters
Variabili indipendenti		
Scope totale	Variazione percentuale complessiva delle emissioni di gas a effetto serra dell'impresa, calcolata come somma delle emissioni Scope 1, Scope 2 e Scope 3, espressa in tonnellate di CO_2 equivalente (tCO_2e).	Thomson Reuters
Scope 1-2	Variazione percentuale complessiva delle emissioni dirette (Scope 1) e indirette da consumo energetico (Scope 2) generate dalle attività operative dell'impresa, espresse in tonnellate di CO_2 equivalente (tCO_2e).	Thomson Reuters
Scope 3	Variazione percentuale delle emissioni indirette lungo l'intera catena del valore dell'impresa (fornitori, logistica, uso dei prodotti, fine vita), espresse in tonnellate di CO_2 equivalente (tCO_2e).	Thomson Reuters
Settore CO_2	Variabile dummy che assume valore 1 se l'impresa opera in un settore ad elevata intensità di emissioni di anidride carbonica (CO_2), e 0 altrimenti. In linea con la letteratura, i settori carbon-intensive includono energia, ferro e acciaio, petrolchimico, cemento, ceramica, vetro, carta, alimentare e bevande.	Thomson Reuters
Variabili di controllo		
Valore contabile per azione		Thomson Reuters
Valore degli utili per azione		Thomson Reuters
Età impresa	Numero di anni trascorsi dalla fondazione dell'impresa.	ORBIS
Grandezza board	Numero totale di componenti del consiglio di amministrazione.	Thomson Reuters
Genere board	Percentuale di donne presenti nel consiglio di amministrazione.	Thomson Reuters
Numero dipendenti	Numero totale di dipendenti dell'impresa.	ORBIS
ROA	Rapporto tra reddito e totale delle attività, indicatore della redditività dell'impresa.	ORBIS

Fonte: elaborazione propria

Variabile dipendente. *Valore di mercato*, misurato come variazione percentuale del valore di mercato per azione alla fine dell'anno di riferimento (Macchioni et al., 2024). Tale indicatore consente di cogliere la dinamica della valutazione dell'impresa da parte del mercato, riflettendo le aspettative degli investitori rispetto alle performance economiche e alla capacità dell'impresa di generare valore nel tempo.

Variabili indipendenti. Le principali variabili indipendenti riguardano la performance ambientale dell'impresa in termini di emissioni di gas a effetto serra, misurata attraverso le variazioni percentuali delle emissioni di CO_2 equivalente (Hettler et al. 2024).

In primo luogo, viene considerato lo *Scope totale*, definito come la variazione percentuale complessiva delle emissioni di gas a effetto serra, calcolata come somma delle emissioni Scope 1, Scope 2 e Scope 3, ed espressa in tonnellate di CO_2 equivalente (tCO_2e). Questo indicatore fornisce una misura sintetica dell'impatto climatico complessivo dell'impresa, includendo sia le emissioni operative sia quelle generate lungo la catena del valore. In secondo luogo, viene utilizzata la variabile *Scope 1–2*, che misura la variazione percentuale delle emissioni dirette (Scope 1) e delle

emissioni indirette derivanti dal consumo energetico (Scope 2) associate alle attività operative dell'impresa. Tale indicatore consente di isolare la componente emissiva maggiormente sotto il controllo diretto del management aziendale. In terzo luogo, viene analizzato lo *Scope 3*, definito come la variazione percentuale delle emissioni indirette generate lungo l'intera catena del valore, inclusi fornitori, logistica, utilizzo dei prodotti e fase di fine vita. Le emissioni di Scope 3, pur presentando una maggiore eterogeneità in termini di misurazione e disclosure, rappresentano una componente rilevante dell'impronta climatica complessiva dell'impresa.
Infine, l'analisi include la variabile *Settore CO_2,* una dummy settoriale che assume valore pari a 1 se l'impresa opera in un settore ad elevata intensità di emissioni di anidride carbonica, e 0 altrimenti (Macchioni et al., 2024). In linea con la letteratura esistente, sono classificati come carbon-intensive i settori dell'energia, del ferro e acciaio, del petrolchimico, del cemento, della ceramica, del vetro, della carta, dell'industria alimentare e delle bevande. L'inclusione di tale variabile consente di controllare per differenze strutturali tra settori caratterizzati da diversi livelli di intensità emissiva.

Variabili di controllo. Tra le variabili di controllo, l'analisi include il *valore contabile per azione*, che misura il valore del patrimonio netto dell'impresa attribuibile a ciascuna azione alla fine dell'anno di riferimento (Macchioni et al. 2024). Questo indicatore riflette la solidità patrimoniale dell'impresa e consente di controllare per differenze nella struttura finanziaria e nel valore contabile sottostante alle azioni, elementi che possono influenzare la valutazione di mercato. Viene inoltre considerato il *Valore degli utili per azione*, che misura l'ammontare degli utili attribuibili a ciascuna azione alla fine dell'anno di riferimento (Macchioni et al. 2024). Tale variabile rappresenta un indicatore chiave della redditività dell'impresa e della sua capacità di generare profitti per gli azionisti, permettendo di isolare l'effetto delle performance economiche sulle dinamiche del valore di mercato.
L'analisi include l'età dell'impresa, misurata come il numero di anni trascorsi dalla fondazione, quale indicatore della maturità aziendale e dell'esperienza operativa accumulata nel tempo (Leggerini et al., 2025). Imprese più mature possono beneficiare di una maggiore stabilità, reputazione e prevedibilità dei flussi di cassa, elementi che influenzano le aspettative degli investitori e, di conseguenza, le variazioni del valore di mercato.
Le caratteristiche del consiglio di amministrazione sono considerate attraverso la dimensione del board, misurata come il numero totale dei componenti del consiglio, e la composizione di genere del board, espressa come percentuale di donne presenti (Leggerini et al., 2025). Tali variabili catturano aspetti della struttura di governance che possono incidere sui processi decisionali, sulla qualità del monitoraggio manageriale e sulla percezione del rischio da parte del mercato, con potenziali effetti sull'andamento del titolo.
La dimensione dell'impresa, misurata dal numero totale di dipendenti, è inclusa per controllare le differenze nella scala operativa e nella visibilità sul mercato finanziario (Pan et al., 2021). Imprese di maggiori dimensioni tendono a presentare una copertura informativa più ampia, una minore volatilità e una diversa sensibilità agli shock di mercato, fattori che possono influenzare le variazioni del valore di mercato.
Infine, la redditività è misurata attraverso il Return on Assets (ROA), definito come il rapporto tra reddito e totale delle attività (Pan et al., 2021). Il ROA rappresenta un indicatore chiave della capacità dell'impresa di utilizzare in modo efficiente le proprie risorse per generare profitti e costituisce un determinante fondamentale delle aspettative degli investitori, incidendo direttamente sulla valutazione di mercato e sulle dinamiche del prezzo delle azioni.

6. Risultati

Per valutare la presenza di multicollinearità, sono stati esaminati i fattori di inflazione della varianza (Variance Inflation Factors, VIF), che risultano tutti inferiori alla soglia prudenziale di 5 (O'Brien et al., 2007). Inoltre, sono stati analizzati i livelli di correlazione tra le variabili indipendenti,

che sono risultati moderati, indicando che la multicollinearità non rappresenta un problema nei modelli stimati. La Tabella 2 fornisce una sintesi completa delle statistiche descrittive relative all'intero campione. La Tabella 3 riporta i risultati.

Tab. 2: Statistiche descrittive

Variabile	Obs	Mean	Std. Dev.	Min	Max
Valore di mercato	11790	0.101	0.493	-0.99	9.951

I risultati riportati in Tabella 3 mostrano che lo *Scope totale* presenta un coefficiente negativo e statisticamente significativo in entrambi i modelli (−0.000930 e −0.000977; $p<0.01$), indicando che un aumento delle emissioni complessive di gas a effetto serra è associato a una riduzione della variazione del valore di mercato. Questo risultato suggerisce che il mercato penalizza le imprese con

peggiori performance emissive, coerentemente con una crescente attenzione degli investitori ai rischi climatici.

La variabile *Settore CO_2* mostra anch'essa un effetto negativo e significativo (−0.0193 e −0.0196; p<0.05), evidenziando che le imprese operanti in settori ad alta intensità carbonica sperimentano variazioni del valore di mercato inferiori rispetto alle imprese appartenenti a settori meno emissivi. Ciò riflette una possibile penalizzazione strutturale legata a maggiori rischi regolatori e di transizione.

Nel Modello 2, l'interazione tra Scope totale e Settore CO_2 risulta positiva ma non statisticamente significativa (0.000553), suggerendo che l'effetto negativo delle emissioni complessive sul valore di mercato non differisce in modo sostanziale tra imprese carbon-intensive e non carbon-intensive. Questo risultato indica che il mercato reagisce in modo simile alle variazioni emissive, indipendentemente dal settore di appartenenza. La Tabella 4 riporta i risultati.

I risultati riportati in Tabella 4 per i Modelli 3 e 4 mostrano che le diverse componenti delle emissioni di gas a effetto serra hanno effetti eterogenei sulle variazioni del valore di mercato.

In particolare, le emissioni *Scope 1–2* non risultano statisticamente significative in entrambi i modelli (−7.27e−05 e −2.45e−05), suggerendo che le variazioni delle emissioni operative dirette e indirette da consumo energetico non sono immediatamente incorporate nelle valutazioni di mercato. Questo risultato indica che il mercato potrebbe percepire tali emissioni come più controllabili o già attese, riducendone l'impatto informativo sul prezzo delle azioni.

Al contrario, le emissioni *Scope 3* mostrano un coefficiente negativo e altamente significativo in entrambi i modelli (−0.000658 e −0.000790; $p<0.01$), evidenziando che un aumento delle emissioni lungo la catena del valore è associato a una riduzione significativa del valore di mercato. Questo risultato suggerisce che gli investitori attribuiscono particolare rilevanza alle emissioni indirette,

probabilmente in quanto più difficili da controllare, più esposte a rischi reputazionali e maggiormente soggette a incertezze regolatorie.
La variabile *Settore CO_2* mantiene un effetto negativo e significativo (−0.0192 e −0.0193; $p<0.05$), confermando che le imprese appartenenti a settori ad alta intensità carbonica sperimentano variazioni del valore di mercato inferiori rispetto alle imprese operanti in settori meno emissivi, anche quando si controlla per le diverse componenti delle emissioni.
Nel Modello 4, le interazioni tra le emissioni e il Settore CO_2 non risultano statisticamente significative. In particolare, l'interazione *Scope 1–2 × Settore CO_2* presenta un coefficiente negativo (−0.00922), mentre l'interazione *Scope 3 × Settore CO_2* è positiva (0.000931), ma in entrambi i casi l'assenza di significatività statistica suggerisce che l'impatto delle variazioni emissive sul valore di mercato non differisce in modo sostanziale tra imprese carbon-intensive e non carbon-intensive. Ciò indica che il mercato reagisce in maniera simile alle informazioni sulle emissioni, indipendentemente dal settore di appartenenza.

6.1 Test di robustezza

La Tabella 5 riporta i risultati dei test di robustezza, nei quali le emissioni sono considerate separatamente per Scope 1, Scope 2 e Scope 3; i risultati confermano quanto emerso nelle analisi precedenti, evidenziando la coerenza degli effetti stimati sul valore di mercato.

Come ulteriore test di robustezza, le emissioni sono state misurate in termini normalizzati per milione di dollari di valore economico aggiunto (EVIC) (Tabella 6,7,8); anche in questo caso, i risultati risultano pienamente coerenti e consistenti con le evidenze emerse nelle analisi principali.

7. Discussione dei risultati

Il presente studio analizza se e in che misura i mercati finanziari distinguano tra le diverse componenti delle emissioni di gas a effetto serra nella valutazione delle imprese, con particolare attenzione al ruolo delle emissioni generate lungo la catena del valore (Scope 3). I risultati empirici mostrano che, sebbene le emissioni complessive siano negativamente associate al valore di mercato,

tale relazione è interamente guidata dalle emissioni di Scope 3, mentre le emissioni operative di Scope 1 e Scope 2 non risultano statisticamente significative. Questa evidenza suggerisce che i mercati finanziari attribuiscano un peso differenziato alle diverse fonti di emissione. In primo luogo, la significatività negativa delle emissioni di Scope 3 è coerente con la letteratura che interpreta le emissioni di gas a effetto serra come indicatori di rischio climatico e di transizione incorporati nelle valutazioni di mercato (Matsumura et al., 2014; Choi e Luo, 2021; Busch et al., 2022). Tuttavia, a differenza di molti studi precedenti che si concentrano sulle emissioni operative o su misure aggregate (Clarkson et al., 2015; Matsumura et al., 2014), i risultati evidenziano che la penalizzazione di mercato è associata principalmente alle emissioni generate lungo la supply chain, ovvero quelle scope 3. Questo risultato è coerente con contributi recenti che sottolineano come le emissioni di Scope 3 riflettano in misura maggiore l'esposizione dell'impresa a rischi sistemici e difficilmente mitigabili nel breve periodo (Blanco, 2021; Hettler e Graf-Vlachy, 2024).

In secondo luogo, la non significatività delle emissioni di Scope 1 e Scope 2 suggerisce che il mercato possa considerare tali informazioni come ampiamente standardizzate e già incorporate nei prezzi. Questo risultato è in linea con l'idea che le emissioni operative, essendo più facilmente misurabili, regolamentate e soggette a obblighi di disclosure, abbiano progressivamente perso contenuto informativo marginale (Eccles et al., 2011; Kalesnik et al., 2021). In questa prospettiva, la gestione delle emissioni di Scope 1 e Scope 2 appare maggiormente associata a logiche di conformità regolatoria piuttosto che a un fattore di differenziazione nelle valutazioni di mercato, confermando evidenze precedenti che mostrano effetti eterogenei o nulli delle emissioni operative sulla performance finanziaria (Gonenc e Scholtens, 2017; Kayser et al., 2026).

Un ulteriore risultato rilevante riguarda l'assenza di un effetto moderatore significativo del settore di appartenenza. Sebbene la letteratura suggerisca che l'impatto delle emissioni sulla performance finanziaria possa variare in funzione dell'intensità carbonica del settore (Clarkson et al., 2015; Desai et al., 2022), i risultati indicano che la relazione tra emissioni e valore di mercato non differisce in modo sostanziale tra settori carbon-intensive e non carbon-intensive. Questo suggerisce che il mercato reagisca in modo simile alle informazioni sulle emissioni, interpretandole come una fonte di rischio che incide sulle prospettive di lungo periodo delle imprese indipendentemente dal settore di appartenenza, in linea con evidenze che descrivono il rischio climatico come un rischio finanziario sempre più generalizzato (Busch et al., 2022).

8. Conclusioni, implicazioni e limiti

Il presente studio analizza la rilevanza valutativa delle emissioni di gas a effetto serra distinguendo tra Scope 1, Scope 2 e Scope 3, fornendo evidenze empiriche su come i mercati finanziari incorporino le informazioni ambientali nella determinazione del valore di mercato delle imprese. I risultati mostrano che, sebbene le emissioni complessive siano negativamente associate al valore di mercato, tale relazione è interamente guidata dalle emissioni di Scope 3, mentre le emissioni operative di Scope 1 e Scope 2 non risultano statisticamente significative. Questa evidenza suggerisce che i mercati finanziari non trattano le emissioni di gas a effetto serra come un indicatore omogeneo, ma attribuiscono maggiore rilevanza alle emissioni generate lungo la catena del valore, interpretando come un segnale più credibile dell'esposizione dell'impresa a rischi climatici, regolatori e strategici di lungo periodo.

Dal punto di vista teorico, lo studio contribuisce alla letteratura sulla "value relevance" delle informazioni ambientali mostrando che il contenuto informativo delle emissioni di gas a effetto serra dipende dalla loro natura organizzativa e strategica e non soltanto dalla loro entità quantitativa (Matsumura et al., 2014; Choi e Luo, 2021). In particolare, le emissioni di Scope 3 emergono come un indicatore rilevante della qualità della governance inter-organizzativa e della capacità dell'impresa di gestire relazioni complesse lungo la supply chain, rafforzando una lettura stakeholder-oriented della creazione di valore (Freeman, 2002; Parmar et al., 2010; Blanco, 2021). Coerentemente con la

Contingency Theory, tali emissioni possono inoltre essere interpretate come un segnale di potenziale disallineamento tra modello di business, configurazione organizzativa e pressioni ambientali del contesto, disallineamento che il mercato tende a penalizzare indipendentemente dal settore di appartenenza (Donaldson, 2001; Volberda et al., 2012). L'assenza di un effetto moderatore significativo del settore suggerisce infine che il rischio climatico sia percepito come sistemico e trasversale, piuttosto che circoscritto a specifiche industrie (Busch et al., 2022).

Dal punto di vista manageriale, i risultati suggeriscono che le imprese dovrebbero superare un approccio alla sostenibilità focalizzato prevalentemente sulle emissioni operative (Scope 1 e Scope 2) e integrare in modo più esplicito la gestione delle emissioni generate lungo la catena del valore. Le evidenze mostrano infatti che i mercati finanziari attribuiscono maggiore rilevanza valutativa alle emissioni di Scope 3, interpretando come un indicatore più informativo dell'esposizione dell'impresa a rischi climatici, regolatori e strategici di lungo periodo. La gestione delle emissioni di Scope 3 emerge quindi come una leva strategica centrale per la creazione di valore. Poiché tali emissioni riflettono la struttura della supply chain e le caratteristiche del modello di business, la loro riduzione richiede interventi che vadano oltre l'efficienza operativa interna, coinvolgendo fornitori, partner e clienti attraverso forme avanzate di coordinamento e governance inter-organizzativa. In questo senso, la capacità dell'impresa di orchestrare la decarbonizzazione della filiera diventa una competenza manageriale distintiva.

Sul piano della comunicazione verso gli investitori, i risultati indicano che la disclosure delle emissioni di Scope 3 assume una valenza strategica. Una rendicontazione trasparente e coerente delle emissioni di filiera, accompagnata da una chiara esplicitazione delle strategie di riduzione adottate, può contribuire a ridurre l'incertezza informativa e a rafforzare la credibilità dell'impresa nel contesto della transizione climatica.

Infine, l'assenza di differenze significative tra settori suggerisce che il rischio climatico sia percepito come sistemico e trasversale. Di conseguenza, tutte le imprese, indipendentemente dal settore di appartenenza, sono chiamate a integrare la gestione delle emissioni di Scope 3 nelle decisioni strategiche e nei processi di pianificazione di lungo periodo.

I risultati devono essere interpretati alla luce di alcuni limiti. Il presente studio si concentra su imprese europee quotate e su dati secondari, in un contesto caratterizzato da livelli relativamente elevati di disclosure ambientale. Sebbene ciò garantisca comparabilità e robustezza delle analisi, i risultati potrebbero non essere immediatamente estendibili a contesti istituzionali differenti. Inoltre, in linea con la letteratura esistente, le misurazioni delle emissioni di Scope 3 possono presentare eterogeneità informative. Tuttavia, i risultati principali risultano stabili rispetto a diverse specificazioni del modello e a test di robustezza alternativi, rafforzando la solidità delle evidenze empiriche. Ricerche future potrebbero approfondire i meccanismi organizzativi e strategici alla base della gestione delle emissioni di filiera, integrando approcci quantitativi e qualitativi.

Navigating the automotive transition. The role of vision capability in adaptation behaviour

FEDERICA GASBARRO[1], FORSTER JUNIOR SHITSI[2]

Abstract

Frame of the research. *The global automotive industry is undergoing a period of profound disruption, characterized by rapid technological upheaval, regulatory mandates, and shifting consumer orientations. To survive this transition, firms might adapt by managing ambidexterity.*

Purpose of the paper. *The paper aims to illustrate how the governing role of vision allows automotive firms to successfully navigate the most complex industrial transition of the 21st century.*

Methodology. *This study adopts a qualitative approach to explore the interplay among vision capability, dynamic capabilities, and organizational ambidexterity during the strategic transition of the current disrupted automotive industry. The data consists of the 2023/2024 sustainability and integrated reports from the top ten global automotive firms.*

Results. *The analysis reveals that vision capability is not merely a symbolic articulation of future aspirations but operates as a governing mechanism that filters managerial attention, defines strategic priorities, and legitimizes large-scale resource reconfiguration.*

Research limitations. *The study is based on qualitative data and analysis. Quantitative analyses are necessary to generalize the findings.*

Managerial implications. *These findings underscore that successful transformation requires a coherent, operationalized vision: traditional carmakers must prioritize socio-cognitive renewal alongside asset reconfiguration, while EV-forward firms must anchor rapid innovation in scalable operational systems.*

Originality of the paper. *We propose a framework to conceptualize adaptation as a co-evolutionary process linking vision, dynamic capabilities, and ambidextrous innovation trajectories under conditions of disruption. By distinguishing the "transition bridge" of incumbents from the "radical leapfrog" of EV-forward firms, the research introduces a recursive model of strategic adaptation.*

Keywords: *Vision capability; dynamic capabilities; ambidexterity; automotive industry; carbon transition*

1. Introduction

The global automotive industry is undergoing a period of profound disruption, characterized by rapid technological upheaval, intensifying regulatory mandates, and fundamentally shifting consumer orientations. This moment constitutes the most consequential turning point for the sector since the introduction of the moving assembly line by Henry Ford more than a century ago. Yet this transformation; marked by the transition from internal combustion engines (ICE) to electric vehicles (EVs), the rise of autonomous driving, and the development of software-defined vehicles, extends beyond a purely technical or economic shift. It is equally an attentional and cognitive challenge, requiring incumbent Original Equipment Manufacturers (OEMs) to operate within an environment characterized by heightened institutional pressures and persistent market uncertainty.

To survive this transition, firms might adapt by managing between exploitative and explorative behaviour. Especially for incumbent automotive firms, they might simultaneously exploit their maturing ICE-based profit centers to generate the liquidity required to explore radical, unproven technologies (March, 1991; O'Reilly & Tushman, 2013). Danneels (2002), argues that technological innovation is bifurcated into two distinct categories: exploratory and exploitative. Exploratory innovation is characterized by the pursuit of radical departures from established technological paradigms, whereas exploitative innovation focuses on the incremental refinement of existing

[1] University of Brescia – Italy, e-mail: federica.gasbarro@unibs.it
[2] University of Brescia – Italy, e-mail: f.shitsi@unibs.it

practices and technologies. The strategic challenge of harmonizing these two divergent modes of innovation, often referred to as organizational ambidexterity (OA), has become a central theme in management literature.

Drawing upon the Dynamic Capabilities (DC) framework, Teece et al. (1997) argue that DCs enable firms to do more than simply allocate resources for product development; they facilitate organizational agility in the face of volatile competitive landscapes. By integrating, building, and reconfiguring both internal and external competencies, DC allow a firm to maintain alignment with a rapidly shifting environment. Building on this foundation, the efficacy of DC is increasingly predicated on the strength of a firm's vision capability (VC). While DCs provide the muscles or engine for resource reconfiguration, VC acts as the eyes or governor, representing the cognitive capacity to anticipate future technological trajectories and conceptualize emerging market states before they fully materialize.

In the contemporary automotive transition, where the industry is undergoing a disruptive shift from ICEs to electrification and autonomous systems, the nexus between VC and DC is critical. VC allows automotive incumbents to look beyond their legacy assets and perceive the necessity of radical change. When effectively coupled with DC, this foresight ensures that resource restructuring is not merely reactive but is strategically directed toward the next-generation mobility ecosystem. Consequently, in technologically disruptive worlds, VC serves as the essential precursor that gives direction to DC, preventing path dependency and enabling firms to successfully navigate the leap from old to new technological regimes.

While extant literature has established that DC are instrumental in managing the tension between exploratory and exploitative innovation, empirical focus has largely remained bifurcated. Research frequently examines the impact of DC on these innovation modes in isolation, often neglecting their simultaneous integration, that is, the combined dimension of ambidexterity (Sheng, 2017). However, a significant conceptual void exists: the role of VC as a cognitive antecedent to these processes is nearly non-existent in current empirical models.

Existing frameworks suggest that DC enables the reconfiguration of resources, yet they often fail to explain where that reconfiguration is directed. To address this, we argue for an integrated model that incorporates corporate VC. It is not merely a static statement of intent but a high-level DC that allows a firm to cognitively transcend current market constraints. By integrating vision into the DC-ambidexterity framework, firms can move beyond reactive adaptation and toward proactive market shaping. This suggests that VC provides the strategic logic that determines how a firm balances the optimization of current assets (exploitation) with the pursuit of disruptive technologies (exploration).

The necessity of this integrated model is most evident when analyzing the path-dependent nature of the automotive industry's transition from Internal Combustion Engines (ICE) to Electric Vehicles (EV). Incumbent (Legacy) OEMs are currently grappling with significant structural and cognitive inertia; their decades-long investment in ICE technology has created a competency trap where existing DC are tethered to a fading technological regime. For these incumbents, VC is essential to break path dependency. It acts as the catalyst for the unlearning of legacy processes and the radical reconfiguration of assets required for electrification.

In contrast, EV-forward OEMs (such as pure-play EV startups) operate without the burden of ICE-related path dependency. Their strategic challenge is not the reconfiguration of old assets, but the rapid assembly and scaling of new ones. Consequently, the transition path for these two types of organizations differs fundamentally: legacy OEMs require vision-driven DC to pivot and survive, while EV-forward firms utilize vision-led DC to establish and dominate new market niches. Current research must, therefore, distinguish between these two cohorts, as the efficacy of their DC is inherently shaped by their historical technological commitments, or lack thereof. By placing VC at the heart of this transition, researchers can better understand why some legacy firms successfully leapfrog to new regimes while others succumb to the rigidity of their past successes.

Despite the proliferation of studies on DC and OA, there remains a significant gap in our understanding of the governance of these constructs. Most existing frameworks treat DC as a neutral

toolkit for change, ignoring the cognitive biases and preconceptions that dictate how those tools are used. Furthermore, the literature has largely overlooked how a firm's vision functions as a functional capability that limits or focuses the use of dynamic resources. Without a governing vision, reconfiguration can lead to organizational chaos, where a firm loses its core identity and fails to maintain the efficiency of its exploitative base.

This research addresses this theoretical gap by proposing an integrated model that positions VC as the antecedent and regulator of DC in the pursuit of OA. The novelty of this work is three-fold: theoretical integration, empirical breath, and the governor concept. First, it provides a unified model that links VC, DC, and OA, demonstrating the relationship between these constructs. Second, by analyzing the 2023/2024 sustainability and integrated reports of ten global leaders including Toyota, Honda, Nissan, Hyundai, GM, Ford, VW, Stellantis, BYD, and Geely, the study provides a comprehensive, global perspective that accounts for different institutional and regional contexts. Third, it shifts the academic discourse from vision as a statement to vision as a capability, emphasizing its role in narrowing the attentional focus to prevent the over-searching and strategic paralysis common in high-velocity industries.

As the subsequent sections will detail, this study utilizes a thematic analysis to explore the theoretical foundations of these concepts. By examining the specific evidence from the global automotive landscape, we aim to illustrate how the governing role of vision allows firms to successfully navigate the most complex industrial transition of the 21st century, ensuring that the engine of DC is steered by a clear and resilient strategic logic. Based on our analysis, we develop a theoretical model on how OEMs respond to the automotive disruptions using the concepts of VC, DC, and OA.

2. Literature Review

2.1 Technological Disruptions in the Automotive Industry

The automotive industry is experiencing an unprecedented wave of technological disruption driven by the convergence of electrification, autonomous driving, artificial intelligence, digitalization, and connectivity (Fojcik, 2012; Koelmel et al., 2025; Pérez-Moure et al., 2023; Renneby & Sommer, 2018; Wittmann, 2016; Ziegler & Abdelkafi, 2023). Electrification and the transition toward battery electric vehicles fundamentally alter powertrain architectures, supply chains, and skill requirements, thereby eroding the traditional competitive advantages of internal combustion engine–focused incumbents, particularly in Germany (Fojcik, 2013; Loder et al., 2024). Empirical evidence shows substantial heterogeneity in how firms interpret and respond to this disruption, with some perceiving electrification as an existential threat and others framing it as a strategic opportunity for renewal and market repositioning (Loder et al., 2024).

At the same time, autonomous driving and AI represent a radical departure from incremental innovation, requiring new competencies in software development, data management, and cloud infrastructure that lie largely outside the historical knowledge base of automotive manufacturers (Renneby & Sommer, 2018). Digitalization and connectivity further transform automotive firms from hardware-oriented manufacturers into software-driven mobility and data platforms, reshaping value creation, sustainability strategies, and industry power dynamics (Pérez-Moure et al., 2023). The convergence of these technologies gives rise to new mobility paradigms, such as mobility-as-a-service and subscription-based models, and generates multiple overlapping technological S-curves that increase strategic complexity and uncertainty (Streloke & Franke, 2024). This environment raises the question of why firms facing similar disruptions pursue markedly different strategic paths.

2.2. The dynamic capabilities

Firms use DC to put their market goals into action (Øyna et al., 2018). These skills are different from the basic skills that keep a business running every day (Randhawa et al., 2021). DC allow a

company to grow and react to what customers want (Teece et al., 1997). They represent the ability of a firm to join and change its internal and external skills to handle a fast world (Bağış et al., 2022; Yuan et al., 2021). According to Teece (2007), these skills have three parts. The first part is sensing. This helps a firm find and check new chances or threats. The second part is learning. This helps a firm move its resources to handle those chances. The third part is changing or transforming. This helps a firm keep its assets fresh and new.

Building these skills requires a company to learn from past experiences and think deeply about its choices (Zollo & Winter, 2002). Some researchers look at how a firm is built and how it connects with others to explore new ideas (Haim Faridian & Neubaum, 2021). On the other hand, exploitation shows how a firm uses what it already has to create value. These skills are vital for making new products for new markets (Teece, 2007). In fast markets, exploitation skills help a firm get value from products that are already for sale (Haim Faridian & Neubaum, 2021). In short, being able to explore and exploit resources helps a company stay strong as the world changes (Monferrer et al., 2021).

The ability to gain a new edge in the market depends on these DC (Øyna et al., 2018; Teece et al., 1997). The word dynamic means a firm can update its skills to stay in harmony with the environment. This is key because technology moves very fast. It is often hard to know what the future of a market will look like. The word capacities highlights the role of managers. Managers must adapt and join resources to meet new needs. Sometimes, these skills can make a firm less efficient because they add more pressure. However, the good side is that they bring more innovation and new chances for the business (Alka et al., 2024; Yuan et al., 2021).

Companies need to include innovation within the larger idea of DC (Monferrer et al., 2021). This helps a company stay competitive by adapting to new information (Grant, 1996). This view also shows that firms have limits when trying to coordinate work or protect their ideas (Teece et al., 1997). Often, there is a gap between what people inside and outside the firm know. While some views focus on these gaps, others argue that social groups can share information to fix these problems (Haim Faridian & Neubaum, 2021).

Resources from both inside and outside the firm create value (Li et al., 2023). How well a company performs depends on many different factors (Battisti et al., 2023; Braunerhjelm & Halldin, 2019; Hou et al., 2024). This is why being ambidextrous is so important for a business (Bhandari et al., 2022; Hughes et al., 2021; Li et al., 2023). Ambidextrous companies are better at being efficient and managing their work. Their goal is to be reliable and sustainable right now. At the same time, they work to find new products that will succeed in the future (Hughes et al., 2021).

Although research shows that being ambidextrous helps companies stay strong, makes them efficient today and ready for tomorrow; our study wants to investigate this further. We will look at our data to see how this works in the automotive sector. A sector of incumbent firms who have different initial operational setup in ICEs and long history of old technology, and EV companies who have no experience of initial ICE setup.

2.3 Organizational ambidexterity

Literature conceptualizes OA as a firm's capacity to simultaneously pursue exploration and exploitation, balancing radical discovery with incremental efficiency (March, 1991). Scholars like O'Reilly & Tushman (2008) found that this is often achieved through structural separation, where distinct units handle different innovation tasks. Conversely, other research highlights contextual ambidexterity, where organizational systems enable individuals to divide their efforts between current alignment and future adaptation (Gibson & Birkinshaw, 2004). This duality is often categorized into balanced and combined dimensions, where the former maintains equilibrium and the latter focuses on the mutual reinforcement of exploratory and exploitative efforts (Cao et al., 2009).

Recent findings suggest that DC serve as a vital link between ambidexterity and business model performance, particularly in complex or shifting markets (Lin & Si, 2018; Yuan et al., 2021). These capabilities allow firms to reconfigure resources and internalize external knowledge through relational networks and strategic alliances (Mondal et al., 2022; Monferrer et al., 2015, 2021).

According to Haim Faridian & Neubaum (2021), ambidextrous firms are defined by learning strategies that influence business model design through resource use and DC. Yuan et al. (2021) examined 493 companies across various sectors in China and found that ambidexterity helps focus business models on both efficiency and innovation. These researchers also show that DC act as a positive mediator between ambidexterity and these specific business models.

The theory of ambidextrous organizations posits a dual function of exploration and exploitation (March, 1991). Monferrer et al. (2021) state that this duality is necessary to understand DC. Their findings suggest that exploratory capabilities are important for development because they support organizational learning. This learning provides the flexibility needed to manage knowledge gained from relationships between firms. It also supports the ability to take in and use new external knowledge (Ramadani et al., 2017). Similarly, Haim Faridian & Neubaum (2021) observe that dynamic environments encourage firms to engage in value capture. In these changing settings, companies often work to create and capture value at the same time. This makes ambidexterity a very effective model for firms to follow. However, Barney (1991) notes that specific resource limits can make this search for both types of value difficult. Lin & Si, (2018) find that firms can create competitive advantages through an ambidextrous strategy. This advantage depends on the ability of the firm to diversify its relationships during times of uncertainty. These authors use the DC perspective to show how firms can be both effective and efficient.

Firms that use ambidextrous approaches often promote incremental innovation. This helps them balance current demand with the search for new opportunities (Farzaneh et al., 2022). Monferrer et al. (2021) suggest that high competition makes collaborative innovation between companies necessary. As a result, relational business networks have become more important for competitive positions. These networks allow members to access knowledge and resources that they could not get alone (Monferrer et al., 2015, 2019, 2021). Lin & Si (2018) link these ambidextrous strategies to higher performance in complex market settings.

While Farzaneh et al. (2022) defines ambidextrous organizations as those that use existing skills for small changes or new opportunities for radical innovation. Ardito et al. (2018) posit that these innovations often come from changes in the capabilities of the organization. When firms pursue market leadership, they look for new developments while also using their own internal knowledge (Farzaneh et al., 2022). Networking strategies, like alliances and joint ventures, help clarify how these firm capabilities work (Dabić et al., 2020; Mondal et al., 2022; Pereira et al., 2022; Zahoor et al., 2020). Tuomisalo & Leppäaho (2019) identify two main impacts of these networks. They help firms gain useful information and accelerate learning through partnerships.

Monferrer et al. (2021) show that knowledge becomes stronger through these networks. Members of a network share benefits from joint innovation and risk taking (Stocker et al., 2022). Bembom & Schwens (2018) show that networks help managers get resources and build trust. This trust can reduce the costs of doing business. Hughes et al. (2021) find that firms seeking legitimacy often use ambidexterity to improve efficiency and value. This helps them stay reliable in the short term while creating new products for the long term.

Research posit that DC serve as a tool to arrange resources for long term success (Lin & Si, 2018). They are used to build new resources and reconfigure them for a new market position (Teece et al., 1997). An ambidextrous approach involves complex routines that help firms win by moving their resources (Lin & Si, 2018). Researchers confirm that ambidexterity and DC are separate constructions but connected ideas (Monferrer et al., 2021; Yuan et al., 2021). While previous studies emphasize the performance benefits of an ambidextrous approach (He & Wong, 2004), current research seeks to investigate how these findings apply to firms with divergent histories. Specifically, the literature suggests that legacy incumbents and EV-forward firms operate with different initial setups, necessitating an examination of how ambidexterity functions across varying business models during technological transitions.

2.4 Vision capability

VC is often defined as the cognitive ability of leaders to create a clear and compelling picture of a future state that does not yet exist (Kirkpatrick, 2011). In management studies, this is characterized as a high-level capability that allows a firm to anticipate market shifts before they happen (Sashkin, 1988). Unlike basic operational goals, VC involves long-term foresight and the ability to inspire a collective effort toward new directions (Kantabutra, 2008). Some researchers argue that this capability is the foundation for strategic intent, acting as a guide for how a firm chooses to grow (Hamel & Prahalad, 1989).

There is a strong link between VC and DC in management literature. Scholars suggest that vision provides the sense of direction that DC need to be effective (Teece, 2007). While DC focus on sensing and seizing chances, VC helps managers decide which chances are worth taking (Adner & Helfat, 2003). In this way, vision acts as a mental framework that helps leaders reconfigure their resources toward a specific future (Schoemaker et al., 2018). However, some studies point out that there is still a lack of empirical research on how exactly VC triggers the different stages of DC, particularly in traditional industries facing total disruption.

VC also plays a central role in achieving OA. Literature suggests that a strong shared vision helps reduce the conflict between exploration and exploitation (O'Reilly & Tushman, 2016). By providing a common goal, VC allows a firm to remain efficient in current operations while also being creative in new areas. It helps employees understand why they must balance these two different tasks (Raisch et al., 2009). While the benefits of vision are often mentioned, some researchers like Jansen et al. (2008) argue that more studies are needed to see how vision affects ambidexterity in sectors with very different types of firms.

In the automotive sector, the role of VC is especially important due to the difference between legacy firms and EV-forward firms. For legacy firms, VC is what helps them break away from their old technology and "unlearn" past habits (Azadegan et al., 2008). For new EV entrants, vision is used to create a new path where one did not exist before. Current research has not yet fully examined how VC directs the transition paths of these two divergent groups. Our study aims to fill this gap by looking at how vision helps both legacy and EV-forward firms use their DC in response to the global disruptions in the automotive sector.

3. Method and Data

This study adopts a qualitative research design to explore the complex interplay between VC, DC, and OA in their strategic transition in the current disrupted automotive industry. Qualitative methods are particularly suited for examining "how" and "why" strategic shifts occur within organizations, allowing for a deep exploration of corporate narratives and strategic intent. The primary data consists of the 2023/2024 formal sustainability and integrated reports from ten global OEMs: Ford Motor Company, Honda Motor Company, Hyundai Motor Company, Stellantis, Volkswagen Group, Nissan Motor Company, Toyota Motor Corporation, Geely Automobile Holdings, BYD Company, and General Motors.

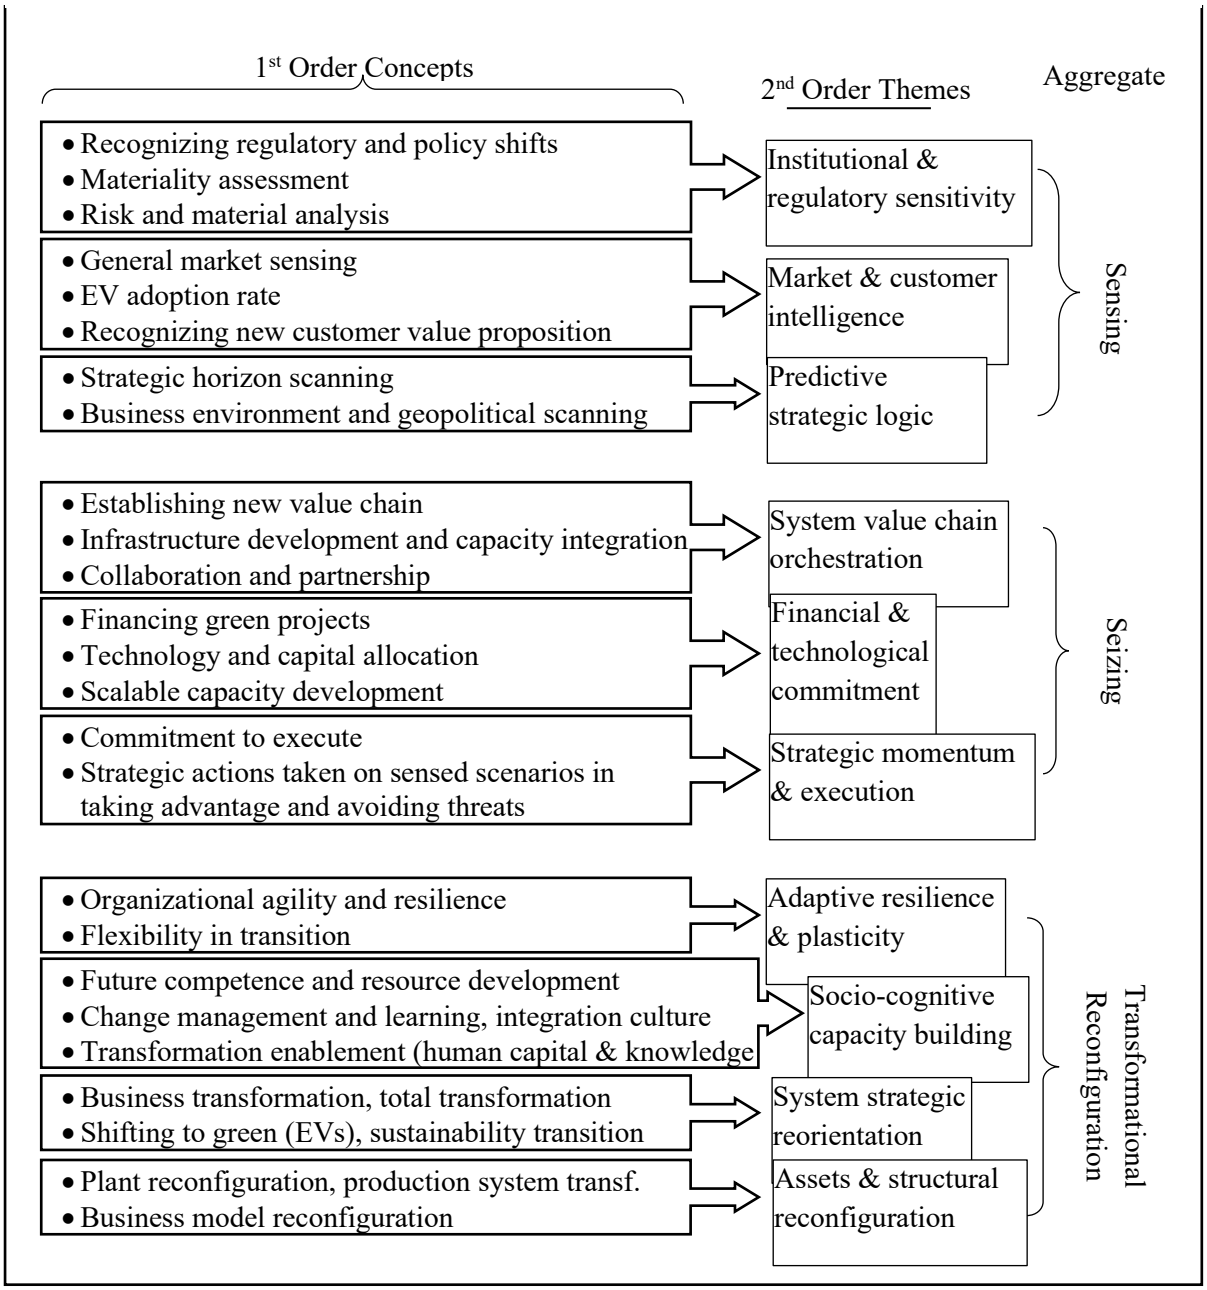
We follow the methodological tradition of Gasbarro & Pinkse (2019), who argue that investigating firm-level responses to systemic disruption requires a deep dive into the organizational narratives that bridge external institutional pressures and internal resource reconfiguration. This approach is particularly suited for our objective of exploring how VC acts as a strategic governor for DC in the pursuit of OA. By treating corporate documents as artifacts of managerial sensemaking, we can observe the noticing and interpreting processes that dictate how a firm navigates technological upheaval. These reports serve as the primary data source because they provide a comprehensive and standardized narrative of a firm's strategic commitments, resource allocations, and long-term environmental goals. In management research, sustainability reports are recognized as high-quality data for qualitative analysis as they reflect the official strategic logic and public accountability of a corporation (Cho et al., 2015). Using these reports allows for a longitudinal view of how firms

articulate their vision and document the evolution of their organizational capabilities over time (Higgins et al., 2020).

3.1 Thematic coding process for VC, DC, and OA

The data analysis followed a systematic, multi-stage coding process to ensure both empirical depth and theoretical rigour. During the initial phase, open coding was employed, allowing for a "free coding" approach where labels were assigned to data segments without the constraints of a pre-existing framework. This initial immersion ensured that the nuances of the automotive transition were captured directly from the raw data.

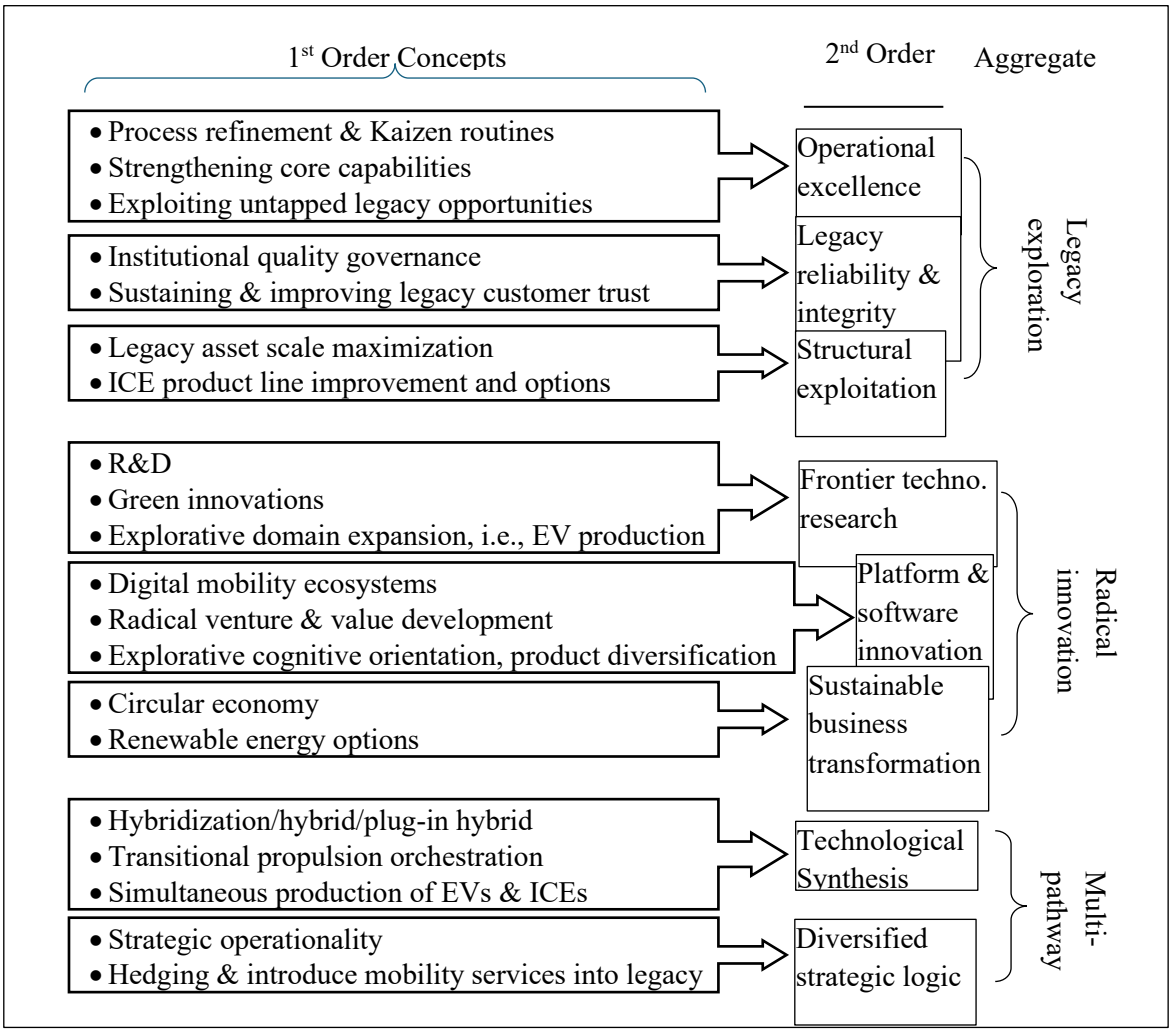
Following this exploratory phase, a rigorous process of code cleaning and refinement was conducted. Redundant or overlapping labels were merged, and inconsistent terminology was standardized to enhance the clarity of the dataset. These refined labels were then strategically regrouped to develop specific sub-codes that represented distinct organizational behaviors and strategic actions.



In the final stage of the thematic analysis, these sub-codes were synthesized into a higher-order hierarchy. They were organized under three key thematic areas: 1. vision capability, which acts as the strategic governor; 2. dynamic capabilities, representing the operational processes of sensing, seizing, and reconfiguring; and 3. Organizational ambidexterity, reflecting the firm's ultimate strategic posture in balancing legacy assets with future innovations.

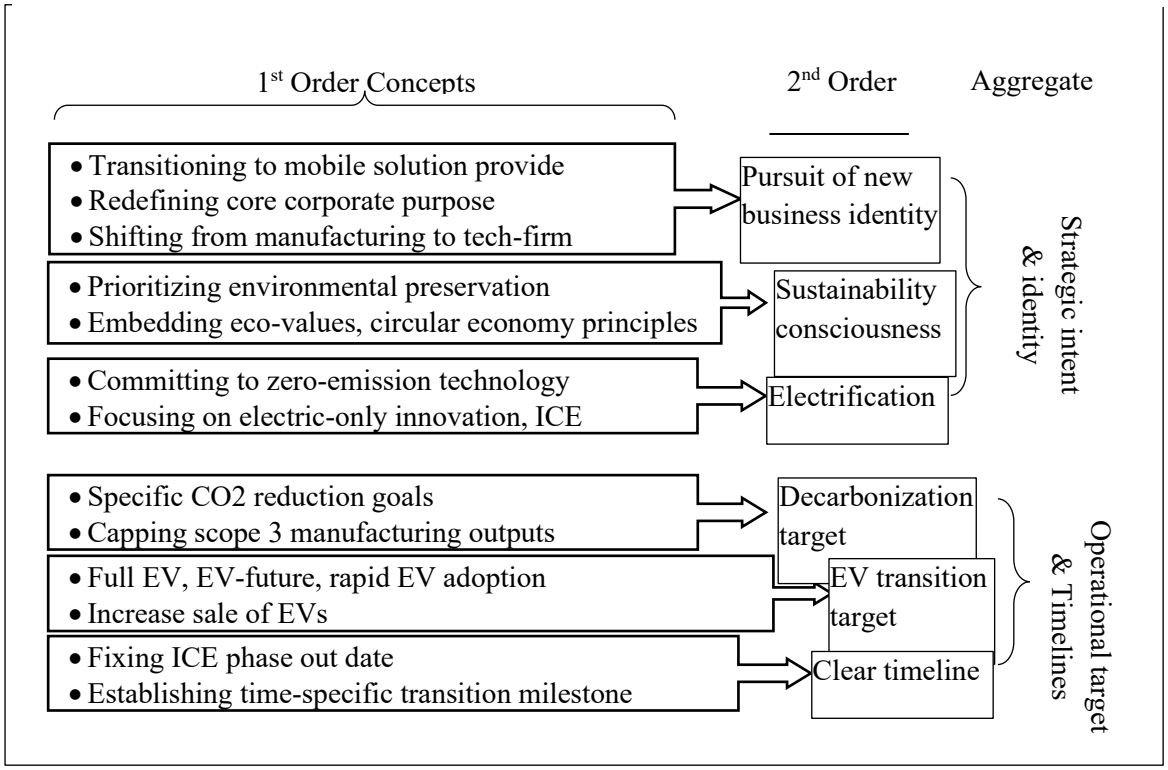
The coding process for DC identifies specific organizational actions categorized into the foundational pillars of sensing, seizing, and transforming. The sensing aggregate dimension is coded through text related to identifying environmental trends, such as monitoring consumer EV adoption or regulatory changes. Key second-order themes include institutional and regulation sensitivity, market and customer intelligence, and predictive strategic logic. Seizing is evidenced by reports of resource mobilization and strategic commitments, such as investments in software hubs, battery gigafactories, or strategic partnerships with technology firms. Associated second-order themes involve system value chain orchestration, financial and technological commitment, and strategic execution momentum. Coding for transformational reconfiguration focuses on factory retooling, employee upskilling, and internal supply chain modifications intended to support electrification. Sub-themes include adaptive resilience, socio-cognitive capacity building, and structural reconfiguration (see Fig. 1).

The coding for OA focuses on identifying a firm's dual commitment to sustaining current operations while simultaneously pursuing future breakthroughs. The first aggregate theme, Legacy Exploitation, is coded from text detailing the continued optimization of the existing fleet and core capabilities, encompassing sub-themes such as operational excellence, legacy reliability and integrity, and structural exploitation. The second theme, Radical Innovation (Exploration), is identified through breakthrough innovations in electric and autonomous mobility, where coding focuses on frontier technological research, platform and software innovation, and sustainable business transitions. Finally, the multi-pathway dimension captures the transitionary phase where firms balance legacy and radical modes, categorized by sub-themes like technological synthesis, such as the simultaneous production of electric vehicles (EVs) and internal combustion engines (ICEs), and a diversified strategic logic (see Fig. 2).



VC coding concentrates on forward-looking statements that define a firm's long-term strategic direction. The aggregate theme of Strategic Intent and Identity is derived from narratives describing a firm's future identity or mission-driven language focused on industry disruption, involving second-order themes such as the pursuit of a new business identity exemplified by the shift from manufacturing to tech-focused firms; electrification, and sustainability consciousness. Parallel to this, the Operational Target and Timelines theme applies codes to specific strategic declarations, such as "2030" or "2050" carbon-neutral targets. This dimension is further defined by themes concerning clear timelines, such as fixing specific ICE phase-out dates, as well as concrete EV transition targets and overarching decarbonization goals.

Fig. 1 -Framing dynamic capability: concepts and coding



Source: our elaboration

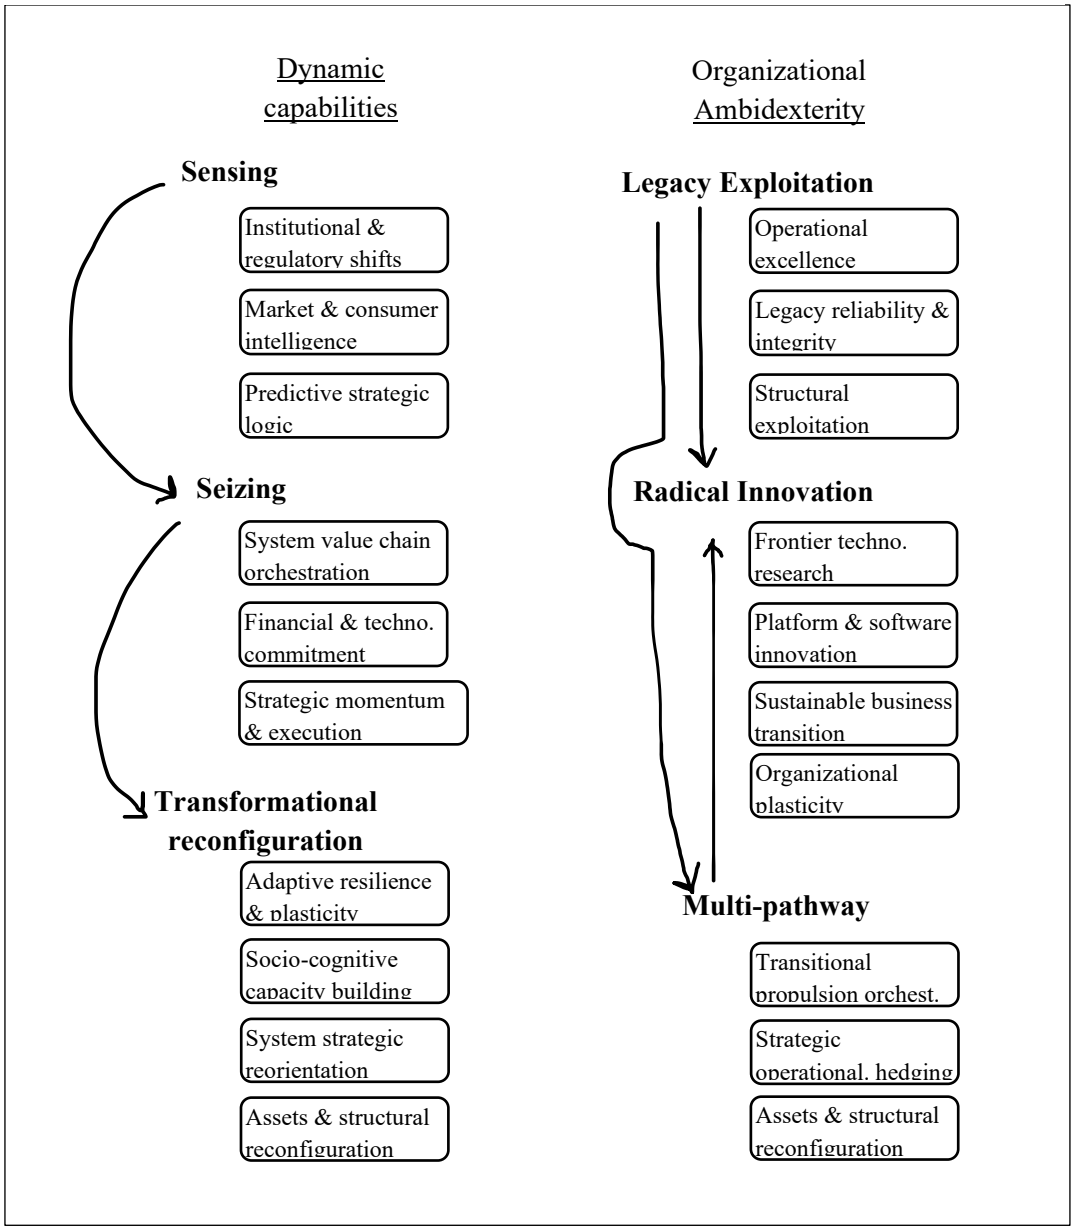
Fig. 2 Framing organizational ambidexterity: concepts and coding

Source: our elaboration

Fig. 3 Framing VC: concepts and coding

Source: our elaboration

By mapping these overlapping codes, the analysis can reveal whether the firm's vision and DC are functioning in a way that supports a successful and coherent strategic transition.



3.2 Internal Linkages and Thematic Relationships

illustrates the internal logical flow within the aggregate dimensions of DC and OA. For DC, Fig. 4 shows a causal progression where Sensing (understanding regulatory and market shifts) directly informs Seizing (orchestrating the value chain and committing capital). Successful seizing then enables Transformational Reconfiguration, which involves deep structural and cognitive shifts within the organization, such as socio-cognitive capacity building and systemic reorientation.

In the context of OA, the figure maps the components that constitute the firm's strategic posture during transition: Legacy exploitation is characterized by operational excellence and maintaining the integrity of legacy products. Radical innovation is driven by frontier research, software innovation, and organizational plasticity. Multi-pathway acts as the synthesis between these two poles, utilizing transitional propulsion orchestration (e.g., hybrids) and strategic operational hedging to manage the shift from legacy assets to future platforms.

By mapping these internal links, the analysis reveals how a firm's internal capabilities and ambidextrous structures function together to support a coherent strategic transition.

Fig. 4 Link within DC and OA

Source: our elaboration

4. Findings

This section presents the qualitative findings structured around the core elements of the conceptual framework (Fig. 1-3): VC, DC, and OA. Following the internal logic illustrated in Fig. 4, results are organized to demonstrate how VC governs the deployment of DC, through sensing, seizing, and transformational reconfiguration, and how these capabilities subsequently shape differentiated transition pathways. The analysis further reveals systematic differences between legacy OEMs and EV-forward firms, reflecting their divergent historical asset bases and strategic constraints.

4.1 Vision capability as strategic governor and cognitive filter

The analysis reveals that VC is not merely a symbolic articulation of future aspirations but operates as a governing mechanism that filters managerial attention, defines strategic priorities, and legitimizes large-scale resource reconfiguration. Vision consistently appears embedded in firm philosophy,

sustainability commitments, and long-term identity narratives, providing both direction and justification for transformation.

For legacy OEMs, VC is typically framed around reconciling continuity with change. Ford articulates this balance by emphasizing responsiveness to both customers and environmental imperatives, stating:

"This values-led approach continues to guide us on the road to a more sustainable and equitable transportation future… as we deliver both what our customers want and what the planet needs" (Ford, pg. 4).

This statement illustrates how vision establishes a dual-objective logic; preserving customer value while advancing sustainability, thereby framing ambidexterity as a moral and strategic necessity.

Honda similarly grounds its transition in a deeply ingrained quality philosophy, emphasizing that even "… a 1% rejection is unacceptable," (Honda, pg. 11), reinforcing its enduring commitment to customer trust while preparing for future technologies. Such narratives indicate that VC in legacy firms often emerges from institutionalized values, which act as stabilizing forces during disruptive change.

Several OEMs further operationalize VC through explicit carbon neutrality targets and electrification milestones. Hyundai, for example, links its 2045 carbon neutrality ambition directly to structural transformation, noting that it is "… transitioning our business structure from internal combustion engine vehicles to an electrification focused approach," (Hyundai, pg. 25) while simultaneously advancing EVs, hybrids, and fuel cell vehicles. This demonstrates how VC delineates both direction (electrification) and modality (multi-technology), shaping subsequent capability deployment.

Toyota's vision reinforces this pluralistic orientation: "we will offer a range of solutions under our multi-pathway strategy to provide options to our customers worldwide. The fundamental idea here is to close in on the "future of energy" and the "expectations of our customers around the world." (Toyota, pg. 4). Here, VC legitimizes technological diversity, positioning ambidexterity not as compromise but as deliberate strategic design.

In contrast, EV-forward firms articulate a more concentrated and directive vision. BYD anchors its identity in long-standing decarbonization principles, "In 2008, we proposed the "three green dreams" of solar energy, energy storage and electric vehicles, and in 2016, we issued the initiative of "Cool the Earth by One Degree", released the strategy of "EVs solve pollution and SkyShuttle solve congestion", and became the first automobile enterprise in the world to stop production of fuel vehicles in 2022." (BYD, pg. 3). This illustrates how VC functions as a path-creation mechanism, eliminating ambiguity surrounding legacy technologies and enabling decisive strategic focus.

Moreover, BYD emphasizes technology as both philosophical foundation and competitive driver, stating that it adheres to:

"The development concept of "Technology Based, Innovation Oriented" and unswervingly adhered to the new energy strategy, constantly spawning, and strengthening new productivity." (BYD, pg.4).

Unlike legacy OEMs, whose visions accommodate historical commitments, BYD's VC enables a singular orientation toward radical innovation. Taken together, these findings indicate that VC operates as a cognitive filter that narrows organizational search spaces and prioritizes specific transition pathways. VC precedes and shapes DC by defining what constitutes relevant opportunities and acceptable strategic trade-offs.

4.2 Dynamic capabilities as the engine translating vision into action

Consistent with Fig. 4, the empirical evidence demonstrates a patterned progression of DC deployment from sensing to seizing and ultimately to transformational reconfiguration. However, the intensity and coherence of this progression vary substantially across firms.

Sensing: Institutional sensitivity and market intelligence

Firms demonstrate strong sensing capabilities through continuous monitoring of regulatory pressures, climate commitments, and evolving customer expectations. For example, Nissan's Arc plan exemplifies this institutional sensitivity:

"Through the Arc plan, Nissan will accelerate the electric vehicle (EV) transition, prioritize reducing CO_2 emissions, innovative technologies, leaner manufacturing systems, smart partnerships and market growth that will contribute to a more sustainable future and our ultimate goal of carbon neutrality." (Nissan, pg. 3).

Volkswagen similarly articulates intermediate emissions targets, aiming to reduce vehicle carbon footprints. "By 2030, we want to reduce the carbon footprint of our passenger cars and light commercial vehicles by 30% per vehicle (compared with 2018)." (Volkswagen, pg. 48).

These statements reflect systematic horizon scanning and predictive strategic logic, aligning with the sensing dimension in Fig. 4. Importantly, sensing is not limited to compliance; it also encompasses emerging customer value propositions. Ford highlights its awareness of heterogeneous market demand by maintaining strong portfolios across EVs, ICEs, and hybrids:

"... We have strong product lineups in all three categories of vehicles – EVs, internal combustion engine vehicles, and hybrids. Hybrid sales rose 20% for the year." (Ford, pg.5).

This illustrates how sensing integrates both regulatory and market signals.

Seizing: Capital commitment and ecosystem orchestration

Sensed opportunities are operationalized through large-scale financial commitments and restructuring of production systems. General Motors demonstrates this seizing capability.

"Under this framework, we issued $2.25 billions of investment-grade green bonds in 2022, our first capital markets activity that specifically supports our EV strategy." (GM, pg. 20)

Ford similarly emphasizes "to facilitate this transformation, we are making substantial investments, recruiting new talent, and optimizing our business model, management system, and organization." (Ford, pg. 56).

Hyundai extends seizing beyond internal investment by actively expanding EV and hydrogen infrastructure: "Additionally, we are actively driving the expansion of electric and hydrogen infrastructure ..." (Hyundai, pg. 25).

These actions reflect system value chain orchestration and strategic execution momentum, as illustrated in Fig. 4.

BYD exhibits particularly rapid seizing dynamics, highlighting its ability to implement R&D outcomes quickly: "implements R&D innovation results as quickly as possible, achieves $1 + 1 > 2$ synergy effects, and continuously reshapes industry standards with continuous disruptive technologies." (BYD, pg. 4). This underscores how EV-forward firms leverage tight coupling between technology development and manufacturing to accelerate strategic momentum.

Transformational Reconfiguration: Structural and socio-cognitive renewal

Transformational reconfiguration emerges as the most demanding phase of DC, involving deep structural, cultural, and cognitive change. Hyundai's repositioning as a Mobility Solution Provider illustrates systemic reorientation across hardware, software, and service domains.

"We will continue to strengthen our business capabilities with the goal of growing into a "smart mobility solution provider" based on sustainability management." (Hyundai, pg. 25).

Toyota similarly emphasizes next-generation BEV architectures and software platforms such as Arene to redefine vehicle design and customer experience:

"… through the software platform Arene, which we developed in collaboration with Woven by Toyota, to make mobility more convenient and fun." (Toyota, pg. 5).

Legacy OEMs face particularly complex reconfiguration challenges due to entrenched ICE assets and organizational routines. Their transformations involve gradual plant retooling, workforce reskilling, and parallel operation of legacy and emerging technologies. EV-forward firms, by contrast,

display higher organizational plasticity. BYD's rapid deployment of proprietary platforms, batteries, and intelligent systems illustrates adaptive resilience enabled by the absence of legacy constraints.

These patterns align with Fig. 4, which conceptualizes reconfiguration as encompassing asset restructuring and socio-cognitive capacity building.

4.3 Organizational ambidexterity as historically conditioned transition outcome

OA emerges as the observable outcome of VC-guided DC, but manifests in structurally different forms.

Legacy OEMs primarily exhibit multi-pathway ambidexterity, balancing exploitation of ICE assets with exploration of electrification and alternative propulsion. Ford explicitly maintains diversified portfolios across EVs, ICE vehicles, and hybrids, reporting a 20% increase in hybrid sales while expanding EV offerings.

"… EVs, internal combustion engine vehicles, and hybrids. Hybrid sales rose 20% for the year." (Ford, pg. 5).

Geely adopts a similar hedging posture to improving carbon performance:

"… improve the carbon emissions performance of ICE vehicle products through technological enhancements (e.g., HEV hybrid technology, methanol technology)." (Geely, pg. 26).

Toyota institutionalizes this approach through hybrids positioned as near-term solutions alongside longer-term investments in BEVs and hydrogen engines

"… while also expanding sales of hybrid vehicles, which are the most promising option for the time being, especially in emerging countries." (Toyota, pg. 5).

These practices exemplify the "multi-pathway" bridge depicted in Fig. 4, where transitional technologies mediate between legacy exploitation and radical innovation.

Conversely, EV-forward firms largely bypass legacy exploitation. BYD's cessation of fuel vehicle production and intensive focus on new energy platforms illustrates an exploration-dominant trajectory characterized by frontier technology development and high organizational flexibility.

"… energy storage and electric vehicles, and became the first automobile enterprise in the world to stop production of fuel vehicles in 2022." (BYD, pg. 3–5). In this context, ambidexterity is expressed not as balance between old and new but as simultaneous radical innovation across multiple emerging domains.

These findings confirm that OA is not a uniform equilibrium but a historically conditioned strategic configuration shaped by prior asset commitments and vision-driven capability deployment.

4.4 Explaining the Transition Pathways

Building on the empirical themes presented in the results section, Fig. 6 and Fig. 7 visually synthesize two fundamentally different transition pathways observed across the sampled firms. These figures illustrate how vision capability conditions the deployment of dynamic capabilities and, ultimately, the form of organizational ambidexterity achieved.

4.4.1 The Transition Bridge Pathway of Legacy OEMs

Fig. 5 captures the dominant trajectory of incumbent automotive manufacturers such as Ford, Toyota, Hyundai, GM, Honda, Nissan, Volkswagen, Stellantis, and Geely. This pathway is characterized by the simultaneous exploitation of internal combustion engine (ICE) assets and gradual exploration of electrification, mediated through what we conceptualize as a multi-pathway bridge; most notably hybrids, plug-in hybrids, and diversified propulsion portfolios.

At the foundation of this bridge lies a vision capability that remains anchored in legacy identity while progressively incorporating sustainability imperatives. Ford exemplifies this dual orientation by explicitly framing its transition as a values-led balancing act:

"This values-led approach continues to guide us on the road to a more sustainable and equitable transportation future… as we deliver both what our customers want and what the planet needs" (Ford, pg. 4).

Here, vision functions as a strategic governor that legitimizes continued ICE exploitation while simultaneously justifying investment in EVs and hybrids.

This duality becomes operationalized through dynamic capabilities. Legacy firms demonstrate strong sensing of institutional and regulatory pressures alongside market signals. Ford highlights its responsiveness to heterogeneous demand by maintaining "strong product lineups in all three categories of vehicles – EVs, internal combustion engine vehicles, and hybrids," while noting that "hybrid sales rose 20% for the year" (Ford, pg. 5).

"… offer a comprehensive and flexible range of electric, hybrid, and internal combustion vehicles." (Ford, pg. 15)

Toyota similarly institutionalizes this logic through its multi-pathway strategy, emphasizing the need to:

"… provide options to our customers worldwide. … close in on the "future of energy" and the "expectations of our customers around the world."" (Toyota, pg. 4).

These sensing activities translate into seizing behaviors characterized by large-scale financial commitments and staged technological investments. GM's issuance of $2.25 billion in green bonds to support its EV strategy (GM, pg. 20), alongside the retooling of Factory ZERO into a fully dedicated EV facility, illustrates how incumbents mobilize capital to incrementally reconfigure production systems. Ford likewise emphasizes "… substantial investments, recruiting new talent, and optimizing our business model, management system, and organization" to facilitate transformation (Ford, pg. 56).

However, Fig. 5 also highlights that transformational reconfiguration for legacy firms is inherently painful and constrained. Unlike EV-forward companies, incumbents must restructure deeply embedded assets, routines, and cognitive frames. Hyundai's transition illustrates this complexity. While committing to carbon neutrality by 2045 and shifting toward an "electrification focused approach," Hyundai continues to develop hybrids, PHEVs, EVs, and FCEVs simultaneously, reflecting the socio-cognitive and structural burden of managing parallel technological regimes (Hyundai, pg. 25).

Geely further illustrates this bridging logic by explicitly retaining ICE offerings:

"The Geely brand will also continue to offer ICE vehicle products to provide options for consumers who, for various reasons, cannot adopt new energy vehicle products." (Geely, pg. 26). This confirms that ambidexterity among legacy OEMs is not a clean switch from old to new, but a prolonged transitional configuration where exploitation finances exploration.

Thus, depicts organizational ambidexterity as an outcome of vision-guided dynamic capabilities operating under historical constraint. The "bridge" represents a necessary intermediary state, allowing firms to preserve profitability from ICE platforms while gradually reallocating resources toward radical innovation. Vision capability here plays a critical stabilizing role: it prevents organizational fragmentation by framing hybridization and hedging as legitimate strategic responses rather than signs of indecision.

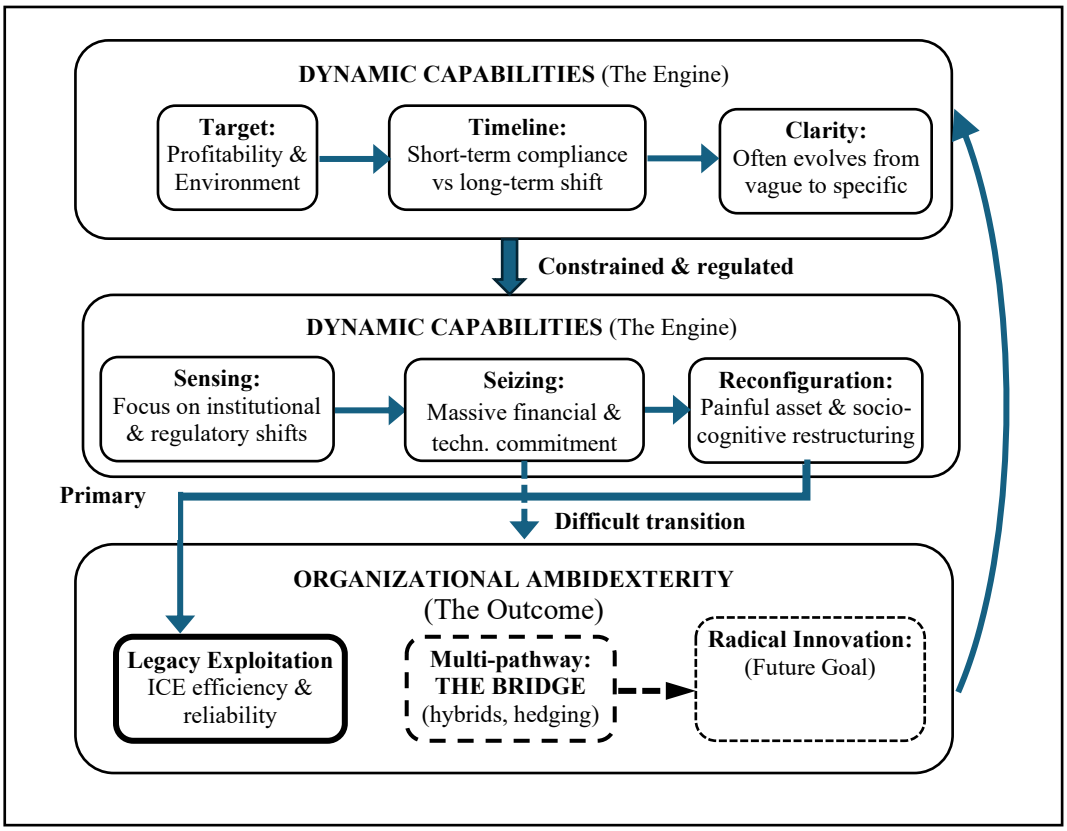
4.4.2 The radical leapfrog pathway of EV-forward firms

In contrast, Fig. 6 represents the transition logic of EV-forward firms, most notably BYD. These firms exhibit a qualitatively different configuration of VC, DC, and OA, characterized by the absence of legacy exploitation and a direct leap toward frontier technologies.

BYD's vision capability is both historically consistent and strategically decisive. Its long-standing commitment to decarbonization is evident in its articulation of the "three green dreams" as early as 2008 and its subsequent decision to become "the first automobile enterprise in the world to stop production of fuel vehicles in 2022" (BYD, pg. 3). Unlike legacy OEMs, BYD's vision eliminates ambiguity regarding technological direction, enabling a focused and aggressive transition.

This clarity profoundly shapes its dynamic capabilities. Sensing is oriented primarily toward market and consumer intelligence rather than regulatory compliance, while seizing is expressed through rapid innovation cycles and vertically integrated technology development. BYD emphasizes

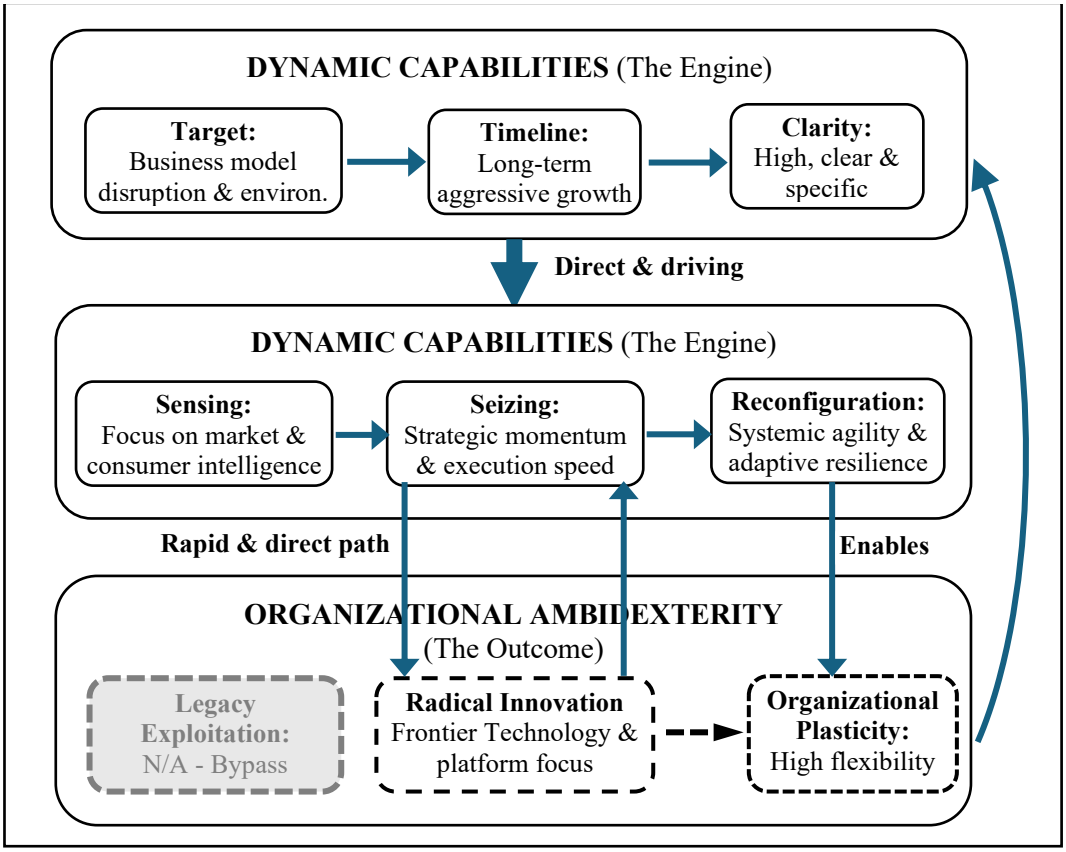
its adherence to technology.



"We have always adhered to the development concept of "Technology Based, Innovation Oriented" and unswervingly adhered to the new energy strategy, constantly spawning, and strengthening new productivity." (BYD, pg. 4)

Transformational reconfiguration in EV-forward firms is correspondingly more direct and systemic. BYD's deployment of proprietary platforms such as Blade Battery, e-Platform 3.0, CTB Technology, and intelligent driving systems demonstrates high organizational plasticity and adaptive resilience (BYD, pg. 4–5). Rather than dismantling legacy structures, these firms build new architectures from the ground up, enabling faster capability alignment and execution speed.

Consequently, organizational ambidexterity in Fig. 6 does not emerge from balancing ICE exploitation with EV exploration. Instead, it manifests as parallel radical innovation across multiple emerging domains (batteries, platforms, intelligent systems), supported by a highly flexible organizational structure. Legacy exploitation is effectively bypassed, allowing EV-forward firms to pursue a rapid and direct transition path.



Together, Fig. 5 and Fig. 6 demonstrate that ambidexterity is not a uniform organizational state but a historically conditioned outcome shaped by vision-guided dynamic capabilities. While incumbents must traverse a complex bridge between old and new, EV-forward firms enact a leapfrog strategy enabled by focused vision and organizational plasticity.

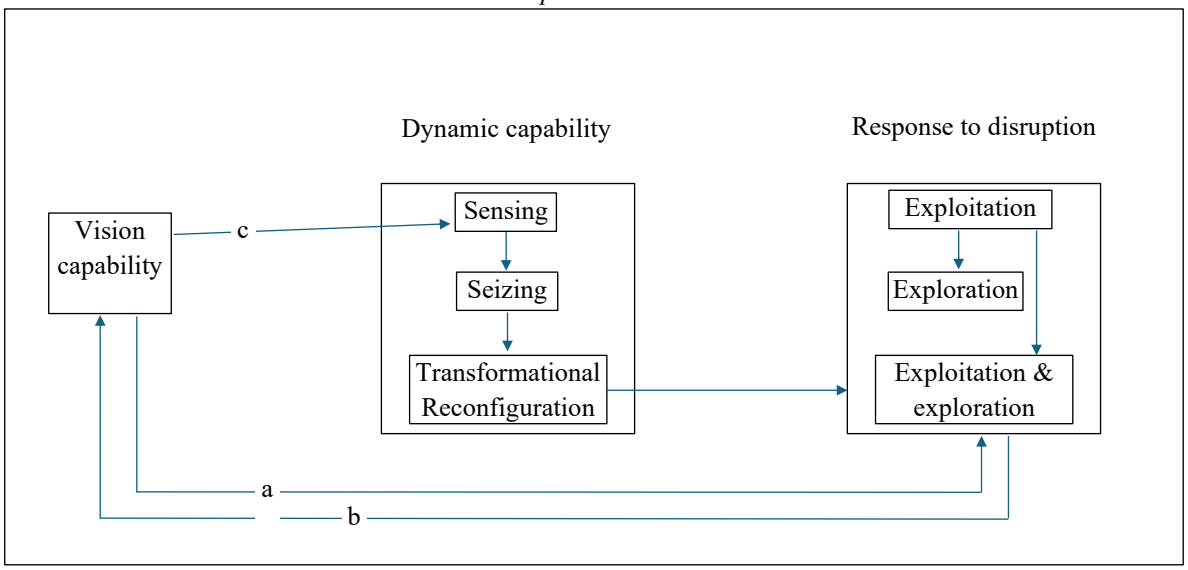
5. Discussion

Building on the literature review and the findings of the study, the study advances a general framework (see Fig. 7) in which vision capability (VC) operates as a higher-order strategic antecedent shaping dynamic capabilities (DC) and firms' transition pathways. Path c captures the indirect effect of VC on transition outcomes through DC, whereby vision guides sensing, seizing, and reconfiguration, leading to exploitation, exploration, or their simultaneous pursuit. Path a reflects the direct influence of VC on transition pathways, enabling firms to accelerate or redirect strategic responses to disruption independent of fully developed operational capabilities. Path b represents recursive feedback effects, through which enacted transition paths prompt re-articulation of organizational vision and recalibration of subsequent sensing and capability deployment. Collectively, the framework conceptualizes adaptation as a co-evolutionary process linking vision, dynamic capabilities, and ambidextrous innovation trajectories under conditions of disruption.

This study examined how vision capability governs dynamic capabilities in shaping organizational ambidexterity during the automotive industry's transition from ICE-based manufacturing to electrified and software-driven mobility. Integrating the study findings with the conceptual framework, the discussion advances a process model in which vision capability operates as a higher-order strategic antecedent that directs the development and deployment of dynamic capabilities, thereby determining firms' transition pathways and ambidextrous outcomes.

First, the findings establish vision capability as a strategic governor rather than a symbolic managerial artifact. Across both legacy and EV-forward firms, vision defines the object of analysis, legitimizes strategic trade-offs, and narrows organizational search spaces. For incumbent OEMs, vision integrates sustainability with continuity, enabling hybridized strategies that preserve customer trust while advancing electrification. For EV-forward firms such as BYD, vision performs a path-

creation function by reducing technological ambiguity and enabling decisive concentration of resources on new energy platforms. In this sense, vision capability shapes not only how firms interpret environmental change but also how rapidly they commit to particular innovation trajectories.



Second, dynamic capabilities emerge as the executional mechanism through which vision is translated into organizational transformation. Vision capability directs managerial attention toward salient environmental signals, thus, regulatory pressures for incumbents and market opportunities for EV-forward firms. This activates sensing processes that lead to seizing behaviors in the form of financial, technological, and organizational commitments. These commitments subsequently enable transformational reconfiguration encompassing both asset restructuring and socio-cognitive change. While this patterned progression from sensing to seizing and reconfiguration is evident across cases, its enactment differs sharply by organizational history. Legacy OEMs deploy dynamic capabilities incrementally, constrained by embedded ICE assets and institutionalized routines, resulting in gradual and socially complex reconfiguration. In contrast, EV-forward firms exhibit tighter coupling between sensing, seizing, and reconfiguration, supported by vertically integrated innovation systems and higher organizational plasticity.

Third, organizational ambidexterity is revealed as a contingent and path-dependent outcome rather than a stable equilibrium. Incumbent firms predominantly enact multi-pathway ambidexterity, balancing exploitation of legacy platforms with exploration of EVs, hydrogen technologies, and software ecosystems. EV-forward firms, by contrast, express ambidexterity through simultaneous radical innovations, largely bypassing legacy exploitation altogether. These findings challenge static conceptualizations of ambidexterity and instead position it as an evolving strategic configuration shaped by historical asset bases and vision-driven capability deployment.

The integrated framework further highlights both indirect and direct effects of vision capability on transition outcomes. While vision primarily influences ambidexterity through dynamic capabilities, it may also directly accelerate strategic shifts in advance of fully developed operational capabilities, helping to explain the rapid transition trajectories observed among EV-forward firms. Moreover, enacted transition paths generate recursive feedback effects, prompting re-articulation of organizational vision and recalibration of sensing and capability deployment. Strategic adaptation is therefore conceptualized as a co-evolutionary process in which vision capability, dynamic capabilities, and innovation trajectories mutually reinforce one another over time.

Collectively, these findings position vision capability as the foundational driver of strategic transformation, dynamic capabilities as the operative bridge between foresight and execution, and ambidexterity as a historically conditioned outcome of their interaction. By foregrounding the recursive and path-dependent nature of this process, the study reframes organizational ambidexterity not as a fixed balance but as a dynamically constructed response to disruption.

Fig. 7 Conceptual framework of how automotive OEMs respond to the disruption leveraging on their DC and corporate vision

Source: our elaboration

6. Conclusion

This study bridges the gap between academic theory and organizational practice by offering a dual-lens perspective that refines dynamic capability frameworks while providing actionable strategic guidance for navigating large-scale industrial transformations. Theoretically, it advances the literature by elevating vision to a higher-order dynamic capability that governs the coherence of sensing, seizing, and reconfiguration, while reconceptualizing organizational ambidexterity as a historically embedded configuration rather than a generic balance. By distinguishing the "transition bridge" of incumbents from the "radical leapfrog" of EV-forward firms, the research introduces a recursive model of strategic adaptation as illustrated in the feedback loops of Fig. 7. This incorporates cognitive governance and temporal co-evolution.

Practically, these findings underscore that successful transformation requires a coherent, operationalized vision to prevent dynamic capabilities from becoming fragmented; legacy OEMs must prioritize socio-cognitive renewal alongside asset reconfiguration, while EV-forward firms must anchor rapid innovation to scalable operational systems. Ultimately, by addressing how firms navigate the shift toward electric mobility, this research confirms that the divergence in strategic outcomes is rooted in the interplay between cognitive foresight and structural agility. These insights provide a comprehensive roadmap for understanding how both legacy and emergent players can maintain competitive advantage by treating ambidexterity as a fluid strategic state requiring continuous recalibration.

Strategic Configurations of Circular Economy in the Battery Value Chain: Evidence from Global Automotive OEMs

MARIA FEDELE[1], VINCENZO FORMISANO[2], GRAZIA MARIA ALESSANDRA LENA[3], SARA KULLAFI[4]

Abstract

Frame of the research. *The study is positioned within the Circular Economy (CE) literature in the automotive sector, focusing on how Original Equipment Manufacturers (OEMs) strategically implement circular practices along the battery value chain.*

Purpose of the paper. *This paper aims to analyze how automotive OEMs configure differentiated CE strategies along the battery value chain through the ReSOLVE levers (Loop, Exchange, Optimise) and to identify whether firms specialize in particular levers and which strategic configurations emerge. In doing so, the study addresses the limited attention paid in the literature to how firms select and combine specific operational and managerial levers into differentiated strategic configurations at the sector level.*

Methodology. *The study adopts quantitative content analysis of 2024 non-financial reports from 45 automotive OEMs, followed by lever-share analysis and ascending hierarchical clustering. This methodological design allows us to map the CE levers mobilized by each OEM, identify dominant strategic priorities, and detect recurring strategic configurations across firms.*

Results. *Findings show that OEMs do not adopt CE uniformly but tend to specialize around a dominant lever. Governance-related actions are particularly recurrent, highlighting the importance of coordination across the battery value chain.*

Research limitations. *The study focuses on three ReSOLVE levers and two managerial levers, rather than the full set of framework dimensions. Moreover, the analysis is based on a single year of reporting.*

Managerial implications. *The results imply the need to clearly define strategic priorities within the battery value chain, avoiding generic CE approaches and focusing resources on the most coherent levers, as effective CE strategies require alignment among strategic choices, organizational structure, internal capabilities, and regulatory frameworks.*

Originality of the paper. *The paper extends the ReSOLVE framework empirically to the battery value chain and adopts a configurational approach, integrating operational and managerial levers to interpret CE strategies in the automotive sector.*

Keywords: *circular economy; battery; automotive OEMs; ReSOLVE framework; quantitative content analysis; cluster analysis*

1.Introduction

The growing and rapid diffusion of electric vehicles (EVs) is profoundly transforming the automotive industry, creating new challenges related to the availability of critical raw materials and the increasingly urgent sustainable management of end-of-life batteries (Rezaei et al., 2025; Dixit et al., 2024; Jannesar et al., 2024; Tembo et al., 2024). The increase in demand, extraction and processing of strategic raw materials such as lithium, nickel and cobalt, characterized by high price volatility, social impact and concentration in specific geographical areas (Zackrisson et al., 2010; Song et al., 2019; Yan et al., 2020; Castro et al., 2022; Abdelbaky et al., 2023; Chen et al., 2023; Lai et al., 2023), require the adoption of production models capable of reducing both dependence on scarce resources and the environmental impact throughout the entire life cycle of batteries.

In this context, the CE emerges as a strategic paradigm to combine sustainability, industrial resilience and competitiveness, allowing automotive OEMs to extend the useful life of batteries, recover materials, contributing to waste reduction and costs along the entire supply chain (Cintra et al., 2025; Beaudet et al., 2020). From this perspective, the adoption of CE principles turns end-of-life

management into a value-creation opportunity, as it helps reduce reliance on suppliers concentrated in specific regions of the world while enhancing the efficiency of production systems. Despite the growing scholarly interest in battery circularity, three gaps remain. First, the CE is mostly interpreted as a holistic transformation of the value chain, with limited attention to the specific operational and managerial levers firms actually mobilize. Second, the literature has rarely examined how these levers combine into differentiated strategic configurations at the sector level. Third, systematic comparative evidence on how automotive OEMs configure CE strategies along the battery value chain is still missing. Addressing these gaps is particularly relevant given the role of OEMs as system integrators and supply chain orchestrators, whose decisions on technology, design, organization and governance shape circularity along the entire battery life cycle.

This study connects two types of research fields that have so far progressed in parallel: on the one hand, studies on the circular economy in operations and supply chain management has produced taxonomies of practices (Centobelli et al., 2020; Bertassini et al., 2021), but tends to treat them as stand-alone instruments rather than as elements of integrated strategic architectures. On the other hand, configurational and neo-configurational approaches in strategic management (Misangyi et al., 2017; Greckhamer et al., 2018; Furnari et al., 2021) have demonstrated the power of multiple, alternative configurations of conditions leading to the same outcome in explaining firm-level heterogeneity, but have only marginally engaged with sustainability transitions and, even less, with the battery value chain. Bridging these streams, OEMs' CE engagement is conceptualized as a strategic configuration in which operational levers (Loop, Optimize, Exchange) interact with two managerial levers (Design, Govern). The empirical relevance of the setting is reinforced by the EU Battery Regulation (Regulation (EU) 2023/1542) and the digital battery passport requirements, which raise the strategic stakes of CE positioning for global automotive OEMs. The aim of this study derives from the above considerations. In line with the aim, we adopt a configurational perspective to empirically examine how automotive OEMs implement CE strategies in the battery value chain through an adapted version of the ReSOLVE framework (Ellen MacArthur Foundation, 2015a). From this perspective, firms are understood as systems of interdependent elements, where strategic outcomes depend on the coherence among organizational structures, processes, capabilities and strategic choices rather than on isolated practices (Miller, 1987; Meyer et al., 1993). The analysis focuses specifically on the levers of the aforementioned framework that are most relevant and observable in the battery supply chain "Loop", "Optimise" and "Exchange" — integrated with two additional managerial levers, "Design" and "Govern", considered enabling factors to make circular practices implementable in complex industrial supply chains. To construct the dataset to be used for the empirical analysis, the non-financial reporting published by OEMs in 2024 (the last year for which reports were available) was used as an institutional source, in order to identify recurring strategic patterns and differentiated configurations of CE implementation. Although these reports have a declarative nature, they represent the formalized communication tool capable of defining and legitimizing one's CE strategies towards all stakeholders (Lanzalonga, 2025; Kamińska-Witkowska & Kaźmierczak, 2024). In addition, non-financial disclosure is an appropriate source for comparatively observing the declared sustainability strategies and strategic priorities communicated by companies to stakeholders.

In line with the objective, the following research questions are formulated:

RQ1: How are automotive OEMs configuring CE strategies along the battery value chain through the "Loop", "Optimise" and "Exchange" levers integrated with "Design" and "Govern"?

RQ2: Do OEMs tend to specialize in specific levers or combinations of levers in the implementation of battery circularity?

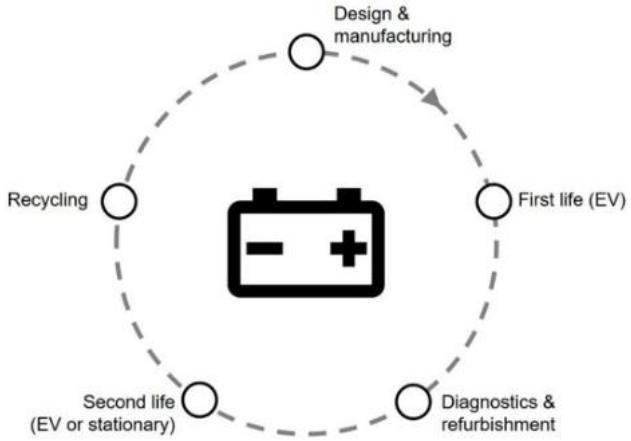
RQ3: What recurring strategic configurations emerge among automotive OEMs when CE strategies are analyzed from a comparative configurational perspective?

The results contribute to the literature on the CE by showing that the CE in the battery value chain emerges empirically as a set of differentiated and recurring strategic configurations to interpret the implementation of the CE, assuming that circularity does not emerge from the isolated adoption of

individual practices, but from the combination of operational and managerial levers that configure different strategic trajectories among automotive OEMs. From an empirical point of view, this work offers one of the first comparative analyses on a large international sample of automotive OEMs, identifying recurring strategic configurations of CE based on the strategies declared in non-financial reporting.

Building on these foundations, an alternative view of Circular Economy (CE) is adopted in this paper. Rather than being treated as a toolkit or as a set of practices from which organisations may choose (Ellen MacArthur Foundation, 2015; Centobelli et al., 2020), CE is here approached through a configurational architecture lens. Drawing on the neo-configurational perspective in management research (Furnari et al., 2021; Misangyi et al., 2017), the implementation of CE strategies is conceptualized as a bundle of operational levers (Loop, Optimise, Exchange) and managerial levers (Design and Govern) whose joint deployment, more than the additive contribution of each lever taken in isolation, gives rise to distinct strategic configurations. The shift from a list-based to a configuration-based reading constitutes the conceptual pivot of the paper.The remainder of the paper is organized as follows. After the next section where the theoretical framework and literature review are developed, the process for the composition of the dataset and the methodological approach used is described. Then the results of the analyses are presented and discussed in the light of the existing literature. Finally, the theoretical and managerial implications, as well as the limitations of the research, are illustrated together with the conclusions.

2. Circular Economy and strategic configurations: a theoretical background



In recent years, the automotive industry has been undergoing a profound structural transformation driven by the need to reduce emissions of carbon dioxide and other greenhouse gases associated with road transport, increasingly shifting production towards EVs (Niri et al., 2024; Bonsu, 2020). Forecasts indicate that, after 2030, about half of the new vehicles produced will be electrified (BloombergNEF, 2024). All this makes sustainable battery management a central issue for the industrial competitiveness and environmental sustainability of the sector.

The transition towards EVs requires adopting CE practices that are able to reduce resource consumption and improve the overall efficiency of production systems (Demartini et al., 2023). The CE is based on the principle that what reaches the end of its life and which would be waste can be transformed into a new production resource, extending the economic and environmental value of materials over several cycles of use (Fedele & Hysa, 2024; Kirchherr et al., 2017; MacArthur, 2013).

However, there is still limited understanding of how these principles are translated into concrete strategic configurations by automotive OEMs, making it useful to analyse the operational and managerial configurations through which circularity is implemented along the battery value chain. In the automotive sector, circularity is particularly important in managing the entire life cycle of batteries, which are destined to generate increasing volumes of waste in the coming decades. Circular management of the value chain, from design to recycling, can mitigate raw material scarcity and reduce the accumulation of industrial waste (Dutta et al., 2026; Almahri & Heungjo, 2025; Bruno et al., 2025; Machala et al., 2025; Bobba et al., 2019). Batteries, indeed, do not generate benefits exclusively during their automotive life cycle, but can be reused or reconfigured when their capacity drops to 70–80% of the original state of health (Machala et al., 2025; Etxandi-Santolaya et al., 2023).

The circular value chain of batteries includes a plurality of interdependent activities: design and production, use during the first life, health assessment, second life in alternative applications and final recycling of materials (Olsson et al., 2018).

Fig. 1: The circular value chain of batteries for electric vehicles

Source: Olsson et al., 2018

During the design and manufacturing phases of batteries, the selection of materials directly affects the possibility of future reuse and recovery, while diagnostic and reconditioning activities require close collaboration among supply chain actors to ensure the safety and quality of reuse (Saari et al., 2026). Similarly, the implementation of circularity requires the development of reverse logistics systems and coordinated collection, disassembly and recycling activities (Gonzales-Calienes et al., 2022; Tadaros et al., 2022). The implementation of CE practices within the battery value chain generates significant environmental and economic benefits, contributing to the possibility of reducing costs and enhancing *brand reputation* in response to increasing consumer sensitivity toward sustainability (Hu et al., 2022; Kautish et al., 2019). However, the multiplicity of activities, processes, and actors involved makes the battery value chain intrinsically complex, configuring circularity as a multidimensional and systemic phenomenon. This complexity necessitates the adoption of an analytical perspective capable of capturing not only individual practices but also their strategic combinations. Within this context, the ReSOLVE framework, developed by the Ellen MacArthur

Foundation in collaboration with McKinsey (2015), represents one of the primary analytical tools utilized to interpret the implementation of CE practices within firms (Sell et al., 2023; Tedesco et al., 2022). The framework translates the fundamental principles of the CE into the six strategic levers, Regenerate, Share, Optimise, Loop, Virtualise and Exchange, which guide operational and organizational choices oriented towards sustainability. In particular, the "Optimise", "Loop" and "Exchange" levers are more observable in the industrial context of the battery value chain: the first concerns process efficiency and waste reduction (Mhatre et al., 2021), the second the closure of material cycles through reuse and recycling, while the third involves the adoption of innovative technologies and materials. In this perspective, the ReSOLVE framework can be interpreted not only as a classification of circular practices, but as a set of combinable policy options, the integration of which generates alternative strategic configurations of CE implementation.

The multidimensional character is linked to the fact that CE integrates economic, environmental and social dimensions and requires technological, organisational and institutional transformations along the entire value chain (Geissdoerfer et al., 2017), highlighting its systemic nature. In line with the configurational perspective, according to which organizations are systems of interdependent elements (Miller, 1987; Meyer et al., 1993), CE can be interpreted not as the result of the isolated adoption of individual practices, but as the outcome of coherent and interdependent strategic configurations of strategies and contextual factors (Zhu et al., 2022). Recent studies have shown that the effective implementation of circularity in batteries requires coordination between different business functions and supply chain actors (Schulz-Mönninghoff et al., 2023), as well as the presence of enabling factors such as technology and infrastructure (battery eco-design, modularization, monitoring, diagnosis, tracking and digitization), interorganizational collaborations (information

sharing, collaboration and alignment of stakeholders), economic incentives (incentives for recycling, more favorable market conditions), consistency with policy and regulatory principles (eco-design directives, standards, certifications, regulatory consistency) and social aspects (social commitment) (Sopha et al., 2022). Since the implementation of circularity in complex industrial supply chains depends not only on operational practices but also on organizational and coordination skills, the need to integrate managerial dimensions into the framework emerges. As a result of adopting the configurational perspective, additional managerial levers become relevant: "Design" and "Govern".

The "Design" lever concerns the design of products and components oriented towards reuse, repair, regeneration and recycling, enabling circular strategies to be technically implemented (Moreno et al., 2016; Shahbazi & Jönbrink, 2020). The "Govern" lever, encompasses the set of supply chain governance mechanisms - formal (policy and audit) or relational (partnership) - necessary to guide and coordinate supply chain partners towards CE and sustainability objectives (Perdana et al., 2023; de Haan-Hoek et al., 2020; Formentini & Taticchi, 2016). In the context of the battery value chain, these mechanisms are particularly relevant because the complexity of battery production and chemical composition affects disassembly and reverse logistics activities, making coordination between the players in the supply chain essential. The integration between operational and managerial levers is reflected in the literature on CE, which highlights the complementary role of technologies and interorganizational collaboration as enabling factors of circular implementation (Cagno et al., 2021; Rusch et al., 2023). Despite the wide diffusion of the ReSOLVE framework in various sectors (Ta et al., 2024; Payne & Kwofie, 2024), there is still limited systematic comparative evidence on automotive OEMs and there is a lack of analyses that explicitly examine the CE as a set of strategic configurations resulting from the integration of operational and managerial levers. Overall, the existing literature has made key contributions in mapping the technical and operational dimensions of battery circularity and in highlighting the enabling role of organizational coordination, governance mechanisms and inter-firm collaboration along the value chain. What remains underexplored, however, is how these dimensions are systematically combined by automotive OEMs into recurring strategic configurations.

Taken together, the CE literature can be understood as comprising two complementary yet largely disconnected strands: on the one hand, rich descriptions of the *what* (i.e., the practices and levers of circularity, often presented as toolkits), and on the other, a separate body of work addressing the *who* and the *why* (i.e., organisational behaviour, capabilities, and managerial commitment in the CE transition) Bertassini et al., 2021. What remains under-theorised is the *how they combine*: the conjunctural logic through which OEMs assemble these levers into coherent strategic profiles. The neo-configurational turn in strategic management (Misangyi et al., 2017; Furnari et al., 2021; Roshan et al., 2025) offers a suitable conceptual scaffolding to address this gap. Building on three core tenets of neo-configurational theory - equifinality, conjunctural causation and causal asymmetry - this study examines whether and how OEMs' CE engagements cluster into recurrent configurations rather than dispersing along a continuum of incremental adoption.

In the light of the theoretical framework outlined, the need emerges to adopt a research design capable of capturing the multidimensional and configurational nature of CE strategies along the battery value chain. In particular, the empirical analysis is oriented towards identifying emerging strategic patterns among automotive OEMs, overcoming a reading of circular practices based on single isolated dimensions. For this purpose, the study adopts a blended methodological approach that combines content analysis techniques and configurational analysis, described in the following section.

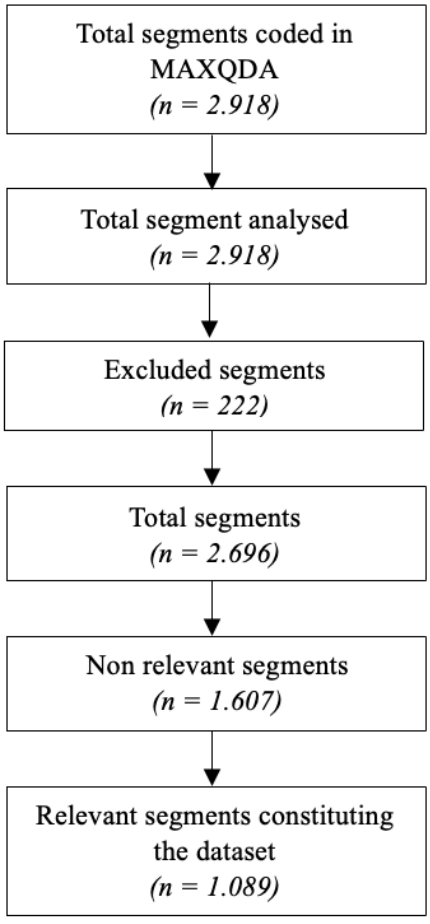
3. Methodology

In line with the theoretical framework and the research questions formulated, the methodological design was developed to empirically analyse the strategic configurations of CE adopted by

automotive OEMs along the battery value chain. Each research question is addressed through a specific analytical step: RQ1 through the quantitative content analysis of non-financial reports, which maps the levers mobilized by each OEM; RQ2 through the calculation of OEM-level lever shares and the identification of a dominant lever for each company; RQ3 through the hierarchical clustering performed on OEM-level lever profiles. Although presented separately, these steps form an integrated research design whose joint application is what allows the configurational nature of CE strategies to emerge.

As shown, this study adopts a mixed analysis method. The first phase consists of a quantitative analysis of the contents (Nicmanis, 2024; White et al., 2006; Rourke et al., 2004) of non-financial reports aimed at identifying the ReSOLVE framework levers attributable to individual OEMs across the battery value chain. The second phase involves a cluster analysis designed to identify and classify OEMs into homogeneous groups based on the CE strategies they pursue, in order to highlight any recurring patterns, structural differences or distinct strategic models within the automotive sector.

Consistent with the configurational perspective adopted, the methodological approach seeks to identify emerging strategic configurations and recurring patterns, rather than the verification of causal relationships between variables. In practical terms, the content of non-financial reports was coded (Nicmanis, 2024; White et al., 2006; Rourke et al., 2004) to assign to the relevant fragments of texts both the ReSOLVE levers and the two managerial levers. The resulting OEM-level profiles were then analysed using ascending hierarchical clustering to uncover recurring strategic patterns from the configurational point of view (Miller, 1987; Meyer et al., 1993). The empirical basis is made up of secondary data drawn from the non-financial reporting published by automotive OEMs (sustainability report, integrated report, annual report), which is widely regarded as a reliable and privileged institutional source for the analysis of declared strategies in the field of sustainability. All the reports date to the year 2024, the last accessible at the time of download. The initial sample included 77 brands; however, for 32 of them a standalone report was not available, as non-financial reporting was included in the parent company's documents. The final sample analysed is therefore made up of 45 brands that include both traditional operators in the automotive sector and new leaders in the electric mobility segment, ensuring coverage of the main regulatory areas (European Union, United States, China, Japan and India), as well as the presence of pioneering companies in activities related to the CE. The decision to rely on official non-financial disclosure is grounded in its role as a privileged institutional source for the analysis of sustainability strategies declared by companies (Hahn & Kühnen, 2013; Gray et al., 1995).



For quantitative content analysis, each report was imported into MAXQDA (version 24.11.1) and subjected to qualitative coding the text segments containing the term "battery" and its variants (e.g. "batteries" or *"BEV" or "BEVs" as acronyms for Battery Electric Vehicle). A "textual segment" refers to the unit of semantic context extracted by MAXQDA around the keyword, preserving the syntactic integrity of the sentence in which the term appears. Among the keywords, terms such as “Battery Energy Storage Systems” and “Battery Storage Systems” were excluded. This methodological decision was made to enhance the precision, avoiding confusion about the terms of the study. In fact, the keyword “Battery Energy Storage System” is mainly used to describe battery storage as a stationary storage system referring to the electricity grid and renewable energies (Meyer et al., 2024; Thakur et al., 2022; Hannan et al., 2021), rather than as a component of the battery value chain of automotive OEMs.

The analysis of the documents, conducted as illustrated in figure 2, led to the identification of 2,696 text segments. The coding procedure was carried out following systematic criteria defined in advance, based on the literature and consistent with the operational definitions of the strategic levers adopted in the study, to ensure interpretative consistency in the attribution of the strategic levers. The coding process was also conducted following iterative procedures of revision and interpretative comparison, to reduce possible classification ambiguities and strengthen the analytical reliability of the assignment of levers. The coding was carried out by a researcher and then subjected to an internal review on a subset of segments (corresponding to 30% of the total and randomly selected) to verify

consistency and interpretative stability of the criteria adopted. Disagreements or ambiguous coding cases were discussed iteratively against the operational definitions of each lever until interpretative consistency was achieved. This procedure strengthened the reliability and theoretical coherence of the coding process. A manual analysis was conducted on this dataset aimed at attributing, where possible, to each segment a specific lever of the ReSOLVE framework with the exclusion of the following three levers: "Regenerate", "Share" and "Virtualise", as they are considered less directly observable and theoretically relevant in the specific context of the battery value chain of automotive OEMs.

This procedure showed that only 1,089 segments, each of which represents a unit of analysis, had characteristics that allowed the attribution of one or more ReSOLVE (multi-tagging) levers, based on the content. The textual segment has been considered an analytical unit as it represents the smallest empirically observable expression of the declared strategies related to the battery value chain. Each segment analysed, which includes the term "battery", was considered as significant for the purposes of the analysis whenever a reference was found for example to cells, battery materials (lithium, nickel, cobalt, graphite, black mass, etc.), production, recovery, reuse, recycling, re-manufacturing, or other R-strategies of the CE, end-of-life, battery supply chain, use of batteries in energy systems. This allowed us creating the final dataset for the analyses (see Figure 2).

Figure 2: Segment identification, screening, and selection

Source: our elaboration

Once the dataset was defined, the analysis was designed in a way that was consistent with the configurational perspective adopted in the study (Miller, 1987; Meyer et al., 1993). Since the implementation of circularity in complex and technology-intensive industrial supply chains, such as batteries and specifically lithium batteries, is inherently multidimensional, it is detectable through the

adoption of a systemic combination of strategic levers (Geissdoerfer et al., 2017). In line with the configurational perspective adopted in the study, the objective of the analysis is not to evaluate the isolated effect of the individual levers, but to identify emerging strategic configurations deriving from their combination. Consequently, the cluster analysis was conducted using an integrated set of variables, combining levers of the ReSOLVE framework relevant to the industrial sector ("Loop", "Optimise", "Exchange") with additional industrial managerial dimensions ("Design" and "Govern") precisely to highlight the multidimensional configuration of the circular strategies adopted by OEMs (Kirchherr et al., 2017). This methodological choice is consistent with configurational studies, in which organizational phenomena are interpreted as the result of simultaneous combinations of conditions rather than as independent effects of single variables. In addition, the approach adopted is in line with studies on sustainability and industrial transitions that emphasize the co-evolution of technological, organizational and institutional elements. Applying the content analysis method, the "Loop" lever was associated with the individual segment analysed whenever closed-loop strategies, recycling, recovery, reuse, second life, end-of-life and battery remanufacturing were detected; the "Optimise" lever was associated whenever aspects related to resource efficiency were found, including energy, emissions and water, battery life, cost reduction, impact reduction and emission reduction; the "Design" lever was associated with the segment analysed when concepts referring to battery safety, battery product architecture, durability and disassembly and recycling oriented design were detected; the "Exchange" lever has been associated when the segment analysed is talking about new chemical formulations or more generally about process innovations or recycling technologies; the "Govern" lever, on the other hand, was associated with the segment analysed when it comes to sourcing, supplier, audit, traceability, partnerships, regulation, and policy. While the text only talks about ESG factors in general, the segment has not been associated with any strategic leverage. The final dataset has a qualitative-quantitative structure, consistent with the methodology adopted and is organized at OEM level of analysis. For each brand, descriptive information was collected through secondary sources, such as the year the company was founded, the group to which it belongs or ownership (i.e. whether it belongs to a group or is independent), the continent and state of the registered office, the market segment served divided into supercars, luxury cars, premium, generalist and multi-segment, as well as an indication of the exclusive production of electric or plug-in hybrid vehicles. From a quantitative point of view, the dataset has been enriched with variables relating to the number of relevant textual segments associated with each strategy of the ReSOLVE framework adapted and integrated with managerial levers applicable to the industrial sector. A relevance share was then calculated, as the ratio between the number of relevant segments and the total of segments identified for each company.

$$\text{Relevance Share}_i = \frac{\text{Number of Relevant Segments}_i}{\text{Total Identified Segments}_i} \times 100$$

As already mentioned, an analysed segment is relevant when the text contained in it allows the association with one or more levers of the ReSOLVE framework adapted and augmented with the managerial levers. This indicator was introduced for standardisation purposes, to mitigate potential distortions arising from differences in report length or from the different degree of in-depth treatment of battery-related issues. Similarly, a share was calculated for each lever. This captures the relative frequency with which each lever is adopted in relation to the total relevant content identified for each OEM.

$$\text{Lever Share}_i = \frac{N_{\text{rows in which lever } i \text{ is identified}}}{N_{\text{relevant rows}}}$$

Finally, a dominant lever was associated with each OEM, intended as a synthesis of the strategies adopted with respect to the entire ReSOLVE framework, identified as the lever that has the highest

share value compared to the others. To achieve the research aim, the statistical analyses were conducted in R (version 4.5.2) to identify the most recurring strategic configurations among OEMs.

For each OEM, the two levers with the highest share (Top1 and Top2) were selected, and the relative pairs were aggregated by frequency. The results were represented through a bubble chart, where the position indicates the combination of levers and the size of the bubble indicates the number of associated OEMs. Finally, an analysis was carried out by groups of companies, taking as a reference variable the dominant lever, identified as the lever with the highest share for each OEM. Following the groupings by dominant lever, a hierarchical cluster analysis was conducted aimed at identifying homogeneous groups of OEMs characterized by similar strategic profiles in terms of CE.

A principal component analysis (PCA) was preliminarily carried out with the aim of synthesizing the complexity of the dataset. On this basis, ascending hierarchical clustering was carried out in R (version 4.5.2) aimed at grouping OEMs according to their degree of similarity. The analysis of the dendrogram made it possible to identify the most appropriate number of clusters (equal to five). This methodological approach therefore makes it possible to systematically and comparatively analyse the strategies declared by automotive OEMs, while preserving the multidimensional complexity of the CE in the battery value chain. The results deriving from this analytical approach are presented in the following section, with the aim of highlighting the empirically observable emerging strategic configurations and structural differences between the OEMs analysed.

Two limitations arise from the use of corporate sustainability reports as the primary data source. First, these documents are prepared autonomously and, in most regulatory contexts, are not yet subject to external assurance comparable to that required for financial reporting; this exposes content analysis to a potential risk of greenwashing, whereby narrative emphasis may overstate actual commitment (He et al., 2024). The recent diffusion of IFRS S1/S2 and the proposed ISSA 5000 sustainability assurance standard indicate a move toward more verifiable disclosure; however, at the time of coding, the institutional infrastructure for assurance remains in a phase of development. Second, reporting practices remain heterogeneous across different frameworks (GRI, SASB, TCFD, IFRS S2) and jurisdictions; even with the entry into force of the EU CSRD in 2024, comparability across OEMs remains limited.

4. Results

4.1 Initial data analysis

In line with the research questions, this section describes the composition of the sample and the distribution of the levers (and their combinations) to provide a preliminary picture of the strategic configurations of CE adopted by OEMs. The descriptive analysis of the sample allows us to contextualize the differences observed in the levers of CE. The primary descriptive statistics relating ownership structure, geographical location, market positioning and technological orientation are presented below. In terms of ownership structure, the reference sample is mainly group-driven, in line with the presence of large multinational groups in the automotive sector. Specifically, 31 brands belong to multinational automotive groups, while 14 brands operate as independent manufacturers, highlighting a substantial presence of operators not integrated into large industrial groups. Regarding the overall distribution of automotive brands based on the registered office, the sample shows a marked geographical polarization, with a strong concentration in some areas of the world that are driving the development of the automotive industry. Europe, America, and East Asia emerge as the main poles: the sample of automotive brands with registered offices in Asia includes 19 OEMs and is characterized by a strong heterogeneity. In terms of market positioning, there is a clear prevalence of the generalist segment, which represents the dominant configuration, while only a minority of brands are in the premium and luxury car segments.

In the sample, EV-only brands coincide with new entrants (recently established brands). The sample of automotive brands with registered offices in Europe is made up of 20 OEMs. From a

chronological point of view, the data show a structure unbalanced towards historical OEMs, with a residual presence of new entrants; only very few cases of recent foundation are placed in the nineties or later. In terms of ownership, there is a clear prevalence of brands belonging to large multinational groups, particularly European, with a more limited share of independent brands, often concentrated in the higher value-added segments. In terms of market positioning, the sample has a distribution strongly oriented towards the premium segments, luxury cars and supercars, which are overrepresented compared to the generalist segment, although present through some major historical brands. This distribution indicates a greater presence, in the European subsample, of brands placed in the premium, luxury, and supercar segments.

As far as technological orientation is concerned, exclusively electric production is marginal and limited to a very small number of brands, while the majority adopts multi-technological strategies
The sample of automotive brands headquartered in the United States is made up of 6 OEMs and has a marked heterogeneity from a historical, proprietary and strategic point of view. From a temporal point of view, the sample includes both historical and recently founded brands, mainly located in the 2000s. In terms of ownership, independent brands prevail, flanked by some OEMs belonging to large multinational groups. Historical brands are more frequently integrated into consolidated industrial groups, while more recently founded brands tend to maintain an independent ownership structure. In terms of market positioning, the sample shows a balanced presence between generalist brands and brands located in the premium and luxury car segments. The generalist brands are mainly attributable to the historical OEMs, while the most recent brands are more concentrated in the higher value-added segments. With a view to technological orientation, exclusively electric production is adopted by a significant part of the sample and is concentrated in newly founded brands, while historical OEMs present a multi-technological offer. Overall, the US sample is characterized by a higher incidence of native electric brands than in the European context. Table 1 reports the respective shares that the five levers occupy in the dataset.

Table 1: Lever-relevant shares

	Loop share	*Optimise share*	*Design share*	*Exchange share*	*Govern share*
Mean	0,353	0,151	0,182	0,161	0,352
Median	0,327	0,100	0,143	0,083	0,333
Standard deviation	0,301	0,204	0,222	0,212	0,259

Source: our elaboration

The shares indicate the relative frequency with which each lever appears compared to the total of the relevant segments identified for each OEM (i.e., relevant rows). All lever shares have values between 0 and 1. The highest average share is associated with the “Loop” lever (0.353) immediately followed by the “Govern” lever (0.352), indicating a higher relative incidence of “Loop” content in the sample (Table 1).

The medians of the “Loop” and “Govern” levers indicate a relatively balanced distribution of values in the sample. The standard deviation varies between levers: “Loop” records the highest value (0.301) so it has the greatest variability between brands. Within the sample analysis, as shown by the distribution of frequencies per dominant lever in Table 2, the two most relevant levers in absolute terms are “Loop” and “Govern”.

Table 2: Frequency distribution per dominant lever

Levers	*No. of OEM*
Design	3
Exchange	6
Exchange/Govern	1
Govern	16
Loops	11
Loop/Govern	1
Loop/Optimise	1
Loop/Optimise/Exchange	1
Optimise	5
Total	45

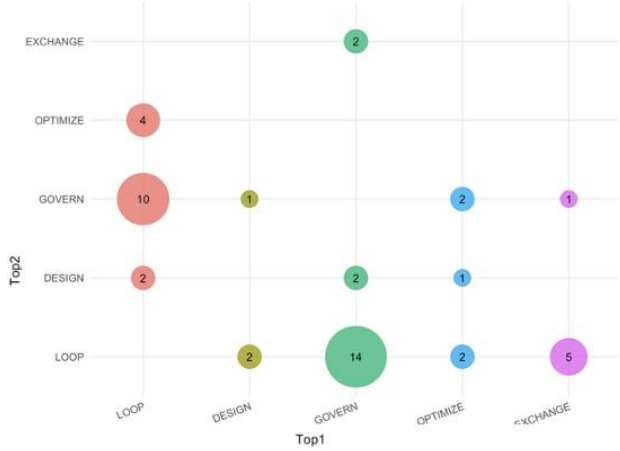
Source: our elaboration

Moreover, across the different market segments (supercars, luxury cars, premium, generalist and multi-segment) substantial differences emerge in the configuration of the CE levers (see Table 3).

The values shown in Table 3 represent the sum of OEM-level shares calculated on relevant rows for each lever within each market segment. As a result, results can exceed one and reflect the overall lever intensity in the segment. Furthermore, since these are aggregate values, they are also affected by the different number of OEMs per segment. In aggregate terms, "Loop" and "Govern" are prevalent, but with varying intensity between segments. The generalist segment has the highest values, especially for "Loop" and "Govern", suggesting that, in sectors with high production intensity and greater logistical complexity, the emphasis on "Loop" and "Govern" is consistent with a reading of the CE as a supply chain coordination challenge (traceability, standardization and inter-organizational collaboration). The management of end-of-life battery flows, in this context, takes on greater industrial importance where economies of scale require systemic recovery and traceability solutions. In the premium and luxury car segments, there is a higher relative incidence of "Design", indicating an approach to CE that is predominantly oriented towards product design, durability and perceived quality, rather than large-scale cycle closure. In the supercar segment, the reduced values - for "Exchange" and "Optimise" - indicate a more limited integration of circular practices, probably related to reduced production volumes and industrial models less dependent on process efficiencies.

Therefore, the CE in the battery value chain does not follow a uniform path among OEMs but develops through differentiated trajectories according to the industrial model and the competitive positioning of the different market segments.

Table 3: Sum of shares on relevant rows by lever and market segment



Segment\ Lever	*GOVERN*	*EXCHANGE*	*DESIGN*	*OPTIMISE*	*LOOP*
Luxury cars	3,2	1,5	2,3	1,9	1,6
Generalist	7,8	3,5	3,3	3,3	10,3
Multi-segment	0,5	0,7	0,3	0,1	0,5
Premium	2,2	1,2	1,8	1,1	2,2
Supercars	1,8	0,0	0,3	0,1	1,0
Total	15,8	7,2	8,1	6,7	15,8

Source: our elaboration

Through the R (version 4.5.2), an exploratory analysis was conducted aimed at identifying the strategic configurations of levers most frequently adopted by OEMs. To this end, for each OEM, the

two levers with the greatest relative weight, measured through the share on the relevant rows, were identified, and the corresponding pairs were subsequently aggregated and analyzed (Figure 3).

Figure 3: Distribution of strategic configurations

Source: our elaboration

The most frequent combination is “Govern-Loop” (top1: govern, top2: loop), with a count of 14. This is followed by “Loop-Govern” (top1: “Loop”, top2: “Govern”) with 10 and “Exchange-Loop” with 5. It should be noted that this analysis does not constitute a cluster analysis in the strict sense, as it is not based on distance measurements or aggregation algorithms, but represents a descriptive exploration of the most recurrent strategic configurations among the dominant levers. The fact that the most frequent combination associates a ReSOLVE lever (“Loop”) and a managerial lever (“Govern”) is consistent with the research assumption that managerial levers can act as enablers in the implementation of ReSOLVE levers.

4.2 *Analysis of groups by dominant lever*

In order to achieve the objective set in this work and for the sake of completeness of information with respect to the analysis of the strategic configurations of the most frequent levers, the sample was divided into groupings taking as a classification variable the dominant lever in absolute terms, defined as the lever with the highest share for each OEM. On this basis, nine distinct groupings have been identified: five composed of OEMs characterized by a single dominant lever and four groupings that include OEMs for which multiple levers are dominant simultaneously (Table 4). The groups' analysis highlights differentiated strategic configurations, associated with geographical and structural patterns. European OEMs show a greater incidence of the "Govern" and "Optimise" levers. Asian OEMs, on the other hand, have a greater emphasis on the operational levers of "Loop" and "Exchange". In addition, the fact that multi-lever strategic configurations are represented exclusively by groupings composed of a single brand highlights a tendency towards focus, rather than balance between different dimensions.

Table 4: Groups Characteristics

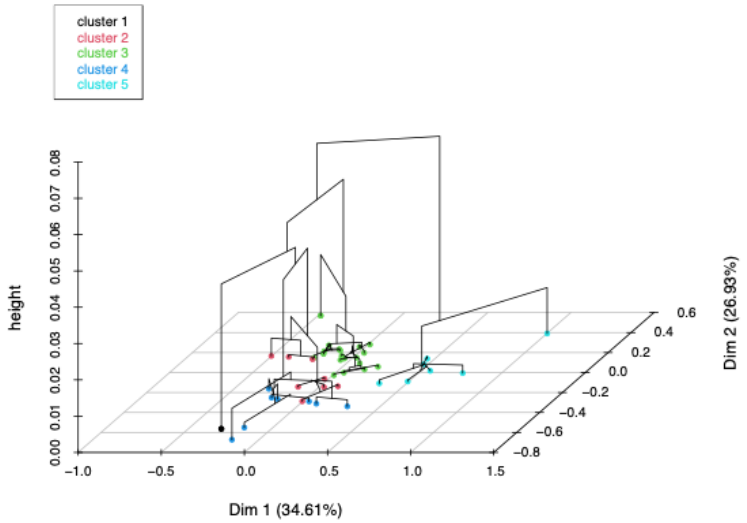
	Groups	Features
1	Govern	It mainly includes OEMs with registered offices in Europe, flanked by American and Asian brands, operating mainly in the generalist and luxury car segments and characterized by heterogeneous ownership structures, united by a strategy in which the "Govern" lever is predominant.
2	Loop	It mainly includes generalist OEMs with registered offices in Asia, flanked by individual cases in America and Europe, characterized by heterogeneous ownership structures and a strategic profile in which the "Loop" lever is predominant compared to the other levers considered.
3	Design	It includes a limited number of OEMs with registered offices equally distributed between Europe and Asia, operating exclusively in the premium segments and luxury cars with all-electric production, characterized by heterogeneous ownership structures and a strategy in which battery eco-design practices are predominant.
4	Exchange	It mainly includes OEMs with registered offices in Asia, supported by some European brands, operating in heterogeneous market segments – with a prevalence of generalist OEMs – characterized by diversified ownership structures and a strategic profile in which the "Exchange" lever is predominant.
5	Optimise	It includes OEMs mainly with registered offices in Europe, supported by some Asian brands, operating in the luxury, generalist and to a lesser extent premium car segments, characterized above all by belonging to large industrial groups and by a strategic profile in which the "Optimise" lever is predominant.
6	Loop-govern	Isuzu is a generalist OEM based in Asia, characterized by a joint dominance of the "Loop" and "Govern" levers, reflecting a balanced distribution between battery circularity strategies and content related to supply chain governance.
7	Exchange-govern	Mazda is an independent OEM based in Asia with a generalist positioning that reflects a greater incidence of exchange and collaboration strategies flanked by supply chain governance content.
8	Loop-Optimise	SEAT is a European-based generalist OEM belonging to the Volkswagen Group, characterized by a dominant combination of the "Loop" and "Optimise" levers, reflecting the coexistence of circularity and resource efficiency strategies
9	Loop-Optimise-exchange	Škoda is a European-based generalist OEM belonging to the Volkswagen Group, reflecting a relatively balanced distribution between circularity, resource efficiency and exchange/partnership strategies.

Source: our elaboration

4.3 *Cluster Analysis*

To maximize the descriptive capability of the dataset and identify homogeneous groups of OEMs characterized by similar strategic profiles, a cluster analysis was conducted. As a preliminary to the cluster analysis, a Principal Component Analysis (PCA) was carried out with the aim of reducing the dimensionality of the data and synthesizing the information contained in the original variables (Figure 4). PCA was used exclusively as an exploratory dimensionality-reduction technique aimed at visualizing similarities and differences among OEMs. The actual classification of firms into homogeneous groups was instead obtained through hierarchical cluster analysis.

Figure 4: Factor Map. PCA



Source: our elaboration

The factor map highlights how OEMs are distributed in the space defined by the first two components, suggesting the presence of structural differences in the strategic profiles of the CE. The distance between the observations reflects the degree of similarity between the strategies adopted, while the presence of densities indicates the existence of recurring strategic configurations among OEMs. Although OEMs are displayed in five colours in the factor map, it should be noted that this colour reflects the membership of the clusters identified later through hierarchical cluster analysis.

The PCA, in fact, does not produce a classification of the observations, but provides an exploratory representation that allows to highlight densities and structural differences in space. Based on this evidence, a hierarchical cluster analysis was applied, to formalize these strategic configurations in homogeneous groups of observations. The hierarchical cluster analysis was conducted on share variables (standardized in z-score), using a Euclidean distance measure and a Ward linkage criterion.

The application of hierarchical cluster analysis has led to the creation of the dendrogram whose analysis allows evaluating the degree of "separation" between the groups and to identify the most appropriate number of clusters, through the observation of jumps in the levels of dissimilarity. In the case at hand, the five-cluster solution is the most suitable as it allows maintaining a good balance between internal homogeneity and differentiation between groups. The dendrogram projected onto the factor map (Figure 5) allows you to visualize the hierarchical structure of the clusters in the space defined by the principal components. The graph shows that OEMs belonging to the same cluster tend to be in contiguous regions of the factor map, confirming the spatial coherence of the identified groups. Branches of the dendrogram that develop at lower levels indicate aggregations between very similar observations, while mergers that occur at higher levels reflect the union of clusters characterized by more distant strategic profiles. The separation between the main branches of the tree is consistent with the distribution of points along the factor dimensions, suggesting that the differences between the clusters are indeed driven by the size identified by the PCA. The consistency between the separation of the dendrogram branches and the distribution of the OEMs on the factor map confirms the validity of the five-cluster solution, highlighting how the identified groups reflect real structural differences in the strategic profiles analyzed.

Figure 5: Hierarchical tree on the factor map

Source: our elaboration

To understand which levers contribute significantly to the definition of the identified clusters, a quantitative characterization analysis of the clusters was conducted (Table 5). Specifically, for each cluster, the levers that show a statistically significant difference compared to the overall average of the sample were identified.

Table 5: Quantitative characterization of clusters

Cluster	Lever	v-test	Mean in category	Overall mean	p-value
1	DESIGN.share.on.relevant.rows	5.323491	1	0.1815324	1.017944E-07
1	GOVERN.share.on.relevant.rows	-1.971908	0	0.3523800	4.862016E-02
2	EXCHANGE.share.on.relevant.rows	5.637479	0.5437882	0.1613531	1.725572E-08
3	GOVERN.share.on.relevant.rows	4.600118	0.55059178	0.3523800	4.222524E-06
3	EXCHANGE.share.on.relevant.rows	-1.978540	0.09157541	0.1613531	4.786780E-02
3	OPTIMISE.share.on.relevant.rows	-2.502368	0.06578716	0.1508673	1.233657E-02
4	OPTIMISE.share.on.relevant.rows	5.396132	0.5037743	0.1508673	6.809270E-08
4	GOVERN.share.on.relevant.rows	-2.543520	0.1415674	0.3523800	1.097417E-02
5	LOOP.share.on.relevant.rows	5.186241	0.8948479	0.3529625	2.145815E-07

Source: our elaboration

For each lever, the *Mean in category* column indicates the average value within the cluster. Overall mean represents the average value over the entire sample. The v-test measures the magnitude of the difference between the cluster and the overall average: positive values indicate an over-representation of lever in the cluster, while negative values indicate an under-representation. The v-test therefore measures how much the average value of a variable within a cluster deviates from the overall average of the sample. The p-value indicates the statistical significance of the observed difference, which is always relevant.

4.3.1 Clusters Description

Cluster 1 is made up of two European OEMs operating in the high-end segment, namely Polestar and Rolls-Royce. Both are part of large industrial groups (Geely Holding and BMW Group respectively) and have a long history, with years of foundation very distant from each other but united by a strong brand identity. From the point of view of market positioning, the cluster includes premium

and luxury car brands, characterized by a high focus on brand value and perceived quality. Only Polestar stands out for its purely electric strategy, while Rolls-Royce maintains a traditional approach.

A key element that unites both OEMs is the dominant lever "Design", (i.e., design with a circularity perspective) which is the only area with a significant share on the rows considered, while the other strategic levers are absent or marginal.

The profile of the cluster shows a concentration of the declared strategies on the dimension of planning and design with a view to circularity. In particular, the average share of the "Design" lever within the cluster is equal to 1, indicating a total concentration of relevant content on the "Design" lever with a view to circularity. The strongly positive value of the v-test and the extremely small p-value confirm that this difference is highly statistically significant. On the contrary, the "Govern" lever is significantly under-represented in the cluster, with an average share of 0, compared to an overall average of 0.35. Again, the negative v-test is statistically significant: it indicates that the OEMs belonging to the cluster show limited attention to this managerial lever.

Cluster 2 is composed of 8 OEMs, founded mainly in the first half of the twentieth century, with a strong geographical presence in Asia and Europe. The cluster includes both industrial groups and independent manufacturers and covers a wide spectrum of market positions, from the generalist segment to premium and luxury. From an electrification perspective, only one player is entirely focused on EVs. On a strategic level, the cluster is clearly characterized by the centrality of the "Exchange" lever, which is dominant or at least prevalent for almost all the OEMs that are part of it.

From a statistical point of view, the "Exchange" lever is strongly over-represented compared to the overall average of the sample. The average share of the "Exchange" lever within the cluster is 0.54, compared to an overall average of 0.16, indicating a marked focus on technological and process innovations (including new chemical formulations and/or recycling technologies) aimed at making the battery value chain more sustainable. The high value of the v-test (5.64) and the extremely low p-value confirm that this difference is highly significant from a statistical point of view.

Cluster 3, consisting of 20 OEMs, represents the largest and most structurally heterogeneous group in the analysis, including large global OEMs with a long industrial tradition and a geographical presence spanning Europe, America and Asia. The brands that are part of it were founded mainly during the twentieth century and include both consolidated industrial groups and independent manufacturers. From the point of view of market positioning, the cluster covers a wide spectrum of segments ranging from generalist to premium and luxury, also including players with high technological specialization.

Electrification is not a uniform hallmark: only a few OEMs are entirely focused on electric vehicles, while the majority take a more traditional approach.

In terms of levers, the cluster is characterized by the centrality of the "Govern" lever, which is dominant for most OEMs. This is confirmed on a quantitative level, in fact the "Govern" lever is significantly over-represented compared to the overall average of the sample. The average share of the "Govern" lever within the cluster is 0.55, compared to an overall average of 0.35. The high value of the v-test (4.60) and the very low p-value confirm the statistical significance of this difference.

Cluster 4 is made up of 8 OEMs operating mainly in Europe and Asia, belonging to both the generalist and premium and luxury car segments. All the brands included have a strong integration within large industrial groups (such as Volkswagen Group, BMW Group and Tata Motors), an element that testifies to a structured industrial approach. The years of foundation are very variable and range from historic brands of the late nineteenth century to OEMs born during the last decade, highlighting a coexistence between tradition and more recent players. From the point of view of market positioning, the cluster includes both high-end brands and generalist brands. The presence of EVs is limited or selective for most OEMs, with some exceptions, but overall electrification is not the distinctive element of the cluster.

From a quantitative perspective, cluster 4 is distinctively characterized by the "Optimise" lever, which is strongly over-represented compared to the overall average of the sample. The average share of the "Optimise" lever within the cluster is 0.50, compared to an overall average of 0.15, highlighting a marked focus on interventions to optimize production processes, efficiency in the use of resources and the incremental improvement of operating performance. The high value of the v-test (5.40) and the extremely low p-value confirm that this difference is highly significant from a statistical point of view. On the other hand, the "Govern" lever is significantly under-represented in the cluster.

Cluster 5 is made up of 7 mainly Asian OEMs, operating primarily in the generalist segment, with the presence of only one supercar brand. The OEMs included have a combination of membership in large industrial groups and strategic independence: some are part of structured groups (such as Great Wall Motors, Hyundai Motor Group, Volkswagen Group and Mitsubishi Motors), while others operate as independent entities. The years of foundation cover a wide period, ranging from historic brands born in the first half of the twentieth century to recently established OEMs, highlighting a strong heterogeneity from the point of view of industrial maturity. From a market positioning perspective, the cluster is dominated by generalist, high-volume, high-volume brands, flanked by a niche OEM in the supercar segment and a newer premium player. The presence of electric vehicles is overall limited to a single OEM. From a statistical point of view, cluster 5 is distinctively characterized by the "Loop" lever, which is strongly over-represented compared to the overall average of the sample. The average share of the "Loop" lever within the cluster is 0.89, compared to an overall average of 0.35, indicating a marked focus on CE practices aimed at closing the cycles of materials and resources. The high value of the v-test (5.19) and the extremely low p-value confirm that this difference is highly significant from a statistical point of view. This cluster is characterized by a profile strongly oriented towards the closure of cycles (recycling/recovery/reuse/second life/remanufacturing). The levers "Optimise" and "Exchange" are present only marginally, while the two managerial levers "Design" and "Govern" take on a secondary or residual role.

5. Discussion

The results of our analyses confirm that OEMs do not apply CE principles uniformly. Instead, they configure differentiated strategies by combining the ReSOLVE framework levers with managerial enabling factors, in line with studies that highlight how the adoption of CE in manufacturing industries takes place through heterogeneous paths that are highly dependent on the industrial and organizational context (Geissdoerfer et al., 2017; Kirchherr et al., 2018). Regarding the first research question (*How are automotive OEMs configuring CE strategies along the battery value chain through the "Loop", "Optimise" and "Exchange" levers integrated with "Design" and "Govern"?*), the high frequency of the "Govern" lever shows that, for many OEMs, circularity can be interpreted as a supply chain coordination challenge. This evidence is consistent with the literature on circular supply chains, which interprets the transition to circular models as a process strongly dependent on mechanisms of inter-organizational governance, traceability and collaboration between actors in the supply chain (Genovese et al., 2017; Batista et al., 2018). This also highlights the systemic nature of the battery value chain, for which traceability, audits and partnerships are fundamental prerequisites to ensure the recovery and valorisation of batteries at the end of their life (Gaines, 2014; Harper et al., 2019).

In contrast, the "Exchange" and "Optimise" levers show lower levels of adoption, suggesting that while technological innovation and resource efficiency are recognized as relevant, they are not yet the main strategic drivers for most OEMs. With regard to the second research question (*Do OEMs tend to specialize on specific levers or strategic configurations of levers in the implementation of battery circularity?*) the results reveal that the adoption of the CE may follow a logic of strategic specialization rather than a path of simultaneous integration, in line with the configurational perspectives of the business strategy, according to which firms favor coherent combinations of

practices rather than the full adoption of all available instruments. As highlighted above, most OEMs focus on "Govern" or "Loop" as dominant lever. This is consistent with the configurational perspectives of organizational strategy, according to which firms tend to develop coherent and selective combinations of practices rather than simultaneously adopting all possible strategic dimensions (Miller, 1996; Fiss, 2007). The higher standard deviation associated with "Loop" lever also shows significant variability in how OEMs pursue closed-loop systems, supporting the idea that while some OEMs are pioneers in recycling and recovery activities, others are still in a more exploratory phase of experimenting with circular practices (Bocken et al., 2016; Frishammar & Parida, 2019).

Finally, regarding to the third and final research question (*What recurrent strategic configurations emerge among automotive OEMs when CE strategies are analyzed in a comparative configurational perspective?*), the most relevant result concerns the emergence of the "Govern–Loop" dyad as the most frequent configuration. This result empirically supports the theoretical approach of the ReSOLVE framework, highlighting how closed-loop strategies require the existence of enabling organizational and institutional mechanisms, such as supply chain governance systems and partnerships with suppliers (Ellen MacArthur Foundation, 2015b; Lacy & Rutqvist, 2015). In the absence of such mechanisms, the operational implementation of "Loop" strategies becomes difficult to scale along the entire supply chain. The analysis of the combinations showed that the "Govern–Loop" dyad is closely followed by the "Loop–Govern" combination. This result confirms the theoretical framework of the study: suggesting that the effective implementation of "Loop" strategies appears empirically associated with the presence of "Govern" mechanisms, including traceability and partnerships with suppliers, necessary to facilitate the return and quality of batteries at the end of their life. Overall, the results offer relevant evidence for the debate on CE in the automotive sector and, more specifically, in the battery value chain. Firstly, the absence of fully integrated strategic configurations of the levers of the ReSOLVE framework suggests that, in the sample analyzed, CE is not implemented as a holistic and cross-cutting approach, but through selective approaches. This evidence is consistent with cluster analysis, which shows the prevalence of groups characterized by the dominance of a single lever rather than by balanced multi-leverage configurations. This evidence differs from a part of the literature that interprets CE as a holistic transformation of industrial value chains (Geissdoerfer et al., 2017; Korhonen et al., 2018), indicating instead a more incremental and partial declination of circular practices.

The prevalence of clusters characterized by the dominance of a single lever (especially "Govern", "Loop" or "Exchange") highlights that OEMs, despite the simultaneous integration of multiple strategic levers along the entire value chain, tend to specialize on specific operational dimensions, rather than evenly distributing efforts along all levers.

The results, in fact, allow us to problematize the concept of integration discussed in the literature.

More generally, the study contributes to the literature on the CE by shifting the focus from a normative and universalistic view of CE adoption to a configurational and contingent perspective. If the theoretical framework interprets CE as a process that requires a simultaneous and consistent coordination of multiple levers along the entire value chain, empirical evidence suggests that such integration does not represent the prevailing configuration among the OEMs analyzed. The strategies observed are in fact mainly focused on a dominant lever, while the remaining ones take on a complementary or marginal role. The application of the ReSOLVE framework as an empirical classification tool allows us to highlight how the CE, in the automotive sector, is not adopted as a unitary model, but as a set of differentiated strategic configurations that reflect selective industrial priorities. Consistent with this, the main contribution of the study consists in demonstrating that the circularity of batteries does not follow a single evolutionary trajectory but develops through a plurality of strategic approaches that vary in intensity, focus, and combination of levers (Kirchherr et al., 2017; Bocken et al., 2016). Beyond the descriptive characterisation of the five clusters, the configurations are interpreted against the backdrop of the incremental versus systemic debate in circular economy transitions (Centobelli et al., 2021; Bertassini et al., 2021). Cluster 4 (Optimise)

and Cluster 5 (Loop) follow an incremental logic: they capture efficiency improvements within the existing linear architecture (Optimise) or end-of-pipe material recovery practices (Loop), without affecting upstream design choices. Cluster 2 (Exchange) represents a substitution-based trajectory, whereby inputs and technologies are replaced while the overall strategic architecture remains largely unchanged. By contrast, Cluster 1 (Design) and Cluster 3 (Govern), as well as the recurring Govern-Loop combination observed in 14 OEMs, reflect a systemic orientation: design for circularity and governance mechanisms act as enabling architectures that shape the deployment of all other levers.

We argue that the prevalence of the Govern-Loop combination indicates that, for global OEMs, governance has become the integrative layer through which circular ambitions are translated into operational practice, consistent with the institutional pressures generated by the EU Battery Regulation and the CSRD.

Theoretically, these findings invite a reconsideration of how the CE literature conceptualizes the integration of circular practices. Whereas mainstream contributions tend to treat integration as a normative end-state our results suggest that integration is more usefully understood as configurational coherence: a fit among a subset of levers that is consistent with the firm's industrial position, supply chain role and strategic priorities. From this perspective, the recurrence of "Govern" as a dominant lever is not merely an empirical regularity, but a theoretically meaningful signal that, in technologically complex and globally distributed value chains, the operational implementation of circular practices is conditional on the prior establishment of governance and traceability mechanisms. This refines the configurational perspective on sustainability by specifying the role of managerial levers not as one dimension among others, but as enabling conditions whose presence determines whether operational levers can effectively unfold. Therefore, the study advances CE theory by showing that circular strategies in complex supply chains should be interpreted not as the simple accumulation of practices, but as coherent strategic configurations in which managerial levers enable, constrain or amplify the operational deployment of circular actions.

6. Conclusions

The present study looks at how automotive OEMs configure their CE strategies along the battery value chain, adopting a configurational perspective, through which the combinations between the operational levers of the ReSOLVE framework (“Loop”, “Exchange” and “Optimise”) and managerial levers (“Design” and “Govern”) are examined. The findings show that OEMs do not adopt a uniform approach to the CE, but have heterogeneous strategic profiles, in which one or more levers emerge as dominant according to the priorities declared in the content analysed.

From a theoretical standpoint, the primary contribution lies in the extension of the ReSOLVE framework to the specific context of the battery value chain and in its integration with two levers of a managerial nature, “Design” and “Govern”, according to the perspective of configurational theory (Meyer et al., 1993; Fiss, 2007). More specifically, the contribution does not consist solely in the empirical application of the framework to a new sectoral context, but rather in its reinterpretation through a configurational lens, showing how the ReSOLVE levers operate empirically as combinable and interdependent elements rather than as simultaneously implemented dimensions. This is particularly relevant in complex industrial supply chains, where the CE emerges from the interaction between technological, organizational and institutional conditions that are difficult to isolate through linear approaches (Fiss, 2007; Misangyi et al., 2017). Indeed, the findings demonstrate how the ReSOLVE framework emerges empirically as a modular set of levers selected and combined by OEMs in accordance with the interorganizational complexity of the battery value chain. The integration of the “Design” and “Govern” levers makes it possible to render explicit the organizational and decision-making dimensions that are implicitly present in the original framework yet not formalized as autonomous analytical components. This study highlights the role of managerial levers as enablers of circularity, showing how supply chain governance and design choices are necessary

organizational conditions to make circular practices implementable (Lieder & Rashid, 2016; Farooque et al., 2019).

In particular, the findings indicate that the "Govern" lever is the most frequently occurring in the content analysed, confirming that governance represents an indispensable element for the circularity of batteries. Managing relationships between manufacturers, cell suppliers, recycling operators and other partners along the value chain requires clear decision-making structures, coordination mechanisms and control systems that reduce information opacity. In this context, traceability requirements emerge with considerable force: in order to effectively disassemble end-of-life batteries, recover critical components and materials and reintroduce them into production cycles, automotive manufacturers must have access to precise information regarding the battery composition, origin of materials, assembly methods and use of batteries. In the absence of adequate traceability and information-sharing systems, the closure of material cycles proves difficult to implement at industrial scale, thereby constraining the effective operationalization of CE strategies. In conclusion, the CE within the battery value chain does not take the form of a standardized model but rather manifests as a set of differentiated strategic configurations, in which circularity results from the dynamic integration of operational levers and managerial capabilities. This evidence suggests that the transition toward circular models in complex industries should be interpreted as an evolutionary configurational process, in which circularity emerges from the progressive alignment among technological innovation, organizational capacities and governance mechanisms, rather than from the linear and universalistic adoption of a single paradigm (Fiss, 2011). From this perspective, the study contributes to a more in-depth realistic understanding of circular transition pathways in technologically complex industries.

7. Implications of the study

The findings allow to deriving three significant theoretical implications. Firstly, the adoption of circular practices in complex industrial supply chains does not follow a logic of linear or cumulative implementation but rather assumes the form of selective strategic configurations. Secondly, the findings extend the ReSOLVE framework by empirically highlighting the role of managerial levers as enabling conditions necessary for the concrete implementation of operational levers. Finally, the research contributes to the configurational perspective applied to sustainability by demonstrating that CE can be interpreted as a multidimensional phenomenon emerging from the coherent combination of technological, organizational and governance choices, rather than as the isolated adoption of individual practices.

The empirical evidence further allows for the derivation of several operational implications for business decision-makers involved in the transition towards circular models. From a managerial standpoint, the findings suggest that the definition of an CE strategy within the battery value chain requires a clear identification of the strategic leverage, but also a structural investment in governance mechanisms and traceability systems. In particular, OEMs should prioritize the development of digital battery traceability systems, interorganisational governance structures and eco-design practices integrated from the earliest stages of product development. In practical terms, managers should first identify the dominant circularity priority of the firm - such as recovery, efficiency, technological substitution, eco-design or governance - and then align investments, supplier relationships, reporting systems and organizational capabilities around that strategic focus. In a complex and global supply chain, the CE needs interorganizational coordination, transparency, and standardization of information. This implies that managers should regard CE not as a set of isolated operational initiatives, but as a strategic process requiring the alignment of supply chain governance, product design and information systems, favoring coordinated investments over non-integrated incremental interventions.

The fact that quantitative content analysis also reveals groupings capable of combining multiple framework levers in a balanced way, a finding that is nonetheless not confirmed from a quantitative and statistical standpoint in the cluster analysis, indicates that CE adoption still appears fragmented and highly dependent on the strategic priorities and structural characteristics of OEMs. From a managerial perspective, this implies the necessity of explicitly defining strategic priorities within the battery value chain, avoiding generic approaches to CE and concentrating resources on the levers considered most consistent with one's own business model. The presence of a dominant lever suggests that CE strategies require consistency among strategic choices, organizational structure, internal competencies and relevant regulatory framework.

From a broader perspective, the findings indicate that the transition toward CE models in technologically complex industries should not be interpreted as a process of convergence toward a single organizational model, but as an evolutionary pathway characterized by plural and dynamic strategic configurations. Circularity emerges from the progressive alignment between technological innovation, managerial skills and interorganizational governance mechanisms, highlighting how industrial sustainability does not represent a predetermined endpoint, but an adaptive process of continuous strategic reconfiguration.

8. Limitations and future research directions

Notwithstanding these findings, several methodological limitations must be considered when interpreting the results. One limitation of the research lies in the fact that the analysis is based on a single reporting year. This choice allows for a snapshot of strategic configurations at a given point in time, but does not permit the capture of their evolution over time. Furthermore, the use of declarative data drawn from public documents may reflect communicated rather than fully implemented strategies; however, the literature on sustainability disclosure highlights how non-financial reporting represents an institutional space through which companies build and legitimize their strategic priorities (Hahn & Kühnen, 2013; Michelon et al., 2015). Moreover, extending the study through a panel analysis over several years would also allow for a better understanding of trends, verification of the stability of the strategic configurations identified and highlight any changes in the CE strategies adopted by OEMs along the battery value chain.

Finally, the research opens avenues for further investigation. Future studies could longitudinally analyse the evolution of strategic configurations, examining whether the current specialization on single levers evolves towards more integrated arrangements. Further research could also extend the analysis to other actors in the battery value chain, in order to understand how governance dynamics develop at the ecosystem level. Future research could also combine content analysis with interviews, case studies or operational performance data in order to compare declared CE strategies with implemented practices and measurable circularity outcomes.

Strategy mix coherence in corporate environmental engagement: Configurations in the global food and beverage industry

SILVIA RITA SEDITA[1], AMIR MAGHSSUDIPOUR[1]

Abstract
Firms increasingly deploy multiple environmental initiatives across products, operations, governance, and stakeholder relationships, yet research rarely examines whether these initiatives form coherent strategy systems. We study environmental strategy mix coherence, defined as the internal alignment of initiatives across strategic domains, using Refinitiv Eikon ESG disclosures for 311 global food and beverage firms. Environmental engagement is captured across five dimensions - product, internal organizational, external stakeholder, CSR governance, and carbon-neutral strategies. Using a two-step clustering procedure, we identify three empirically recurring configurations: All-Round Leaders, characterized by high and balanced engagement; Active Followers, characterized by moderate but outward-skewed engagement; and Shy Laggards, characterized by low and fragmented engagement. The findings show that heterogeneity in corporate environmental engagement reflects not only intensity but also internal balance, distinguishing firms that integrate initiatives across domains from those that expand selectively. The study advances a configurational understanding of corporate environmental strategy and provides an empirically grounded taxonomy of coherence profiles.

Keywords: *Corporate environmental strategy; strategy mix coherence; sustainability management; configurations; cluster analysis; food and beverage industry*

1. Introduction

Environmental sustainability has become an increasingly salient dimension of corporate strategy, influencing how firms design products, organize operations, interact with stakeholders, and govern their activities (Walsh & Dodds, 2017). In response to regulatory pressures, stakeholder expectations, and growing awareness of environmental risks, firms across industries have adopted a wide range of environmental initiatives, including eco-design practices, internal process improvements, governance mechanisms, and carbon reduction policies (Dong et al., 2026). As these initiatives proliferate, managers face a central strategic challenge: how to integrate multiple environmental actions into a coherent and effective strategic approach.

Existing research on corporate environmental strategy has generated substantial insights into the drivers and consequences of firms' engagement with environmental sustainability (Wagner, 2015). Prior studies have extensively examined specific environmental practices, such as pollution prevention, eco-efficiency initiatives, green innovation, and the adoption of environmental management systems, highlighting their implications for competitiveness, legitimacy, and firm performance (Aragón-Correa & Sharma, 2003; Delmas & Toffel, 2004). This stream of research has demonstrated that environmental initiatives can represent strategic resources when aligned with organizational capabilities and external pressures (Aragón-Correa & Sharma, 2003). However, much of the literature has tended to analyze these practices in isolation or as additive elements, implicitly assuming that the adoption of multiple environmental actions naturally translates into a coherent strategy. As a result, we still lack a system-level understanding of how firms combine heterogeneous environmental initiatives into internally consistent strategic systems, despite evidence that organizational structures and internal dynamics shape the configuration of environmental practices

[1] Dept. Of Economics and Management "MarcoFanno", University of Padua, Padua, Italy

(Delmas & Toffel, 2008). This gap matters because many firms simultaneously expand sustainability portfolios while struggling to align product, operational, governance, and stakeholder-facing initiatives into a unified strategic architecture.

From a business research perspective, addressing this gap is relevant because environmental initiatives typically require coordination across organizational units, alignment with governance structures, and integration with external stakeholder relationships (Hart, 1995; Hoffman, 2001). When sustainability actions are implemented in a fragmented or poorly coordinated manner, firms may incur substantial coordination costs, experience internal inconsistencies, or generate symbolic rather than substantive environmental outcomes, thereby undermining their strategic value (Delmas & Burbano, 2011). In contrast, when environmental initiatives are aligned and mutually reinforcing, they can enhance strategic coherence, organizational credibility, and the overall effectiveness of sustainability efforts (Porter & Kramer, 2006; Hart & Dowell, 2011). Accordingly, understanding how firms structure, coordinate, and integrate their environmental strategies represents a critical managerial and strategic issue, with important implications for both performance and stakeholder relationships.

Building on this premise, the present study focuses on the coherence of the environmental strategy mix, defined as the degree of internal alignment among multiple dimensions through which firms enact environmental sustainability. Rather than examining single practices in isolation, we originally apply a configurational perspective (Meyer et al., 1993) to the study of environmental strategy, viewing it as a system of interdependent strategic choices. Within this perspective, the effectiveness of environmental engagement depends not only on the presence of specific initiatives, but on how these initiatives are combined and governed as part of a unified strategic architecture. In this study, we conceptualize strategy mix coherence as a combination of (i) intensity - how extensively firms engage across strategic domains - and (ii) internal balance - how evenly initiatives are distributed across domains in ways that reduce internal contradictions.

Thus, we aim at answering the following research question: Which configurations of environmental strategy mix coherence emerge among firms, and how do these configurations differ in terms of (i) the overall intensity of environmental engagement and (ii) the internal balance with which initiatives are combined across strategic domains?

Empirically, the study examines firms in the global food and beverage industry, a sector characterized by significant environmental impact and increasing scrutiny along the entire value chain (Clark et al., 2020; Crippa et al., 2021; Sovacool et al., 2021). Using ESG data from the Refinitiv Eikon database (Refinitiv, 2021), we analyze the environmental strategies of 311 firms across five dimensions: product strategy, internal organizational strategy, external stakeholder strategy, CSR governance strategy, and carbon-neutral strategy. These dimensions capture key areas through which firms operationalize environmental sustainability and reflect both internal and external aspects of environmental engagement.

To identify distinct patterns of environmental strategy coherence, we apply a two-step clustering procedure combining hierarchical and k-means methods. This approach allows us to uncover empirically grounded configurations of environmental engagement based on similarities in how firms combine sustainability initiatives across strategic domains. The analysis reveals three configurations. All-Round Leaders exhibit high levels of engagement and balanced integration across all five dimensions. Active Followers display moderate engagement with partial and uneven alignment among dimensions. Shy Laggards show low levels of engagement and fragmented approaches, characterized by limited strategic integration. Taken together, these configurations highlight that environmental strategy heterogeneity is not only a matter of "how much" firms do, but also of how coherently initiatives are combined into an internally aligned system.

By identifying these configurations, the study provides three main contributions. First, it advances a configurational understanding of corporate environmental strategy by shifting attention from the presence of individual practices to the coherence of the environmental strategy mix as a distinguishing feature among firms. Second, it operationalizes coherence in terms of intensity and internal balance and provides an empirically grounded taxonomy of configurations in a high-impact industry,

illustrating how firms differ in the structure - not merely the breadth - of their environmental engagement. Third, it offers actionable insight for aligning sustainability initiatives across domains by showing where configurations concentrate effort (e.g., outward-facing governance and stakeholder initiatives versus product and operational change) and where internal balance is weaker.
Thus, the study reframes corporate environmental engagement from a list of discrete initiatives to a coherent strategy architecture, and provides an empirical taxonomy that can be used to compare firms' sustainability systems across contexts and over time.
The remainder of the paper is organized as follows. Section 2 develops the theoretical framework and motivates the research question. Section 3 describes the data and methodology. Section 4 presents the empirical results. Section 5 provides further analysis adopting a geographical perspective and including a set of financial and economic characteristics. Section 6 discusses the findings, and Section 7 concludes.

2. Literature review

Corporate environmental strategy has attracted extensive scholarly attention, reflecting the growing recognition that environmental issues are no longer peripheral to business decision-making. Early contributions conceptualized firms' environmental engagement primarily in terms of compliance, efficiency, and pollution control, emphasizing internal process improvements and cost reduction as responses to regulatory pressures (Hart, 1995; Rugman & Verbeke, 1998). Subsequent research broadened this view by highlighting the strategic potential of proactive environmental initiatives and by distinguishing among different strategic types, such as pollution prevention, product stewardship, and sustainable development (Orsato, 2006; Kolk & Pinkse, 2005).
Building on these foundations, scholars have sought to operationalize corporate environmental strategy through measurable categories of practices spanning the value chain and organizational arrangements. For instance, Albino et al. (2009) proposed a classification encompassing material and energy efficiency, green management, and green supply-chain integration. Similarly, research has emphasized governance mechanisms, environmental management systems, and stakeholder engagement as key dimensions through which firms institutionalize sustainability practices (Delmas & Toffel, 2008; Lindgreen & Swaen, 2010). Collectively, these contributions document substantial heterogeneity in environmental initiatives and the organizational domains they cover.
Despite these advances, much of the literature still analyzes environmental practices as discrete or additive elements, focusing on the presence, intensity, or breadth of specific initiatives (Aragón-Correa & Sharma, 2003; Walsh & Dodds, 2017; Naidoo & Gasparatos, 2018). This practice-by-practice perspective offers limited understanding of how heterogeneous environmental initiatives interact within the firm and how they are combined into broader strategic approaches. This limitation is consequential because environmental initiatives typically span multiple organizational domains and require coordination across functions, hierarchical levels, and external relationships; fragmented implementation may generate internal inconsistencies and increase the likelihood of symbolic adoption, decoupling, or greenwashing dynamics (Delmas & Toffel, 2008; Delmas & Burbano, 2011; Lee & Raschke, 2023).
Configurational theory provides a useful lens to address this gap by treating strategies as systems of interdependent choices and by emphasizing internal fit among multiple dimensions of strategy (Meyer et al., 1993). This insight resonates with the natural resource–based view, which argues that environmental strategies create value not simply through individual practices, but through the orchestration of resources and capabilities into complex and difficult-to-imitate configurations (Aragón-Correa & Sharma, 2003; Hart & Dowell, 2011). Accordingly, the present study focuses on the coherence of the environmental strategy mix, defined as the degree of internal alignment and mutual reinforcement among multiple dimensions of corporate environmental engagement. Rather than viewing environmental strategy as a checklist of practices, we conceptualize it as a

multidimensional configuration encompassing product-related initiatives, internal organizational practices, governance mechanisms, stakeholder relationships, and carbon-related actions.
This focus implies that two properties are central for distinguishing firms' environmental strategy systems: intensity (how extensively firms engage across domains) and balance (how evenly and consistently initiatives are combined across strategic domains). Strategy research emphasizes that value creation depends on fit and complementarities among activities: the payoffs from one initiative often increase when other aligned initiatives are in place, whereas misaligned choices can erode effectiveness (Porter, 1996; Milgrom & Roberts, 1995). In environmental strategy, complementarities similarly depend on supporting management systems and complementary assets that enable coordinated execution (Christmann, 2000; Sharma & Vredenburg, 1998). More broadly, organizations can be conceived as "bundles" of interacting elements, where coherence emerges when multiple choices reinforce each other within an activity system (Siggelkow, 2011).
A configurational perspective is particularly appropriate for theorizing such coherence because it treats strategies as multidimensional constellations that tend to recur as empirically observable patterns (Meyer, Tsui, & Hinings, 1993). It also foregrounds equifinality - different internally consistent combinations can exist - while stressing that only a subset of all theoretically possible combinations is likely to be viable in practice (Doty, Glick, & Huber, 1993; Fiss, 2007). This implies that firms facing similar environmental pressures can still develop distinct configurations depending on motivations, resources, and capability-building paths (Bansal & Roth, 2000; González-Benito & González-Benito, 2005). Methodologically, uncovering such recurring patterns aligns with the use of cluster-based taxonomies widely adopted in strategy research (Ketchen & Shook, 1996).
Building on this logic, we expect firms to differ systematically not only in "how much" they engage environmentally, but also in how coherently they integrate initiatives across domains. Some firms should exhibit high coherence, characterized by strong and balanced engagement; others may display partial coherence, with meaningful but uneven engagement across dimensions; and others may show low coherence, where initiatives remain isolated and weakly coordinated, increasing the risk of symbolic adoption and decoupling (Bromley & Powell, 2012; Delmas & Burbano, 2011). Coherent configurations should be more likely when firms possess complementary assets and supporting organizational arrangements that enable coordinated implementation (Christmann, 2000; Delmas & Pekovic, 2018).

3. Data and methodology

The empirical analysis focuses on firms operating in the global food and beverage industry, a sector characterized by significant environmental impact and increasing scrutiny along the entire value chain (Poore & Nemecek, 2018; Springmann et al. 2018). Environmental issues related to food production, processing, packaging, and distribution have become central to corporate strategy in this industry, making it a suitable empirical context for examining how firms structure and coordinate environmental initiatives (Maloni & Brown, 2006; Hartmann, 2011).
Firm-level data were collected from the Refinitiv Eikon database (Refinitiv, 2021), which provides standardized information on corporate environmental, social, and governance practices based on publicly available disclosures. The database compiles data from sustainability reports, annual reports, and corporate websites, allowing for cross-firm comparability of environmental engagement. The analysis focuses on firms that disclosed sufficient environmental information to allow a systematic assessment of their sustainability initiatives.
As of 2021, the Refinitiv Eikon database included a broad population of food and beverage firms worldwide. From this population, the sample consists of 311 firms that published a CSR or sustainability report in 2021. Restricting the analysis to firms with available sustainability disclosures ensures consistency in the measurement of environmental initiatives, while still preserving substantial heterogeneity in firm size, geographic location, and strategic orientation. The resulting sample

provides a comprehensive overview of environmental engagement patterns within the global food and beverage industry.

To operationalize corporate environmental strategy, we identify five strategic dimensions capturing key areas through which firms enact environmental sustainability: product strategy, internal organizational strategy, external stakeholder strategy, CSR governance strategy, and carbon-neutral strategy. These dimensions reflect both internal and external aspects of environmental engagement and are consistent with the multidimensional nature of corporate environmental strategy discussed in the literature review.

Each strategic dimension is measured using a set of specific environmental initiatives available in the Refinitiv Eikon database. Individual initiatives are coded as binary variables (1 = initiative disclosed/implemented; 0 = otherwise). For each firm, indicators are summed within each strategic dimension, yielding a dimension score that captures the breadth of engagement in that domain. This operationalization ensures cross-firm comparability while retaining variation in the scope of environmental initiatives.

The five resulting scores capture how firms allocate attention across distinct areas of environmental strategy. Product strategy reflects initiatives related to eco-design, sustainable materials, and product impact reduction. Internal organizational strategy captures actions aimed at embedding sustainability within internal processes and organizational practices. External stakeholder strategy includes initiatives related to supply-chain management and partnerships with external actors. CSR governance strategy reflects the formalization of sustainability through governance mechanisms and incentive structures. Carbon-neutral strategy captures initiatives related to emissions reduction and climate-related targets (GHG Protocol, 2016; Task Force on Climate-related Financial Disclosures [TCFD], 2017). Appendix Table A1 reports the complete list of initiatives composing each dimension.

Each dimension is computed as an equal-weighted sum of its binary indicators, to enhance measurement consistency across domains. The five dimension scores share the same bounded range (0–4), thus the main clustering analysis is conducted on unstandardized scores to preserve the substantive meaning of differences in the number of disclosed initiatives across domains. Hierarchical clustering is implemented using Ward's method with squared Euclidean distance to explore the data structure and inform the number of clusters (Kaufman & Rousseeuw, 2009; Murtagh & Legendre, 2014). Ward's method with squared Euclidean distance is appropriate here because it constructs clusters by minimizing the increase in within-cluster variance, providing a parsimonious hierarchical baseline for selecting k. We then apply k-means clustering (k = 3) with multiple random initializations (n_init = 5) and retain the solution minimizing within-cluster sum of squares. K-means then refines membership by directly minimizing within-cluster sum of squares for the chosen k, improving separation relative to the hierarchical initialization.

Appendix Tables A4–A5 report internal validity indices and stability checks supporting the three-cluster solution, and a sensitivity check using standardized (z-scored) dimensions (ARI ≈ 0.49; ~22% reassignment), with reassignments concentrated between Cluster 2 and Cluster 3.

Table 1 reports descriptive statistics for the five environmental strategy dimensions.

[Table 1 around here]

Table 1 indicates that environmental engagement in the sample is generally moderate across the five dimensions (median = 2 for all), with the highest average levels in CSR governance (M = 2.10) and external stakeholder strategies (M = 1.99) and comparatively lower engagement in internal organizational (M = 1.52) and carbon-neutral strategies (M = 1.65), alongside substantial heterogeneity particularly for external stakeholder (SD = 1.46) and product strategies (SD = 1.32).

4. Results

We employed a two-step clustering procedure aimed at uncovering empirically recurring patterns in how firms combine environmental initiatives across product, internal organizational, external stakeholder, CSR governance, and carbon-neutral strategies, to identify distinct configurations of corporate environmental strategy in the global food and beverage industry (Ketchen & Shook, 1996; Kodinariya & Makwana, 2013). In the first step, hierarchical clustering (Ward's method) was used to explore the underlying structure of the data and to inform the appropriate number of clusters.
Figure 1 displays the dendrogram from the hierarchical clustering procedure.

[Figure 1 around here]

Figure 1 suggests that firms separate into a small number of groups, with a three-cluster solution offering the most interpretable and parsimonious representation of the sample. The dendrogram shows a marked increase in within-cluster heterogeneity when fewer than three clusters are retained, whereas additional clusters yield finer partitions that add limited interpretive value. Appendix Tables A4–A5 report internal validity indices (k = 2–6) and stability checks.
In the second step, we implemented non-hierarchical k-means clustering to refine cluster membership and maximize within-cluster similarity while enhancing between-cluster separation. We assessed between-cluster differences across the five environmental strategy dimensions using ANOVA and post-hoc comparisons (Hair et al., 2010). Table 2 reports cluster means and ANOVA results.

[Table 2 around here]

Table 2 shows that the three clusters are statistically distinct across all five dimensions and differ both in overall intensity and in the balance with which initiatives are combined across domains. Cluster 1 exhibits consistently high engagement across dimensions (e.g., product = 3.77; internal organizational = 2.03; external stakeholder = 3.22), indicating a broad and internally aligned sustainability approach. Cluster 2 displays an intermediate but outward-skewed profile: engagement is comparatively stronger in external stakeholder (3.04) and CSR governance (2.49) strategies than in product (1.77) and carbon-neutral (1.86) strategies. Cluster 3 shows uniformly low engagement (e.g., product = 1.01; internal organizational = 1.03; external stakeholder = 0.66), consistent with weak and fragmented environmental engagement. The cluster-average score reinforces this ordering (2.65 for Cluster 1; 2.10 for Cluster 2; 0.97 for Cluster 3), and the distribution of firms supports meaningful comparison (82 firms, 26%, in Cluster 1; 113 firms, 36%, in Cluster 2; 116 firms, 37%, in Cluster 3).
We computed an outward–inward imbalance index defined as average engagement in outward-facing dimensions (external stakeholder and CSR governance strategies) minus average engagement in operational and product-facing dimensions (product, internal organizational, and carbon-neutral strategies), to make "balance versus unevenness" explicit[2]. As reported in Table 2, this index is close to zero for Cluster 1 (0.24), positive for Cluster 2 (0.93), and close to zero (slightly negative) for Cluster 3 (−0.07), indicating that Cluster 2 concentrates disproportionately on governance and stakeholder-facing initiatives relative to product/operational and carbon-related actions. We also computed a relative dispersion (RD) index capturing within-firm balance across the five dimensions (standard deviation divided by the mean across dimensions) to complement this measure[3]. RD is

[2] The outward–inward imbalance index is computed as the difference between average engagement in outward-facing dimensions (external stakeholder and CSR governance strategies) and average engagement in operational and product-facing dimensions (product, internal organizational, and carbon-neutral strategies): $OI_i = (ES_i + GOV_i)/2 - (PROD_i + ORG_i + CN_i)/3$. Positive values indicate a relative emphasis on governance and stakeholder-oriented initiatives, whereas values close to zero indicate a more balanced engagement across domains.

[3] The relative dispersion (RD) index captures within-firm balance across the five environmental strategy dimensions and is computed as the standard deviation divided by the mean across dimensions: $RD_i = \sqrt{[(1/5) \cdot \sum_{k=1}^{5} (x_{ik} - \bar{x}_i)^2]} / \bar{x}_i$, where $\bar{x}_i = (1/5) \cdot \sum_{k=1}^{5} x_{ik}$.

lowest for Cluster 1 (0.34), moderately higher for Cluster 2 (0.39), and higher for Cluster 3 (0.87), consistent with decreasing strategy mix coherence across configurations.

We labeled the three clusters based on their combination of overall engagement and internal alignment across the five dimensions to provide an interpretable typology consistent with the concept of strategy mix coherence. We label Cluster 1 as All-Round Leaders because firms in this group combine high and comparatively balanced engagement across product initiatives, internal practices, stakeholder strategies, governance mechanisms, and carbon-neutral actions—consistent with high strategy mix coherence. We label Cluster 2 as Active Followers because firms show meaningful environmental activity but a less balanced architecture, with stronger outward-facing governance and stakeholder engagement that is not matched by comparable depth in product and carbon-neutral strategies - consistent with partial coherence. We label Cluster 3 as Shy Laggards because firms display low engagement across all dimensions, indicating low or absent strategy mix coherence.

To facilitate comparison and make configuration differences visually explicit, Figure 2 illustrates the three profiles as a radar chart.

[Figure 2 around here]

Figure 2 shows that All-Round Leaders form a broad and relatively rounded profile, reflecting high and balanced engagement across dimensions. Active Followers display a more uneven shape, driven by comparatively stronger external stakeholder and governance strategies alongside weaker product and carbon-neutral engagement. Shy Laggards show a compact profile close to the center, indicating consistently low engagement across domains.

Appendix Table A2 reports anonymized firm examples (selected to be close to the cluster centroids). Appendix Table A3 provides short vignettes grounded only in the pattern of disclosed initiatives reflected in the five dimension scores (i.e., no additional firm-level information is used), to facilitate interpretation of the three configurations.

5. Further analysis

5.1. Geographical distribution of configurations

We analyzed the distribution of cluster membership across firms' headquarters regions to examine whether environmental strategy mix coherence is patterned by geographical context. Figure 3 reports the regional composition of the three configurations.

[Figure 3 around here]

Figure 3 suggests systematic cross-regional differences in the prevalence of All-Round Leaders, Active Followers, and Shy Laggards, indicating that the identified configurations are not randomly distributed across institutional environments. In some regions, firms are overrepresented among All-Round Leaders and Active Followers, whereas in other regions Shy Laggards constitute a comparatively larger share. This pattern is consistent with the idea that regional contexts shape both (i) the overall intensity of environmental engagement and (ii) the internal structuring of that engagement across domains[4].

These differences plausibly reflect variation in regulatory stringency and enforcement, the salience of stakeholder scrutiny, and the maturity of ESG reporting norms across regions. In settings where disclosure expectations and external monitoring are stronger, firms may have both greater incentives and greater organizational impetus to formalize sustainability initiatives across multiple domains,

Lower values indicate a more even distribution of engagement across strategic domains, whereas higher values indicate a more uneven strategy mix.

[4] We performed a chi-square test of independence to formally assess whether configuration membership varies across headquarters regions. The association is statistically significant ($\chi^2(14) = 41.45$, $p = 0.00015$) with Cramer's $V = 0.26$, indicating a moderate relationship. Standardized residuals indicate that All-Round Leaders are overrepresented in Japan ($z = 4.29$) and underrepresented in China ($z = -3.35$), while Shy Laggards are underrepresented in Europe ($z = -3.05$) and overrepresented in China ($z = 2.08$). Table A6 in the Appendix reports the full cluster-by-region contingency table and standardized residuals.

thereby increasing the likelihood of high-coherence profiles. Conversely, where environmental requirements and stakeholder pressures are weaker or more heterogeneous, sustainability initiatives may remain more fragmented and selectively adopted, increasing the share of low-coherence profiles. Importantly, the regional distribution also aligns with the notion that institutional contexts can encourage different "routes" to environmental engagement - for instance, some environments may promote outward-facing governance and stakeholder initiatives earlier than deeper operational or product-oriented change - thereby contributing to the emergence of partially coherent profiles.

5.2. Firm characteristics across environmental strategy configurations

We compared firms' governance and economic characteristics across clusters to further contextualize the three configurations. Table 3 reports mean differences and ANOVA tests for board size, employees, revenues, and accounting performance (ROA and ROE), while Table 4 provides Tukey HSD post-hoc comparisons for characteristics showing statistically significant differences.

[Table 3 around here]

Table 3 indicates that the most robust differences across configurations relate to organizational scale. All-Round Leaders are substantially larger than the other groups both in terms of employees and revenues, suggesting that resource availability and organizational capacity are closely associated with the ability to develop an internally aligned environmental strategy system. This is consistent with the view that high coherence requires investments in coordination, cross-functional integration, and monitoring systems that are more feasible for large firms with broader managerial infrastructure and greater slack resources. Active Followers occupy an intermediate position, which is consistent with a configuration where firms can sustain meaningful sustainability initiatives but may face constraints in extending and integrating them evenly across all strategic domains.

In contrast, board size does not significantly differ across clusters, suggesting that the sheer size of the board is not a discriminating governance characteristic for environmental strategy mix coherence in this sample. This result also implies that what matters for coherence is less likely to be board "capacity" measured by headcount and more likely to be board attention, expertise, incentive alignment, or committee structures - features that are not captured by board size alone.

Finally, the absence of statistically significant differences in ROA and ROE should be interpreted cautiously. Accounting performance is often noisy and temporally lagged relative to strategic investments; moreover, environmental coherence may affect outcomes such as risk exposure, reputational resilience, cost of capital, or long-term productivity rather than contemporaneous ROA/ROE. Thus, the pattern is consistent with an interpretation in which coherence is primarily associated with capability-building and strategic organization, with performance implications that may unfold over longer horizons or through channels not captured by short-term accounting indicators.

[Table 4 around here]

Table 4 clarifies that the significant ANOVA results for employees and revenues are driven primarily by the contrast between All-Round Leaders and Shy Laggards. The magnitude of these differences is substantial, reinforcing the interpretation that highly coherent strategy systems are disproportionately observed among large firms. Differences between All-Round Leaders and Active Followers are also statistically significant for both employees and revenues, indicating that the transition from partial to high coherence is associated with a further step change in scale.

By contrast, the comparison between Active Followers and Shy Laggards is weaker and does not reach conventional significance thresholds, suggesting that the key structural divide is between firms that develop a fully integrated, high-coherence strategy system and those that do not, rather than between the two lower-coherence groups. Substantively, this pattern supports a "threshold" interpretation: scale appears especially important for achieving high and balanced integration across domains, while moderate outward-facing engagement (typical of Active Followers) may be attainable even without the scale associated with fully coherent systems.

As an additional external validation, we estimated OLS models with firm size as the outcome, using log(employees) and log(revenues) as dependent variables and configuration dummies as predictors

(All-Round Leaders as the reference category), controlling for headquarters region. Consistent with the descriptive comparisons, Active Followers and Shy Laggards are significantly smaller than All-Round Leaders in terms of employees and revenues. Regression results are reported in Table A7 in the Appendix.

6. Discussion

This study asked which empirically recurring configurations of environmental strategy mix coherence emerge among firms, and how these configurations differ in terms of overall intensity and internal balance across strategic domains. Using a configurational perspective, we identified three empirically recurring profiles of environmental engagement in the global food and beverage industry - All-Round Leaders, Active Followers, and Shy Laggards - distinguished by the overall intensity of engagement and, crucially, by the internal alignment with which initiatives are combined across strategic domains. The first configuration, All-Round Leaders, reflects a highly integrated environmental strategy system. Firms in this cluster exhibit strong and relatively balanced engagement across product-related initiatives, internal organizational practices, governance mechanisms, stakeholder-oriented actions, and carbon-related strategies. This pattern is consistent with a sustainability approach that is embedded across organizational domains rather than concentrated in a single area. Importantly, the profile suggests that high engagement is accompanied by a relatively even distribution across dimensions, indicating that environmental action is organized as a coordinated bundle rather than as a set of disconnected interventions.

The Active Followers configuration exhibits a different architecture. While these firms show meaningful environmental engagement, their initiatives are unevenly distributed across domains. The outward-facing dimensions - governance and stakeholder-related strategies - are comparatively more developed than product/operational and carbon-related actions, consistent with an environmental strategy system characterized by partial alignment. This "imbalance" pattern indicates that sustainability engagement can expand selectively, with some domains advancing faster than others. One plausible interpretation is that governance and stakeholder-oriented initiatives are comparatively easier to introduce and communicate, whereas product redesign and operational transformations are more resource-intensive and require longer investment horizons, cross-functional coordination, and technical capabilities. In this sense, Active Followers may represent a configuration in which firms formalize and externalize sustainability commitments without fully translating them into deep operational and product-oriented change.

The Shy Laggards configuration reflects low engagement and limited integration across all dimensions. Firms in this cluster implement fewer initiatives overall and display a fragmented strategy mix, suggesting that sustainability remains peripheral to core strategic priorities. The low and relatively flat profile indicates that environmental actions, when present, are not organized into an internally reinforcing system, which is consistent with a compliance-oriented or episodic approach rather than an integrated strategy system.

The three configurations highlight that heterogeneity in corporate environmental engagement is not only a matter of "how much" firms do, but also of how initiatives are structured across domains. The results point to two analytically separable dimensions underlying this heterogeneity: intensity (the overall level of engagement) and balance (the extent to which engagement is distributed evenly across strategic domains). Importantly, the Active Followers profile illustrates that intermediate intensity can coexist with pronounced unevenness, suggesting that partial coherence may arise when sustainability engagement is built around outward-facing commitments that outpace product, operational, and carbon-related transformation.

These findings underscore that environmental sustainability can be understood as a multidimensional strategy system in which the internal alignment of initiatives varies meaningfully across firms. Examining configurations of engagement - and distinguishing intensity from balance - helps clarify why firms facing similar sustainability pressures may nonetheless exhibit different strategic

architectures, ranging from integrated bundles to selective outward-facing engagement and fragmented low-activity profiles.

7. Conclusion

This study examined how firms combine multiple environmental initiatives into coherent strategy systems and introduced the concept of environmental strategy mix coherence, defined as the internal alignment and mutual reinforcement among strategic dimensions of environmental engagement. Using a configurational approach on ESG disclosures for global food and beverage firms, the analysis identified three empirically recurring profiles - All-Round Leaders, Active Followers, and Shy Laggards - showing that heterogeneity in environmental engagement is not only a matter of "how much" firms do, but also of how initiatives are organized and integrated across domains.

From a theoretical standpoint, the results support a system-level view of corporate environmental strategy (Mårtensson and Westerberg, 2016). Rather than treating sustainability practices as isolated or additive elements, the findings indicate that firms differ in the degree to which environmental initiatives are structured as coordinated bundles spanning product, internal organizational, governance, stakeholder, and carbon-related dimensions. In doing so, the study reinforces a configurational understanding of environmental engagement (Walker et al., 2015) and clarifies that intensity and internal balance represent distinct properties of corporate environmental strategy systems.

For managers, the configurations provide a diagnostic lens for assessing whether environmental engagement reflects an integrated strategy system or a selective, uneven mix of initiatives. Firms resembling Active Followers may strengthen coherence by translating outward-facing commitments (governance and stakeholder-oriented actions) into deeper product and operational initiatives, thereby reducing domain imbalances. For Shy Laggards, progress is likely to require building basic internal foundations and governance mechanisms that can support a more coordinated expansion of initiatives over time. More broadly, the results suggest that environmental efforts are likely to be more credible and effective when designed as interdependent elements of a unified strategic architecture rather than as disconnected programs.

The cross-regional differences in the prevalence of configurations also point to the relevance of institutional environments in shaping not only the adoption of environmental initiatives but their internal structuring. Policy frameworks focused primarily on disclosure or isolated practices may risk encouraging symbolic compliance, whereas mechanisms that facilitate coordinated implementation - particularly for smaller firms facing resource constraints - may support the development of more coherent environmental strategy systems.

This study has limitations that offer avenues for future research. First, the cross-sectional design does not allow assessment of how firms transition across configurations over time; longitudinal studies could examine pathways of capability building and the dynamics through which coherence emerges or deteriorates. Second, the focus on a single industry limits generalizability; comparative analyses across sectors with different environmental pressures would help clarify boundary conditions. Third, while the study provides a taxonomy of strategy systems, it does not establish causal relationships between coherence and performance outcomes; future research could investigate how configurations relate to longer-term competitiveness, risk exposure, and value creation. Finally, our measures capture disclosed environmental initiatives from Refinitiv Eikon, which may reflect differences in reporting practices as well as substantive implementation.

Data availability statement

Data were retrieved from the Refinitiv Eikon database. Access to the underlying ESG data is available via Refinitiv subscription. The derived variables used in the analyses (dimension scores, imbalance/dispersion indices, and cluster assignments) can be made available by the authors upon request.

Shy Laggards	S2	1	1	1	1	1	1.00	0.00
Shy Laggards	S3	1	1	0	2	1	1.00	0.00

Source: our elaboration. Note: Examples are anonymized and selected as the firms with the smallest Euclidean distance to the cluster centroids in standardized space (based on the five dimension scores).

Table A3. Brief descriptive vignettes for anonymized firm examples (illustrative).

Configuration	Anonymized firm	Descriptive vignette
All-Round Leaders	L1	This profile combines strong product-oriented initiatives, well-developed stakeholder engagement, formal governance mechanisms supporting sustainability, with concrete carbon-related actions. Internal organizational practices are present, supporting a relatively balanced strategy system across domains.
All-Round Leaders	L2	This profile combines strong product-oriented initiatives, well-developed stakeholder engagement, governance mechanisms in place, with concrete carbon-related actions. Internal organizational practices are present, supporting a relatively balanced strategy system across domains.
All-Round Leaders	L3	This profile combines solid product-related initiatives, well-developed stakeholder engagement, governance mechanisms in place, with concrete carbon-related actions. Internal organizational practices are present, supporting a relatively balanced strategy system across domains.
Active Followers	F1	This profile shows meaningful engagement but a more selective architecture: stakeholder-facing initiatives are comparatively stronger than product and internal practices. Governance mechanisms are present but do not fully translate into stronger product or internal initiatives. Overall, the pattern reflects a pronounced outward–inward imbalance.
Active Followers	F2	This profile shows meaningful engagement but a more selective architecture: stakeholder-facing initiatives are comparatively stronger than product and internal practices. Governance structures are particularly developed, reinforcing an outward-facing orientation. Overall, the pattern reflects a pronounced outward–inward imbalance.
Active Followers	F3	This profile shows meaningful engagement but a more selective architecture: stakeholder-facing initiatives are comparatively stronger than product and internal practices. Governance mechanisms are present but do not fully translate

		into stronger product or internal initiatives. Overall, the pattern reflects moderate imbalance and partial integration across domains.
Shy Laggards	S1	This profile reflects limited environmental engagement across domains, with few initiatives reported in product, internal processes, and carbon-related actions. Stakeholder-oriented initiatives are largely absent, suggesting weak external integration. Governance structures are minimal, consistent with a fragmented and low-coherence strategy mix.
Shy Laggards	S2	This profile reflects limited environmental engagement across domains, with few initiatives reported in product, internal processes, and carbon-related actions. Stakeholder engagement is present but remains modest. Governance structures are minimal, consistent with a fragmented and low-coherence strategy mix.
Shy Laggards	S3	This profile reflects limited environmental engagement across domains, with few initiatives reported in product, internal processes, and carbon-related actions. Stakeholder-oriented initiatives are largely absent, suggesting weak external integration. Governance mechanisms appear somewhat more developed than other domains, but the overall mix remains sparse and weakly coordinated.

Source: our elaboration. Note: Vignettes summarize the pattern of disclosed initiatives reflected in the five dimension scores reported in Appendix Table A2; no additional firm-level information is used.

Table A4. Internal validity indices for alternative cluster solutions (k = 2–6).

k	Silhouette (avg) ↑	Calinski–Harabasz ↑	Davies–Bouldin ↓
2	0.341	216.91	1.145
3	0.255	157.08	1.441
4	0.214	131.65	1.560
5	0.212	116.34	1.549
6	0.215	108.22	1.464

Source: our elaboration. Note: Indices are computed on unstandardized dimension scores using k-means clustering; higher values indicate better fit for Silhouette and Calinski–Harabasz, whereas lower values indicate better fit for Davies–Bouldin.

Table A5. Stability checks for the three-cluster solution.

Check	Specification	ARI mean	ARI SD	ARI min–max
Multiple initializations	k = 3; 10 different random seeds (n_init = 5), compared to baseline solution	0.881	0.128	0.682–1.000
Subsampling stability	k = 3; 10 random 80% subsamples (n_init = 3), compared to baseline labels on the subsample	0.878	0.118	0.676–0.987

Source: our elaboration. Note: These diagnostics indicate that the three-cluster solution is stable under alternative initializations and resampling. While internal validity indices are highest for k = 2 in this dataset, the three-cluster solution provides additional interpretive resolution consistent with the dendrogram-based assessment and the study's focus on distinguishing intensity and internal balance across domains.

Table A6. Cluster membership across headquarters regions.

Configuration	Americas	Asia	China	Europe	Japan	Others	UK	USA	Total (N)

Experience Economy Dimensions and Guest Satisfaction in Peer-to-Peer Accommodation: Comparative Analysis of Airbnb Reviews in Rome and Paris

ANTON PUSTOVALOV[1], OKSANA TOKARCHUK[2], OSWIN MAURER[1]

Abstract

Frame of the research. *Peer-to-peer accommodation platforms such as Airbnb increasingly position accommodation as an experiential product, yet large-scale empirical applications of the Experience Economy framework to Airbnb user-generated content remain limited.*
Purpose of the paper. *The paper investigates how the four Experience Economy dimensions — education, entertainment, escapism, and esthetics — shape guest satisfaction in Airbnb accommodation reviews, comparing Rome and Paris.*
Methodology. *The study analyzes nearly one point six million Airbnb accommodation reviews from Rome and Paris. Experiential dimensions are operationalized through validated scales from Mody et al. combined with NLP-assisted coding, validated against human-coded reviews. Satisfaction is measured through sentiment scores and listing ratings.*
Results. *Esthetics is the strongest predictor of affective satisfaction, while education has the strongest association with rating-based satisfaction. Entertainment has positive but moderate effects across both outcomes. Escapism shows a more complex pattern: it is negatively associated with sentiment and non-significant in the baseline rating model, but becomes a significant rating driver in Paris. City interaction models show that experiential effects differ between Rome and Paris.*
Research limitations. *The study uses publicly available Airbnb data and relies on automated text analysis; therefore, sentiment classification and experiential coding may not fully capture irony, implicit meanings, or culturally specific expressions.*
Managerial implications. *Hosts and platforms should treat accommodation not only as functional lodging but also as an experiential product, investing in esthetics, cultural guidance, and destination-specific experiential positioning.*
Originality of the paper. *The paper provides large-scale empirical validation of the Experience Economy framework in peer-to-peer accommodation and demonstrates that experiential dimensions influence affective and cognitive satisfaction differently across destination contexts.*

Keywords: *Experience Economy, Airbnb, guest satisfaction, Rome, Paris, large-scale analysis*

1. Introduction

Peer-to-peer accommodation has transformed the urban tourism sector, giving travelers flexibility and affordability owing to Airbnb's popularity in this accommodation space (Gutiérrez et al., 2017; Moon et al., 2019). Airbnb has changed the norms of what a host property can be, positioning accommodation as more than simple lodging and connecting it to local culture, authenticity, and a sense of belonging (Mody et al., 2017; Guttentag, 2019; Capineri & Romano, 2021). Nevertheless, the constant and rapid increase in listings (over 8 million, as reported by Airbnb last year) has led to commodification and serious competition between hosts, making increasingly challenging what is already difficult - to continually meet guests' varying expectations (Sthapit, 2019; Voltes-Dorta & Inchausti-Sintes, 2020; Airbnb, 2025, July 5).

In this context, the Experience Economy (EE) framework (Pine & Gilmore, 1999) represents a compelling solution for differentiation by providing engaging experiences with four dimensions: education, entertainment, escapism, and esthetics. While previous research has examined the four realms in bed-and-breakfasts (Oh et al., 2007), cruise tourism (Hosany & Witham, 2010), festivals (Mehmetoglu & Engen, 2011), and Airbnb studies (Mody et al., 2017; Bao et al., 2021), confirming its applicability in tourism, hospitality, and that the experience varies depending on context, most

[1] University of Bolzano
[2] University of Trento

studies have been conceptual, survey-based with small sample sizes, or descriptive analyses with a limited scope of reviews.

Furthermore, although these studies underscore the significance of reviews, they have not applied the framework broadly in relation to Airbnb review datasets, hence restricting the generalizability of findings. Empirical applications of the EE framework to peer-to-peer accommodations are quite limited, and only a few studies have utilized reviews to extract their dimensions. Comparative analyses across destinations are even scarcer, despite evidence suggesting that reviews of Airbnb properties differ by market and cultural dimensions prioritized in online reviews (Mody et al., 2017; Zhang & Fu, 2020). This highlights a serious gap: A lack of scalable and data-driven approaches to quantify how experiential dimensions contribute to satisfaction in Airbnb.

The present study seeks to fulfil this gap through a comparison of two cities (Rome, Paris), with each city offering thousands of Airbnb reviews, and to examine whether the experiential dimensions appear consistently or reflect the distinctive characteristics of the two destinations. Guest reviews on Airbnb frequently emphasize different experiential aspects that contribute significantly to the overall guest satisfaction during the stay, for example, host-guest interaction, the host's hospitality, location, feeling welcome, home experience, apartment facilities (Tussyadiah & Zach, 2017; Xu et al., 2019; Sthapit et al., 2021), which makes the EE framework particularly relevant and provides a natural way to operationalize these dimensions.

Various research has highlighted that satisfaction in tourism and hospitality has mostly been examined using star ratings, structured surveys, and service quality models such as SERVQUAL or HOLSERV (Pizam & Ellis, 1999; Li et al., 2013; Pizam et al., 2016; Oh & Kim, 2017). In the context of Airbnb reviews, different studies link review scores, sentiment, and booking outcomes (Lawani et al., 2019; Zhu et al., 2019; Zhu et al., 2020; Thomsen & Jeong, 2020; Zervas et al., 2021) and show that Airbnb review scores correlate well with sentiment scores from both titles and full content of reviews (Subroto & Christianis, 2021).

Two cities, Paris and Rome, were chosen as the two empirical cases because of the size and maturity of the Airbnb market (Heo et al., 2019; InsideAirbnb.com, 2025, August 10), ensuring sufficient data availability. The choice for this study enables a comparative analysis that captures both destination-specific and generalizable experiential patterns, thereby generating insights of relevance not only for hosts and destination managers in these cities, but also for stakeholders operating in other urban tourism contexts.

This paper, therefore, aims to extend the EE to peer-to-peer accommodation by investigating how the four dimensions are represented in user-generated content (UGC) and to what extent they contribute to guest satisfaction. The analysis focuses specifically on Airbnb accommodation-related reviews and does not include Airbnb Experiences, tours, or activities. Accordingly, the paper examines how accommodation stays acquire experiential value through guests' review narratives. Moreover, the study offers a new approach that employs natural language processing as a methodology that can scale experiential constructs rather than adopting survey or small sample approaches as previous studies have.

The study addresses the following research questions:

RQ1 How do the four EE dimensions (education, entertainment, esthetics, and escapism) influence guest satisfaction in peer-to-peer accommodation?

RQ2 Do the effects of EE dimensions on guest satisfaction differ when satisfaction is operationalized as affective (textual sentiment) versus cognitive (numerical ratings)?

RQ3 Which EE dimensions are most salient in Airbnb guest reviews, as reflected in the intensity of experiential language used in review texts?

RQ4 How do the salience and satisfaction effects of EE dimensions differ between Rome and Paris?

2. Methodology

2.1 Data Source

Data for both cities were retrieved from the website called InsideAirbnb.com, a project that was launched in 2015 by Murray Cox. This platform compiles, cleans, and aggregates data from Airbnb to inform communities about rentals' housing impacts (InsideAirbnb, 2025, August 2). For this study, datasets for Rome and Paris were downloaded as separate CSV files containing different information about listings and reviews. After cleaning and merging, the combined dataset yielded approximately 1,600,000 reviews; all preprocessing and analyses were conducted using Python.

The qualitative coding process was grounded in Pine and Gilmore's (1999) four realms of experience - education, entertainment, escapism, and esthetics - as operationalized and validated by Mody et al. (2017) in the comparative study about hotels and Airbnb accommodations. Their validated scale items (Table 2) provided the conceptual and linguistic anchors and were integrated directly into the system prompt developed to instruct OpenAI models to classify user reviews according to the defined dimensions. The following sub-sections, taken from Mody et al. (2017), describe how each dimension was defined and operationalized during the coding process.

Table 1. Validated scales from Mody et al. (2017). The accommodation experiencescape: a comparative assessment of hotels and Airbnb

Entertainment (Fun, Amusement, Enjoyment)	Education (Learning, Enrichment)	Escapism (Immersion, Escape, Transformation)	Esthetics (Design, Surroundings, Atmosphere)
The hotel / Airbnb experience was fun The hotel / Airbnb was entertaining I really enjoyed this hotel / Airbnb experience	I learned a lot through my experience The hotel/Airbnb experience stimulated my curiosity to learn new things Staying at the hotel/Airbnb was a real learning experience	Staying at the hotel / Airbnb made me feel I was in a different world Staying at the hotel / Airbnb made me feel I was living in a different time or place I completely escaped from reality during the hotel / Airbnb experience	It was pleasant just being at the hotel / Airbnb The setting of the hotel / Airbnb provided pleasure to my senses The setting of the hotel / Airbnb really showed attention to detail in terms of design

Source: our elaboration

Mody et al. (2017) adapted these realms for the peer-to-peer accommodation sector from the study by Oh et al. (2007) and also added new dimensions (e.g., serendipity, localness, communitas, and personalization). The current study focuses on the four core realms, and any other extended dimensions are noted for future research directions.

2.2 Coding Procedure

For manual coding, a random sample of 100 reviews per city (200 total) was selected using simple random sampling without replacement from the cleaned review corpus, and each dimension was scored on a 0-4 Likert scale (0 = not present; 1 = minor presence; 2 = moderate presence; 3 = strong; 4 = dominant presence), capturing intensity of experiential language (Koo & Yang, 2025). The zero-to-four scale was selected because it captures increasing intensity of experiential language, from absence to dominant presence, while remaining sufficiently simple for reliable human coding and automated replication. Two coders independently read each review of the subset and scored all four dimensions. All discrepancies were discussed between coders to align interpretation standards, enhancing consistency in coding decisions.

The manual coding sub-sample of 200 reviews (100 per city) serves as a reference benchmark against which GPT-4.1-nano-generated EE scores are evaluated, enabling validation of automated coding accuracy prior to full-scale application. The validated model was subsequently applied to the

complete dataset of approximately 1.6 million reviews, and all analyses reported in this study are based on this full-scale corpus.

2.3 Validation

To develop an automated measurement tool that will be both accurate and reliable in its ability to classify each review, this study utilized a multi-step validation model selection process considering human coded results. Instead of relying on a single AI configuration, different large language model (LLM) variants were tested against a manually coded review dataset in terms of accuracy, reliability, and performance.

Multiple coding configurations, each assisted by OpenAI's coding, were used for a single review set. The three configurations include: (1) GPT-4.1-nano vs. human coding, (2) GPT-4.1 vs. human coding, and (3) GPT-4.1-nano classification across independent runs. Four separate measures of model performance are examined: Pearson correlation coefficients (to determine if there is an association in linear terms), mean absolute error (MAE) (the average difference between GPT-4.1-nano and human coding), exact score agreement, and the proportion of scores within ±1 point of the 0-4 EE Scale.

As shown in Table 3, GPT-4.1-nano achieves high correlation with human ratings ($r \approx 0.73–0.96$) as well as very low MAE values (0.20 or less). In addition, GPT-4.1-nano achieves 100% agreement within ±1 of human judgments on every dimension. While Table 4 shows that the GPT-4.1 model had strong correlations, it had higher MAE values than GPT-4.1-nano, and much smaller exact match rates, which indicates much more variability around human scores.

Table 2. GPT4.1 Nano versus Human Validations

City	Dimension	Pearson r	MAE	Exact match (%)	Within ±1 (%)	N used
Rome	Education	0.949	0.120	88.0	100.0	100

The reliability of GPT-4.1-nano was also assessed by running it independently two times on the same review set (Table 5). Agreement between these two runs was extremely high ($r > 0.9$ for each dimension) with a very close to 100% exact match rate and minimal MAE. These results indicate that GPT-4.1-nano, when provided with a well-defined and specific prompt, provides consistent and reliable classification and minimizes the potential for random variability in automated coding.

Table 4. GPT4.1 Nano Consistency (Attempt 1 vs 2)

City	Dimension	Pearson r	MAE	Exact match (%)	Within ±1 (%)	N used
Rome	Education	1.000	0.000	100.0	100.0	100
Rome	Entertainment	0.986	0.010	99.0	100.0	100
Rome	Escapism	0.924	0.040	96.0	100.0	100

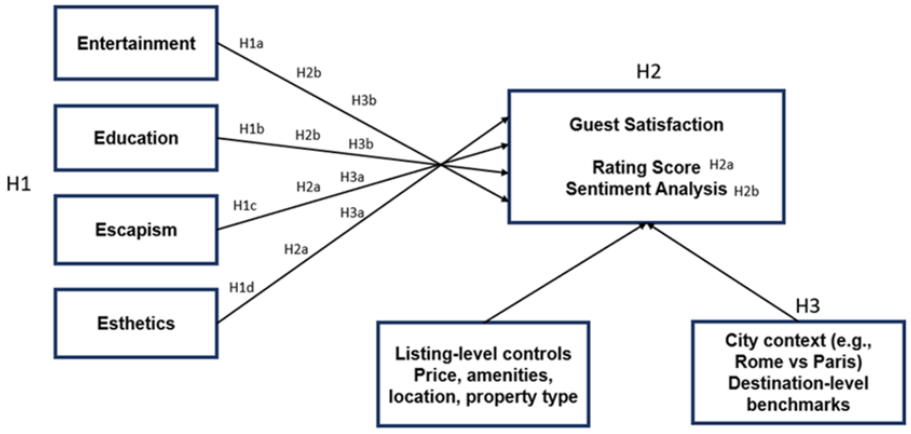
Source: our elaboration



The comparative analysis led to the selection of GPT-4.1-Nano to use as the operational model for EE measurements within this study. As a result of its superior performance relative to both accuracy and computational resources, the model was able to replicate human-coding with an acceptable level of error, while also providing consistent results from run-to-run. Therefore, all further analysis is based upon EE scores generated by GPT-4.1-Nano that were compared to human-coded benchmarks.

3. Conceptual Framework and Econometric Models

3.1 Conceptual Explanation

Drawing on Pine and Gilmore's (1999) EE framework, Figure 1 proposes that the four dimensions constitute key experiential value drivers in tourism settings.

Fig. 1: A Conceptual Model for Understanding the Influence of the Experience Economy Framework on Guest Satisfaction

Source: our elaboration

Prior empirical studies demonstrate that these dimensions are measurable and significantly associated with tourist satisfaction, although their relative importance varies across contexts. Moreover, prior research indicates that the four EE dimensions do not exert uniform effects across contexts, with certain dimensions (e.g., esthetics or entertainment) often emerging as more salient depending on the experiential setting and type of activity (Oh et al., 2007; Hosany & Witham, 2010; Mehmetoglu & Engen, 2011; Flores-Gómez et al., 2025). This suggests that the influence of experiential dimensions on satisfaction may vary rather than follow a strictly uniform pattern.

Building on this literature, the four experiential dimensions are generally expected to contribute positively to guest satisfaction in the Airbnb context, articulated in the following hypotheses:

H1: The four EE dimensions - education, entertainment, escapism, and esthetics have a positive effect on guest satisfaction.

H1a: Education - Satisfaction (+)

H1b: Entertainment - Satisfaction (+)

H1c: Escapism - Satisfaction (+)

H1d: Esthetics - Satisfaction (+)

Review sentiment analysis was implemented by VADER, Valence Aware Dictionary and sEntiment Reasoner (Hutto & Gilbert, 2014), yielding scores from -1 (negative) to +1 (positive). Reviews > +0.05 were positive (satisfied), < -0.05 negative (dissatisfied), and in-between neutral. Macro-level satisfaction is drawn from review scores, aggregating guest ratings per listing for long-term quality insights. Prior research demonstrates that numerical ratings primarily capture an overall, evaluative judgment of service performance, while textual reviews convey richer emotional and experiential responses expressed through language (Oliver, 1980; Pang & Lee, 2008; Sparks & Browning, 2011). Using both measures allows for a more comprehensive assessment of satisfaction and reduces reliance on a single evaluative metric. Affective-experiential (sentiment) and cognitive-evaluative (ratings) (Wang et al., 2023) are both captured by this dual approach, providing long-term quality insights for satisfaction in peer-to-peer stays for this study.

H2: The EE dimensions influence both rating-based satisfaction and sentiment-based satisfaction, but the magnitude of effects differs across the two measures.

H2a: The effects of esthetics and escapism on guest satisfaction are stronger for rating scores than for sentiment measures.

H2b: The effects of entertainment and education on guest satisfaction are stronger for sentiment measures than for rating scores.

To isolate the experiential contribution of the EE dimensions, the model incorporates listing-level control variables (price, amenities, neighborhood, and property type), which are known to influence guest evaluations in peer-to-peer accommodation markets (Guttentag et al., 2017; Huang et al., 2025).

Finally, the model introduces city context (Rome vs. Paris) as a comparative benchmark logic, consistent with destination competitiveness research (Crouch, 2010), enabling an assessment of whether the relative importance of experiential dimensions varies across two globally competitive tourism cities with distinct experiential profiles. Prior literature provides conceptual grounds for expecting such destination-level moderation. Paris is widely recognized as a global center of aesthetic culture, architecture, and fashion, an urban identity deliberately constructed through spatial engineering for the tourist gaze (Urry, 2002; Montagné Villette & Hardill, 2010). This culturally saturated esthetic environment is likely to amplify the salience of esthetics and escapism in guest evaluations, as visitors arrive with elevated aesthetic expectations and aspirational identity narratives (Seyfi et al., 2020). Rome, by contrast, is rooted in tangible historical and cultural heritage (Gemmiti, 2019), positioning it as a site of knowledge acquisition and cultural enrichment. Prior studies in cultural and heritage tourism contexts show that educational value is a particularly strong driver of

satisfaction in destinations with dense historical resources (Radder & Han, 2015; Hwang & Lyu, 2015). Together, these distinct destination identities provide a theoretical basis for expecting that esthetics and escapism effects will be stronger in Paris, while education and entertainment effects will be more pronounced in Rome.

H3: The strength of the relationship between EE dimensions and guest satisfaction differs between Rome and Paris.

H3a: The positive relationship between Esthetics and Escapism on guest satisfaction will be stronger for listings in Paris compared to those in Rome.

H3b: The positive relationship between Education and Entertainment on guest satisfaction will be stronger for listings in Rome compared to those in Paris.

3.2 Econometric Specification

To examine the relationship between EE dimensions and guest satisfaction, the empirical analysis employs linear regression models specified at both the review level and the listing level, reflecting the dual operationalization of satisfaction as affective and cognitive.

At the review level, affective guest satisfaction is measured using sentiment scores derived from review text. The baseline econometric specification models review-level sentiment as a function of the four Experience Economy dimensions and a vector of control variables:

$$Sentiment_i = \alpha + \beta^1 Education_i + \beta^2 Entertainment_i + \beta^3 Esthetics_i + \beta^4 Escapism_i + \gamma X_i + \varepsilon_i$$

where $Sentiment_i$ denotes the sentiment score of review i, $Education_i$, $Entertainment_i$, $Esthetics_i$, and $Escapism_i$ represent the intensity of the four Experience Economy dimensions expressed in the review, X_i is a vector of review- and listing-level control variables (including price, accommodation capacity (accommodates, bedrooms, beds), availability, and host listing characteristics), and ε_i is an error term. This model is used to test Hypotheses H1 and H2 regarding affective satisfaction.

Because numerical ratings are available only at the listing level and reflect cumulative guest evaluations over time, a separate listing-level model is estimated to capture cognitive satisfaction. Experience Economy dimensions are aggregated to the listing level by averaging review-level scores for each listing. The corresponding specification is:

$$Rating_l = \alpha + \beta^1 Education_l + \beta^2 Entertainment_l + \beta^3 Esthetics_l + \beta^4 Escapism_l + \gamma Z_l + \varepsilon_l$$

where $Rating_l$ denotes the average rating score of listing l, $\bar{Education}_l$, $\bar{Entertainment}_l$, $\bar{Esthetics}_l$, and $\bar{Escapism}_l$ represent the mean Experience Economy scores across all reviews associated with listing l, Z_l is a vector of listing-level control variables, and ε_l is the error term. This specification allows for testing Hypotheses H1 and H2 using rating-based satisfaction.

To test whether effects differ between Rome and Paris, we estimate interaction models with a city indicator and EE × city. A binary city indicator is defined, where City = 1 for Paris and City = 0 for Rome, which serves as the reference category. At the review level, city-level moderation for sentiment-based satisfaction is examined using the following interaction model:

$$\begin{aligned} Sentiment_i = {} & \alpha + \beta_1 Education_i + \beta_2 Entertainment_i + \beta_3 Esthetics_i + \beta_4 Escapism_i \\ & + \theta City_i + \delta_1 (Education_i \times City_i) + \delta_2 (Entertainment_i \times City_i) \\ & + \delta_3 (Esthetics_i \times City_i) + \delta_4 (Escapism_i \times City_i) + \gamma X_i + \varepsilon_i \end{aligned}$$

In this specification, coefficients β capture the effects of Experience Economy dimensions in Rome, while interaction coefficients δ indicate whether and how these effects differ for Paris. Positive

and statistically significant interaction terms imply stronger effects in Paris, whereas negative interaction terms indicate stronger effects in Rome. This model directly tests Hypotheses H3a and H3b for affective satisfaction.

An analogous interaction specification is estimated at the listing level to assess city-level moderation for rating-based satisfaction:

$$Rating_l = \alpha + \beta_1 Education_l + \beta_2 Entertainment_l + \beta_3 Esthetics_l + \beta_4 Escapism_l + \theta City_l + \delta_1(Education_l \times City_l) + \delta_2(Entertainment_l \times City_l) + \delta_3(Esthetics_l \times City_l) + \delta_4(Escapism_l \times City_l) + \gamma' Z_l + \varepsilon_l$$

Categorical listing characteristics (e.g., room type and property type) are included as dummy variables. Together, these models allow for a systematic examination of how EE dimensions influence guest satisfaction across destinations and whether their relative importance differs between Rome and Paris.

4. Results

Table 5 reports descriptive statistics of Experience Economy dimension scores by city based on approximately 798,000 reviews per destination (1,596,000 total). Esthetics exhibits the highest mean values in both Paris and Rome, followed by education and entertainment, while escapism shows the lowest average intensity. Standard deviations indicate substantial within-city variation across all dimensions.

Tab 5: Descriptive Statistics of Experience Economy Dimensions by City

City	Education (Mean)	Education (SD)	Entertainment (Mean)	Entertainment (SD)	Esthetics (Mean)	Esthetics (SD)	Escapism (Mean)	Escapism (SD)	Reviews
Paris	0.646	0.86	0.419	0.67	1.591	1.09	0.200	0.60	798,000
Rome	0.748	0.86	0.395	0.64	1.434	1.08	0.148	0.51	798,000

Source: our elaboration

Table 6 reports descriptive statistics of sentiment scores by city. Mean sentiment values are nearly identical across Paris (0.845) and Rome (0.845), with the difference statistically non-significant (p = 0.591), with comparable dispersion and quartile distributions. Median sentiment scores exceed 0.92 in both destinations, indicating generally positive affective evaluations.

Tab 6: Descriptive Statistics of Sentiment Scores by City

City	Number of Reviews	Mean (The average sentiment score)	SD (Standard Deviation)	Min (The most negative sentiment score observed)	Q1 (First Quartile)	Median (Q2)	Q3 (Third Quartile)	Max (The most positive sentiment score observed)
Paris	798,000	0.8451	0.228	-0.988	0.839	0.931	0.969	0.999
Rome	798,000	0.8449	0.223	-0.989	0.826	0.925	0.965	0.999

Escapism	-0.0115	0.002	-4.756	<0.001

Source: our elaboration

Table 10 presents results from the listing-level regression estimating the relationship between aggregated Experience Economy dimensions and rating-based satisfaction across 23,918 listings. The model is jointly significant (Prob > F < 0.001) and explains approximately 19.7% of the variation in listing ratings.

Education ($\beta = 0.133$, $p < 0.001$), entertainment ($\beta = 0.036$, $p < 0.001$), and esthetics ($\beta = 0.105$, $p < 0.001$) exhibit positive and statistically significant associations with rating scores. Escapism shows a positive but non-significant coefficient ($\beta = 0.012$, $p = 0.190$), indicating that its effect on cognitive satisfaction is not robust at scale.

Tab 10: Listing-Level Regression of Rating-Based Satisfaction (n = 23,918)

Source: our elaboration

Table 11 reports results from the listing-level regression including city interaction terms, allowing the relationship between Experience Economy dimensions and rating-based satisfaction to differ between Rome and Paris. In the baseline category, Rome, education, entertainment, and esthetics are positively and significantly associated with ratings. Escapism is negative but not statistically significant, indicating that it is not a general rating driver in Rome. The interaction term for escapism is positive and statistically significant ($\beta = 0.0495$, $p = 0.013$), indicating that escapism becomes a distinct driver of rating-based satisfaction in Paris. The interactions for education, entertainment, and esthetics are not statistically significant in the rating model.

Tab 11: Listing-Level Regression of Rating-Based Satisfaction with City Interaction Effects (n = 23,918)

Source: our elaboration

This study examined the extent to which Pine and Gilmore's (1999) four Experience Economy dimensions shape guest satisfaction in peer-to-peer accommodation. Overall, the findings provide partial support for Hypothesis H1.

At the review level, sentiment-based analyses show that education, entertainment, and esthetics are positively and significantly associated with affective guest satisfaction. Among these, esthetics emerges as the strongest predictor of sentiment, confirming earlier hospitality and tourism research that highlights the central role of design, atmosphere, and sensory appeal in shaping emotional responses to accommodation experiences (Oh et al., 2007; Mehmetoglu & Engen, 2011; Mody et al., 2017). These results suggest that experiential elements related to learning, enjoyment, and aesthetic appreciation are consistently reflected in guests' emotional narratives.

By contrast, escapism exhibits a small but negative association with sentiment, indicating that explicit references to escape or immersion may be linked to more ambivalent emotional expressions in review texts. This suggests that escapism does not uniformly translate into positive affective evaluations in accommodation contexts, consistent with prior research emphasizing the context-dependent nature of experiential effects (Mehmetoglu & Engen, 2011; Bao et al., 2021).

At the listing level, education, entertainment, and esthetics display positive and statistically significant associations with rating-based satisfaction. Escapism is positive but not statistically significant in the baseline rating model, suggesting that its effect on cognitive satisfaction is conditional rather than general. This indicates that escapist experiences do not operate as a general satisfaction driver in the baseline models, but may become relevant under specific destination conditions. Taken together, these results indicate that H1a, H1b, and H1d are supported, while H1c is not supported in the baseline models because escapism is negatively associated with sentiment and non-significant for ratings.

A central contribution of this study lies in its dual operationalization of guest satisfaction, distinguishing between affective satisfaction captured through sentiment analysis and cognitive satisfaction measured through numerical ratings. The findings confirm the broader premise of H2 that Experience Economy dimensions operate differently across affective and cognitive satisfaction measures. However, H2 is not supported in its directional form. Contrary to the original expectation, esthetics has the strongest effect on sentiment-based satisfaction, while education has the strongest association with rating-based satisfaction. Entertainment shows positive but moderate effects across both outcomes, whereas escapism is negatively associated with sentiment and non-significant in the baseline rating model.

These results reinforce the view that satisfaction is not a unidimensional construct. Rather, emotional expression in review text and overall evaluative judgment in ratings capture distinct aspects of guest satisfaction. The findings, therefore, highlight the importance of modeling sentiment and ratings separately when examining experiential value in peer-to-peer accommodation.

Hypothesis H3 proposed that the strength of the relationship between Experience Economy dimensions and guest satisfaction differs between Rome and Paris. The results provide partial support for H3.

City interaction models reveal that escapism has a significantly stronger association with rating-based satisfaction in Paris than in Rome ($\beta = 0.050$, $p = 0.013$), providing partial support for H3a. In Paris, escapism, expressed as aspirational identity performance, living like a local, or immersion in romantic urban aesthetics, constitutes a distinct value driver for ratings, while it does not significantly influence ratings in Rome. This distinction is theoretically grounded in Paris's identity as a deliberately aestheticised urban spectacle (Urry, 2002) where visitors arrive with aspirational self-narratives, and corroborates prior research on place-based meaning and cultural immersion (Seyfi et al., 2020; Mody et al., 2017). Additionally, sentiment-level interaction models (not shown) confirm that esthetics exerts a significantly stronger effect on affective satisfaction in Paris ($\beta = +0.005$, $p < 0.001$), while education is comparatively more salient for sentiment in Rome ($\beta = -0.004$, $p < 0.001$).

In contrast, education and entertainment do not show statistically significant city differences in the rating model. Therefore, H3b is not supported in the rating-based analysis. Overall, H3 receives partial support: esthetics is more strongly associated with sentiment in Paris, while escapism becomes a significant rating driver in Paris, but the remaining city interaction effects are not consistently significant. These findings indicate that while the EE framework is broadly applicable across destinations, esthetic and escapist experiences are particularly sensitive to city context, reinforcing the importance of experiential benchmarking in destination analysis (Bao et al., 2021).

5. Research limitations

The research complies with ethical guidelines for research using publicly available online data and poses no risk to individual users. Publicly available data obtained from InsideAirbnb.com were considered reliable for this study, and no private, identifiable, or sensitive personal data was collected or analyzed. Analyses were conducted at the review and listing levels, and reviewer usernames or identifiers were not used for profiling or inference.

The use of automated OpenAI-assisted text analysis introduces some limitations. VADER's sentiment analysis, while suitable for short informal review texts, may not fully capture sarcasm, irony, or culturally specific references. Similarly, the way in which the EE dimensions are classified using prompts depends on the strength and the clarity of the experiential cues expressed in the review text and may underrepresent implicitly conveyed experiences. Although the automated coding method was tested against manually coded reviews, some degree of measurement error is unavoidable when attempting to automate qualitative constructs through automated methods.

Another limitation concerns the structure of Airbnb rating data. InsideAirbnb.com does not provide any numeric ratings for individual reviews. This is because rating scores are provided as a full listing level only and reflect cumulative evaluations over time. Consequently, the study cannot directly associate specific review narratives with corresponding numerical ratings. This limitation is addressed by operationalizing satisfaction in two ways, distinguishing affective review-level sentiment from cognitive listing-level ratings.

6. Managerial implications

The results, based on nearly 1.6 million Airbnb accommodation reviews, demonstrate that esthetics and education are the strongest experiential drivers of affective and cognitive satisfaction, respectively. Hosts should therefore invest in both sensory-atmospheric design and informational richness rather than treating accommodation as purely functional lodging. Improvements in lighting, visual coherence, decoration, spatial atmosphere, and attention to detail can strengthen the emotional tone of guest reviews. At the same time, clear instructions, curated local recommendations, neighborhood guides, and cultural information can improve guests' overall evaluative judgments.

The results also suggest that experience design should be destination-sensitive. In Paris, where escapism becomes a distinct driver of rating-based satisfaction, listings that facilitate aspirational "living like a local" identities through curated interiors, neighborhood immersion, and locally embedded recommendations are more likely to receive higher evaluations. In Rome, where education is comparatively more salient for sentiment, hosts can benefit from structured cultural and historical guidance, including explanations of nearby heritage sites, walking routes, and practical information that helps guests interpret the city.

At the platform level, Airbnb could enrich recommendation and ranking systems by incorporating destination-relevant experiential attributes alongside aggregate star ratings. Experience-oriented listing tags, such as design atmosphere, local immersion, cultural learning, or neighborhood authenticity, could help guests identify listings that match their desired form of experience. In competitive urban Airbnb markets, experience design becomes a strategic differentiation mechanism rather than a cosmetic enhancement.

7. Originality of the paper

This study stands out on three grounds. First, it provides one of the first large-scale empirical validations of the EE framework, analyzing nearly 1.6 million Airbnb accommodation listing reviews, two orders of magnitude larger than prior EE studies in hospitality (Oh et al., 2007; Bao et al., 2021), demonstrating that the four dimensions are detectable and analytically robust at scale using NLP. Second, by simultaneously modeling affective (sentiment) and cognitive (rating) satisfaction, it reveals asymmetries that single-measure studies cannot detect: esthetics shapes emotional narratives most strongly, while education dominates evaluative judgments. Third, city-level interaction effects demonstrate that experiential value is destination-sensitive, escapism drives ratings in Paris but not Rome, and esthetics amplifies sentiment more strongly in Paris, opening new ground at the

intersection of Experience Economy theory and destination competitiveness research (Crouch, 2010; Seyfi et al., 2020).

8. Conclusions

This study examined how the four Experience Economy dimensions shape guest satisfaction in peer-to-peer accommodation using nearly 1.6 million Airbnb accommodation reviews from Rome and Paris. The findings show that experiential value is present in Airbnb reviews, but its effects vary across dimensions, satisfaction measures, and destination contexts. Esthetics is the strongest driver of sentiment-based satisfaction, while education is the strongest predictor of rating-based satisfaction. Escapism shows a more complex and context-dependent pattern, being negatively associated with textual sentiment but positively associated with ratings in Paris.

The study contributes to Experience Economy research by demonstrating that validated experiential constructs can be scaled through user-generated content, by distinguishing affective and cognitive satisfaction mechanisms, and by showing that experiential value is shaped by destination identity. For practitioners, the findings suggest that hosts, platforms, and destination managers should combine reliable functional service with destination-specific experience design. Future research could extend the analysis to additional cities, compare alternative sentiment models, and incorporate extended peer-to-peer accommodation dimensions such as localness, communitas, personalization, and serendipity.

Rethinking Tourism Intensity: A Compositional Approach to Resident Life Satisfaction

OKSANA TOKARCHUK, MARTIN OLIVERA, JUAN GABRIEL BRIDA, UMBERTO MARTINI

Abstract

Frame of the research. *Tourism-intensive destinations increasingly face tensions between economic reliance on visitor flows and residents' quality of life. Public debate often frames these tensions as a problem of "too many tourists," typically measured through officially recorded overnight stays. However, tourism pressure is rarely decomposed into distinct visitor typologies, and same-day visitation is largely absent from official statistics despite its potential relevance for congestion and short-term disruption.*

Purpose of the paper. *This paper examines whether different visitor typologies—overnight and day visitors—are associated differently with residents' short-term life satisfaction in a highly seasonal destination.*

Methodology. *The study combines survey data from 897 residents across thirteen municipalities in Garda Trentino (Italy), collected during a tourism week in May 2025, with anonymized municipal-level mobility data from Vodafone Italy. Tourism intensity is measured as overnight visitors per resident and day visitors per resident. OLS and ordered probit models with municipality-clustered standard errors are estimated, including quadratic terms to test for non-linear effects.*

Results. *Overnight visitor intensity shows no statistically significant association with life satisfaction. In contrast, day visitors display a robust non-linear relationship consistent with short-term disruption dynamics: negative marginal effects are strongest at lower exposure levels and attenuate as exposure increases.*

Research limitations. *The analysis focuses on one destination and a single high-intensity week, limiting causal inference and generalizability.*

Managerial implications. *Governance strategies should differentiate between overnight tourism and excursionism, prioritizing the management of day visitors rather than indiscriminate visitor reduction.*

Originality of the paper. *The study integrates mobility data with individual well-being measures and conceptualizes tourism pressure as compositional rather than homogeneous.*

Keywords: *tourism intensity; day visitors; resident well-being; mobile data; seasonality*

1. Introduction

Across Europe and beyond, residents of tourism-intensive destinations increasingly voice concerns about being "overrun" by visitors. Public debates often call for limiting tourism growth, reducing promotional efforts, or capping accommodation capacity. In these discussions, tourism pressure is typically framed in aggregate terms, as a matter of "too many tourists." Yet the category of "tourist" conceals important differences in how visitor flows are composed and experienced in everyday life (Koens et al., 2018; Milano et al., 2019).

Academic research has long documented that tourism generates both benefits and costs for host communities, and that residents' support for tourism depends on the balance between these outcomes (Ap, 1992; Perdue et al., 1990; Gursoy et al., 2002). More recently, the debate on overtourism has shifted attention toward the limits of growth and toward the effects of congestion and crowding on residents' quality of life (Koens et al., 2018; Dodds & Butler, 2019; Milano et al., 2019). However, empirical assessments of tourism pressure frequently rely on aggregate indicators, most commonly overnight stays per resident, derived from official statistics (United Nations, 2010; Ivlevs, 2017; Croes et al., 2021). Such measures implicitly treat all visitors as equivalent and focus predominantly on those who spend at least one night in the destination.

From the standpoint of everyday lived experience, however, residents do not encounter "overnight stays" as statistical units; they encounter people in space—on streets, in public transport, in parking areas, and along access routes. Research on perceived crowding emphasizes that congestion is experienced through spatial density and interference with daily routines rather than through abstract numerical indicators (Shelby & Heberlein, 1987; Manning, 1999; Vaske & Shelby, 2008). The

operational definition of a "tourist," as established by international statistical standards, typically requires at least one overnight stay in the destination (United Nations, 2010). Yet the experiential reality of congestion does not differentiate between individuals who spend the night and those who return home the same day.

Despite their growing prominence in public debates and overtourism discussions (Koens et al., 2018; Milano et al., 2019; Peeters et al., 2021), excursionist flows remain insufficiently distinguished in empirical analyses of social impacts. Existing research has extensively examined residents' perceptions of tourism impacts and their implications for quality of life (Andereck & Nyaupane, 2011; Woo et al., 2015), but relatively few studies explicitly disentangle different visitor typologies when analysing well-being outcomes (Tokarchuk et al., 2021). As a result, tourism pressure is often operationalized as a homogeneous aggregate construct.

This paper addresses this gap by examining whether different components of tourism intensity, overnight visitors, and same-day visitors, are differently associated with residents' week-specific life satisfaction. The study is conducted in a mature, highly seasonal destination in Northern Italy, characterized by substantial cross-municipal heterogeneity in visitor-to-resident ratios. Using anonymized and aggregated mobile phone data to measure objectively both overnight and day visitors per resident during an intense tourism week in 2025 and linking these measures to individual-level survey data on life satisfaction collected within the same temporal window, the analysis disentangles the compositional and temporal dimensions of tourism pressure.

The findings indicate that same-day visitation is more strongly associated with lower levels of residents' week-specific life satisfaction than overnight tourism, whose relationship with well-being appears weaker and, in some cases, non-negative. By distinguishing visitor typologies and aligning objective flow measurement with short-term well-being assessments, the study contributes to the literature on tourism impacts and overtourism in three ways. First, it shifts attention from aggregate tourism volume to the compositional structure of visitor flows. Second, it highlights the importance of short-term disruption dynamics in shaping residents' everyday evaluations. Third, it provides policy-relevant evidence suggesting that strategies aimed at reducing "tourists" in general may be less effective than differentiated governance approaches targeting specific forms of visitation.

In doing so, the paper bridges the growing sophistication in measuring tourism flows (Ahas et al., 2008; Salas-Olmedo et al., 2018) with the still-limited empirical understanding of their differentiated social consequences for host communities.

2. Literature review

2.1 Residents, tourism, and well-being

A substantial body of research has examined how tourism development affects host communities, with particular attention to residents' attitudes, perceived impacts, and overall quality of life (Ap, 1992; Gursoy et al., 2002). Early studies were largely grounded in social exchange theory and focused on residents' support for tourism as a function of perceived economic benefits and social or environmental costs. Over time, this literature has progressively incorporated broader well-being constructs, including subjective quality of life and life satisfaction (Andereck & Nyaupane, 2011; Woo et al., 2015). More recent reviews highlight the growing integration of tourism and well-being research, emphasizing multidimensional and community-based perspectives (Uysal et al., 2016).

Research consistently shows that tourism generates both positive and negative outcomes for residents (Perdue et al., 1990; Jurowski et al., 1997). On the one hand, tourism development may contribute to local income, employment opportunities, improved services, and infrastructure. On the other hand, it may produce congestion, environmental degradation, rising housing costs, and perceived erosion of local identity (Andereck et al., 2005; Milano et al., 2019). These tensions are reflected in long-standing conceptual models such as Doxey's Irridex and Butler's tourism area life cycle, which emphasize that residents' responses evolve with increasing tourism intensity (Doxey,

1975; Butler, 1980). Consequently, the net effect of tourism on residents' well-being is contingent rather than uniform, potentially varying across destinations, stages of development, and social groups (Nunkoo et al., 2013b; McCool & Lime, 2001).

Empirical approaches in this stream of research typically rely on two main types of measurement. One strand adopts residents' subjective perceptions of tourism impacts—economic, social, or environmental—and relates them to overall support for tourism or to individual quality of life (Andereck & Nyaupane, 2011; Kim et al., 2013). These studies frequently employ structural equation models or attitudinal frameworks that capture perceived rather than objectively measured tourism exposure (Nunkoo et al., 2013a). A second strand links macro-level indicators of tourism development, such as tourist arrivals or overnight stays, to aggregated measures of economic performance or national well-being (Ivlevs, 2017; Croes et al., 2021). While these approaches have generated valuable insights, they tend to operationalize tourism intensity as a single, undifferentiated construct.

Only a limited number of studies have directly linked objectively measured tourism intensity to individual-level well-being within the same temporal framework (e.g., Tokarchuk et al., 2021). Much of the empirical literature instead relies either on subjective perceptions of tourism impacts (e.g., Bimonte & Faralla, 2016) or on aggregate indicators of tourism development, most commonly overnight stays per resident. As a result, tourism pressure is frequently operationalized as a single aggregate measure that implicitly treats all non-resident presence as equivalent. Such an approach overlooks the possibility that overnight tourists and same-day visitors differ not only in duration of stay, but also in their spatial concentration, patterns of infrastructure use, and potential to generate short-term congestion and disruption effects.

2.2 Overtourism and the problem of measurement

In recent years, the concept of overtourism has gained increasing prominence in both academic research and policy debates. Overtourism is commonly described as a situation in which tourism intensity leads to a perceived deterioration in residents' quality of life and visitors' experience, shifting the focus from growth-oriented development toward the social limits of tourism expansion (Koens et al., 2018; Milano et al., 2019). The concept builds on earlier discussions of carrying capacity (Butler, 1980; McCool & Lime, 2001) and resident irritation or antagonism (Doxey, 1975), but reframes them in light of contemporary urban pressures and global mobility patterns.

A defining feature of the overtourism debate is its relational character: tourism becomes problematic not merely because of its scale, but because of the interaction between visitor presence, spatial concentration, and the lived experience of host communities. As emphasized in recent contributions, overtourism is not solely a matter of absolute numbers, but of how tourism intensity intersects with local infrastructures, governance capacity, and residents' everyday routines (Koens et al., 2018; Milano et al., 2019).

Policy discussions and destination governance practices have responded to concerns about tourism pressure by developing benchmarking systems to identify thresholds for congestion or "excessive" tourism intensity. These monitoring frameworks often draw on concepts derived from debates over carrying capacity (Butler, 1980; McCool & Lime, 2001) and, more recently, from overtourism scholarship (Koens et al., 2018; Milano et al., 2019). In practice, however, the operationalization of tourism pressure often relies on official statistics, particularly the number of tourist arrivals or overnight stays, as primary indicators of intensity. Such metrics are attractive because they are standardized, comparable across destinations, and embedded in established statistical systems. Public debate tends to mirror this statistical framing, referring generically to "too many tourists" as the source of local tensions, without further differentiation across visitor types. As a result, governance responses often focus on reducing overall tourist numbers or capping accommodation capacity, implicitly assuming that tourism pressure is adequately captured by overnight-based measures and that all visitors contribute similarly to local disruption.

However, from the perspective of everyday lived experience, residents do not encounter tourism

as a statistical aggregate. They encounter people in space—on streets, in public transport, in parking areas, and along access routes. Research on perceived crowding has long emphasized that congestion is experienced through spatial density and interference with daily routines rather than through abstract numerical indicators (Shelby & Heberlein, 1986; Manning, 2011). The operational definition of a "tourist," as established by international statistical standards, typically requires at least one overnight stay in the destination (United Nations, 2010). Yet the experiential reality of crowding and congestion does not differentiate between individuals who spend the night and those who return home the same day. From the standpoint of social impacts and quality of life, the presence of non-residents in shared spaces—regardless of duration of stay—may generate similar or even differentiated pressures, a distinction that remains underexplored in overtourism research (Koens et al., 2018; Milano et al., 2019).

This creates a conceptual gap. While the dominant measurement frameworks privilege overnight stays as the central indicator of tourism pressure, the composition of visitor flows—particularly the distinction between overnight tourists and same-day visitors—may matter substantially for social impacts. Despite growing attention to overtourism, the empirical distinction between different visitor typologies remains largely unexplored in the analysis of residents' well-being.

2.3 Day visitors and short-term disruption

Day visitors are increasingly mentioned in public debates as a source of congestion, pressure on infrastructure, and deterioration of everyday livability in tourism-intensive areas. Media reports and local policy discussions frequently attribute traffic saturation, parking shortages, and spatial crowding to same-day flows, particularly during peak weekends and holiday periods. Although academic research has traditionally focused on overnight tourism, several studies highlight that short-stay or excursionist flows can generate disproportionate pressure on public space and urban infrastructure due to their temporal concentration and limited economic embeddedness (Peeters et al., 2021). Research on overtourism further documents how congestion and crowding during peak periods—rather than aggregate annual volumes—are central to residents' perceptions of tourism-related stress (Milano et al., 2019; Dodds & Butler, 2019).

Despite this growing recognition, day visitation remains rarely measured in a systematic and comparable manner. Official tourism statistics, following international statistical standards, primarily capture arrivals and overnight stays (United Nations, 2008), while same-day flows are often only indirectly estimated or remain unrecorded (Koens et al., 2018; Peeters et al., 2018). As a consequence, empirical research on residents' well-being has largely relied either on subjective perceptions of tourism impacts (Andereck et al., 2005) or on aggregate tourism development indicators at the macro level (Croes et al., 2021). Even studies that link objective tourism intensity to social outcomes have seldom distinguished systematically between different visitor typologies (Tokarchuk et al., 2021).

The literature on crowding and perceived congestion provides important insights into how individuals experience dense environments. However, much of this research focuses on perceptual constructs—such as perceived crowding or perceived impact—rather than on objectively measured visitor flows. Studies rarely isolate excursionism as a distinct component of tourism intensity, and even more rarely link objectively measured day visitation to individual-level well-being outcomes.

This limitation is conceptually relevant. Day visitors differ structurally from overnight tourists in several respects: they are typically more temporally concentrated and spatially clustered, display distinct time–space consumption patterns, and are less dispersed through accommodation infrastructures (Shoval & Isaacson, 2007; Grinberger et al., 2014). In contrast to overnight tourism, which is mediated through formal accommodation and service systems, same-day visitation is often more dependent on private mobility and concentrated around highly accessible nodes and public spaces (Gutiérrez et al., 2017).

Their presence may therefore generate acute, short-term disruptions of daily routines—such as traffic congestion, parking shortages, noise, and overcrowding of public spaces—without necessarily contributing proportionally to longer-term economic integration within the local community (Milano

et al., 2019; Peeters et al., 2018; Bimonte & Farfalla, 2016).

Building on this distinction, the present study proposes that tourism pressure operates through multiple temporal channels. In addition to long-term structural effects on housing markets, labor structures, and local development trajectories, tourism intensity may generate short-term disruptions of everyday routines—such as congestion and crowding—that fluctuate sharply during peak periods and may directly shape residents' week-specific well-being. In mature, highly seasonal destinations, fluctuations in visitor intensity may produce episodic stress dynamics that are not adequately captured by annual statistics or generalized evaluations of tourism development. By explicitly distinguishing overnight tourism from day visitation and linking both to week-specific life satisfaction, the analysis shifts attention from static notions of tourism volume toward the dynamic and compositional nature of tourism pressure.

2.4 Measuring tourism intensity: limits and opportunities

Recent years have witnessed a rapid expansion in the use of digital trace data to measure tourism flows. Beyond traditional accommodation statistics, researchers increasingly rely on data derived from mobile phone networks, GPS tracking, social media geotags, Wi-Fi sensors, and other location-based technologies to capture spatial and temporal patterns of visitor presence. These data sources enable fine-grained observation of mobility dynamics, allowing the identification of peak periods, spatial concentration, and intra-destination movement patterns (Girardin et al., 2008; Frias-Martinez et al., 2012; Ahas et al., 2010). Despite these methodological advances, the analytical focus of digital mobility data has remained largely centred on analyzing tourist mobility behaviour, destination attractiveness, spatial clustering, and the distribution of visitors across urban and natural areas (Ahas et al., 2008; Raun et al., 2016; Salas-Olmedo et al., 2018).

Such applications demonstrate the methodological potential of digital mobility data to overcome key limitations of official statistics, especially the inability to systematically capture same-day visitation and real-time fluctuations in exposure. The social consequences of these flows, particularly their diverse effects on residents' well-being, remain largely unexplored. Even when mobility indicators are available at fine spatial and temporal scales, they are rarely integrated with individual-level measures of life satisfaction or everyday quality of life within the same observation window.

Building on these strands of literature, the present study seeks to bridge a conceptual and empirical gap. While previous research has examined residents' well-being primarily through subjective perceptions or aggregate tourism indicators, and while digital mobility data have increasingly refined the measurement of tourism flows, the two approaches have rarely been integrated. In particular, the differentiated social consequences of structurally distinct visitor typologies, overnight tourists, and same-day visitors, remain underexplored in relation to individual-level well-being within the same temporal window.

By combining high-resolution mobility data with week-specific measures of residents' life satisfaction, the present analysis advances a compositional perspective on tourism pressure. Rather than treating tourism intensity as a single aggregate volume, the study distinguishes between different forms of non-resident presence and examines how their temporal and spatial characteristics relate to short-term well-being dynamics in host communities. In doing so, it contributes to a more nuanced understanding of how tourism pressure operates across multiple temporal and structural channels.

3. Methodology

3.1 Empirical setting

The empirical analysis is conducted in a mature tourism system located in Northern Italy, characterized by high seasonal intensity and substantial variation in visitor exposure across municipalities. The empirical setting corresponds to the territorial area governed by the local Destination Management Organization (APT Garda Dolomiti), which includes thirteen municipalities

in the northern part of the Lake Garda basin and its surrounding hinterland.

Importantly, not all municipalities are directly located on the lake shore. While Riva del Garda, Arco, and Nago-Torbole constitute the core lakefront areas, other municipalities are situated inland and differ substantially in terms of accessibility, spatial structure, and exposure to tourism flows. Despite operating under a shared tourism governance framework, municipalities exhibit marked heterogeneity in visitor-to-resident ratios and tourism pressure.

The area hosts approximately 49,000 residents and records more than four million overnight stays annually. Tourism represents a central economic sector of the local economy. At the same time, the territory experiences significant volumes of same-day visitors, particularly during the summer season, although these flows are not systematically recorded in official statistics.

Accessibility constraints contribute to the intensity of perceived pressure. The area is primarily reachable by road, and seasonal congestion, limited parking capacity, and bottlenecks along main access routes amplify the spatial concentration of visitor flows. Internal heterogeneity is therefore not only quantitative but also spatial and infrastructural.

In recent years, increasing tourism intensity has been accompanied by visible public concern and resident protests related to congestion, environmental pressure, and perceived declines in quality of life. These tensions coexist with the economic relevance of tourism, creating a context in which different forms of visitor presence may generate differentiated social impacts.

The coexistence of structurally distinct visitor typologies—overnight tourists and day visitors—within a territorially heterogeneous multi-municipal system makes this setting particularly suitable for examining whether different components of tourism intensity are associated with residents' life satisfaction. The pronounced cross-municipality variation in exposure during the same seasonal period provides the empirical variation necessary to investigate these relationships within a shared institutional and governance framework.

3.2 Survey Design and Measurement of Resident Well-being

Primary data on residents' well-being were collected through an online survey administered to adult residents across the thirteen municipalities included in the study area. The survey remained open for ten days and was conducted immediately after the first high-intensity tourism weekend of the season, following the May 1st holiday period. This timing was intentional. In mature destinations characterized by strong seasonality, tourism pressure is expected to operate primarily through short-term disruptions of daily routines—such as crowding, congestion, and mobility constraints—that fluctuate sharply during peak moments. Anchoring the well-being question to the previous week increases temporal precision and reduces reliance on generalized attitudes toward tourism.

The questionnaire was disseminated by APT Garda Dolomiti through its official communication channels, including direct email invitations to registered contacts and announcements on institutional social media platforms. Participation was voluntary and open to all residents of the municipalities included in the destination's governance area. Although the territorial framework comprises fourteen municipalities, one municipality was excluded from the empirical analysis due to insufficient survey responses and the absence of anonymized mobility data at the required aggregation level.

Tourism intensity is conceptualized in this study as a short-term contextual exposure, and the analysis tests whether its association with residents' well-being exhibits non-linear patterns consistent with seasonal disruption dynamics. Rather than capturing long-run or trait-like life satisfaction, the survey was explicitly designed to measure residents' evaluation of their everyday life during a period of salient tourism pressure.

The key dependent variable was measured through the following question:"Thinking about the intensity of tourism presence in the past week (May 5–11), how satisfied were you with your everyday life as a resident in Garda Trentino?". Responses were recorded on a ten-point scale. The survey instrument also included standard socio-demographic controls, such as age and length of residence in the municipality.

The final analytical sample for the first wave consists of 897 valid responses distributed across the

thirteen municipalities included in the empirical analysis. Participation reflects both the demographic relevance and the tourism salience of the largest municipalities. In absolute terms, the highest number of responses originates from Riva del Garda (302) and Arco (337), followed by Nago–Torbole (84), Ledro (57), and Dro (43), while smaller municipalities contribute more limited but non-negligible observations.

When expressed relative to municipal population, participation rates range approximately between 0.1% and 3.6%, with an average participation rate close to 1.5% across the area. Larger municipalities such as Riva del Garda and Arco exhibit participation rates around 2%, while Nago–Torbole—characterized by the highest tourism pressure per resident—shows one of the highest participation rates in proportional terms (approximately 3.6%). Participation is also comparatively visible in Tenno (around 1.6%), a municipality experiencing substantial day visitation to Lake Tenno. This spatial distribution is consistent with the timing of the survey, conducted immediately after a high-intensity tourism weekend, when tourism exposure was particularly salient across the destination.

Life satisfaction responses span the full ten-point scale (1–10), indicating substantial heterogeneity in week-specific evaluations. Mean values differ across municipalities, with averages ranging roughly between 4.5 and 7.9. This cross-municipality dispersion is coherent with the analytical strategy, which exploits variation in tourism exposure within the same temporal window rather than intertemporal changes.

The sample is predominantly composed of long-term residents. Overall, 59.5% of respondents report being born in the municipality, and an additional 19.2% have lived there for more than twenty years. Only 5.7% report residing in the municipality for less than five years. This distribution suggests that responses largely reflect evaluations from established residents with deep local attachment rather than recent movers.

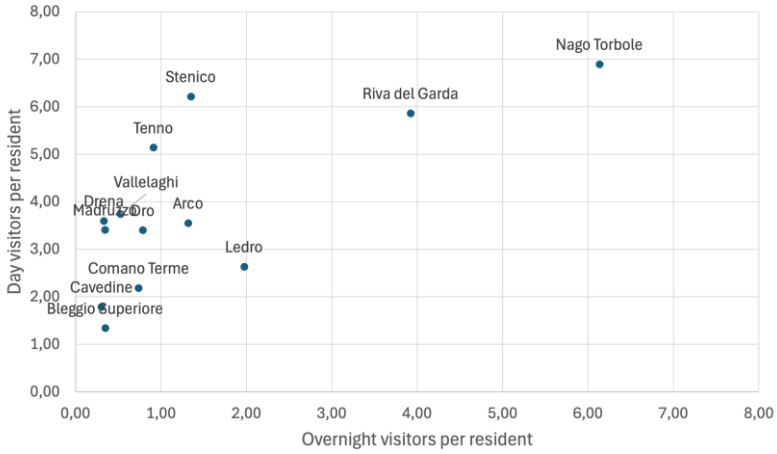
In terms of age composition, the sample is concentrated in middle and older age groups. The largest share of respondents falls in the 50–65 age category (35.5%), followed by 40–49 (24.9%) and 30–39 (21.1%). Younger adults (21–29) account for approximately 9.5% of responses, while individuals above 65 represent 8.7%. The age distribution therefore reflects substantial representation of mature residents, consistent with the demographic structure of many small and medium-sized Italian municipalities.

The aim of this study is to identify the relationships between contextual tourism exposure and short-term well-being. To achieve this, the analysis examines variations across different municipalities within a similar time frame. The survey is not designed to generate population-representative prevalence estimates; instead, it focuses on providing detailed individual assessments that are connected to the objectively measured intensity of tourism in each municipality.

3.3 Visitor Intensity Data (Vodafone Mobility Data)

Visitor intensity is measured using anonymized and aggregated mobility data provided by Vodafone Italy. These data are derived from mobile network activity and enable the identification of the presence of individuals within municipal boundaries during the reference period. The information is aggregated at the municipality–week level and does not permit any form of individual identification.

For the week corresponding to the survey reference period (May 5–11, 2025), the Vodafone data allow the classification of individuals based on presence patterns within each municipality. Users are identified as residents when their habitual presence is detected within the municipality. Non-residents are classified as overnight visitors if they spent at least one night within the municipality during the reference week, and as day visitors if they were present during the day without an overnight stay.



Importantly, the measure of overnight visitors is not restricted to officially recorded accommodation stays. It captures all individuals who physically spent the night in the municipality, including those staying in private apartments, second homes, or with friends and relatives. This feature allows the analysis to overcome a key limitation of administrative tourism statistics, which typically exclude informal or non-registered stays.

The identification of day visitors constitutes a central methodological contribution of the study. Unlike overnight stays, same-day flows are not systematically recorded in official statistics, despite their potential relevance for congestion, crowding, and short-term disruption dynamics. The availability of mobility data makes it possible to quantify this component of visitor pressure at the municipal level.

To ensure comparability across municipalities of different demographic size, both visitor categories are normalized by resident population. We therefore construct two measures of tourism intensity at the municipal level: overnight visitors per resident (ON_j) and day visitors per resident (DV_j). Resident population figures are derived from the same Vodafone dataset to ensure internal consistency in measurement.

Substantial cross-municipality heterogeneity is observed. During the reference week, overnight visitors per resident range from approximately 0.30 in smaller inland municipalities to over 6 in Nago–Torbole. Day visitors per resident vary between roughly 1.34 and nearly 6.9, with the highest levels recorded in lakefront and highly accessible municipalities. Riva del Garda and Nago–Torbole exhibit the highest overall exposure, whereas inland municipalities display lower overnight intensity but, in some cases, still substantial levels of day visitation. Figure 1 illustrates the joint distribution of overnight and day visitors per resident across municipalities.

Fig. 1: Cross-municipality variation in overnight and day visitors per resident during the reference week (Vodafone mobility data)

3.4 Econometric model

To examine the association between tourism intensity and residents' life satisfaction, we estimate cross-municipality regression models exploiting variation in visitor exposure across municipalities within the same observation period. The empirical design compares individuals residing in municipalities characterized by different levels and compositions of tourism pressure.

The dependent variable, LS_{ij}, denotes self-reported life satisfaction of individual i living in municipality j, measured on an ordered scale from 1 to 10. Tourism intensity is captured through two distinct measures defined at the municipal level: ON_j, overnight visitors per resident living in municipality j; DV_j day visitors per resident living in municipality j. Both variables are normalized by resident population to ensure comparability across municipalities and to reflect tourism pressure from the residents' perspective.

3.4.1 OLS specifications

We estimate three alternative specifications:

Model (1): Overnight visitors only

$$LS_{ij} = \beta_0 + \beta_1 ON_j + \beta_2 ON_j^2 + \gamma X_{ij} + \varepsilon_{ij}$$

Model (2): Day visitors only

$$LS_{ij} = \beta_0 + \beta_1 DV_j + \beta_2 DV_j^2 + \gamma X_{ij} + \varepsilon_{ij}$$

Model (3): Joint specification

$$LS_{ij} = \beta_0 + \beta_1 ON_j + \beta_2 ON_j^2 + \beta_3 DV_j + \beta_4 DV_j^2 + \gamma X_{ij} + \varepsilon_{ij},$$

where X_{ij} includes individual-level controls (age and length of residence) for resident *i* living in municipality *j*.

Quadratic terms allow for potential non-linear effects of tourism intensity. All models are estimated using ordinary least squares with standard errors clustered at the municipality level (13 clusters) to account for intra-municipality correlation in unobserved contextual factors.

The inclusion of separate and joint specifications enables us to assess whether the association of one visitor category remains robust when controlling for the other, and whether different visitor typologies exhibit structurally distinct relationships with life satisfaction.

For quadratic specifications, the turning point is computed as:

$$-\frac{\beta_1}{2\beta_2}$$

To assess whether a U-shaped pattern is statistically meaningful, we evaluate the marginal effect at the minimum and maximum observed values of tourism intensity. This procedure verifies whether the slope is negative at the lower bound and positive at the upper bound of the observed range.

3.4.2 Ordered probit robustness

Given that life satisfaction is measured on an ordered categorical scale, we re-estimate all three specifications using ordered probit models.

We assume the existence of a latent continuous well-being variable LS_{ij}^* such that:

$$LS_{ij}^* = \beta_0 + \beta_1 ON_j + \beta_2 ON_j^2 + \beta_3 DV_j + \beta_4 DV_j^2 + \gamma X_{ij} + u_{ij}$$

with u_{ij} following a standard normal distribution.

$$u_{ij} \sim N(0,1)$$

The observed outcome LS_{ij}^* is determined by threshold parameters

$$LS_{ij} = k \quad if \quad \mu_{k-1} < LS_{ij}^* \leq \mu_k$$

Separate ordered probit models are estimated corresponding to the three OLS specifications (overnight only, day visitors only, joint model). Standard errors are clustered at the municipality level.

Although ordered probit coefficients are not directly comparable in magnitude to OLS estimates, consistency in sign, statistical significance, and curvature across models provides robustness to the ordinal scaling of the dependent variable. Marginal effects at the lower and upper bounds of tourism intensity are evaluated analogously to the OLS framework to confirm the non-linear pattern.

4. Results

We begin by examining the aggregate association between visitor intensity and residents' life satisfaction across municipalities (Table 1). The estimates exploit cross-municipality variation in tourism exposure within the same observation period, comparing contexts characterized by different levels of visitor intensity.

Overnight visitors per resident do not exhibit a statistically significant association with life satisfaction. Neither the linear nor the quadratic term reaches conventional levels of significance (Table 1, columns 1 and 3). The estimated coefficients are small and statistically indistinguishable from zero.

This suggests that cross-municipality differences in the intensity of overnight stays are not systematically associated with differences in residents' reported life satisfaction.

In contrast, day visitors per resident display a statistically significant non-linear association with life satisfaction. When estimated separately (column 2), the linear term is negative and significant ($\beta = -1.162$, $p < 0.05$), while the quadratic term is positive and significant ($\beta = 0.117$, $p < 0.05$). When both visitor types are included simultaneously (column 3), the magnitude increases (linear term β =

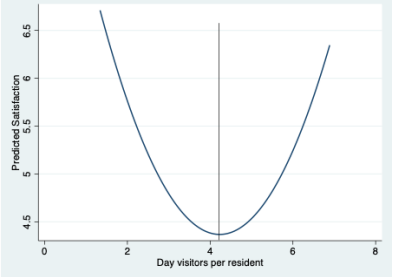
−2.379, $p < 0.01$; quadratic term $\beta = 0.289$, $p < 0.01$), indicating a robust convex relationship.

The estimated turning point of the quadratic specification is located at approximately 4.1 day visitors per resident, within the observed range (1.34–6.89). Marginal effect tests confirm this non-linear pattern: at the minimum observed level of day visitation, the marginal effect is negative and statistically significant ($\beta = -1.60$, $p = 0.009$), while at the maximum observed level the marginal effect becomes positive and statistically significant ($\beta = 1.61$, $p = 0.019$).

Figure 1 illustrates the predicted life satisfaction as a function of day visitors per resident based on the OLS specification.

The curve shows a pronounced negative slope at lower and moderate levels of day visitation, reaching a minimum around the estimated turning point. Beyond this level, the curve flattens and gradually increases. Importantly, the right-hand side of the curve does not indicate a strong recovery of life satisfaction; rather, it reflects an attenuation of the marginal negative effect in highly exposed municipalities.

Thus, the results do not suggest the existence of a normative "optimal" threshold. Instead, they indicate that the marginal impact of additional day visitors diminishes as exposure increases.



The contrast between the absence of significant aggregate effects for overnight stays and the significant non-linear association observed for day visitors highlights the importance of distinguishing visitor typologies. Aggregate measures of tourism intensity that do not separate overnight tourism from day visitation may obscure materially different patterns across municipalities.

Source: our elaboration

To account for the ordinal nature of the life satisfaction measure, we re-estimate the models using ordered probit specifications (Table 2).

The results are fully consistent with the OLS estimates. Overnight visitor intensity remains statistically insignificant across specifications, both in linear and quadratic form. This confirms that cross-municipality differences in overnight tourism are not systematically associated with residents' reported life satisfaction.

In contrast, day visitors per resident display a robust non-linear association. In the joint specification (Table 2, column 3), the linear term is negative and statistically significant ($\beta = -0.815$, $p < 0.01$), while the quadratic term is positive and statistically significant ($\beta = 0.099$, $p < 0.01$), confirming a convex relationship.

Following the same marginal effect procedure, the effect evaluated at the minimum observed level of day visitation (1.34) is negative and statistically significant ($\beta = -0.549$, $p = 0.001$), whereas at the maximum observed level (6.89) it becomes positive and statistically significant ($\beta = 0.550$, $p = 0.007$).

The ordered probit estimates, therefore, reinforce the substantive interpretation derived from OLS: the marginal negative impact of day visitors diminishes at higher levels of exposure, indicating attenuation rather than a strong reversal.

5. Discussion

This study examined whether different forms of tourism intensity are associated with residents' life satisfaction across municipalities within a highly tourism-dependent territory. By explicitly distinguishing overnight visitors from day visitors, the analysis provides a more differentiated perspective on tourism pressure and its potential implications for resident well-being.

Two central patterns emerge from the results. First, overnight visitor intensity does not exhibit a statistically significant association with life satisfaction at the aggregate municipal level. Neither the linear nor the quadratic specification produces significant coefficients, and this finding is consistent across both OLS and ordered probit models. Taken together, these results indicate that cross-municipality differences in overnight stays per resident are not systematically linked to variations in reported well-being. In this context, overnight tourism appears to be economically and institutionally embedded in ways that do not translate into measurable differences in average life satisfaction across municipalities.

By contrast, day visitors per resident display a robust non-linear association with life satisfaction.

Across modelling strategies, the linear term is negative while the quadratic term is positive and statistically significant, pointing to a convex functional form. The estimated turning point lies within the observed range of the data, and marginal effect tests confirm that the effect is significantly negative at lower levels of exposure and significantly positive at the upper bound. However, the graphical representation clarifies that the right-hand side of the curve should not be interpreted as a substantive improvement in well-being. Rather than indicating recovery, the pattern reflects attenuation of the marginal negative effect as exposure increases. In substantive terms, increases in day visitation are associated with reductions in life satisfaction at low to moderate levels of pressure, but the marginal disruptive impact of additional visitors weakens in municipalities that are already highly exposed.

This attenuation may reflect multiple, non-mutually exclusive mechanisms. Highly exposed municipalities may have developed infrastructural capacities, traffic management systems, or institutional routines that absorb additional flows more effectively. Residents in such contexts may also display forms of adaptation to structurally high levels of day-based tourism. Importantly, the results do not suggest that high levels of excursionism enhance well-being; instead, they indicate that the relationship between exposure and life satisfaction is not linear and that marginal effects vary across the distribution. Linear models would therefore misrepresent the nature of the association and potentially overstate the uniformity of negative impacts.

The contrast between the absence of aggregate effects for overnight stays and the significant non-linear pattern for day visitors underscores the analytical importance of distinguishing visitor typologies. Public debates frequently frame “tourism intensity” as a homogeneous phenomenon, yet the present evidence suggests that different forms of visitor flows may be associated with different well-being patterns. In this setting, day-based tourism appears more closely related to cross-municipality differences in life satisfaction than overnight tourism. This distinction has implications for how tourism pressure is measured, interpreted, and governed.

From a governance perspective, the findings speak directly to ongoing public debates on tourism pressure. In many destinations, including the one examined here, public discussions and media narratives tend to focus primarily on overnight stays, as these are the only visitor figures that are systematically available through official statistics. Residents’ concerns are often directed toward perceived increases in overnight accommodation, particularly in privately rented apartments that may not be fully captured by administrative records.

However, the present analysis relies on a behavioural definition of overnight presence—capturing all individuals who spent the night in the area, including those staying in informal or non-commercial accommodation. Within this broader measurement framework, overnight intensity does not exhibit a significant association with life satisfaction. By contrast, day visitation, which is typically absent from publicly reported statistics, shows a clear and robust relationship with well-being outcomes.

This suggests a potential misalignment between the indicators that structure public debate and the forms of visitor pressure that are statistically associated with resident life satisfaction. In the period examined, it is day-based tourism rather than overnight stays that appears more closely linked to variations in perceived quality of life across municipalities. Consequently, governance systems that rely exclusively on official accommodation statistics may overlook a structurally relevant component of tourism exposure.

The estimated turning point should not be interpreted as a normative policy threshold. Rather, it indicates that the marginal association between day visitors and life satisfaction is not constant across exposure levels. What emerges is not a prescriptive optimal level of tourism, but the need for monitoring systems capable of distinguishing between different types of visitor flows and their potentially distinct implications for resident well-being.Overall, the study contributes to ongoing debates on tourism intensity and resident well-being by showing that the relationship between exposure and life satisfaction is neither uniform nor linear. Distinguishing between overnight and day visitors offers a clearer understanding of how tourism intensity relates to residents’ perceived quality of life across municipalities and highlights the limitations of treating tourism pressure as a single

aggregated construct.

6. Conclusions

This study started from a simple but often overlooked question: when residents call for "fewer tourists," who are they referring to? In destinations where tourism pressure is framed in aggregate terms, visitor flows are typically measured through overnight statistics, implicitly treating all non-residents as equivalent contributors to congestion and social impact.

By distinguishing between overnight visitors and same-day visitors and linking objectively measured mobility data to individual-level, week-specific life satisfaction, this study shows that tourism pressure is not compositionally neutral. The findings indicate that same-day visitation is more strongly and consistently associated with lower levels of residents' short-term well-being, whereas overnight tourism exhibits weaker and in some cases non-negative associations. These results suggest that the social consequences of tourism depend not only on volume, but on the structural characteristics and temporal concentration of different visitor flows.

Conceptually, the analysis contributes by shifting attention from static notions of tourism intensity toward the dynamic and compositional nature of tourism pressure. It highlights the importance of short-term disruption dynamics—such as congestion peaks and spatial crowding—in shaping residents' everyday evaluations. Methodologically, it demonstrates the value of integrating fine-grained mobility data with temporally aligned well-being measures, bridging the gap between advanced flow measurement and social impact analysis.

From a governance perspective, the findings imply that undifferentiated strategies aimed at reducing "tourists" may overlook the specific forms of visitation that generate the greatest short-term disruption. More nuanced policies that distinguish between overnight tourism and excursionism may be better aligned with residents' lived experiences and quality-of-life concerns. Ultimately, the study suggests that understanding who is present in space, and when, matters as much as how many visitors a destination records annually.

Strategie di valorizzazione dell'enoturismo di montagna: il caso del Trentino

SAMUELE DI MARZIO[1]* FEDERICA BUFFA[2]· LUCIA GATTI[3]♠ UMBERTO MARTINI[4]**

Abstract

Frame of the research. *L'enoturismo sta evolvendo da visita in cantina a esperienza culturale e relazionale. Cambiamenti della domanda, trasformazione digitale e assetti di governance incidono sulla competitività delle wine destination. Tali fattori risultano amplificati nei contesti montani nei quali emergono criticità strategico-manageriali connesse a sistemi multistakeholder e stagionalità dell'offerta.*
Purpose of the paper. *La ricerca esplora come un territorio di montagna possa sviluppare un'offerta enoturistica distintiva, ricostruendo visioni, priorità e strategie degli attori territoriali per evolvere verso un modello di destinazione integrato e coordinato.*
Methodology. *Lo studio adotta un approccio esplorativo-interpretativo nell'analisi di un caso studio. Dati e informazioni sono stati raccolti tramite 21 interviste semi-strutturate a stakeholder chiave del territorio. L'analisi dei dati si avvale del metodo Gioia.*
Results. *Emergono tre dimensioni chiave per lo sviluppo di una wine destination: (1) governance e coordinamento: regia unitaria, strumenti condivisi e pratiche di coopetition; (2) value proposition e design dell'esperienza integrati: connessione tra vino, gastronomia, cultura e outdoor; (3) fattori abilitanti: digitalizzazione e customer relationship management (CRM), professionalizzazione dell'ospitalità, visione di lungo periodo.*
Research limitations. *Natura esplorativa della ricerca riferita all'analisi di un'unica destinazione.*
Managerial implications. *La ricerca contribuisce a identificare buone pratiche per la valorizzazione dell'offerta enoturistica di una destinazione montana. Per policy maker e DMO emerge necessità di attivare una cabina di regia multi-attore con mandato operativo, definire standard minimi di accoglienza e un calendario integrato, sviluppare un hub unico orientato al booking e alla misurazione di KPI. Per le imprese diviene prioritario progettare prodotti modulari e prenotabili, adottare pratiche condivise di CRM e follow-up e investire in competenze di ospitalità.*
Originality of the paper. *La ricerca propone una lettura integrata dell'enoturismo come progetto di destinazione, traducendo evidenze qualitative in condizioni organizzative e priorità operative.*

Keywords*: enoturismo; sistema multi-stakeholder; governance; destinazioni territoriali; Trentino*.

1. Introduzione

L'Organizzazione Mondiale del Turismo definisce l'enoturismo come un segmento del turismo enogastronomico il cui scopo principale è visitare vigneti, cantine e festival del vino. Durante queste esperienze, la degustazione, il consumo o l'acquisto di vino rappresentano la motivazione principale del viaggio, che spesso si svolge proprio nel luogo di produzione o nelle sue vicinanze[5]. Proprio in virtù del legame con il territorio, l'enoturismo si è affermato come uno dei campi più dinamici del turismo contemporaneo perché incrocia trasformazioni economiche, culturali e organizzative che investono sia i consumi turistici, sia le filiere territoriali (Scarpellini 2019; Alonso et al., 2023; Cohen & Ben-Nun, 2023).

La rilevanza del comparto è oggi sostenuta da evidenze di mercato che mostrano un ampliamento della base di domanda e una qualificazione dei comportamenti di spesa. In una prospettiva storica, le stime di metà anni 2000 già indicavano volumi considerevoli in Italia (Censis, 2007 in Maizza & Rosato, 2008), ma analisi più recenti descrivono un comparto in forte evoluzione e sempre più

orientato all'esperienza (Garibaldi, 2020, 2022; Censis, 2023; UNWTO, 2023). Il Rapporto sul Turismo Enogastronomico Italiano del 2024 evidenzia una partecipazione diffusa ad attività legate al vino nei viaggi degli italiani, con un progressivo spostamento da un consumo di nicchia a una pratica più trasversale (Garibaldi, 2024b). Dal lato dell'offerta, analisi settoriali mostrano che l'enoturismo non è soltanto leva di immagine: è un canale capace di generare ricavi diretti (ticket di visita, esperienze, shop) e ricadute territoriali indirette, perché la spesa si distribuisce su ospitalità, ristorazione, trasporti e cultura (Wine Suite, 2024; Nomisma Wine Monitor, 2024). Non meno importante, i comportamenti di fruizione evidenziano vincoli concreti di progettazione: la domanda tende a concentrarsi nel fine settimana, rendendo centrali continuità di apertura, gestione delle prenotazioni e qualità dell'accoglienza, cioè quelle componenti che trasformano il desiderio in visita effettiva. Parallelamente, la presenza di visitatori internazionali richiede standard di servizio, capacità multilingue e processi "frictionless" lungo l'esperienza (Wine Suite, 2024).

Queste evidenze rendono chiara una specificità strutturale dell'enoturismo: è un turismo intrinsecamente "di sistema". L'esperienza enoturistica non dipende unicamente dall'impresa vitivinicola, ma da una molteplicità di attori e servizi (si pensi ai trasporti, alla ricettività, alla ristorazione, alle infrastrutture digitali, per citare alcuni esempi) che concorrono a determinare qualità percepita, valore e reputazione (Mastroberardino, 2002; Quadri-Felitti & Fiore, 2012; Scorrano et al., 2013; Mastroberdino et al., 2022). La letteratura sul wine tourism individua driver ricorrenti di successo delle wine destination - qualità dell'esperienza, integrazione di prodotto, accessibilità informativa e logistica, coerenza identitaria e capacità di coordinamento - sottolineando come la performance dipenda dall'interdipendenza di tali dimensioni, e non dalla sola eccellenza del vino (Getz & Brown, 2006; Mitchell & Hall, 2006; Festa et al., 2020; Alonso et al., 2023).

All'interno di tale dibattito scientifico, il paper presenta e discute i risultati di una ricerca avente un duplice obiettivo: *a)* analizzare se e come i key player coinvolti nella governance e nel management di destinazione, e le imprese e le organizzazioni che operano nel settore vitivinicolo, condividono visioni, priorità e strategie orientate ad affermarsi come destinazione enoturistica; *b)* identificare possibili fattori abilitanti il posizionamento di un territorio come destinazione enoturistica. La ricerca, di natura esplorativa, è stata svolta avvalendosi di un caso studio. Tra agosto e ottobre 2025 sono state condotte 21 interviste semi-strutturate a stakeholder chiave del territorio. Per l'analisi dei dati, ci si è avvalsi del metodo Gioia (Gioia et al., 2013).

Il paper si articola in cinque sezioni principali. Il paragrafo che segue illustra il contesto teorico di riferimento, evidenzia i concetti chiave e le specificità dell'enoturismo nonché le sfide che i territori devono affrontare per emergere come *wine destination*. Il terzo paragrafo descrive la metodologia di ricerca. I risultati sono illustrati e discussi alla luce della letteratura di riferimento, ponendo in evidenza le tre principali dimensioni emerse dalla ricerca (par. 4). Nella quinta sezione si illustrano le principali implicazioni manageriali e di policy riferite alla destinazione oggetto di studio. Nelle conclusioni sono evidenziati i limiti della ricerca e alcune proposte di linee di ricerca future.

2. Contesto teorico di riferimento

L'enoturismo si configura oggi come una delle forme più dinamiche e promettenti di turismo esperienziale, capace di coniugare la scoperta del territorio, la valorizzazione delle produzioni vitivinicole e l'immersione culturale del visitatore. Si tratta di una pratica che, nel tempo, ha assunto significati e funzioni diversi, evolvendo da semplice visita in cantina a esperienza multisensoriale legata alla narrazione del territorio, alla convivialità, al benessere e alla sostenibilità (Garibaldi, 2024).

Getz e Brown (2006) definiscono l'enoturismo come una tipologia turistica interpretabile da tre prospettive distinte: quella dei produttori (che vedono nel turismo un'opportunità di reddito supplementare), quella degli operatori turistici (che ne colgono le potenzialità commerciali), e quella dei consumatori (alla ricerca di esperienze edonistiche e culturali). Per Carlsen (2004), l'enoturismo

rappresenta uno strumento di sviluppo locale e una leva per la valorizzazione delle piccole e medie imprese vitivinicole. Hall e Mitchell (2000) lo descrivono come un fenomeno ibrido, in cui industria turistica e vitivinicola si intrecciano, dando vita a un prodotto situato all'interno di paesaggi rurali ad alta valenza culturale. In tale prospettiva si inseriscono ulteriori studi che evidenziano come nell'offerta enoturistica il vino assolva al ruolo di dispositivo interpretativo del territorio: paesaggi vitati, pratiche agricole, patrimoni immateriali, identità locali e relazioni sociali diventano parte integrante della proposta di valore (Hall & Mitchell, 2002; Carlsen & Charters, 2006; Mitchell & Hall, 2006; Capitello et al. 2013; Panke, 2020; Richards, 2018; Richards, 2021a, b).

L'adozione di tale prospettiva pone in luce implicazioni strategico-manageriali non solo per la singola impresa, ma anche per il territorio in cui l'esperienza è vissuta. Coerentemente con l'idea di destinazione come amalgama di prodotti, servizi ed esperienze (Buhalis, 2000; Pike & Page 2014) anche nel caso dell'enoturismo la competitività dell'offerta non dipende unicamente dalla qualità del prodotto, bensì dalla capacità di costruire un sistema coerente di significati, servizi, accessibilità e narrazione lungo tutta la customer journey, dal momento dell'ispirazione all'acquisto e al follow-up (Getz & Brown, 2006; Festa et al., 2020; Privitera et al., 2024; Durrieu et al., 2026).

Dal punto di vista scientifico, numerosi studi hanno sottolineato l'importanza del *terroir turistico* (Hall & Mitchell, 2002) come fattore chiave dell'attrattività delle regioni vinicole. Il terroir turistico è definito come la combinazione di caratteristiche fisiche, naturali e culturali che conferiscono a ogni regione vinicola un fascino distintivo e un'identità percepita come unica. La percezione e l'immagine delle regioni vinicole sono evolute dagli anni '90, passando da una focalizzazione sulla produzione a un'immagine più ampia e sensoriale, che include paesaggi, cucina, tempo libero e attività all'aperto (Williams, 2001). Inoltre, il passaparola e la reputazione del binomio prodotto-territorio sono tra i fattori più influenti nelle scelte degli enoturisti, pari o superiori a quelli legati alla conoscenza diretta del prodotto o alle guide specialistiche (Maizza & Rosato, 2008; Scorrano et al., 2013).

In virtù del legame tra prodotto (vino) e territorio, la valorizzazione dell'enoturismo pone in luce almeno quattro sfide di carattere strategico-manageriale. La prima riguarda la governance: la destinazione non è un soggetto unitario, ma una rete di attori con obiettivi e capacità differenti; la costruzione di value proposition e standard richiede dunque forme di governance collaborativa e strumenti condivisi (Ansell & Gash, 2008; Provan & Kenis, 2008; Dredge, 2006; D'Angella & Go, 2007). La seconda concerne la coerenza identitaria: la destinazione deve bilanciare semplificazione (per essere riconoscibile sui mercati) e profondità (per valorizzare pluralità e autenticità) evitando sia la frammentazione narrativa, sia l'appiattimento (Mitchell & Hall, 2006; Kavaratzis & Hatch, 2013; Cai, 2002). La terza riguarda l'interazione con il cliente in tutte le fasi della customer journey attraverso canali digitali, informazioni standardizzate, processi di prenotazione e pagamento, e gestione del post-visita (Buhalis, 2000; Serio et al., 2024; Divinea, 2025; Wine Suite & Divinea, 2025). La quarta riguarda competenze e standard di ospitalità: l'esperienza promessa dalla destinazione deve essere "consegnata" in modo coerente, soprattutto in presenza di domanda internazionale e segmenti più selettivi (Dodd, 2022; Garibaldi, 2024b). In questo quadro, l'enoturismo diventa un laboratorio utile anche per la ricerca su reti, innovazione place-based, e creazione di valore territoriale: sono gli attori, attraverso scelte di cooperazione, standardizzazione e investimento in abilitatori a "fare il sistema".

Vergamini et al. (2019) evidenziano il ruolo cruciale delle strategie di marketing territoriale e della capacità di racconto del vino come parte integrante di un sistema culturale. I territori che riescono a posizionarsi in modo distintivo sono quelli che trasformano il vino in simbolo identitario, collegandolo a narrazioni profonde che includono storia, tradizioni, tecniche colturali e paesaggi. La narrazione enoturistica - intesa come processo di co-creazione di senso tra visitatore e territorio - rappresenta dunque una leva fondamentale per attrarre segmenti di domanda qualificati, interessati non solo alla degustazione, ma all'interazione autentica con il luogo visitato.

Alla luce di quanto evidenziato, emerge chiaramente che l'enoturismo contemporaneo si configura come un sistema articolato di relazioni tra attori, territori, prodotti e visitatori. La dimensione di rete è particolarmente sensibile: laddove i territori sono frammentati e policentrici, la cooperazione

competitiva (coopetition) può diventare un meccanismo essenziale per costruire massa critica e valore collettivo, ma solo se sostenuta da governance e strumenti operativi (Bouncken et al., 2015; Bouncken et al., 2019; Zamarreño Aramendia et al., 2021).

In questa prospettiva, l'enoturismo rende particolarmente evidente una tematica insita nel management e nella governance delle destinazioni territoriali, ossia il coordinamento in contesti multistakeholder. Ampiamente dibattute al riguardo sono le criticità che concernono l'integrazione di risorse diffuse in un'offerta integrata, coordinata e riconoscibile (Bramwell & Lane, 2011; Pike & Page, 2014; Martini 2017; Reinhold et al. 2023). Esempi emblematici in tal senso sono le destinazioni montane che si caratterizzano per gli elementi distintivi delle destinazioni turistiche di tipo community (Flagestad & Hope, 2001; Murphy & Murphy, 2004). In questi territori, la capacità degli attori di fare rete e di alimentare relazioni collaborative rappresenta una delle principali sfide del management per raggiungere obiettivi condivisi e creare valore a livello collettivo (Beritelli et al., 2016; Beritelli, 2011). Tali sfide si riflettono anche nella definizione e promozione dell'offerta enoturistica di destinazione che richiede pertanto visione e scelte strategiche ed operative che permettano di superare la frammentazione ed evolvere verso un'offerta integrata e condivisa.

Le destinazioni montane possono considerare le opportunità di sviluppo connesse all'enoturismo come leva per raggiungere obiettivi di destagionalizzare e redistribuzione dei flussi turistici. Nel fare ciò, tuttavia, esse incontrano vincoli amplificati dalle specificità territoriali ossia, accessibilità geografica (raggiungibilità) non sempre garantita, frammentazione spaziale, pluralità di micro-territori, rischi di disallineamento tra offerta e picchi di domanda e, spesso, competizione con altre motivazioni turistiche già consolidate (Dalla Torre & Marchiori, 2021). In tali contesti, l'enoturismo richiede un disegno di destinazione capace di organizzare la pluralità di prodotti e offerte turistiche espresse dal territorio, integrando vino, gastronomia, cultura e outdoor, e rendendolo fruibile e prenotabile (Mitchell & Hall, 2006; Getz & Brown, 2006).

3. Metodologia della ricerca

La ricerca adotta un disegno qualitativo con finalità esplorativo-interpretative avvalendosi di un caso studio (Eisenhardt 1989; Yin, 2018). Tale scelta è coerente con l'oggetto di indagine: quando il fenomeno è contestualizzato, multi-attore e guidato da interpretazioni e decisioni organizzative, la ricerca qualitativa consente infatti di ricostruire logiche d'azione, tensioni e *trade-off* (Maxwell, 2013; Creswell & Poth, 2018; Patton, 2023).

La destinazione eletta a caso studio è il Trentino. Tale scelta è motivata da due condizioni: a) la presenza di un capitale turistico e reputazionale rilevante e di un patrimonio vitivinicolo stratificato e riconoscibile di alto valore che rende possibile interrogarsi su come una destinazione "*non wine-first*" possa costruire riconoscibilità enoturistica; b) la presenza di una traiettoria di consolidamento esplicita che consente di osservare dinamiche di pre-*governance* e implementazione (Dalla Torre & Marchiori, 2021; Cimino & Rigger, 2025). Al contempo si riscontrano criticità tipiche dei contesti community che ostacolano la definizione di strategie orientate al raggiungimento di un posizionamento chiaro, riconoscibile e difendibile come *wine destination*. Il caso è quindi informativo perché permette di analizzare "cosa manca" per trasformare iniziative e risorse in un sistema operativo, non perché rappresenti statisticamente tutte le destinazioni montane. Le evidenze non sono quindi generalizzabili statisticamente, ma offrono spunti di riflessione per altre destinazioni montane vitivinicole con caratteristiche organizzative simili.

La raccolta dati si basa su 21 interviste semi-strutturate a stakeholder chiave dell'ecosistema enoturistico provinciale (istituzioni e governance turistica; consorzi e associazioni; cantine di diversa scala; intermediari digitali; formazione), integrate da analisi documentale. La scelta dei key player da intervistare si basa su un campionamento ragionato orientato alla massima variabilità per coprire differenti prospettive, scale organizzative e ruoli nella filiera (Patton, 2015). In particolare, sono stati inclusi: cantine con modelli di business e dimensioni differenti, attori coinvolti nell'attività di

promozione e governance territoriale (destination management organisation - DMO, aziende per il turismo[6] e istituzioni), consorzi, soggetti di servizio/intermediazione e formazione. La numerosità del campione è stata definita in modo progressivo, fino a raggiungere un livello soddisfacente di saturazione concettuale sulle principali dimensioni analitiche emerse (Guest et al., 2006). Di seguito i dati di campo complessivi relativi alle interviste effettuate (Tabella 1) e il profilo degli intervistati (Tabella 2).

Tab. 1: Le interviste effettuate, dati di campo complessivi

Voci	Dati di campo
Interviste programmate	36
Interviste effettuate	21
Tasso di risposta	58%
Periodo	Agosto-ottobre 2025
Modalità	Videocall (Google Meet) oppure risposte via mail.

Le interviste sono state condotte con traccia semi-strutturata, consentendo comparabilità tra casi e, al contempo, flessibilità per approfondire temi emergenti (Kallio et al., 2016). La traccia è stata progettata per: (1) rilevare percezioni sullo stato dell'offerta (punti di forza, criticità, opportunità, barriere); (2) esplorare visioni di sviluppo (azioni prioritarie, modelli di riferimento, plausibilità del posizionamento competitivo entro dieci anni). La Figura 1 riporta i principali quesiti utilizzati nel protocollo di intervista, con i relativi obiettivi e la letteratura di riferimento.

[6] Le aziende di promozione turistica (APT) del Trentino sono denominate Aziende per il Turismo.
[7] Per il numero di dipendenti si è fatto riferimento ai dati della Camera di Commercio di Trento (2025).

La ricerca è stata svolta nel rispetto dei principi etici della ricerca qualitativa e del Regolamento (UE) 2016/679 – GDPR. Ad ogni intervistato/a è stato richiesto il consenso informato alla partecipazione e alla registrazione audio, precisando finalità e trattamento dei dati; è stata garantita la possibilità di mantenere l'anonimato (Orb et al., 2001). Le interviste sono state realizzate tra agosto e ottobre 2025 da remoto tramite Google Meet. Previo consenso, le interviste sono state trascritte integralmente con l'ausilio di Transkriptor.

Fig. 1: Quesiti inseriti nel protocollo di intervista con indicazione di obiettivo di raccolta delle informazioni e raccordo con la letteratura di riferimento

#	Quesito	Obiettivo	Fonti bibliografiche
1	Perché, secondo lei, il Trentino dovrebbe puntare sull'enoturismo?	Comprendere i vantaggi percepiti (economici, identitari, relazionali) da parte degli stakeholder nel valorizzare questo comparto.	Cimino & Rigger (2025), Getz & Brown (2006), Carlsen (2004), Hall et al. (2000); Festa et al. (2020); Getz et al. (1999)
2	Quale parola chiave le viene in mente quando pensa al legame tra enoturismo e Trentino?	Individuare concetti guida, parole simboliche e immagini forti per un posizionamento autentico.	R.Kavaratzis & Ashworth (2005), Cai (2002); Vergamini et al. (2019)
3	Quali sono, oggi, i principali punti di forza e di debolezza dell'offerta enoturistica in Trentino?	Mappare le percezioni SWOT attuali (Strengths & Weaknesses), utile per analisi strategica bottom-up.	Garibaldi (2023), Dredge & Jenkins (2011), Cimino & Rigger (2025), UNWTO (2020); Festa et al. (2020); Getz et al. (1999)
4	Si sente parte di un sistema territoriale che si riconosce come destinazione enoturistica?	Verificare il senso di appartenenza e l'identità collettiva nella filiera enoturistica.	Saxena et al. (2007), March & Wilkinson (2009), Hall (2005); Vergamini et al. (2019)
5	Quali sono, se ne scorge, le criticità che la preoccupano maggiormente rispetto a un piano di sviluppo enoturistico?	Identificare le Threats percepite (ambientali, gestionali, identitarie), cruciali nella pianificazione strategica.	Cimino & Rigger (2025), Hall & Mitchell (2008), Maizza & Scorrano (2008), Garibaldi (2023); Festa et al. (2020)
6	In che direzione dovrebbe evolvere l'enoturismo in Trentino nei prossimi anni per essere competitivo e attrattivo?	Far emergere visioni desiderate e scenari di sviluppo sostenibile e distintivo.	Cimino & Rigger (2025), Getz (2000), Panke (2020), Hall et al. (2004); Vecchio et al. (2024)
7	Quali sono, secondo lei, le azioni più urgenti o strategiche che aziende, consorzi e istituzioni dovrebbero intraprendere?	Elicitare raccomandazioni pratiche e priorità operative dagli attori locali.	D'Angella & Go (2007), Bramwell & Lane (2011), UNWTO (2020); Vergamini et al. (2019); Festa et al. (2020)
8	Ci sono destinazioni enoturistiche, in Italia o all'estero, che considera un modello di riferimento positivo? E perché?	Raccogliere benchmark spontanei, utili per un confronto competitivo e per comprendere buone pratiche.	Hall & Mitchell (2008), Garibaldi (2020, 2023); Festa et al. (2020); Getz et al. (1999)
9	Cosa dovrebbe fare il Trentino di diverso rispetto alle altre regioni vinicole italiane per distinguersi come destinazione enoturistica di montagna?	Far emergere il potenziale differenziante rispetto a competitor nazionali (brand positioning alpino).	Getz & Brown (2006), Cimino & Rigger (2025), Dalla Torre & Marchiori (2021), Panke (2020); Vergamini et al. (2019)
10	Quanto ritiene plausibile (da 1 a 10) che il Trentino, entro 10 anni, sia tra le prime 5 destinazioni enoturistiche italiane?	Misurare il grado di fiducia degli stakeholder sulla scalabilità e visibilità futura dell'enoturismo trentino.	Hall et al. (2000), Wine Suite (2024), Nomisma (2024); Vecchio et al. (2024)

Fonte: Elaborazione propria

L'analisi dei dati è stata condotta seguendo la metodologia Gioia, che struttura la costruzione teorica a partire dalle evidenze empiriche in modo tracciabile e replicabile (Gioia et al., 2013). Per aumentare la robustezza analitica, sono state utilizzate matrici di sintesi trasversale per verificare ricorrenze e differenze tra intervistati e mantenere una catena di evidenze coerente con le pratiche di analisi qualitativa rigorosa (Miles et al., 2014; Saldaña, 2021). La codifica delle interviste è stata sostenuta da un confronto costante dati - letteratura e attenzione ai criteri di credibilità e trasferibilità (Lincoln & Guba, 1985). I risultati sono stati interpretati anche alla luce di un'analisi documentale volta a contestualizzare le interviste sulla base di materiali di contesto (documenti pubblici,

comunicazione e materiali informativi di consorzi/enti, report di settore, dataset e pubblicazioni di riferimento). Come suggerito dalla letteratura (Bowen, 2009; Denzin, 1978), l'obiettivo di tale analisi documentale è stato quello di rafforzare la credibilità interpretativa, ridurre il rischio di dipendere esclusivamente dal discorso degli attori e ricostruire cornici normative e comunicative.

4. Presentazione e discussione dei risultati della ricerca

Come anticipato, i dati emersi dalle 21 interviste sono stati analizzati con l'approccio di Gioia et al. (2013), procedendo in tre passaggi successivi. Le trascrizioni sono state codificate partendo da concetti di primo ordine, poi aggregate in temi di secondo ordine e infine sintetizzate in dimensioni interpretative. Nella prima fase sono stati quindi estratti i concetti (*1st order concepts*) direttamente dal linguaggio degli intervistati (ad esempio "superare la frammentazione", "standard minimi condivisi", "prenotazione frictionless").

Nella seconda fase i concetti emersi sono stati raggruppati in temi (*2nd order themes*) capaci di spiegare regolarità e differenze (ad esempio Sviluppo della destinazione-sistema, Coopetition, Brand identity, Offerta integrata, Digitalizzazione, Orientamento al futuro). Infine, tramite iterazione tra dati e letteratura, i temi sono stati aggregati in tre dimensioni (*Aggregate dimensions*) che organizzano l'intero fenomeno:

1. Governance & Coordinamento: comprende gli snodi di visione unitaria/regia, convivenza tra grandi e piccoli, standard e allineamento di filiera.
2. Value proposition & Design dell'esperienza: integra brand identity, progettazione dell'offerta e calendarizzazione eventi.
3. Fattori abilitanti: comprendono digitalizzazione e dati, competenze e formazione, raggiungibilità, mobilità e orientamento all'innovazione e al posizionamento futuro.

Seguendo l'approccio della metodologia Gioia (Gioia et al., 2013) la Tabella 3 riporta sinteticamente il *Coding Tree* dei risultati, evidenziando la progressione dai concetti iniziali (*1st order concept*) alle astrazioni teoriche (*2nd order themes*) fino alle dimensioni aggregate (*Aggregate dimenions*), e fornendo una guida alla lettura dei risultati.

Tab. 3: Sviluppo offerta enoturistica: Coding Tree visione degli stakeholders

1st order concepts	***2nd order themes***	***Aggregate dimensions***
● Superamento della frammentazione & Visione unitaria ● Regia unica	● Sviluppo della Destinazione-Sistema	(1) Governance & Coordinamento
● Autonomia operatori, meno paternalismo istituzionale ● Convivenza grandi-piccoli ● Standard minimi & Orientamento alla qualità ● Allineamento Ho.re.ca & Valorizzazione prodotti locali	● Coopetition	
● Trento Doc come porta ● La narrazione della futura Wine destination ● Canali di comunicazione	● Brand Identity	(2) Value proposition & Design dell'esperienza
● Complementarietà dell'enoturismo al turismo ● Sostenibilità ● Sviluppo dell'esperienza & Innovazione ● Destinazione Wine-related, Eventi & calendario integrato	● Offerta integrata	
● Prenotazione frictionless ● Approccio data-driven	● Digitalizzazione	(3) Fattori abilitanti

● Pricing, mobilità & ricettività	● Raggiungibilità, mobilità	

Fonte: Elaborazione propria

3.1 Dimensione 1 - Governance & coordinamento: dall'"arcipelago" alla destinazione-sistema

Un primo nucleo di evidenze riguarda governance e coordinamento. Gli attori descrivono un contesto in cui la ricchezza di iniziative locali non è sempre traducibile in posizionamento e continuità perché mancano dispositivi comuni. La richiesta non è una struttura centralizzata pesante, ma una regia "leggera ma esigente", cioè capace di selezionare priorità, definire responsabilità, e soprattutto costruire strumenti operativi condivisi. Tre strumenti ricorrono con particolare intensità: un hub digitale enoturistico che consenta discovery e prenotazione; un calendario integrato che renda leggibile la continuità e abiliti co-programmazione; una carta/standard minimi di accoglienza che riduca incertezza e variabilità della qualità percepita. La rilevanza di questo risultato aumenta se letta alla luce dei trend riscontrati nell'enoturismo di montagna: la concentrazione delle visite nel weekend implica che aperture, staffing e standard non possono essere lasciati alla discrezionalità individuale, perché il "momento di domanda" coincide con il "momento di fragilità organizzativa" di molte imprese (Wine Suite, 2024). Qui la letteratura sulle reti e sui policy network è utile per interpretare la richiesta degli attori: in sistemi turistici complessi, la rete esiste quasi sempre, ma ciò che fa la differenza è la capacità di governarla attraverso regole, strumenti condivisi e coordinamento inter-organizzativo (Dredge, 2006; D'Angella & Go, 2007; Pike & Page, 2014).

In questa dimensione emergono anche pratiche e bisogni di coopetition. Gli intervistati descrivono il rischio di polarizzazione su pochi marchi/attori "forti" e, specularmente, la difficoltà delle micro-cantine e dei territori minori nel trasformare autenticità e qualità in flussi e ricadute economiche. La coopetition viene interpretata come dispositivo organizzativo capace di comporre queste tensioni: i grandi player possono fungere da piattaforme di visibilità e garanzia; i piccoli da laboratori di autenticità e differenziazione. Tuttavia, secondo gli intervistati, questa complementarità produce valore territoriale solo se la destinazione dispone di meccanismi operativi (referral, pacchetti multi-attore, standard comuni) che consentano al visitatore di muoversi tra offerte diverse senza attrito. La letteratura sulla coopetition nei cluster turistici spiega che la cooperazione competitiva può costruire massa critica e aumentare performance collettiva, ma richiede governance e coordinamento, altrimenti resta collaborazione episodica (Bouncken et al., 2015; Bouncken et al., 2019; Zamarreño Aramendia et al., 2021). Nel caso trentino, il risultato implica che la rete potenziale è alta, ma la sua attivazione come "catena di esperienza" è ancora incompleta.

3.2 Dimensione 2 - Value proposition & experience design: identità "a doppio respiro" e prodotti prenotabili

Un secondo nucleo di evidenze riguarda la *value proposition* e l'architettura identitaria. Gli *stakeholder* convergono su una configurazione "a doppio respiro": Trento DOC come *gateway* di riconoscibilità e "vini di montagna" come cornice narrativa e strategica per valorizzare pluralità di micro-territori, vitigni autoctoni e paesaggi vitati senza perdere leggibilità verso l'esterno. Questo risultato è coerente con le ricerche in questo ambito che evidenziano come le destinazioni vinicole debbano bilanciare semplificazione e profondità: una narrazione troppo complessa genera confusione, una troppo semplice genera appiattimento (Mitchell & Hall, 2006; Festa et al., 2020). Nel caso trentino, la tensione è particolarmente rilevante perché l'identità di montagna può diventare un elemento di differenziazione solo se tradotta in un portafoglio di esperienze coerenti e fruibili: l'identità "montana" non è un attributo descrittivo, ma un principio progettuale che dovrebbe orientare format, stagionalità, servizi e linguaggi.

Dal lato dell'offerta, emerge l'esigenza di trasformare degustazioni isolate in prodotti integrati, modulari e prenotabili che connettano vino, gastronomia, cultura e *outdoor*. Questa evidenza si allinea con la letteratura *sull'experiential turn* e con la lettura dell'enoturismo come forma di turismo culturale-relazionale (Panke, 2020; Richards, 2018; Richards, 2021a, b). Si allinea anche con i *trend* di domanda: crescita di esperienze immersive, premiumizzazione selettiva e attenzione a sostenibilità e autenticità (Garibaldi, 2024a; Garibaldi, 2024b). In questa cornice, l'offerta trentina appare competitiva quando integra il valore paesaggistico e la fruizione lenta con l'ospitalità e la capacità di prenotazione; appare fragile quando non è intermediabile, quando manca continuità, e quando la

filiera ricettiva/ristorativa non "aggancia" la proposta enoturistica. Qui l'evidenza empirica rafforza un punto spesso discusso nella letteratura sulle *wine destination*: la destinazione non è la cantina, è l'ecosistema (Getz & Brown, 2006; Pike & Page, 2014). Anche gli eventi, spesso evocati come *asset*, emergono in modo non retorico: la loro utilità dipende dal passaggio da episodicità a calendario integrato, capace di trasformare i picchi in un percorso continuativo verso l'offerta ordinaria. Emerge quindi dalle interviste la necessità di avere un calendario unico e prenotabile che permetta di coordinare gli eventi e le esperienze del territorio. In particolare, un intervistato richiama un esempio di destinazione che ha costruito un calendario unico per gestire l'offerta di esperienze: *"[La destinazione "X"] per me è il paradiso. Tu hai questo calendario che si apre su un unico sito in cui puoi prenotare esperienze… all'epoca c'erano un paio di esperienze al giorno, ad oggi ne trovi 20 esperienze diverse…"* (R5).

3.3 Dimensione 3 - Fattori abilitanti: digitale/CRM, competenze e standard, raggiungibilità

Il terzo nucleo di evidenze riguarda i fattori abilitanti e spiega perché la "strategia" rischi di restare retorica. Gli stakeholder descrivono un gap tra ispirazione e conversione: il Trentino non è ancora percepito immediatamente come *wine destination* e il percorso digitale appare frammentato. Ne deriva un risultato cruciale: la digitalizzazione è un'infrastruttura di destinazione, non solo un canale. *Hub* digitale, prenotazione *frictionless*, disponibilità e prezzi chiari, pagamenti e conferme, *policy* condivise, logistica post-acquisto e CRM sono considerati elementi necessari per ridurre attrito e aumentare conversione e qualità percepita. A questo proposito, le dichiarazioni degli stakeholder intervistati riflettono quanto emerso dalla letteratura sul turismo digitale (Buhalis, 2000) e da fonti settoriali specifiche sul turismo del vino digitale e sul *direct-to-consumer* (DTC) (Divinea, 2025; Wine Suite & Divinea, 2025; Serio et al., 2024). Le evidenze su tecnologie immersive e *gamification* – che mostrano impatti su interazioni e prenotazioni dirette – rafforzano l'idea che l'innovazione digitale può essere leva competitiva quando è integrata in un disegno di *customer journey* e non frammentata in sperimentazioni isolate (Osservatorio Innovazione Digitale nel Turismo, 2024; Wine Tech Observatory, 2023).

Accanto al digitale emerge con forza l'esigenza di professionalizzazione dell'ospitalità e di standardizzazione della qualità. Per esempio, l'internazionalizzazione della domanda e la crescente selettività (anche generazionale) richiedono accoglienza multilingue, capacità di service design e coerenza tra promessa e consegna. Gli stakeholder richiamano la necessità di investire in competenze trasversali e in figure professionali dedicate (ad esempio, hospitality manager territoriale) per ridurre asimmetrie tra imprese, presidiare standard e alimentare un ciclo di apprendimento data-driven (Garibaldi, 2024b). In questo senso, il Trentino appare come un caso in cui la sfida non è "inventare nuove esperienze", ma rendere l'offerta enoturistica integrata a livello di destinazione attraverso *governance*, digitale e competenze. Tale interpretazione è coerente con l'ambizione di posizionamento come wine destination e con l'idea che l'enoturismo di montagna diventi competitivo quando è trattato come progetto di destinazione (Cimino & Rigger, 2025; Dalla Torre & Marchiori, 2021).

5. Implicazioni manageriali e di policy

La ricerca suggerisce che la transizione verso una wine destination in contesto montano dipende fortemente dalla capacità di trasformare pluralità e frammentazione in coerenza di sistema e in conversione lungo la customer journey. Questo risultato è coerente con la letteratura, che identifica nella governance e nella progettazione dell'esperienza - insieme alla capacità digitale - i fattori critici che distinguono le destinazioni in grado di raggiungere risultati concreti da quelle che restano somme di iniziative (Mitchell & Hall, 2006; Getz & Brown, 2006; Pike & Page, 2014).

I risultati confermano e specificano, nel caso del Trentino, la tesi secondo cui le wine destination competono come sistemi: risorse e reputazione non bastano se non vengono tradotte in strumenti

operativi, qualità diffusa e prenotazione *frictionless* (Pike & Page, 2014; Mitchell & Hall, 2006). Il contributo del caso studio è mostrare come, in una destinazione montana non completamente *wine-first*, il nodo competitivo sia l'implementazione: trasformare una pluralità di micro-identità e attori intermedi in un *funnel* di destinazione, con regia, standard e infrastrutture digitali condivise. In tale prospettiva, la proposta di posizionamento del Trentino come *wine destination* richiede un passaggio da *vision* a *operating model* (Cimino & Rigger, 2025): chi fa cosa, con quali strumenti, con quali metriche. Affinché si realizzi uno sviluppo enoturistico di destinazione, l'identità (vini di montagna) deve quindi diventare principio progettuale (prodotti, servizi, stagionalità, mobilità) non solo frame narrativo. Inoltre, la coopetition si qualifica come meccanismo chiave: non basta la collaborazione simbolica, servono pacchetti e standard condivisi per distribuire valore e aumentare la permanenza.

Alla luce di tali considerazioni, dalla ricerca emergono chiare quattro principali evidenze: 1) senza una governance efficace, la destinazione non costruisce strumenti condivisi; 2) senza strumenti condivisi non ottieni sistemi di prenotazione accessibili ed efficaci; 3) senza tali sistemi e standard comuni non intercetti e consolidi la domanda; 4) senza il consolidamento della domanda non si consolida valore territoriale e posizionamento. Per i *policy maker* e le DMO ciò significa spostare l'attenzione dalla sola promozione alla costruzione di una regia di destinazione, coerente con l'evoluzione delle DMO come orchestratori di ecosistemi (Pike & Page, 2014). Nel caso del Trentino, la priorità è attivare una cabina di regia multi-attore con mandato operativo e responsabilità su *deliverable* misurabili, in modo da rendere scalabile la pluralità di attori e micro-identità che caratterizza una destinazione montana (Dalla Torre & Marchiori, 2021; Cimino & Rigger, 2025). Questa regia dovrebbe concentrarsi su un set minimo di infrastrutture di sistema: un *hub* unico orientato al *booking* (inventario esperienze, pagamenti, *policy* e conferme), un calendario integrato esperienze-eventi per la co-programmazione e la destagionalizzazione, e una carta di standard minimi di accoglienza, idealmente costruita con un modello "a soglie" che permetta anche alle micro-imprese di innalzare progressivamente diffusione e qualità degli strumenti operativi di prenotazione e commercializzazione online (Mitchell & Hall, 2006; Getz & Brown, 2006).

Contestualmente, la governance dovrebbe adottare KPI di sistema per favorire un approccio data-driven consapevole nella gestione del territorio (ad es. *conversion rate, no-show*, valutazioni/Net Promoter Score, permanenza media, spesa media, stagionalità e distribuzione territoriale dei flussi) (Divinea, 2025; Wine Suite, 2024). Per una destinazione montana, le politiche di mobilità non sono accessorie: diventano leve per rendere fruibili territori periferici e sostenere l'obiettivo di diffusione dei flussi, con ricadute su sostenibilità e coesione territoriale (Dalla Torre & Marchiori, 2021).

Per *imprese e consorzi*, le implicazioni sono speculari ed operative: l'offerta deve essere riprogettata come portafoglio modulare e prenotabile (format chiari, durata/prezzo, *add-on* come trasporti/guide/spedizione), coerente con *driver* di successo delle wine destination e con la trasformazione dell'enoturismo in esperienza culturale-relazionale (Getz & Brown, 2006; Panke, 2020; Richards, 2018; Richards, 2021). Il CRM e il *follow-up* dovrebbero diventare pratiche standard per trasformare la visita in relazione e riacquisto, in linea con le dinamiche DTC e con l'evidenza settoriale sull'importanza della conversione digitale (Divinea, 2025; Wine Suite & Divinea, 2025; Serio et al., 2024).

Infine, la professionalizzazione dell'ospitalità (accoglienza multilingue, service design, storytelling, gestione prenotazioni) è condizione per intercettare domanda internazionale e segmenti più selettivi; investire in competenze e in figure "ponte" territoriali per ridurre asimmetrie tra imprese e sostenre qualità diffusa (Garibaldi, 2024b).

In questa prospettiva, la coopetition diventa un meccanismo concreto di scalabilità: pacchetti multi-attore e *referral* strutturati permettono di distribuire valore, aumentare la permanenza e mitigare la polarizzazione su pochi *player*, in coerenza con la letteratura sui cluster turistici (Bouncken et al., 2015; Bouncken et al., 2019; Zamarreño Aramendia et al., 2021).

6. Conclusioni, limiti e sviluppi futuri della ricerca

La ricerca ha analizzato lo sviluppo dell'enoturismo in Trentino con l'obiettivo di comprendere come un territorio di montagna possa sviluppare un'offerta enoturistica distintiva e sostenibile a livello di destinazione. In particolare, si è analizzato a) se e come i key player coinvolti nella governance e nel management di destinazione, e le imprese e le organizzazioni che operano nel settore vitivinicolo, condividono visioni, priorità e strategie orientate ad affermarsi come destinazione enoturistica, e b) i possibili fattori abilitanti il posizionamento di un territorio come destinazione enoturistica.

Dai key player intervistati emerge una visione coerente. La ricerca suggerisce che la competitività di una wine destination montana dipende dall'orchestrazione congiunta di governance, value proposition e abilitatori (digitale/CRM, standard e competenze, raggiungibilità). Il caso studio mostra un paradosso tipico delle destinazioni in consolidamento: la presenza di asset e iniziative non produce automaticamente posizionamento e performance; questi emergono quando la pluralità viene organizzata in un modello operativo coerente e prenotabile (Mitchell & Hall, 2006; Pike & Page, 2014). In questo senso, l'ambizione di posizionamento come wine destination (Cimino & Rigger, 2025) richiede un salto implementativo: regia multi-attore, infrastrutture comuni (hub, calendario, standard) e metriche di sistema per trasformare visibilità in conversione, permanenza e valore territoriale (Buhalis, 2000; Garibaldi, 2024b).

Il principale limite della ricerca è riconducibile alla natura esplorativa e alla considerazione di un unico caso studio che ne limita la generalizzazione dei risultati. Tuttavia, le evidenze emerse suggeriscano implicazioni manageriali e di policy di rilievo, che si ritiene possano essere di ispirazione per altre destinazioni montane che presentano potenzialità ancora inespresse con riferimento all'offerta enoturistica territoriale.

Studi multi-caso in altri contesti montani potrebbero testare la robustezza delle dimensioni emerse, integrando misure quantitative su KPI di conversione e impatti (permanenza, spesa, destagionalizzazione, distribuzione dei flussi). Ulteriori ricerche potrebbero valutare l'efficacia comparata di strumenti di sistema (hub, standard a soglie, figure ponte) nell'abilitare la coopetition e la qualità diffusa.

A “dual-purpose” teammate: working with GenAI

PAOLA PISANO[1], MARIA CALIGARIS[1], MASSIMO PESCAROLLO[1], MIRNA ROSSI[1], ANTONELLA AURELI[2]

Abstract

Frame of the research. *Human-AI teams hold substantial promise due to the complementary strengths of human cognition and artificial intelligence. Despite this potential, a growing body of research suggests that AI-augmented teams do not consistently deliver the expected performance and in some cases contribute to undermine core team properties introducing negative aspects that may adversely affect employee well-being, including psychological distress and depression (Kim et al., 2025). A critical but underexplored question concerns whether these outcomes depend not merely on AI access, but on the structural properties of the human team through which AI is used.*

Purpose of the paper. *This study asks: (RQ1) how do team size and seniority composition influence performance outcomes in AI-enabled task execution? And (RQ2) how do team size and seniority composition shape emotional dynamics in the same context? We argue that the introduction of GenAI as a broadly capable collaborator alters the mechanisms through which team diversity traditionally confers its advantage — shifting the primary performance bottleneck from idea generation to coordination and integrative execution.*

Methodology. *To address these questions we conducted an experiment within Accenture, where consultants were randomly assigned to teams consisted of either a single individual or two individuals working with AI, who could hold the same or different roles within the organization. Participants received a use case to be developed throughout the day. Each solution submitted received three independent single-blind evaluations from different experts to reduce evaluation bias and increase reliability. Evaluators rated each solution on five dimensions: quality, impact, novelty feasibility, and technical sophistication.*

Results. *Our findings indicate that homogeneous teams, characterized by the same level of seniority, outperformed both individuals and heterogeneous teams, attaining the highest levels of feasibility. In contrast, heterogeneous teams did not exhibit statistically significant performance advantages relative to individuals. Beyond performance outcomes, teamwork was associated with more favorable emotional experiences. Participants working in teams reported lower increases in frustration and stress compared to individuals, for whom both measures rose substantially. These results suggest that collaborative settings can mitigate negative emotional responses connected with working with Generative AI.*

Managerial implications. *hese findings reframe AI as a dual-purpose organizational tool: one that simultaneously enhances team performance and buffers workers against the negative emotional consequences of AI-enabled work — but whose benefits are strongly contingent on seniority composition. Organizations should treat team structure, not merely AI access, as a strategic lever for realizing AI's competitive value.*

Research limitations. *We also acknowledge two key limitations. First, our experiment relied on one-day virtual collaborations, which do not fully capture the day-to-day complexities of organizational. Second, we examined small, two-person teams specifically constructed for the experiment. These factors may influence both performance and emotional dynamics in ways that our experimental design could not fully replicate.*

Originality of the paper. *This study makes three contributions. First, it qualifies the diversity–performance relationship under AI augmentation, showing that seniority homogeneity outperforms heterogeneity when GenAI externalizes ideational variety. Second, it extends exploration–exploitation theory to hybrid human-AI configurations, arguing that AI decouples the two functions by handling exploration and leaving convergence to the human team. Third, it advances human–AI teaming theory by demonstrating that seniority composition is a first-order boundary condition for AI-enabled team performance, a dimension largely absent from prior experimental designs.*

Keywords: *Artificial intelligence, Teamwork, Human-machine interaction, Feasibility, Impact, Field experiment.*

1. Introduction

Recent scholarship converges in framing artificial intelligence (AI) not merely as a technological innovation, but as a systemic driver of change operating across multiple levels of analysis. At the macro-economic and industry level, AI has been conceptualised as a general-purpose technology with pervasive implications for productivity, value creation, and competitive dynamics, requiring firms to

[1] University of Torino, Highest Lab.
[2] Accenture

rethink how economic value is generated and scaled in data-intensive environments (Wagner, 2020). At the organizational level research highlights how AI reshapes strategic architectures, pushing firms toward modular experimentation, human–machine collectives, and new forms of organisational configuration suited to managing learning systems and continuous recombination of capabilities (Wagner, 2020; Secundo et al., 2024).

At the micro level of everyday work, AI-driven transformation requires organizations to reconcile agility with stability, and individual agency with collective coordination.

Prior research demonstrates that team performance is not simply the aggregation of individual abilities, but is fundamentally shaped by complex collective processes and team-level dynamics (DeChurch & Mesmer-Magnus, 2010; Mathieu et al., 2008; Woolley et al., 2010). Effective team functioning relies on collaboration, coordination, the development of shared understanding among team members (Bittner et al., 2019; Seeber et al., 2020) and the ability to cultivate and foster a positive emotional climate. Although generative AI holds considerable promise for enhancing these processes, how to design and manage hybrid human-AI teams to enhance productivity while mitigating AI's potential adverse effects on workers remains an open and critical question (Ju & Aral, 2025). A growing body of empirical evidence underscores the urgency of this question. A large-scale study by Upwork (n = 2,500) shows that while 96% of managers expect productivity gains from GenAI adoption, 47% of workers report difficulty meeting these heightened expectations, and 77% perceive AI tools as decreasing their productivity or increasing their workload (Burlacu & Monahan, 2024). These figures suggest that the value of AI is not automatically realized, and that the organizational conditions under which AI is deployed —including team structure and composition — may be decisive. Crucially, the emerging literature on human–AI teaming has documented performance effects of AI augmentation while largely treating the human side of the team as undifferentiated — comparing individuals to teams, or human-only to human-AI configurations, without examining how variation in human composition moderates AI-augmented outcomes (Seeber et al., 2020; McNeese et al., 2021; Dell'Acqua et al., 2025). At the same time, the team diversity literature, which has long positioned heterogeneity as a driver of performance on complex tasks (Van Knippenberg et al., 2004; Page, 2007), has not been tested in contexts where AI serves as a broadly capable collaborator that may itself supply the ideational variety heterogeneous teams traditionally provided. Our study addresses this intersection directly.

To address this challenge and systematically examine how to manage this new technology to enhance team and individual performance, we conducted a large-scale field experiment at Accenture, a global consulting firm, between October and December 2025. Participants were randomly assigned to teams with different configurations based on their seniority level (Analyst, Consultant, or Manager) and their functional background (i.e., more technical versus more functional).

In contrast to prior research designs, which typically rely on control groups composed of individuals or teams without access to AI, this study grants all participants access to GenAI. This design choice reflects contemporary workplace dynamics, in which rapid technological advancement and the growing diffusion of artificial intelligence increasingly require individuals to collaborate not only with other humans but also with AI technologies to achieve complex goals. From healthcare, where professionals work alongside AI systems for diagnostic and decision support (Kocak et al., 2026), to emergency response teams operating with autonomous agents and intelligent support systems (McNeese et al., 2021), from organizational and decision-making contexts in which managers and knowledge workers rely on AI tools for analysis, forecasting, and coordination, to our daily life, the prevalence of human–AI collaboration continues to expand significantly.

Building on the considerations outlined above and the design of our empirical experiment, this study departs from two assumptions that are largely taken for granted in prior literature. First, that collaboration, whether human–human or human–AI, systematically leads to superior outcomes in both performance and individual well-being. Second, the study of GenAI requires a shift from technology-driven questions toward a human-centred perspective that places individuals and evolving teams at the core of analysis (Berretta, 2023).

On this basis, and grounded in the empirical structure of our experiment, we formulate the following research questions, which jointly address performance outcomes and emotional dynamics across individual and team-based AI-enabled work configurations:

RQ1. How do teamwork and team composition influence performance outcomes in AI-enabled task execution?

RQ2. How do teamwork and team composition influence emotional dynamics in AI-enabled task execution?

These two research questions position the study between two theoretical traditions that have largely developed in isolation. The first is the diversity–performance literature in organizational behavior, which has long held that heterogeneous teams, by virtue of their broader informational resources and cognitive repertoires, outperform homogeneous teams on complex, non-routine tasks (van Knippenberg, De Dreu & Homan, 2004; Page, 2007; Harrison & Klein, 2007). The second is the emerging literature on human–AI teaming, which has documented the performance effects of AI augmentation but has overwhelmingly treated the human side of the team as undifferentiated. This literature so far compared individuals to teams, or human-only teams to human-AI configurations, without examining how variation in human team composition moderates AI-augmented outcomes (Seeber et al., 2020; McNeese et al., 2021; Dell'Acqua et al., 2025).

Our study addresses this intersection directly. By holding AI access constant across all conditions and varying only the human composition of the team, we are able to isolate the role of seniority homogeneity as a moderating factor in AI-enabled performance. This design allows us to test whether the performance advantages traditionally attributed to heterogeneous teams generalize to AI-augmented contexts, or whether the introduction of GenAI as a broadly capable collaborator alters the underlying mechanisms through which diversity confers its advantage.

The paper is structured as follows. Section 2 reviews relevant literature on AI's impact on work, individual-level effects, team dynamics, diversity and performance trade-offs, and emotional well-being in AI-enabled contexts. Section 3 describes the experimental design and context. Section 4 outlines the data collection procedures. Section 5 reports the empirical findings, comparing performance and emotional outcomes across individual, homogeneous team, and heterogeneous team conditions. Section 6 concludes with a discussion of theoretical contributions, managerial implications, study limitations, and promising avenues for future research.

2. Related Literature

As generative AI becomes increasingly embedded in organisational workflows, scholars have begun to reassess foundational assumptions about performance, collaboration, and well-being at work. The emerging literature develops along two complementary streams that examine AI's impact at the individual and team levels. This body of research collectively reframes AI not merely as a technological artefact, but as an actor that reshapes coordination patterns, diversity dynamics, and the psychological experience of work.

A first stream of research has examined the extent to which AI augments individual capabilities (Grønsund & Aanestad, 2020; Jia et al., 2024; Raisch & Krakowski, 2021). Field experiments at the individual level document substantial productivity gains, with evidence that generative AI increases task completion rates by approximately 14% in customer support contexts (Dell'Acqua et al., 2023). Importantly, these effects are highly heterogeneous. Prior studies show that novice and lower-skilled workers benefit disproportionately from AI assistance, whereas more experienced workers exhibit more modest performance improvements. Complementing these findings, recent evidence indicates that lower-skilled workers primarily benefit from AI in terms of output quality, whereas higher-skilled workers tend to gain mainly in efficiency (Marsal et al., 2025). Extending this heterogeneity perspective, Wang et al. (2023) show that while AI generally benefits workers with greater task-based experience, senior workers realise smaller productivity gains than their junior counterparts.

Importantly, this attenuated effect is not attributable to seniority per se, but rather to lower levels of trust in AI, likely stemming from senior workers' broader job responsibilities and heightened accountability.

Alongside these positive effects, emerging research has begun to document potential behavioural downsides of AI use. In particular, heavy reliance on AI systems may induce a form of attentional disengagement, or "falling asleep at the wheel," in which individuals reduce critical evaluation, allocate less cognitive effort to task execution, and develop excessive trust in AI-generated outputs (Dell'Acqua, 2022). Extending this concern, recent evidence suggests that outsourcing tasks to, or co-creating tasks with, GenAI can substantially narrow the scope of human work, thereby reducing the range of tasks associated with certain roles and weakening existing knowledge ties (Glaser et al., 2024; Retkowsky et al., 2024). This contraction of task portfolios appears especially consequential for novice workers, whose roles often centre on low-status, mundane activities —so-called *scut work* — that traditionally serve as important entry points for learning and skill development (Huising, 2015). Consequently, the involvement of GenAI complicates the attribution of individual contributions to work outputs, making performance evaluation more difficult. This reduced transparency may, in turn, hinder the assessment of employees' skill development and obscure emerging career trajectories.

Whereas a first stream of research has robustly documented the impact of generative AI on individual performance (Dell'Acqua et al., 2023; Jia et al., 2024; Noy & Zhang, 2023), an emerging second stream redirects attention toward teams, examining how AI is adopted and embedded within team dynamics and structural characteristics to accomplish collective objectives.

Throughout history, teams have been the cornerstone of human achievement, enabling us to tackle complex tasks that require diverse ideas and collaborative efforts (Woolley, Chabris, Pentland, Hashmi, & Malone, 2010; Wu, Wang, & Evans, 2019; Wuchty, Jones, & Uzzi, 2007, T. Malone, 2018). Yet, teams are not always effective. Some of the major challenges to successful collaboration include poorly designed tasks, ineffective collaborative work practices, and inadequate technological systems that fail to facilitate teamwork (Hackman, 2009).

Prior to the emergence of generative AI, research on team dynamics largely adopted a human-centric perspective, in which technology was conceptualized as an incremental enabler of human work rather than a core component of team functioning (Grønsund & Aanestad, 2020; Puranam, 2021). Technologies were typically treated as supplementary artefacts that supported or optimised existing human capabilities, with AI systems primarily deployed as specialized tools for automating discrete tasks (Dell'Acqua, Kogut, & Perkowski, 2025; Jia et al., 2024). As a result, AI was rarely theorized as an active team participant with the capacity to generate novel ideas, engage in open-ended communication, and contribute across multiple domains. However, when AI is treated as a broadly capable partner rather than a narrow tool (Dell'Acqua et al., 2023; Noy & Zhang, 2023; Hagemann et al., 2023; McNeese et al., 2021; Seeber et al., 2020), and potentially as an equal team member (Haase & Hanel, 2023), established assumptions in the team and management literature warrant systematic re-examination.

Building on insights related to team performance and distinctive characteristics, such as collaboration (Puranam, 2021; Seeber et al., 2020) and the capacity to integrate and leverage diverse perspectives (Kozlowski & Ilgen, 2006; Mathieu et al., 2008; Woolley et al., 2010), this stream of literature raises a fundamental question: can human teams, with their rich social and cognitive dynamics, be meaningfully compared to "cyborg" configurations consisting of an individual working with AI, or do teams that collectively collaborate with AI ultimately outperform both individual-AI pairings and traditional human teams? Dell'Acqua et al.'s recent evidence from Procter & Gamble workers (2025) reveals that AI enhances the performance of both individuals and teams, suggesting that AI may replicate certain functional benefits typically associated with human collaboration (Dell'Acqua et al., 2025).

In a similar vein, Ning Li et al. (2024) compared the general performance of individual-AI dyads with that of human-only teams and AI-assisted teams to assess whether generative AI can scale

individual productivity to levels comparable to or exceeding those achieved through team collaboration. Consistent with prior research, their findings confirm that generative AI enhances productivity (Noy & Zhang, 2023; Dell'Acqua et al., 2025). However, the incremental contribution of AI at the team level accounted for only an additional 2–4% of the variance in performance outcomes, a substantially smaller effect size than those reported in studies focusing on individual-level augmentation.These findings underscore the persistent benefits of collaboration that cannot be fully reproduced by individuals, even when working intensively with generative AI (Woolley et al., 2010; Lebovitz et al., 2022). Moreover, the experiment suggests that while individual-AI dyads can eventually achieve performance levels comparable to those of traditional teams when given sufficient time, AI-assisted teams continue to exhibit a performance advantage.

McNeese et al. (2021) found that mixed human-AI teams outperformed human-only teams in a simulated emergency response scenario, with AI-only teams achieving the highest performance. In a comparison of human-only, human-human-AI, human-AI-AI, and AI-only teams, their findings revealed that perceived team cognition was highest in human-only teams and significantly lower (58% below) in mixed teams. This dichotomy between objective performance and subjective experience represents a critical challenge for human-AI team design.

Carter et al. (2024) synthesise research from the literature on team effectiveness, decision making, and human-technology interaction to develop a comprehensive theory of AI–human team effectiveness. The authors argue that introducing AI as a member of decision-making teams can generate confusion, uncertainty, and fragmented cognitive processes, as well as erode trust among team members-ultimately undermining team effectiveness.

Importantly, this work highlights the central role of leadership in mitigating these challenges, especially when managers promote transparency, clarify the role of AI within the team, set explicit performance expectations, and foster open and participative leadership. Together, these factors shape whether AI functions as a disruptive presence or as a productive contributor to team decision-making.

A substantial body of organizational research positions team diversity as a driver of innovation and complex problem-solving because heterogeneous teams access broader informational resources and cognitive repertoires (Page, 2007). The dominant theoretical framework in this tradition — the Categorization-Elaboration Model (CEM) — holds that information elaboration, defined as the exchange, discussion, and integration of task-relevant knowledge, is the primary mechanism through which diversity translates into performance gains (van Knippenberg, De Dreu & Homan, 2004). However, meta-analytic evidence consistently shows that the diversity–performance relationship is contingent rather than universally positive, depending on the type of diversity and the nature of task demands (Horwitz & Horwitz, 2007). Conceptually, diversity may reflect variety (knowledge differences), separation (value or opinion divergence), or disparity (status inequalities), each carrying distinct process implications (Harrison & Klein, 2007). Seniority diversity, in particular, maps primarily onto the disparity dimension, which is associated with status-based tensions, evaluation apprehension, and coordination costs, effects that may attenuate or reverse the performance benefits associated with informational variety.

From an exploration–exploitation perspective, diversity has traditionally been valued for its contribution to exploration, the generation of novel ideas, broad search, and recombination of distant knowledge, whereas homogeneity has been associated with exploitation: convergence, efficiency, and disciplined execution (March, 1991; Gupta, Smith & Shalley, 2006). Crucially, however, this theoretical logic presupposes that ideational variety is primarily a function of the human team's composition. The emergence of generative AI as a broadly capable collaborator challenges this assumption at its root.

Recent empirical evidence demonstrates that while GenAI can substantially enhance individual creativity and output quality, it simultaneously reduces the collective diversity of ideas due to shared model priors and anchoring effects (Doshi & Hauser, 2024; Meincke, Nave & Terwiesch, 2025). This suggests that GenAI functions as an external generator of synthetic variety (Lee & Chung, 2024) partially substituting for the exploratory function historically attributed to heterogeneous human

teams. In this context, GenAI may partially substitute for the exploratory function historically attributed to team heterogeneity.

If the ideational variety that diverse teams traditionally provided is increasingly externalized through AI, then the marginal benefit of within-team heterogeneity for exploration may decline, while the demands for coordination, convergence, and disciplined integration of AI-generated alternatives remain, or intensify. Under these conditions, the primary performance bottleneck may shift from idea generation to idea selection and execution, favoring teams whose shared cognitive frames and aligned seniority expectations reduce integration frictions. Homogeneity in seniority can facilitate faster alignment around planning horizons, role expectations, and feasibility thresholds: what team cognition research describes as shared mental models and transactive memory systems, both of which are central predictors of performance in interdependent tasks (Mathieu et al., 2000; DeChurch & Mesmer-Magnus, 2010). This theoretical reframing generates a non-obvious prediction: in AI-enabled contexts, seniority-homogeneous teams may outperform heterogeneous teams not despite their relative uniformity, but because of it and specifically on dimensions such as feasibility and quality that require integrative alignment rather than exploratory breadth.

Indeed, as with other workplace technologies, GenAI influences multiple aspects of work life, affecting not only performance outcomes but also employees' psychological and emotional well-being (Parteka et al., 2024). The adoption of new technologies is often accompanied by anxiety, arising either from difficulties in mastering new systems or from concerns about inadequate performance when using them in professional settings (Havrda & Klocek, 2023). At the same time, the study by Shahzad et al. (2025) showed that the use of GenAI can have positive effects on psychological well-being, but these vary depending on the social context and the mode of use. Favourable employee attitudes toward generative AI are typically associated with the belief that these technologies can enhance work effectiveness, streamline routine activities, and enable faster, more precise outcomes (Sallam et al., 2024). Employees tend to be more receptive to AI when they perceive it as instrumental in supporting goal attainment and easing task execution. Individuals who experience a strong sense of personal agency, or who interpret AI as a developmental challenge rather than a barrier, are more inclined to adapt, reskill, and embed AI into their everyday work practices, thereby fostering higher levels of engagement and performance (Innocenti & Golin, 2022).

In contrast, workers who experience limited autonomy within their organizations, as well as those at earlier stages of their careers, tend to approach AI with greater scepticism and apprehension, which can undermine their confidence in their own capabilities and hinder adaptive responses (Leonard & Tyers, 2021). In these cases, unfavourable attitudes toward GenAI are frequently rooted in concerns that these technologies may displace jobs, constrain career advancement, or render existing competencies obsolete (Innocenti & Golin, 2022). Accordingly, employees who construe AI as a threat are more likely to report heightened job insecurity, increased anxiety, lower work engagement, and diminished organisational commitment (Arias-Pérez & Vélez-Jaramillo, 2022).

Although group-level evidence is comparatively limited, Vats & Sharma (2025) conducted a systematic review process to understand the impact of AI on teams, revealing that shared perceptions of AI within teams influence collective well-being and coping responses. Teams that engage in collective sensemaking around AI-discussing its purpose, limitations, and implications-are better able to normalise AI use and reduce uncertainty among members (Murphy, 2025). Such shared understanding contributes to lower stress and greater psychological safety in AI-enabled work environments.

Supportive team climates, characterized by open communication and collaborative problem-solving, help buffer negative emotional responses to AI-related change (Alkhayyal et al., 2024; Aubouin-Bonnaventure et al., 2023). In contrast, fragmented teams and weak leadership exacerbate negative perceptions, intensifying anxiety and resistance to AI adoption.

As evidenced by the existing literature, scholarly attention has increasingly shifted toward understanding how AI shapes both individual and team performance in organizational contexts. While early studies concentrated on the human-AI relationship or on comparisons between human-only and

hybrid teams, more recent research broadens the perspective to examine variations in team composition, including homogeneous and heterogeneous configurations. Furthermore, the focus is progressively extending beyond performance metrics to encompass well-being, investigating how AI influences team processes, collective affect, and individual psychological experiences.

3. Experimental Design

From October 2025 to December 2025, we conducted an experiment within Accenture with the primary objective of investigating how artificial intelligence can enhance teamwork and how such changes the company's organisational structure in the context of its "Reinvention" initiative. Accenture operates in more than 120 countries and employs nearly 800,000 people worldwide, with a strong focus on continuous reinvention to deliver tangible value.

Over several months, we worked closely with Accenture Italia to tailor the experimental design, ensuring alignment with the company's organisational structure, operational practices, and strategic priorities. The decision to investigate the effects of AI on project quality, innovation outcomes, and interfunctional relationships within teams, as well as its potential implications for organisational structure and well-being, emerged from a series of discussions with the organisation's leadership team, and it is part of the overall global reorganisation program.

As is common in organisations of this size and complexity, work at Accenture is predominantly team-based and follows well-defined routines, often requiring close cross-functional collaboration. Teams are generally structured according to a classical pyramidal model, with analysts, consultants, and managers at progressively higher levels of seniority, responsibility and autonomy. Analysts are typically responsible for executing more elementary tasks under the guidance and supervision of consultants, who operate autonomously and can independently deliver specific project workstreams. Managers ensure the overall quality of deliverables, cultivate professional relationships with clients, and oversee team management and project economics across multiple engagements. Within individual projects, teams are composed of both functional profiles, characterised by deep knowledge of and expertise in the relevant business context, and technical profiles capable of efficiently and effectively integrating the technologies required to address project-specific challenges. This structure represents a standard configuration for generating, refining, and ultimately translating innovative ideas into practical, client-ready projects. Enhancing innovativeness at this stage, together with improving the ability to define appropriate project steps from the outset, is critical for maximising client value and retention, project effectiveness, creative performance, and overall impact at speed and at scale. This motivation is further reinforced by the need to understand how to design the most effective teams in the AI era, for project execution and how such design choices may influence organisational structure. Consistent with existing research and leading organisations (Challapally et al., 2025), Accenture aims not only to enhance individual performance and efficiency through AI, but also to realise its full potential at the organisational level. These considerations are particularly salient in light of Accenture's new strategy announced in June 2025, which reorganised all services, bringing them together into a single integrated business unit, *Reinvention Services,* grounded in the assumption that AI, data, and cloud are foundational capabilities rather than add-ons, and that value is created faster when capabilities are integrated rather than deployed sequentially. In practice, this model reveals a profound organisational reconfiguration in which the boundaries between consulting, technology, and operations become increasingly blurred, supporting a more holistic approach to value creation. Collaboration across roles and seniority levels is enabled through an organizational structure that becomes less constrained and hierarchical, forming the foundation for a new way of addressing client challenges and sustaining long-term growth.

3.1 Accenture Italia

With a workforce exceeding 22,000 professionals - an increase of 70% over the past five years - Accenture Italia represents a cornerstone of the Industry, Consumer good-Goods & Services, Energy and

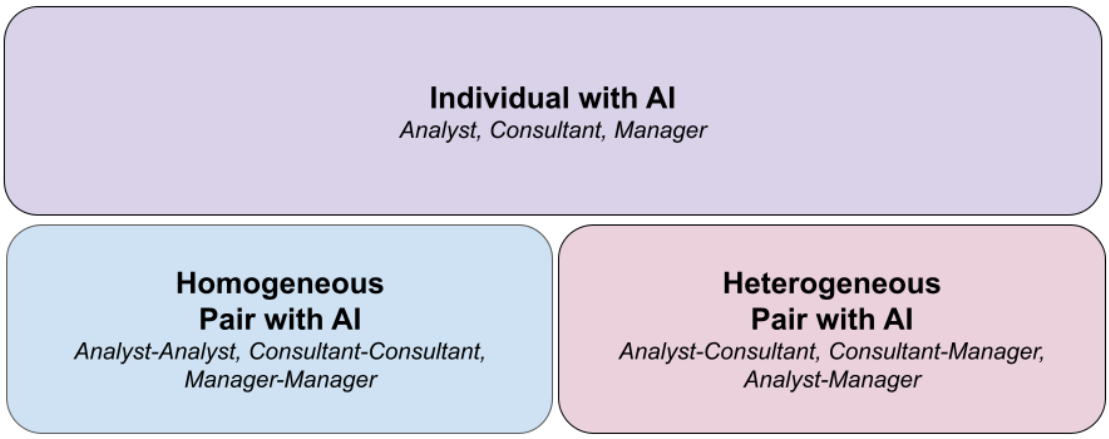
Goverment (ICEG) market unit and a strategic hub within the company's global network. Its national footprint is articulated through a system of 11 Innovation Centers, including the Industry X hubs in Modena and Turin and the Digital Platform, Cloud, and Government Innovation Center in Rome, complemented by four Advanced Technology Centers in Southern Italy (Naples, Bari, Cagliari, and Cosenza) that integrate design, prototyping, and end-to-end delivery capabilities. This infrastructure enables Accenture to support nearly all major industrial and banking groups across 13 industries and four divisions (Strategy & Consulting, Song, Technology, and Operations), powered by a broad ecosystem of partners. Italy remains the fourth-largest country within Accenture in terms of workforce and revenue, sustained by a hiring rate of approximately 3,500 new professionals per year.

This scientific study has been facilitated by the Strategy & Consulting division that supports public and private organizations in defining and implementing high-impact business, technology, and operating strategies.

3.2 Experimental Approach

A total of 330 consultants were initially recruited for the study. Of these, 291 (88.2%) completed the experimental protocol and were included in the final analysis. The experiment was designed to reflect the organisation's existing structures and working practices. A total of 291 consultants participated in the study; 56% were female, and 44% were male. The sample is predominantly young (majority under 34); participants are highly educated, with a large majority holding a master's degree. The dataset includes comprehensive information on participants' professional context, including their business unit, team, job level, years of experience at Accenture, and whether their role is primarily technological or functional. Skills and competencies were treated as distinct from formal roles and functions.

Participants were randomly assigned to teams with different configurations based on their seniority level (Analyst, Consultant, or Manager) and the functional unit they belonged to (technical or functional). Team composition also reflected varying levels of organisational experience, with Managers typically exhibiting higher tenure and experience than Analysts, who generally had lower tenure and experience within the organisation. Teams consisted of either a single individual or two individuals, who could hold the same or different roles within the organisation. In total, nine team types were defined (see Table 1), ensuring a combination of functional and cross-functional collaboration aligned with Accenture's actual organisational arrangements.



Tab. 1: Sample Distribution by Team Composition

Team composition	**n**
Individual - Analyst	41
Individual - Consultant	40
Individual - Manager	20
Team - Analyst & Analyst	36
Team - Consultant & Consultant	46
Team - Manager & Manager	16
Team - Analyst & Consultant	56
Team - Analyst & Manager	20
Team - Consultant & Manager	16
TOTAL	**291**

Source: our elaboration

Participants were assigned to one of three work conditions (see Figure1): (1) working individually, (2) working in a homogeneous team, or (3) working in a heterogeneous team.

Fig. 1: Treatment Matrix

Source: our elaboration. Note: This figure illustrates the experimental design, which includes a between-condition comparison (individual vs. team) and a within-team comparison (homogeneous vs. heterogeneous teams), all working with AI assistance.

All teams could use generative AI tools, including ChatGPT, Microsoft Copilot, and Amethyst Studio, an agent-based AI platform developed by Accenture. Amethyst leverages advanced large language models (LLMs) from OpenAI's GPT (Generative Pre-trained Transformer) family. The internal platform is designed to support a broad spectrum of activities. This approach mirrored both the typical working practices of consultants, who autonomously select the AI tools they consider most effective, and Accenture's broader bottom-up organisational approach, which allows employees the freedom to choose the tools best suited to their tasks.

Tab. 2: AI tools used during the experiment.

GenAI tool used	n	Proportion
Accenture Copilot 365	226	51.36%
Amethyst Studio	59	13.41%
Accenture ChatGPT Enterprise	56	12.73%
ChatGPT	39	8.86%
Reinvention Console	37	8.41%
Other tools	23	5.22%

Source: our elaboration

The experiment was conducted over a single day, starting at 8:30 a.m. and concluding at 5:00 p.m. Throughout the day, research staff from both Accenture and the University of Turin were present to assist participants with practical and technical issues. The day began with a one-hour training session on prompting techniques led by the University of Turin Research team. This session focused not only on effective interaction with generative AI tools but also on formulating questions that support idea generation and project structuring, including evaluating multiple perspectives and identifying potential practical pitfalls. This standardised training ensured that all participants had comparable familiarity with

GenAI tools. Following this session, the use case was presented, and the teams were given time to ask questions and clarify any remaining doubts.

The experiment was conducted remotely via Microsoft Teams. Within each team, one member was designated to share the screen, interact directly with the GenAI tools, and submit the final solution. This configuration was designed to allow both team members to contribute in real time while maintaining a consistent and controlled workflow.

Following the training session, participants received a use case to be developed throughout the day. The use case was aligned with the types of projects consultants typically encounter in their professional activities, and the organisation provided all relevant background information and materials necessary for its development.

4. Collected data and outcome

The data collection occurred in multiple stages. All data were collected in compliance with privacy and confidentiality requirements, ensuring the protection of participants' personal information. Prior to the training session, participants completed a baseline survey designed to collect individual-level information. Following the experiment, participants completed a post-experiment survey assessing their interactions with AI and its perceived impact on task execution, skill development, emotional responses, solution quality, and team dynamics.

During the experimental period, all prompts submitted to GenAI tools, the corresponding AI-generated responses, and team member interactions were transcribed. This data collection enabled an in-depth analysis of the relationships among AI usage, team interactions, and the resulting solutions, as well as the dynamics among team members. Following the submission of the deliverables, a post-activity questionnaire was administered to collect feedback and examine participants' interactions with AI, as well as its perceived impact on task execution, skill development, emotional responses, delivery outcomes, and team management. The study thus draws on three primary data sources: (1) a pre-experiment survey, (2) a post-experiment survey, and (3) transcripts of AI interactions and team communications.

The pre-experiment survey (1) consists of 330 unique participants (after removing four duplicates identified by email address). The dataset comprises 37 variables capturing demographic characteristics (gender, age, education, and job level), professional background (years of experience, skills, and role), and baseline perceptions of AI technology. In addition, the pre-survey includes measures of participants' emotional states prior to the experiment (e.g., enthusiasm, anxiety, and stress), which serve as control variables to assess the emotional changes induced by the experimental task.

The post-experiment survey (2) collected 291 responses, corresponding to a retention rate of 88.2%. Thirty-nine participants completed only the pre-survey, resulting in an attrition rate of 11.8%. The post-survey contains 39 variables, including experimental group assignment, deliverable identifiers, patterns of GenAI tool usage, perceived solution quality, measures of team coordination, and post-experiment emotional states.

4.1 Experts and Evaluation

Each solution received three independent single-blind evaluations to reduce bias and enhance reliability. The evaluation dataset consists of 586 expert assessments. Evaluators—senior Accenture Italia executives with business and technical expertise—rated each deliverable on five dimensions using 10-point scales: quality (clarity, structure, and coherence), impact (potential to generate value), novelty (originality and innovation), feasibility (realistic implementability), and technical sophistication (technical vs. business orientation).

5. Results

Participants were assigned to one of three work conditions: (1) working individually, (2) working in a homogeneous team, or (3) working in a heterogeneous team.
To estimate the causal effect of working in a team – relative to working individually – we estimate a series of linear regression models, one for each outcome variable. There are five basic outcome variables – quality, feasibility, novelty, impact, and technicality – which the evaluators use to measure the participants' deliverables. In addition, we construct three summary performance scores designed to capture overall task performance using different aggregation approaches.

Score 1, a composite performance index, is constructed using principal component analysis (PCA). Due to the fact that the five performance measures are positively correlated (e.g., higher quality may co-occur with higher feasibility), PCA offers a data-driven method for summarising the shared variance across these dimensions. This score is a linear combination of the five measures that captures the largest share of the total variance and can be interpreted as an overall performance index. Score 2 is simply the average of the five performance measures for each observation. Some analysts might prefer this to the PCA-based score, since it is easy to understand and interpret. Finally, score 3 is an average performance score based on three core dimensions - quality, impact, and feasibility - excluding technical sophistication and novelty. By excluding dimensions that may be more peripheral to the core task or potentially more subjective, this measure checks whether the main findings hold under a more conservative definition of performance.

Consistent patterns across these alternative indices increase confidence that our findings are not driven by a specific measurement choice.

5.1 First Analysis | Performance: Team with AI vs Individual with AI

Given the relatively small sample sizes in the two team conditions, we collapse homogeneous and heterogeneous teams into a single "team" category in the first analysis. This approach allows us to compare outcomes between two conditions: (i) working individually and (ii) working in a team. Dummy variables are constructed to represent these experimental conditions in the empirical analyses.
Each regression takes the following form:

$$Y_i = \beta_0 + \beta_1 \text{Team}_i + \varepsilon_i$$

where Y_i is the outcome of interest for observations i, Team_i is a binary indicator equal to 1 if the observation is for a pair of participants assigned to work as a team, and 0 if the observation is for a participant assigned to work individually. In this specification, the intercept β_0 represents the average outcome for individuals, while the coefficient β_1 captures the causal effect of team assignment. The error term ε_i reflects unobserved idiosyncratic variation. We used robust standard errors, which help deal with potential heteroskedasticity in the error term across observations.

Tab. 3: Evaluations of Teams vs. Individuals

	(1) Score 1	(2) Score 2	(3) Score 3	(4) Quality	(5) Technicality	(6) Impact	(7) Novelty	(8) Feasibility
Team	0.375	0.185	0.241*	0.205	0.177	0.149	0.0263	0.370**
	(0.260)	(0.127)	(0.129)	(0.151)	(0.197)	(0.143)	(0.150)	(0.147)
Const.	-0.182	6.201**	6.403**	6.391**	5.715**	6.465**	6.083**	6.353**
	(0.191)	(0.0932)	(0.0981)	(0.115)	(0.141)	(0.104)	(0.107)	(0.109)
N	196	196	196	196	196	196	196	196

Source: our elaboration
Note: Standard errors in parentheses * p < 0.10, ** p < 0.05

Table 3 summarises the results of eight separate regression analyses estimating the causal effect of being assigned to work in a team, relative to working individually, on performance and efficiency outcomes. The results show that team assignment is positively associated with performance across all outcome measures; however, statistical significance varies by dimension. The strongest and most robust effect emerges for feasibility, where teams significantly outperform individuals ($\beta = 0.370$, $p < 0.05$). Team effects on the composite performance indices are positive and marginally significant for Score 1 (PCA-based index) and Score 3 (core-dimension average), suggesting that teams tend to achieve higher overall performance when performance is measured holistically and in ways that might reduce measurement errors. In contrast, team assignment does not yield statistically significant improvements in individual performance dimensions such as quality, impact, novelty, or technical sophistication.

5.2 Second analysis | Performance: Individual versus Homogeneous and Heterogeneous team

In the second analysis, we compare all three conditions – homogeneous teams, heterogeneous teams, and individuals. Again, we run 8 regressions, one for each of the performance variables or indices.

$$\text{Outcome} = \beta_0 + \beta_1(\text{homogeneous team}) + \beta_2(\text{heterogeneous team}) + \varepsilon_i$$

Tab. 4: Evaluations of Homogeneous and Heterogeneous Teams vs. Individuals

	(1) Score 1	(2) Score 2	(3) Score 3	(4) Quality	(5) Technicality	(6) Impact	(7) Novelty	(8) Feasibility
Team	0.603*	0.293*	0.377**	0.384**	0.258	0.303*	0.0740	0.443**
Homog	(0.329)	(0.161)	(0.163)	(0.185)	(0.234)	(0.180)	(0.186)	(0.186)
Team	0.131	0.0711	0.0968	0.0147	0.0898	-0.0161	-0.0245	0.292*
Heterog	(0.292)	(0.144)	(0.142)	(0.170)	(0.248)	(0.162)	(0.181)	(0.164)

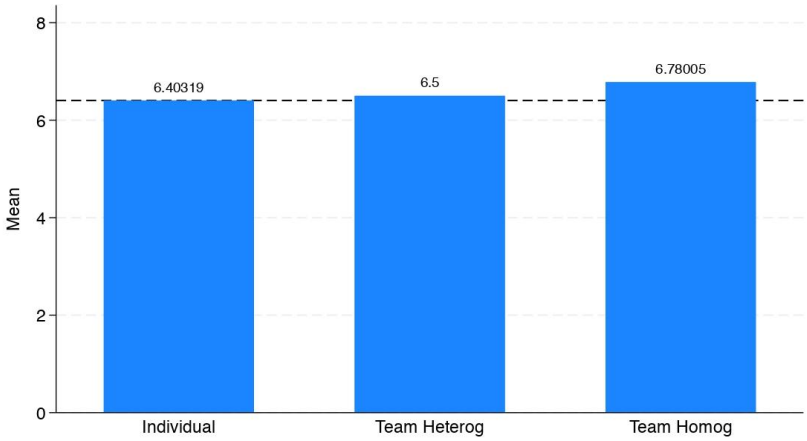
	(0.192)	(0.0934)	(0.0983)	(0.115)	(0.141)	(0.105)	(0.108)	(0.109)
N	196	196	196	196	196	196	196	196

Source: our elaboration
Note: Standard errors in parentheses * $p < 0.10$, ** $p < 0.05$

The results reveal a clear asymmetry between homogeneous and heterogeneous teams. Homogeneous teams consistently outperform individuals across several performance dimensions. In particular, homogeneous team assignment is associated with significantly higher performance on the core composite index (Score 3), quality, and feasibility, with additional marginally significant improvements observed for impact and the broader performance index (Score 2). These findings indicate that performance gains from teamwork are concentrated in teams composed of members with similar seniority levels.



In contrast, heterogeneous teams show little evidence of performance advantages relative to individuals. Across most outcome measures—including quality, impact, novelty, and technical sophistication—the coefficients for heterogeneous teams are small and statistically insignificant. An exception is feasibility, where heterogeneous teams exhibit a positive but weaker effect relative to homogeneous teams. Taken together, this three-way comparison demonstrates that team composition is a critical boundary condition for AI-assisted teamwork. While homogeneous teams yield robust improvements over individual work, heterogeneous teams fail to deliver comparable performance gains. These results help reconcile mixed findings in the literature by showing that the team-based advantages of AI are not universal but depend strongly on team structure.

5.3 Third analysis | Emotions: Individual versus Team

Concerning emotional outcomes for individuals and teams, we examined three positive emotions – enthusiasm, energy and excitement – and a composite measure of overall positive emotions (Table 5), as well as three negative emotions – anxiety, frustration and stress – and a composite measure of overall negative emotions (Table 6) using regression analysis.

Although the coefficients for enthusiasm ($\beta = 0.126$, SE = 0.170) and energy ($\beta = 0.179$, SE = 0.181) are positive (Table 5), they are small in magnitude and statistically insignificant. Excitement is similarly unaffected ($\beta = -0.050$, SE = 0.190). These findings suggest that working in teams does not systematically enhance positive affect relative to working alone.

In contrast, Table 6 reveals a markedly different pattern for negative emotions. For those working alone, frustration and stress increased significantly during the course of the experiment. Those working in teams, however, reported significantly lower increases in frustration ($\beta = -0.591$, SE = 0.225, $p < 0.05$) and stress ($\beta = -0.463$, SE = 0.198, $p < 0.05$). The composite measure of negative emotions is also significantly negative in the team condition ($\beta = -0.458$, SE = 0.174, $p < 0.05$). In sum, the results suggest an asymmetric emotional effect of teamwork. Team participation does not increase positive emotional activation but significantly reduces negative affective states. These

patterns suggest that teams may primarily serve as emotional buffers, mitigating stress and frustration, rather than as mechanisms that amplify enthusiasm or excitement.

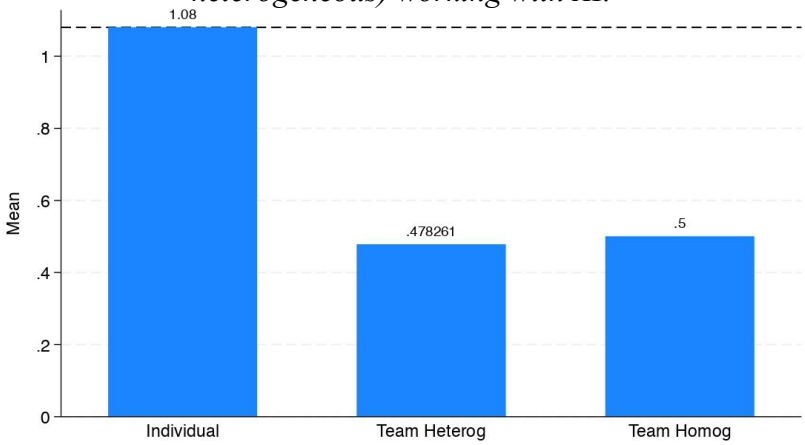
Team Homog	-0.436**	-0.580**	-0.496**	-0.515**
	(0.215)	(0.252)	(0.224)	(0.194)
Team Heterog	-0.163	-0.602**	-0.428*	-0.398**
	(0.222)	(0.262)	(0.227)	(0.202)
Const.	0.250	1.080**	0.700**	0.677**
	(0.160)	(0.190)	(0.166)	(0.147)
N	289	290	290	289

Source: our elaboration
Standard errors in parentheses* $p < 0.10$, ** $p < 0.05$



Collectively, the results reveal a clear asymmetry in the emotional impact of teamwork. Neither homogeneous nor heterogeneous teams significantly increase positive affect. However, both team structures significantly reduce negative emotional experiences relative to individual work. Importantly, homogeneous teams exhibit statistically significant reductions across all negative emotion measures, whereas heterogeneous teams show weaker and partially significant effects, especially for anxiety. This suggests that while collaboration in general mitigates stress-related emotions, emotional stabilization may be more pronounced in homogeneous teams. These findings indicate that the primary emotional benefit of teamwork lies not in amplifying positive affect, but in buffering against adverse emotional states.Team composition appears to matter primarily for the magnitude and consistency of reductions in negative emotions rather than for the enhancement of positive ones.

6. Discussion, conclusion and future research questions

Through our analysis, we address two central questions concerning how team composition influences performance outcomes and emotional dynamics in AI-enabled task execution. With regard to performance, our findings allow us to articulate three theoretical contributions to the literatures on exploration–exploitation, team diversity, and human–AI collaboration.

First, team-based advantages cannot be assumed to generalize across all forms of team composition relative to individual work. Our results suggest that GenAI reweights the trade-off between teams and individuals by reducing the exploratory premium traditionally associated with heterogeneous teams and narrowing the performance gap between heterogeneous teams and individuals (see Fig. 3). Prior theory positions heterogeneous teams as better suited to exploration and homogeneous teams to exploitation. Our findings suggest that GenAI effectively decouples these two functions: by handling the exploratory dimension of the task — generating diverse alternatives, broadening the solution space, and providing rapid synthetic variety — AI shifts the team's core challenge entirely toward exploitation, convergence, and execution. In this reconfigured division of cognitive labor, homogeneous seniority becomes an amplifying factor rather than a constraint, because it reduces the status-based frictions and divergent planning horizons that would otherwise impede integrative alignment. This represents a meaningful extension of March's framework: the exploration–exploitation trade-off, when mediated by GenAI, is no longer symmetrically distributed between team diversity types, but is instead functionally reallocated between the human team and the AI system.

Second, the Categorization-Elaboration Model (van Knippenberg et al., 2004) predicts that heterogeneous teams should outperform homogeneous ones on complex tasks by virtue of broader information elaboration. Our findings do not confirm this prediction in AI-enabled contexts: homogeneous teams significantly outperform both individuals and heterogeneous teams on feasibility, quality, and impact, while heterogeneous teams fail to demonstrate statistically significant performance advantages relative to individuals working alone with AI. This result is not simply an anomaly — it can be theoretically accounted for by the displacement of the mechanism through which diversity traditionally operates. When GenAI externalizes ideational variety, the informational breadth argument for heterogeneity loses traction, while the coordination costs associated with seniority disparity (Harrison & Klein, 2007) remain. Diversity's traditional advantage is thus conditional on a scarcity of ideas that AI removes.

Third, our study advances the human–AI teaming literature by opening the black box of human team composition in AI-augmented settings. Prior work in this stream has largely compared human-

only teams to human-AI configurations (McNeese et al., 2021; Li et al., 2024; Dell'Acqua et al., 2025), treating the human component of the team as homogeneous or unexamined. By holding AI access constant and varying human composition, we demonstrate that seniority homogeneity functions as a boundary condition for the performance benefits of AI-enabled teamwork: team-based advantages over individuals are robust and significant for homogeneous teams, but absent for heterogeneous ones. This finding underscores that the value of human–AI collaboration is not determined solely by access to AI, but is moderated by the structural properties of the human team through which AI outputs are processed, evaluated, and integrated. Future theoretical development of human–AI teaming models should therefore incorporate team composition — and particularly seniority alignment — as a first-order variable, rather than treating it as a contextual nuance.

These findings also carry significant organizational implications. First, organizations may need to fundamentally rethink optimal team size and composition to achieve specific performance objectives. The fact that AI-enabled individuals can perform at levels comparable to heterogeneous teams suggests opportunities for more flexible, smaller, and potentially more efficient organizational structures.

Importantly, our results also reveal a significant emotional dimension. Seniority-homogeneous teams exhibit statistically significant reductions across all negative emotion measures, whereas heterogeneous teams display weaker and only partially significant effects, particularly with respect to anxiety. These findings suggest that while collaboration generally mitigates stress-related emotions, emotional stabilization is more pronounced in homogeneous teams. This suggests that seniority alignment operates not only as a coordination mechanism but also as a source of psychological safety in AI-enabled work — a finding that connects to broader arguments about the role of team climate in buffering technostress (Alkhayyal & Bajaba, 2024; Murphy, 2025) and points toward emotional stabilization as a potential mediating mechanism linking team composition to performance outcomes.

Taken together, the results indicate that AI should no longer be conceptualized as a passive tool, but rather as a dual-purpose teammate that functions as an active collaborator—supporting not only performance outcomes but also the stabilization of anxiety and other negative emotional states.
Several important caveats shape the interpretation of these findings. First, although our participants were relatively experienced in AI prompting techniques and received dedicated prompt training at the beginning of the experiment, we are observing a technology that is still in the early stages of organizational adoption. As users develop more sophisticated AI interaction strategies and as AI systems continue to evolve, the advantages of AI-enabled work may increase substantially over time.

We also acknowledge two key limitations. First, our experiment relied on one-day virtual collaborations, which do not fully capture the day-to-day complexities of organizational teamwork, such as prolonged coordination challenges, iterative feedback cycles, and cumulative relational dynamics. Second, we examined small, two-person teams specifically constructed for the experiment. In real organizational contexts, collaboration often involves larger teams operating over extended periods, with pre-existing relationships, role histories, and more complex humans interaction patterns. These factors may influence both performance and emotional dynamics in ways that our experimental design could not fully replicate.

Our findings open several promising directions for future research. In particular, they underscore the emotional benefits of teamwork in AI-enabled settings, reinforcing the view that performance outcomes cannot be meaningfully separated from affective experience. Future studies should investigate whether emotional comfort predicts the depth and quality of collaborative AI engagement. For example, do lower levels of frustration and stress foster more iterative and exploratory interaction with AI systems, thereby indirectly enhancing feasibility and execution quality? In this perspective, how emotional stabilization may operate as a key mechanism linking team composition to performance under AI-enabled conditions.

In addition, unlike many prior experiments relying on a single large language model, real-world teams often combine multiple AI systems. Future studies should investigate whether the use of multiple AI tools enhances performance and whether such effects depend on skill homogeneity.
Equally important is the systematic study of failure modes. Under what conditions does skill heterogeneity undermine AI-enabled collaboration? Potential mechanisms may include over-reliance on domain experts, underutilization of AI capabilities, anchoring effects, or coordination breakdowns. Understanding these negative dynamics is just as critical as examining positive effects in order to develop robust design principles for AI-assisted teamwork.

Finally, contextual moderators warrant greater attention. Organizational AI maturity, hierarchical norms, and broader cultural attitudes toward authority and technology may significantly shape the effectiveness of skill-aligned teams. Advancing research along these dimensions will be critical for building a comprehensive theory of human–AI collaboration and its impact on organizational structures, operations, and strategy.

The Orchestration Imperative: Completing the Relational Paradigm Shift Ahead of the Emerging Agentic Economy

ELISABETTA HORVATH, ANTONIO SPECCHIA, SIMONETTA ZAMPARELLI

Abstract

Framing of the research: *In 1994, Grönroos declared a paradigm shift from transactional to relationship marketing. Three decades later, that revolution remains incomplete: entire stakeholder categories — most notably job applicants — were left in transactional systems designed for volume processing rather than relationship building. The emerging agentic economy makes this incompleteness urgent. As AI agents take on mediating roles in stakeholder interactions, organisations face two compounded risks: transactional systems that produce waste at machine speed, and the progressive erosion of the relational capabilities that justify human involvement in consequential decisions. This paper examines what we call the "orchestration imperative": the strategic case for extending the relational paradigm into talent acquisition before the agentic economy embeds transactional logic by default.*

Purpose of the paper: *The paper offers two complementary contributions. First, through cross-sector documentary analysis of recent AI deployments in insurance, banking, healthcare, and legal services, we identify what we term the orchestration paradigm — a pattern of human-AI collaboration in which AI does not substitute the human operator but empowers a capable human kept in command of consequential decisions. Second, we propose Applicant Relationship Management (ARM) as a framework that combines the orchestration paradigm with Grönroos's relational paradigm, extending both into the domain of talent acquisition.*

Methodology: *This is a conceptual contribution drawing on three analytical components: theoretical synthesis of five established streams (Grönroos on relationship marketing; Packard on efficiency without purpose; Harari on cognitive opacity; Kahneman, Sibony and Sunstein on judgment noise; Meijerink et al. on algorithmic HRM); cross-sector documentary analysis using structured thematic pattern analysis across four sectors; and regulatory analysis of the EU AI Act. We do not claim mixed-method status in the conventional empirical-design sense; the empirical components are used to illustrate and inform the conceptual argument, not to test it.*

Findings: *The paper offers three sets of conceptual propositions. Cross-sector: organisations deploying AI for stakeholder-facing processes increasingly adopt human-in-the-loop governance, suggesting orchestration, not automation, as the emerging design logic. Framework: ARM articulates four tenets addressing relationships, opacity, noise reduction, and the orchestration-versus-augmentation distinction; an Agent Triad of Human Operator, AI Agent, and Human Stakeholder; a "capable orchestrator" role; and a compensatory rather than multiple-hurdle evaluation architecture. Regulatory: the EU AI Act's high-risk requirements for employment AI structurally align with ARM's design principles, supporting independent convergence toward orchestration norms.*

Research limits: *The cross-sector analysis is illustrative, drawing on recent corporate communications, industry reports, and institutional publications; longitudinal validation is needed. The ARM framework requires empirical testing across industries, cultures, and organisational contexts. The atrophy argument regarding the erosion of relational capacity, while logically grounded, requires longitudinal investigation to establish causal mechanisms.*

Practical implications: *The orchestration imperative reframes the strategic question for AI adoption from "how can AI process faster?" to "how can AI help build better stakeholder relationships?" In recruitment, ARM shifts talent acquisition from transaction processing to relationship orchestration — and aligns organisations with the EU AI Act's high-risk requirements for employment AI.*

Originality of the paper: *The paper's contribution is in the conceptual integration and extension of established streams, not in the development of new theory. It synthesises an emerging cross-sector pattern (the orchestration paradigm), extends Grönroos's relational paradigm into the under-theorised domain of talent acquisition through the ARM framework, and responds to recent calls in the recruitment and selection literature (Mori et al., 2025) for stakeholder integration in AI-mediated hiring.*

Keywords: *human-AI collaboration; orchestration paradigm; agentic economy; applicant relationship management; relationship marketing; human-in-the-loop; EU AI Act; stakeholder management; talent acquisition*

1. Introduction

1.1 The Agentic Economy arrives

The deployment of artificial intelligence agents in organisational decision-making has moved from speculation to operational reality. In January 2026, Gartner predicted that by 2028, 33% of enterprise

software applications would include agentic AI, up from less than 1% in 2024. The same month, at the World Economic Forum in Davos, Anthropic CEO Dario Amodei estimated that 50% of entry-level knowledge work could be performed by AI within three years (Amodei, 2026), while DeepMind CEO Demis Hassabis countered that new potentially more meaningful categories of work would emerge in parallel (World Economic Forum, 2026). What neither disputed was the fundamental premise: AI agents are becoming economic actors.

This transformation is particularly acute in talent acquisition, where algorithmic decision-making intersects with high-stakes human outcomes at scale. Yet the introduction of AI agents into this domain raises a question that extends beyond recruitment: when algorithms participate in decisions about human stakeholders, does the governing logic of the system, transactional or relational, determine the quality of the outcome?

1.2 The Efficiency Trap

The dominant paradigm in talent acquisition since the 1990s has been the Applicant Tracking System, designed to solve a volume problem: too many applications, too few recruiters. The logic was explicitly transactional: process faster, filter more efficiently, reduce cost-per-hire. By conventional metrics, ATS succeeded. Processing times fell, recruiter workloads became manageable, and organisations could handle application volumes that would overwhelm manual systems.

Yet this efficiency has produced what Vance Packard (1960) would recognise as a familiar pathology: waste-making through purposeless acceleration. The ATS paradigm created a self-reinforcing cycle: easier application processing generated faster and unexplained rejections, which encouraged applicants to adopt volume strategies relying on the law of large numbers. This volume increase demanded more aggressive filtering and even faster rejection. Conversely, this loop significantly reduced candidate quality signals, applicants investing less in each application, recruiters spending less time on each evaluation, which, in turn, required yet more applications to achieve the same hiring outcomes. The system optimised for throughput while degrading the relationship it was meant to facilitate. When AI agents are introduced into this architecture, they risk doing what Packard warned against, making waste at unprecedented speed.

The parallel to Packard's original critique is instructive. He argued that industrial efficiency, divorced from human purpose, produces sophisticated systems for creating things nobody needs. In recruitment, the ATS produces sophisticated systems for rejecting people nobody truly evaluated. The question is not whether AI can accelerate this process, it manifestly can, but whether acceleration of a flawed logic constitutes progress.

The risk extends beyond inefficiency. The transactional paradigm encourages a minimum effort logic, from organisations that reduce evaluation to algorithmic filtering, and from applicants who reduce candidacy to mass-submitted CVs. When AI agents enter this dynamic, they offer a seductive acceleration of minimum effort on both sides. But the consequence is a progressive atrophy of the relational capabilities, contextual judgment, empathic evaluation, trust-building, that arguably constitute humanity's unique differentiator from machines. If organisations delegate relationships to algorithms, and individuals delegate self-presentation to AI-generated applications, both parties hollow out the very capacities that justify human involvement in consequential decisions.

This creates a paradox at the heart of the agentic economy. The argument for human-in-the-loop governance rests on the assumption that humans bring relational intelligence that AI cannot replicate. But if transactional systems have already eroded that intelligence through decades of minimum effort incentives, the assumption may not hold. The orchestration imperative is therefore not merely a design preference, it is a use-it-or-lose-it proposition. Either organisations invest in relational capacity now, ahead of the emerging agentic economy, or they risk discovering that the human contribution they assumed was irreplaceable has been quietly abandoned through disuse.

1.3 Research Question and Contributions

This paper addresses a central question: *How can organisations preserve and strengthen relational capacity in stakeholder-facing processes before the emerging agentic economy renders its absence irreversible?*

The argument proceeds from a single conceptual gap. In 1994, Grönroos proposed a paradigm shift in marketing — from transactional to relational logic — that has since transformed how organisations engage customers, suppliers, communities, and other stakeholders. One stakeholder category was left almost entirely outside this transformation: job applicants. The systems built to manage them, applicant tracking systems above all, encode transactional logic in their architecture: receive, filter, rank, reject, forget. Three decades into the relational paradigm shift, the most consequential stakeholder relationship of all — the one through which an organisation constitutes itself — remains governed by the very logic Grönroos's tradition rejected everywhere else.

This gap has not gone unrecognised within the recruitment and selection literature, but it has been articulated in different terms. The most recent systematic review of AI in R&S (Mori et al., 2025), synthesising 120 studies, identifies stakeholder integration as one of three perspectives the field requires to move beyond efficiency-driven adoption — alongside sustainable AI-HRM and information asymmetry management. Their analysis ends at the call. ARM responds to it by extending the relational paradigm Grönroos initiated into the domain it has not yet reached.

The agentic economy makes this extension urgent and, for the first time, economically viable. As AI agents assume mediating roles in stakeholder interactions (Section 1.2), the governing logic embedded in these systems — transactional or relational — will determine outcomes at scale and speed previously unattainable. The same AI capability that threatens to deepen transactional logic also enables relational approaches that were prohibitive in cost when sustained by human evaluators alone.

The paper offers two complementary contributions. The first is empirical-conceptual: through cross-sector analysis of recent AI deployments in insurance (Allianz, 2026), banking (BNY Mellon, DBS), healthcare (FDA and HHS frameworks), and legal services (A&O Shearman, 2025), we identify what we term the orchestration paradigm — a pattern of human-AI collaboration in which AI does not substitute the human operator but empowers a capable human kept in command of the decision. The second is integrative: we propose Applicant Relationship Management (ARM) as a framework that combines the orchestration paradigm with Grönroos's relational paradigm, extending both into the domain of talent acquisition. ARM draws together insights from relationship marketing (Grönroos, 1994), efficiency critique (Packard, 1960), epistemological symmetry (Harari, 2017), behavioural economics (Kahneman et al., 2021), algorithmic HRM (Meijerink et al., 2021), and the field's own most recent ethical synthesis (Mori et al., 2025). ARM's contribution lies in the conceptual integration and extension of these established streams — not in the development of new theory — and the framework is currently under empirical study in real cases.

1.4 Paper Structure

The paper proceeds as follows. Section 2 describes the research methodology. Section 3 establishes the theoretical foundations through four intellectual streams: Packard's efficiency-effectiveness distinction, Harari's argument for epistemological humility regarding both human and artificial cognition, Kahneman et al.'s research on decision noise, and the emerging literature on human collaboration as the distinctive human capacity. Section 4 introduces the ARM framework for the agentic economy, presenting its four principles, the Agent Triad and the capable orchestrator concept. Section 5 applies the framework to recruitment as an agentic ecosystem, including cross-sector evidence of the orchestration pattern. Section 6 discusses implications for management in the agentic economy, including the new competencies orchestration demands and regulatory alignment with the EU AI Act. Section 7 acknowledges limitations and proposes a future research agenda. Section 8 concludes with implications for researchers, practitioners, and policymakers.

2. Research Methodology

This paper employs a mixed-method conceptual approach combining three analytical components: theoretical synthesis, cross-sector documentary analysis, and regulatory analysis. The methodology is designed to address a phenomenon — the emergence of orchestration patterns in AI-mediated stakeholder processes — that is too recent for longitudinal empirical study but too consequential to await one.

2.1 Theoretical Synthesis

The paper's primary analytical method is the integration of five established theoretical streams into a unified framework for human-AI collaboration in talent acquisition. The streams were selected not for comprehensiveness but for complementarity: each addresses a distinct dimension of the problem that the others leave unresolved.

Grönroos (1994) provides the paradigm-level argument — the shift from transactional to relational logic — and the identification of its incompleteness. Packard (1960) supplies the critique of efficiency divorced from purpose, explaining why transactional systems produce waste rather than merely underperforming. Harari (2017) establishes epistemological symmetry between human and artificial opacity, reframing the trust question from a binary choice to a design challenge. Kahneman, Sibony, and Sunstein (2021) expose the noise problem in human judgment and, by extension, in AI systems, grounding the case for collaborative rather than substitutive approaches. The collaboration literature contextualises human-AI partnership within humanity's broader capacity for productive coordination with diverse forms of intelligence.

The synthesis follows abductive logic: iterative dialogue between theoretical propositions and observable patterns. Each ARM tenet is traceable to a specific theoretical foundation, with derivation paths made explicit in Section 4.2.

2.2 Cross-Sector Documentary Analysis

The paper's second component examines recent AI deployments in four sectors — insurance, banking, healthcare, and legal services — to identify common design patterns in human-AI collaboration for stakeholder-facing processes.

Source material. The analysis draws on corporate communications (partnership announcements, press releases, media statements), industry reports (Capgemini 2026, Gartner 2025), institutional publications (BNY Institute 2026), and trade press coverage. These are documentary sources, not primary data. The analysis does not claim access to internal deployment metrics, proprietary outcome data, or direct observation of how these systems operate in practice.

Sector selection. The four sectors were chosen on three criteria: (a) documented deployment of AI agents in processes involving direct stakeholder decisions (claims, credit, diagnosis, legal counsel); (b) availability of public documentation describing the human-AI collaboration architecture, not merely the AI capability; and (c) temporal relevance — deployments announced or significantly expanded within the 2024–2026 period, reflecting the current state of agentic AI rather than earlier-generation automation. The selection does not claim to be exhaustive. Other sectors present analogous dynamics but were excluded to maintain analytical depth within conference paper constraints.

Analytical approach. Each sector case was examined for the presence or absence of three design features: (a) structured human oversight of AI-generated recommendations, as distinct from post-hoc exception handling; (b) explicit stakeholder-facing accountability mechanisms (explanation, appeal, dialogue); and (c) system architecture that allocates tasks based on complementary human-AI capability rather than cost-driven substitution. A summary scorecard across the four sectors is provided in Table 1. The convergence of these features across independently evolving sectors constitutes the basis for identifying what the paper terms the "orchestration paradigm."

Limitations of documentary analysis. Corporate communications describe intended designs, not verified outcomes. Organisations have strategic incentives to present their AI deployments as

responsible, human-centred, and stakeholder-friendly, regardless of operational reality. The paper cannot rule out mimetic isomorphism — the possibility that cross-sector convergence reflects conformity to a legitimising narrative rather than independent discovery of a superior design. The cross-sector material is therefore presented as indicative of an emerging pattern, not as proof of orchestration's superiority. The paper's argument does not rest on these cases alone; it rests on the theoretical synthesis that the cases illustrate.

Table 1. *Cross-sector design feature scorecard. "Yes" indicates the feature is explicitly described in source documents; "Yes (limited)" indicates the feature is referenced but not fully elaborated.*

Sector	***Key documents reviewed***	***Human oversight***	***Stakeholder accountability***	***Complementary allocation***
Insurance	*Allianz–Anthropic partnership (2026); Capgemini Research Institute (2026)*	*Yes*	*Yes*	*Yes*
Banking	*DBS Bank (2025); BNY Institute (2026); Capgemini Research Institute (2026)*	*Yes*	*Yes (limited)*	*Yes*
Healthcare	*U.S. HHS AI Strategy (2025); FDA governance frameworks*	*Yes*	*Yes*	*Yes*
Legal services	*A&O Shearman–Harvey (2025)*	*Yes*	*Yes (limited)*	*Yes*

2.3 Regulatory Analysis

The third component examines the European Union's Artificial Intelligence Act (European Parliament and Council, 2024) as the most comprehensive regulatory framework governing AI deployment in employment contexts. The analysis focuses specifically on the Act's high-risk classification of employment AI and its operational requirements: human oversight, transparency, explicability, data governance, and the rights of affected persons.

The regulatory analysis serves two purposes. First, it identifies structural alignment between the Act's requirements and the ARM framework's design principles, suggesting that regulatory and theoretical thinking are converging independently toward orchestration norms. Second, it provides the compliance context within which ARM's practical implications should be understood: the framework is not only theoretically grounded but addresses obligations that organisations operating in or serving EU markets will face under the AI Act's Annex III high-risk regime, with the original 2 August 2026 application date still legally binding while a proposed postponement is in trilogue (analysed in Section 6.2).

The paper acknowledges a potential circularity: if the ARM framework was developed with awareness of the AI Act's requirements, alignment between them is partly by construction. We address this transparently. The four ARM tenets were derived from their respective theoretical foundations (Packard, Harari, Kahneman, Grönroos) and the alignment with the AI Act was identified subsequently, not designed prospectively. The convergence reflects shared underlying logic — that consequential AI-mediated decisions about people require human oversight, transparency, and relational accountability — rather than reverse-engineering from regulatory requirements.

3. Theoretical Foundations

The ARM framework for the agentic economy draws on four distinct intellectual streams that, when synthesised, challenge the assumptions underlying current approaches to AI deployment in stakeholder-facing processes. Each stream contributes a necessary dimension: Packard provides the critique of efficiency without purpose; Harari supplies epistemological humility regarding both human and artificial cognition; Kahneman et al. expose the unreliability that relationship, not replacement, can address; and the collaboration literature explains why human-AI partnerships can exceed either intelligence operating alone.

3.1 The Waste Makers: Efficiency vs Effectiveness (Packard, 1960)

In 1960, Vance Packard published *The Waste Makers*, a systematic critique of how American industry had perfected producing things people did not need. His central argument was deceptively simple: efficiency is not effectiveness. A system can be extraordinarily efficient at producing waste. The faster and cheaper it operates, the more waste it generates, and the harder it becomes to question the underlying logic, because the metrics of efficiency all point upward.

Packard identified three mechanisms of institutional waste-making: planned obsolescence (designing products to fail), perceived obsolescence (persuading consumers that functional products are inadequate), and systemic overproduction (manufacturing beyond genuine demand because the production system requires continuous throughput). In each case, the organisation optimises an internal metric, units produced, cycle time, cost per unit, while ignoring whether the output serves a genuine human purpose.

The application to talent acquisition is striking. The ATS paradigm exhibits all three of Packard's mechanisms. Planned obsolescence manifests in application processes designed to be repeated, often within the same organisation, by the very same applicants, for the very same role just months later, rather than to build lasting relationships. Perceived obsolescence appears in the constant demand for updated CVs, new keywords, and reformatted profiles to satisfy evolving algorithmic preferences. Systemic overproduction is the most visible: organisations generate thousands of rejections per hire, each consuming resources yet producing no value for either party. The cost-per-hire metric, the recruitment equivalent of cost-per-unit, drives the same logic Packard criticised, optimise the transaction, ignore the relationship.

What makes Packard's framework particularly relevant to the agentic economy is his insight that technological sophistication amplifies rather than corrects flawed logic. Post-war manufacturing did not produce waste because it lacked technology, but because its technology served a logic disconnected from human purpose. Similarly, introducing AI agents into recruitment does not inherently solve the ATS's waste-making tendency. If the governing logic remains transactional, process more, filter faster, reject cheaper, AI simply produces waste at a scale Packard could not have imagined.

The distinction between efficiency and effectiveness thus becomes the foundational question for AI deployment. Efficiency asks: *can we process this faster?* Effectiveness asks: *are we producing the right outcome?* In recruitment, these questions yield radically different design principles. An efficient system minimises time-to-rejection. An effective system maximises relationship quality between the organisation and its talent ecosystem, including the candidates it does not hire today but may need tomorrow.

3.2 Two Black Boxes: Epistemological Humility in the Age of AI (Harari)

A persistent objection to AI participation in consequential decisions is that we do not understand how these systems reach their conclusions. Large language models, neural networks, and deep learning architectures operate as functional black boxes: inputs enter, outputs emerge, and the intermediate reasoning remains opaque even to their designers. This opacity, critics argue, renders AI fundamentally untrustworthy for decisions affecting human lives.

Yuval Noah Harari (2017) offers a disruptive counter-argument. In *Homo Deus*, he observes that the human brain is itself a black box, one we have studied for millennia without fully understanding. Neuroscience can map neural correlates of decision-making, but the subjective experience of judgment, the precise mechanisms by which a hiring manager forms an impression remains as opaque as any algorithmic process. We do not reject human decision-making because we cannot fully explain it. We trust it because we have developed institutions, relationships, and feedback mechanisms that make it accountable.

This epistemological symmetry has profound implications for how organisations approach AI in stakeholder-facing processes. If the objection to AI is opacity, intellectual consistency demands we apply the same standard to human judgment, which we manifestly do not. A recruiter who reviews a CV for an average of six seconds (the commonly cited industry figure) and renders a proceed/reject decision is operating with a degree of opacity that rivals any algorithm. The difference is not transparency but familiarity: we are accustomed to trusting human black boxes because we have embedded them in relational structures, supervision, accountability, feedback, professional development, that manage the risk of their opacity.

Two further positions sharpen the terrain. Harari's epistemological humility cuts in one direction: trust neither human nor AI uncritically, design accountability structures for both. Rudin (2019) cuts in another: for consequential decisions, do not rely on opaque AI at all — design inherently interpretable models from the start. The two readings can sound opposed — one redesigns the trust relationship around opacity, the other rejects opacity in the AI itself. ARM is the bridge on which they come to agree. Capable human judgment, exercising deep understanding and override authority over AI, anchored in stakeholder-facing accountability, honours what Harari demands at the relational layer and what Rudin demands at the AI-design layer. Neither position is contradicted; both are operationalised through the orchestration paradigm.

This reframes the central question. It is no longer "*can we trust AI?*" but "*can we design relationships between human and artificial intelligence that produce trustworthy outcomes?*"

This reframing is essential for the agentic economy. As AI agents assume more consequential roles, the temptation is to frame the challenge as a binary: trust humans or trust machines. Harari's epistemological humility suggests a third path, trust the relationship between them, designed with appropriate oversight, feedback mechanisms, and human authority over final decisions affecting stakeholders. This is precisely what the orchestration paradigm, observed in practice across sectors, appears to be converging toward.

3.3 Noise: The Unreliability of Human Judgment (Kahneman, Sibony, and Sunstein, 2021)

If Harari establishes that human judgment is a black box, Kahneman, Sibony, and Sunstein (2021) demonstrate that it is a noisy one. In *Noise: A Flaw in Human Judgment*, they distinguish between bias (systematic deviation from correct judgment) and noise (unwanted variability in judgments that should be identical). Their central finding is that noise is pervasive, largely unrecognised, and in many domains more damaging than bias.

The implications for recruitment are severe. Kahneman et al. document what they term "occasion noise", the same individual judging the same case at different times, and "system noise", different individuals in the same role making systematically different judgments. In recruitment contexts, this translates to a well-documented phenomenon: the same CV, reviewed by the same recruiter on different days, or by different recruiters on the same day, produces different outcomes. The "trust your gut" tradition in hiring is not merely unscientific; it is a recipe for noise amplification.

Traditional responses to noise in recruitment have focused on standardisation: structured interviews, scoring rubrics, competency frameworks. These approaches reduce noise but at a cost, they impose rigidity that can suppress the contextual judgment that distinguishes exceptional selection decisions from adequate ones. The challenge is to reduce noise without eliminating the human capacity for nuanced evaluation.

AI agents do not resolve this tension as straightforwardly as is often assumed. A common claim is that algorithmic consistency can compensate for human noise. Yet large language models and generative AI systems introduce their own forms of variability: the same input can produce different outputs within the same conditions, and variability increases further depending on prompt construction, context window, and model parameters. AI noise differs from human noise in its patterns and triggers, but it is noise nonetheless. When deployed as automation, replacing human judgment with algorithmic processing, organisations do not eliminate noise; they substitute one form of unreliability for another, while losing the contextual sensitivity that human judgment, for all its inconsistency, can provide.

Orchestration does not automatically solve this problem, it only sets the conditions under which a solution becomes possible. And those conditions carry a risk. If humans default to the minimum effort approach described in Section 1.2, accepting algorithmic outputs uncritically, delegating judgment rather than exercising it, the two noisy systems do not compensate for each other; they multiply each other's unreliability, producing compounded error with a veneer of rigour. However, if orchestration is designed to develop human recognition capability, to cultivate awareness of when AI outputs require challenge, when contextual judgment must override algorithmic pattern-matching, when the human contribution is genuinely irreplaceable, then the complementary nature of human and AI noise patterns can reduce overall decision noise beyond what either achieves alone. The outcome depends entirely on whether the human participant is enabled and expected to bring relational intelligence to the collaboration, or permitted to abdicate it.

This distinction matters because noise in recruitment is not merely a measurement problem; it is a relationship problem. Applicants subjected to noisy decision-making experience the system as arbitrary, undermining trust in the organisation and the process. Kahneman et al.'s research thus provides empirical grounding for ARM's emphasis on relationship quality: reducing noise is not only statistically desirable but relationally necessary. An applicant who receives a consistent, explicable evaluation, even an unfavourable one, maintains a fundamentally different relationship with the organisation than one who suspects their outcome was determined by which recruiter happened to review their file, or what time of day the review occurred.

3.4 Collaboration as the Distinctive Human Capacity

The three preceding streams, Packard's efficiency critique, Harari's epistemological humility, Kahneman et al.'s noise analysis, collectively undermine the assumption that either human or artificial intelligence alone can be trusted with consequential stakeholder decisions. This raises an obvious question: if neither is sufficient alone, what makes their combination potentially superior?

The answer lies in what arguably constitutes humanity's most distinctive evolutionary achievement: the capacity for productive collaboration with diverse forms of intelligence. Harari (2017) himself makes this point in his broader work, *Homo sapiens* did not dominate through superior individual cognition but through the unprecedented ability to coordinate action among large numbers of agents with different capabilities, perspectives, and knowledge bases. Language, institutions, markets, legal systems, all are technologies for orchestrating diverse intelligences toward outcomes none could achieve independently. Tomasello (2009) identifies this capacity for shared intentionality, the ability to coordinate action toward jointly understood goals with diverse partners, as the cognitive foundation distinguishing human collaboration from all other species.

This observation reframes the human-AI question entirely. The relevant precedent is not "human versus machine" but rather every previous instance in which humans extended their cognitive capacity through partnership with non-human intelligence systems, writing, mathematics, scientific instruments, organisational hierarchies. In each case, the breakthrough was not the tool itself but the design of the collaboration between human judgment and the tool's capabilities.

The agentic economy represents the latest, and perhaps most significant, iteration of this pattern. AI agents are not merely tools that execute instructions; they are systems capable of pattern recognition, natural language interaction, and adaptive responses approximating cognitive partnership. The

question is not whether humans can collaborate with AI agents, the capacity for cross-intelligence collaboration is our defining strength, but whether we design that collaboration for transactional efficiency or relational effectiveness.

The emerging evidence suggests that organisations achieving the best outcomes from AI deployment are those that treat the human-AI interface as a relationship to be designed rather than a process to be automated. In insurance claims, the most effective deployments pair algorithmic assessment with human judgment for complex or sensitive cases. In healthcare, the most promising AI applications augment clinical reasoning rather than replace it. In each domain, the pattern is consistent: orchestration outperforms automation when stakeholder relationships are at stake.

This collaborative pattern has a formal vocabulary in the algorithmic HRM literature. Meijerink et al. (2021) distinguish augmentation from automation: where automation replaces human decision-making, augmentation empowers human capability — supporting humans in reaching better decisions through stronger AI tools. ARM's orchestration concept extends this further. Orchestration requires more than enhanced capability; *it requires that the human operator possesses sufficiently deep understanding of how and why the AI works to override any algorithmic output that does not fit the relational, human-centric paradigm.* Augmentation strengthens the operator; orchestration strengthens the operator and establishes relational logic as the governing criterion against which every AI output is evaluated. In Meijerink's frame, AI makes humans more capable; in ARM's frame, capable humans command AI within a relational paradigm in which the human stakeholder is an active participant, not merely the recipient of an augmented decision.

This convergence across sectors suggests that human-AI collaboration is not merely a pragmatic compromise between full automation and full human control. It is a design principle grounded in the recognition that complex stakeholder decisions require both the consistency and scale of artificial intelligence and the contextual judgment and relational capacity of human intelligence. The formula, to use a deliberately provocative shorthand, is not 1+1=2 but 1+AI>2, the orchestrated combination produces outcomes that exceed the sum of its components, provided the human contribution is actively cultivated rather than passively assumed.

4. The ARM Framework for the Agentic Economy

4.1 Extending the Relational Paradigm Shift (Grönroos, 1994)

In 1994, Christian Grönroos proposed what remains one of the most influential reconceptualisations in management thought: the shift from a transactional to a relational paradigm. His argument was that organisations had become trapped in logic treating every interaction as a discrete exchange, optimised, completed, forgotten, when the evidence overwhelmingly showed that long-term relationships, not individual transactions, determined organisational success. Marketing, he argued, should be reconceived as the management of relationships, not the execution of campaigns.

The paradigm shift Grönroos described has been remarkably successful, but selectively so. Customer relationship management transformed how organisations think about buyers. Supply chain management extended relational logic to vendors and partners. Stakeholder theory broadened the lens further to include communities, regulators, and investors. Yet one category of stakeholder was left almost entirely within the transactional paradigm: the future workforce itself, without whom there is no organisation to manage, no customer to serve, no strategy to execute. Organisations spent three decades building relational systems for every stakeholder except the one they cannot exist without: the people they hire. The very systems designed to manage them, applicant tracking systems, encode transactional logic in their architecture: receive, filter, rank, reject, forget. The language is revealing. Organisations do not speak of building relationships with applicants; they speak of processing them. The candidate experience literature has documented this damage extensively: applicant perceptions of fairness and organisational attractiveness are shaped decisively by selection process quality, not outcome alone (McCarthy et al., 2017).

This is not an oversight. It reflects a deep assumption that the employment relationship begins at the point of hire, and that everything preceding it is a selection mechanism, a funnel to be optimised, not a relationship to be cultivated. This assumption dramatically overlooks the fact that what motivates people toward an organisation, and what sustains their commitment once there, cannot, and definitively does not anymore, depend on mere transactional parameters. Compensation, career progression, job title: these are necessary conditions, not sufficient ones. The evidence from every generation entering the workforce since the turn of the millennium points in the same direction, people seek purpose, belonging, alignment with values, the sense that they are recognised as human beings rather than processed as resource units. And they are paying attention. A system that reduces the entire pre-hire relationship to a transaction does not merely fail to attract the best talent, it actively repels it. The ATS is the first conversation the organisation has with its future workforce, and for thirty years that conversation has been: *we will process you, rank you, and if you are lucky, we will remember your name.* Organisations that invest in employer branding while funnelling every applicant through a transactional ATS are sending mixed signals. Dangerously mixed.

Grönroos himself, focused primarily on customer and service relationships, did not extend his critique to talent acquisition, and for thirty years, neither did anyone else. The omission is remarkable. An entire discipline built around the proposition that transactional logic destroys value in stakeholder relationships somehow failed to notice that the most consequential stakeholder relationship of all, the one that determines who constitutes the organisation itself, was still being governed by precisely the transactional logic it had rejected everywhere else. The paradigm shift transformed how organisations relate to their customers, their suppliers, their communities. It left untouched how they relate to the people they need most. Recent scholarship has begun to register this gap, though without yet naming it as such. Mori et al. (2025), in the most comprehensive synthesis to date of AI in recruitment and selection, identify stakeholder integration as one of three perspectives the field requires to move beyond efficiency-driven adoption — alongside sustainable AI-HRM and information asymmetry management. Their analysis ends at the call. ARM responds to it by reading that call through Grönroos's relational paradigm.

Why now? Because the four theoretical streams examined in Section 3 converge on an uncomfortable conclusion: the gap cannot simply be filled by extending existing relational frameworks into recruitment. Packard reveals that transactional talent acquisition doesn't merely underperform, it actively manufactures waste. Kahneman et al. demonstrate that the noise pervading human decision-making cannot be trusted as we routinely grant it, and that replacing it with algorithmic consistency is no solution, because algorithmic consistency is itself a myth. Harari establishes that the problem runs deeper still: neither human nor artificial intelligence operates transparently, both are black boxes, and the comforting assumption that at least we understand our own reasoning is precisely that, an assumption. The only honest response is to stop pretending either deserves unconditional trust and start designing systems where both are held accountable, not to their own internal logic, which neither can fully explain, but to the people whose lives their decisions affect. And the collaboration literature points to the only viable path forward: designed partnerships between human and artificial intelligence that produce what neither achieves alone. Extending Grönroos's paradigm shift into talent acquisition is not a matter of applying known principles to a new domain. It requires a framework built for the specific challenges that domain presents, challenges that the agentic economy is about to amplify beyond recognition.

4.2 The Four Tenets of ARM

Applicant Relationship Management (ARM) is the framework we propose to operationalise this extension. It translates each theoretical stream into a concrete design principle, a tenet, that governs how human and artificial intelligence should interact in talent acquisition processes. ARM is then built on four tenets, each derived from a specific theoretical foundation and each addressing a distinct failure of the transactional paradigm.

Tenet 1: Relationships precede transactions. The quality of the relationship between organisation and applicant determines the quality of the hiring outcome, not the speed or volume of transaction processing. This is Packard's efficiency-effectiveness distinction applied to its most neglected domain. In practice, it means designing systems that treat every interaction with an applicant as a contribution to an ongoing relationship, regardless of whether that specific interaction leads to a hire. The applicant who is not selected today does not cease to exist in the organisation's ecosystem. They become a client, a supplier, an opinion leader, a shareholder, a competitor's strategist who remembers exactly how they were treated. Systems that forget this, that treat rejection as the end of a transaction rather than a moment in a relationship, do not merely produce Packard's waste. They actively damage the organisation's future across every stakeholder category Grönroos's paradigm shift was designed to protect.

A concrete expression of this principle is the concept of the Silver Medallist: the candidate who reaches the final stages of selection but is not chosen for a specific role. In transactional systems, this person disappears, their file is closed, their evaluation is archived, their relationship with the organisation is severed. But that person does not disappear from the world. They may not remember the exact words of the rejection email. They may not remember the name of the recruiter who never called back. But the feeling of how they were treated will stay with them, and every time they encounter that organisation again, as a customer, as a partner, as an industry voice, as an investor, that feeling will surface, whether they want it to or not. In a relational system, the Silver Medallist is not a future hiring option to be warehoused. They are a stakeholder whose relationship with the organisation has been shaped, for better or worse, by the selection experience, and whose influence extends far beyond whether they ever become an employee.

Tenet 2: Opacity is universal; design for accountability. Neither the recruiter nor the algorithm can fully explain how they reach their conclusions, and as Harari's epistemological symmetry argument establishes, pretending otherwise is the first dishonesty in a system that will compound many. The recruiter who 'just knows' a candidate isn't right and the algorithm that scores a CV at 67% are both operating behind closed doors. The difference is that we have spent centuries excusing human opacity as 'experience' and 'intuition' while demanding that machines justify themselves, a double standard that protects no one, least of all the applicant.

ARM's response is not to choose which black box to trust. It is to refuse the choice entirely and instead design for accountability in all directions. Human judgments must be made explicit, not because recruiters are untrustworthy, but because unexplained decisions are unexplainable decisions, and unexplainable decisions cannot sustain relationships. AI recommendations must be accompanied by reasoning traces, not because transparency is technically convenient, but because an applicant who cannot understand what shaped their evaluation cannot improve, cannot engage, cannot trust, and an organisation that cannot explain its own decisions cannot learn from them, cannot defend them, and cannot build the talent relationships its survival depends on. Opacity is not just unfair. It brings costs. And the human operator must be accountable to themselves, honest about when they are exercising genuine judgment and when they are defaulting to the path of least resistance, letting the algorithm decide so they don't have to.

A design distinction matters here. Suen and Hung (2024), in field experiments with real job applicants, found that disclosing an AI's evaluation criteria upfront produced strategic gaming — fewer honest signals, more deceptive ones — and cautioned against unchecked advocacy for AI transparency. ARM's accountability commitment is of a different kind. What ARM discloses is not the predictive rubric by which the AI scores candidates, but the prioritised requirements of the role, surfaced through dialogue with the applicant and oriented around the applicant's success. The design hypothesis — currently under empirical study in real cases — is that relational requirements transparency invites self-selection among applicants who want to build a genuine match, and backfires on those who would attempt to game it. This distinguishes ARM's approach from the conditions tested by Suen and Hung; cross-cultural validation remains open.

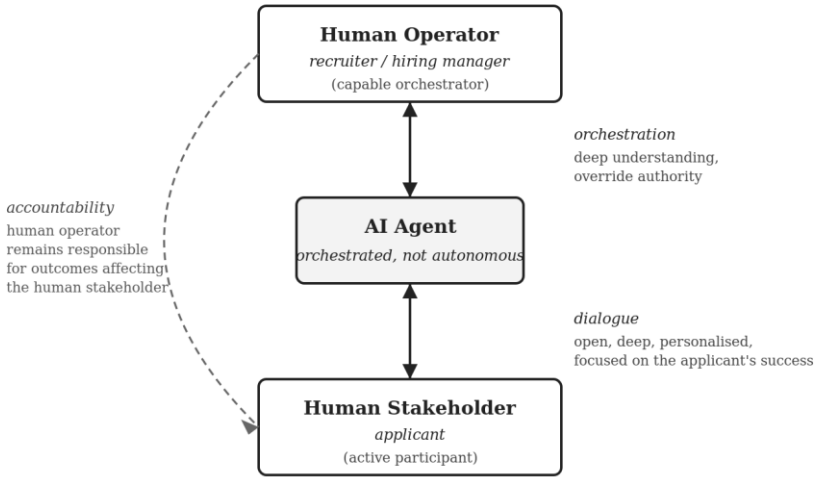
This is not a commitment to transparency as corporate virtue. It is a structural requirement. Opacity that is unmanaged becomes opacity that is exploited, by organisations that hide behind algorithmic complexity, by recruiters who hide behind gut feeling, and by systems that allow both to avoid the one thing relational accountability demands: ***looking the applicant in the eye and explaining why***.

Tenet 3: Noise reduction requires collaboration, not replacement. Grounded in Kahneman et al.'s analysis, this tenet rejects the common assumption that AI should replace noisy human judgment with consistent algorithmic processing. As established in Section 3.3, AI systems, particularly large language models, introduce their own variability patterns. The goal is not to eliminate human noise by substituting machine noise but to design collaboration structures where the complementary nature of human and AI noise patterns produces better outcomes than either achieves alone.

This tenet has a critical corollary: the collaboration must be genuinely active. If the human participant defaults to minimum effort, rubber-stamping algorithmic outputs, delegating rather than exercising judgment, the two noisy systems compound rather than compensate. ARM therefore requires not just the presence of human judgment but its active development: training, feedback mechanisms, and system design that cultivates the human operator's capacity to recognise when AI outputs require challenge.

Tenet 4: Orchestration supersedes automation. Automation asks a seductive question: *which tasks can we remove from human responsibility?* Every answer feels like progress, fewer touches, faster processing, lower cost. But the question contains its own trap. Each task removed is a capability that atrophies. Each human touch eliminated is a judgment that will never be exercised again, a relational muscle that weakens from disuse. Automation doesn't just change who does the work. It changes what the organisation is capable of, permanently.

Orchestration asks a fundamentally different question: *how do we design the collaboration between human and artificial intelligence to produce the best possible outcome for all stakeholders?* This is not a softer version of the same question. It is a different design philosophy with different architecture, different economics, and different consequences over time. Automation converges toward a system that no longer needs humans and humans who are no longer capable of contributing. Orchestration builds a system where both intelligences grow stronger through interaction, where the AI becomes more useful because the human knows how to challenge it, and the human becomes more capable because the AI expands what they can see.



The distinction maps directly to Packard's foundational challenge. Automation pursues efficiency: replace human cost with cheaper algorithmic processing. At best, it is additive, the 1+AI>2 introduced in Section 3.4 as a deliberately provocative shorthand. Orchestration pursues something qualitatively different: H+AI=2^x, where x represents the quality of orchestration design, investment in human capability, sophistication of collaboration architecture, depth of relational framework. The returns are not additive. They are exponential. As a rhetorical artifact, the equation highlights the power of the capable human beyond simple AI augmentation. And the atrophy argument delivers its most devastating implication here: when H hollows out through disuse, when decades of transactional systems have eroded the contextual judgment, the relational intelligence, the capacity for nuanced evaluation that orchestration demands, x collapses toward zero. And 2^0 = 1, no matter how powerful the AI becomes. An organisation can deploy the most sophisticated artificial intelligence available. If the human capability it was designed to orchestrate with has been quietly abandoned through disuse, the result is indistinguishable from having no AI at all.

4.3 The Agent Triad and the Capable Orchestrator

The four tenets demand more than principles. They demand an operational architecture, a structure that specifies not just what should happen but who is accountable for making it happen. ARM proposes the Agent Triad: a three-actor model comprising the Human Operator, the AI Agent, and the Human Stakeholder.

Figure 1. The ARM Agent Triad

Human Operator – AI Agent – Human Stakeholder

The AI Agent mediates between two humans. The Human Operator orchestrates the AI; the AI engages the Human Stakeholder in dialogue; accountability flows back to the Operator.

In talent acquisition, these roles map to the recruiter (or hiring manager), the AI system, and the applicant. But the model is deliberately generalised, because the design principle it captures recurs across every domain where orchestration outperforms automation. In insurance: the claims assessor, the AI system, the policyholder. In healthcare: the clinician, the AI system, the patient. In each case, the AI agent mediates between two humans, and the quality of both relationships, operator-to-AI and AI-to-stakeholder, determines the quality of the outcome. Get either relationship wrong and the triad collapses into something far less useful: an automated pipeline with humans decoratively attached.

The triad embodies a specific, and provocative, allocation of authority. The AI agent handles what AI does best: pattern recognition at scale, screening large volumes of information, identifying relevant signals, flagging inconsistencies, generating initial assessments. The Human Stakeholder, the applicant, in recruitment, is not a passive object of processing but an active participant. What they engage in is not mere data transfer — uploading a CV, filling a form, ticking competency boxes — but an open, deep and personalised dialogue that the AI agent builds and maintains, strongly focused on the applicant's success. It is a process of creating context, clarifying intent, and building meaning that no pre-formatted application form can capture. This dialogue structure is currently under empirical study in real cases. The applicant who explains *why* they made a career change, who contextualises a gap in their CV, who articulates what they are looking for beyond job title and salary, this person is contributing intelligence that the system needs but can only access through interaction, dialogue, and exchange, never through extraction. Their experience, their feedback, their evolving understanding of the organisation are system inputs, not externalities to be managed.

And the Human Operator sits at the centre of it all. Not as a bottleneck, not as a compliance requirement, but as the architecture's most significant opportunity. What ARM terms the 'capable orchestrator' represents an entirely new professional capability, one that the agentic economy is creating demand for faster than organisations are developing it. The capable orchestrator understands AI's strengths well enough to leverage them, recognises its limitations well enough to challenge them, and brings relational skills that no algorithm can substitute. This is not a diminished role for humans in an increasingly automated world. It is an elevated one, a professional whose judgment has been actively developed through training, feedback, and system design that cultivates the distinctively human capabilities the agentic economy makes more valuable, not less. Organisations that recognise this early, that invest in developing capable orchestrators alongside AI capability, are not just building better systems. They are building the competitive advantage that will define the next generation of talent-intensive industries.

A critical feature of the triad is its commitment to compensatory rather than eliminatory evaluation, and here the professional opportunity becomes concrete. Traditional selection systems follow what Ock and Oswald (2018) term a multiple-hurdle approach: candidates must pass each stage sequentially, and failure at any point produces elimination. The logic is transactional to its core, reduce the person to a sequence of pass/fail gates and discard them at the first failure. A multiple-hurdle system doesn't need a capable orchestrator. It needs a gatekeeper. And gatekeeping is a professional dead end, a role that shrinks with every improvement in algorithmic filtering, because the algorithm will always be a faster, cheaper gatekeeper than the human.

The compensatory model inverts this logic entirely. It allows strength in one dimension to offset relative weakness in another, preserving the multi-dimensional complexity of a human being rather than flattening them into a binary score. A candidate with exceptional collaborative intelligence and moderate technical skills is not the same as one with moderate collaborative intelligence and exceptional technical skills, but a multiple-hurdle system, filtering on technical threshold first, may never discover the difference. The flattening has measurable consequences: Deriu et al. (2024), across three controlled experiments with job applicants, show that AI evaluators are perceived as less capable than human evaluators of assessing candidates' unique skills — and that this perception erodes trust in the agent and intention to accept a job offer. ***The problem is not AI itself; it is the single-dimensional logic through which AI has typically been deployed***. This is where the capable orchestrator becomes irreplaceable: the judgment to weigh competing dimensions against each other, to recognise potential that no single metric captures, to see the whole person rather than a sequence of scores, this is a capability that grows more sophisticated with practice, not less relevant with automation. The recruiter operating within a compensatory framework is not processing applicants. They are making complex, consequential, deeply human evaluations that no algorithm can replicate, and building professional expertise that the agentic economy will make increasingly valuable.

ARM adopts the compensatory approach because it is the only evaluation architecture consistent with treating applicants as stakeholders rather than data points. You cannot claim to build relationships with people you have already reduced to pass/fail gates before you even met them. But equally: you cannot develop capable orchestrators within a system that requires nothing of them except saying yes or no at a gate someone else designed.

The automation case is not without merit. Speed, cost reduction, and scale are genuine organisational needs, and advocates of full automation are responding to real pressures. But the question this paper raises is not whether those needs are legitimate. It is whether meeting them through automation alone produces outcomes that serve the organisation's long-term interests, and the evidence, across every domain examined here, suggests it does not.

The Agent Triad resolves the fundamental tension in current AI deployment, not through compromise but through complementarity. Full automation gains consistency and speed while introducing undetected noise, losing contextual judgment and relational accountability. Full human control preserves the illusion of judgment and cannot scale. Both, in isolation, remain hostage to the noise Kahneman et al. document. The triad is designed so that each actor contributes what the others cannot. If organisations invest in capable orchestrators with the same seriousness they invest in AI capability. If they design systems that develop human judgment rather than bypass it. If they treat the professional growth of their people as a strategic asset rather than a cost to be minimised. Then the triad doesn't just work. It compounds, H+AI=2^x, with x rising every year.

5. Application: Recruitment as Agentic Ecosystem

5.1 Cross-Sector Convergence

The orchestration paradigm ARM proposes for talent acquisition is not emerging in isolation. Across sectors where AI deployment intersects with consequential stakeholder decisions, a remarkably

consistent pattern is appearing, and it is appearing independently, driven not by shared theory but by shared failure.

In insurance, early attempts to fully automate claims processing produced efficiency gains and customer rebellion. Policyholders whose life-altering claims were assessed by algorithms they could not question, explained by chatbots they could not reason with, and denied through processes they could not appeal experienced the system as adversarial, regardless of whether the outcome was technically correct. The response, visible in deployments such as Allianz's partnership with Anthropic (Allianz, 2026), has been to redesign the human-AI interface: algorithmic assessment for routine claims, human judgment for complex or sensitive cases, and structured dialogue between the system and the policyholder at every stage. Not automation with human exception-handling. Orchestration by design.

In banking, a parallel trajectory. DBS (2025) and BNY Mellon (2026), among others, discovered that algorithmic decision-making in client-facing processes, credit assessment, investment advisory, relationship management, generated measurable efficiency while eroding the trust relationships that differentiated them from purely digital competitors. The response: AI handles pattern recognition and data synthesis, human advisors handle the relational complexity that clients value and algorithms cannot replicate. The human role did not shrink. It was elevated, freed from data processing to focus on judgment and relationship.

In healthcare, the convergence is most visible in regulatory frameworks. The FDA and HHS have moved toward governance models (U.S. Department of Health and Human Services, 2025) that assume neither full automation nor full human control but structured collaboration, clinical AI that augments rather than replaces physician judgment, with explicit accountability for how human and artificial intelligence interact in diagnostic and treatment decisions.

In legal services, firms like A&O Shearman (2025) have deployed AI for document analysis and legal research while maintaining human judgment for interpretation, strategy, and client counsel, recognising that the value clients pay for is not information retrieval but the relational and contextual intelligence that transforms information into advice.

The pattern is unmistakable. In every domain where organisations attempted full automation of stakeholder-facing processes, the result was the same: efficiency gains accompanied by relational damage that ultimately threatened the efficiency gains themselves. And in every domain, the corrective has converged on a shared design logic — AI in a supporting rather than substitutive role, with human judgment kept in command at the point of consequential decision. This is the orchestration paradigm, and the cross-sector evidence is primarily evidence for it. ARM draws on this convergence and goes one step further: it couples the orchestration paradigm with Grönroos's relational paradigm, treating the human stakeholder — here, the applicant — as an active participant in the process rather than the recipient of an orchestrated decision. That relational extension is ARM's specific contribution to talent acquisition; the orchestration paradigm is what makes it operationally viable.

This convergence is significant because it was not coordinated. No single theory drove these sectors toward orchestration. They arrived there through independent experimentation and independent failure. When multiple domains, facing different stakeholder populations and different regulatory environments, independently converge on the same design logic, the convergence itself is indicative. The orchestration paradigm is not a theoretical preference. It is an observable pattern, one that talent acquisition is the last major stakeholder domain to recognise.

5.2 The Missing Domain

Talent acquisition is not merely one more domain left behind. It is the universal gap. Every organisation, in every sector, of every size, in every market, hires. It is the foundational process through which every organisation constitutes itself. The field itself has acknowledged this omission: Potočnik et al. (2021), synthesising a decade of meta-analyses, identify strategic recruitment as a critical gap, noting that only Phillips and Gully's (2015) multilevel model had attempted to align

recruitment with organisational strategy. Yet even that model remains within a transactional frame, treating applicants as resources to attract rather than stakeholders to engage. The orchestration paradigm has reached customers, supply chains, legal affairs, and clinical decisions. It has not reached the people without whom none of those activities exist..

The urgency is not abstract. Every domain that has converged on orchestration did so the hard way, after full automation had already inflicted the damage. Talent acquisition is approaching the same inflection point, but with a critical difference. In insurance or banking, a damaged stakeholder relationship means a lost client.In talent acquisition, a damaged stakeholder relationship means a lost contributor, someone whose talent, creativity, and commitment will now flow to a competitor, or simply never materialise. And unlike every other domain, this damage is silent. No KPI measures it. No balance sheet includes it. No quarterly review surfaces it. It is a cost nobody acknowledges, not because they don't understand it, but because nobody sees it. The best candidates don't complain. They simply go elsewhere. The organisation never knows what it lost, only that, over time, the quality of its workforce no longer matches its ambitions. The stakes are higher because the asset at risk is not immediate revenue but capability and the damage to talent acquisition goes unnoticed.

ARM positions talent acquisition within the orchestration paradigm already validated, painfully, wherever it has been adopted. The four tenets are not theoretical inventions. They are the principles we are already converging on, translated into the domain that needs them most. The Agent Triad is not a novel architecture. It is the operational structure that every domain adopting orchestration has independently arrived at, applied to the one, stakeholder relationship, that every organisation depends on and almost none has thought to design for.

The question is not whether the orchestration paradigm will reach talent acquisition. The cross-sector evidence suggests it will, eventually. The question is whether organisations will complete the shift proactively, building capable orchestrators and relational architectures before the agentic economy embeds transactional logic so deeply into talent acquisition that no relational alternative remains viable. The path of every domain that has converged on orchestration is already unfolding here: full automation came first, the relational damage has begun to surface, and the corrective is now within reach. The opportunity is to make that third step proactively, while it remains tractable.

6. Discussion: Managing in the Agentic Economy

6.1 The Capable Orchestrator: New Competencies for the Agentic Economy

The orchestration paradigm does not merely redesign systems. It redefines what it means to be a professional in a stakeholder-facing role. If the capable orchestrator is, as Section 4.3 argued, the load-bearing element of the entire architecture, then the question of how organisations develop this capability becomes strategic, not operational, not a training line item, but a fundamental rethinking of what competence means in an age where AI handles the tasks that used to define professional identity.

For decades, recruitment professionals have been valued for skills that automation is rapidly absorbing: screening CVs efficiently, managing high-volume pipelines, administering structured interviews at speed. These are precisely the capabilities that AI agents perform at scale. The professional who defines their value through transaction processing is, in Tenet 4's terms, a gatekeeper, and gatekeeping is a role the agentic economy is eliminating, not enhancing.

The capable orchestrator requires a fundamentally different competency profile. Three capabilities emerge as essential, each grounded in the theoretical foundations established in Section 3. Table 2 summarises ARM's four tenets and their corresponding managerial implications.

First, **relational intelligence**: the capacity to build, sustain, and repair relationships with stakeholders whose experience of the organisation is mediated by AI. This is not customer service. It is the ability to recognise when an algorithmic output needs human interpretation before reaching the applicant, when a rejection requires a conversation rather than a notification, when the Silver Medallist warrants

personal engagement rather than database storage. Relational intelligence is the competency that Packard's efficiency-effectiveness distinction demands, the human capacity to ask not "*was this processed correctly?*" but "*did this interaction build or damage a relationship that matters?*"
Second, **critical AI literacy**: the ability to understand what AI systems are doing well enough to leverage their strengths and challenge their limitations. This is not technical expertise. The capable orchestrator does not need to understand neural network architecture. They need to recognise when an AI recommendation reflects genuine pattern recognition and when it reflects the noise that Kahneman et al. demonstrate pervades human judgment and that, as Section 3.3 argues, manifests differently but no less consequentially in AI systems. They need the professional confidence to override algorithmic output when contextual judgment demands it, and the intellectual humility to recognise when their own judgment is the noisier input.
Third, **accountability practice**: the willingness and skill to make one's own decision-making explicit, to document reasoning, to provide applicants with evaluations that are consistent and explicable. This is Harari's epistemological humility made operational, the recognition that opacity in one's own judgment is as dangerous as opacity in the algorithm's, and that the only honest response is to design for transparency in both directions.

Table 2. *ARM tenets and managerial implications.*

ARM Tenet	***Theoretical foundation***	***Managerial implication***
1.Relationships precede transactions	*Packard (1960); Grönroos (1994)*	*Treat every applicant interaction — including rejections and Silver Medallists — as a contribution to an ongoing relationship that extends beyond hire.*
2.Opacity is universal; design for accountability	*Harari (2017); Rudin (2019); Suen and Hung (2024)*	*Require reasoning traces from AI, explicit documented reasoning from human operators, and explicable outcomes for applicants. Disclose role requirements, not predictive scoring rubrics.*
3. Noise reduction requires collaboration, not replacement	*Kahneman, Sibony and Sunstein (2021)*	*Develop critical AI literacy in recruiters; reject rubber-stamping of algorithmic outputs; design feedback mechanisms that cultivate active judgment.*
4.Orchestration supersedes automation	*Meijerink et al. (2021); ARM extension*	*Invest in capable orchestrator development with the same seriousness as AI capability; design systems that develop human capability rather than bypass it.*

These competencies are not being developed at scale. Management education continues to train recruitment professionals for a transactional paradigm that is already failing. Organisational development programmes invest in AI literacy as a technical skill rather than as a component of professional judgment. The capable orchestrator is the role the agentic economy demands; the gap between that demand and the current supply of professionals equipped to fill it represents both a risk and, for organisations that move first, a decisive competitive advantage.

6.2 Regulatory Alignment: ARM and the EU AI Act

The orchestration paradigm is not only emerging from practice. It is being codified in regulation. The European Union's AI Act (European Parliament and Council, 2024) represents the most comprehensive attempt to govern AI deployment in stakeholder-facing processes, and its requirements align remarkably with ARM's design principles.
The AI Act classifies AI systems used in employment, worker management, and access to self-employment as **high-risk**, triggering a demanding set of obligations: human oversight, transparency, data governance, accuracy, robustness, and the right of affected persons to receive meaningful explanations of AI-assisted decisions. These are not abstract regulatory aspirations. They are legally enforceable requirements that will reshape how every organisation operating in or serving EU markets designs its talent acquisition processes.

The two-track high-risk regime. The Act creates two routes into high-risk classification. Under Article 6(1) and Annex I, AI systems are high-risk when they function as safety components of products already governed by EU harmonised legislation — medical devices, machinery, vehicles, aviation systems, and similar regulated categories. Under Article 6(2) and Annex III, AI systems are high-risk by virtue of their intended use across eight stand-alone domains, of which the fourth — employment, workers' management, and access to self-employment — is the locus of the systems this paper addresses. Talent acquisition AI sits squarely within the Annex III track. The distinction matters because the two tracks proceed on different conformity-assessment logics: Annex III on largely internal assessment supported by harmonised standards still under development at CEN-CENELEC JTC 21; Annex I on layering AI-specific requirements onto pre-existing sectoral regimes such as the Medical Devices Regulation or motor-vehicle type-approval. ARM addresses Annex III's particular challenge directly: how to operationalise human oversight, transparency, and explicability in a domain where the substantive obligations are already clear but the technical standards are not yet codified.

A moving compliance horizon. The legally binding application date for Annex III obligations remains 2 August 2026. As this paper goes to press, the European Commission's Digital Omnibus on AI — proposed in November 2025, with converging Council and Parliament negotiating positions adopted in March 2026 — is in trilogue with a proposed postponement of Annex III obligations to 2 December 2027 and Annex I obligations to 2 August 2028. A political agreement on a consolidated postponement text is expected at the trilogue meeting of 28 April 2026, with potential adoption by Parliament and Council in May and June and publication in the Official Journal in July. Until that sequence completes, the August 2026 deadline holds; organisations operating in EU markets cannot reliably plan against the proposed 2027 date.

The delay, should it be enacted, is procedural rather than substantive: it reflects the late arrival of harmonised standards, the incomplete designation of national competent authorities, and a shortage of accredited conformity-assessment bodies, not a softening of what the Act requires of organisations deploying employment AI. This regulatory uncertainty has a paradoxical implication for the argument advanced in this paper. Organisations that read the postponement as permission to defer ARM-aligned redesign mistake its meaning: when the harmonised standards are eventually cited in the Official Journal, they will be drafted around the practices of organisations that adopted orchestration early. Those that waited will inherit a compliance regime shaped by those that did not. ARM's relevance is not contingent on the August 2026 deadline holding; it rests on the substantive obligations the Act codifies, regardless of when they take operational effect.

Whatever timing the trilogue ultimately produces, the alignment with ARM is structural, not coincidental. The AI Act's human oversight requirement mirrors the Agent Triad's allocation of authority: AI handles pattern recognition, human operators exercise contextual judgment, and the human stakeholder receives explicable outcomes. The Act's transparency obligations correspond to Tenet 2's insistence that opacity must be managed through accountability, not because it is virtuous but because it brings costs when unmanaged. The requirement for meaningful explanations to affected persons echoes ARM's treatment of the applicant as an active stakeholder whose understanding of the process is a system input, not an afterthought.

What the AI Act does not provide, and what ARM is designed to deliver, is the how. Regulation specifies what organisations must achieve: human oversight, transparency, explicability. It does not, and it cannot, specify the operational architecture through which these requirements are met. ARM's Agent Triad, compensatory evaluation model, and capable orchestrator concept offer a concrete framework for compliance that is grounded not in legal minimalism but in the conviction that what the regulation requires is also what effective talent acquisition demands.

This convergence between regulatory requirement and relational design is significant. Organisations that adopt ARM's principles are not merely preparing for compliance. They are building systems that the regulation validates because both, the law and the framework, emerged from the same recognition: that AI deployment in consequential stakeholder processes requires orchestration, not automation,

and that the stakeholder's experience is not an externality to be managed but a measure of whether the system is working at all.
For organisations outside EU jurisdiction, the trajectory is nonetheless instructive. The AI Act represents the direction in which AI employment governance is moving globally. Recent experimental evidence also suggests these requirements align with what applicants themselves prefer: Xiong and Kim (2025) find that third-party AI audits increase applicants' trust and positive attitudes toward hiring organisations more effectively than self-disclosed information sharing. ARM-aligned organisations are building for the paradigm that regulation, practice, and theory are independently converging toward.

7. Limitations and Future Research

This paper's argument rests on conceptual synthesis rather than empirical testing, and it would be dishonest to claim otherwise while demanding honesty from everyone else.
The cross-sector evidence for orchestration draws on recent deployments and regulatory frameworks, not longitudinal data. The pattern is consistent and the convergence is real, but the evidence base is young. Whether orchestration's advantages hold as AI capabilities evolve, as organisational learning curves steepen, and as the agentic economy reveals dynamics none of us can fully anticipate, these are empirical questions this paper can frame but not answer.
The ARM framework has not been validated across diverse recruitment contexts. The four tenets and the Agent Triad are theoretically grounded, but their effectiveness across different industries, organisational sizes, labour markets, and cultural contexts remains to be demonstrated. The compensatory evaluation model, while theoretically superior to the multiple-hurdle approach, has historically been impractical at scale, not because it proved inferior, but because the resources it demanded were prohibitive. The agentic economy removes this constraint for the first time: AI agents can sustain multi-dimensional, continuous evaluation at a fraction of the cost that made compensatory models unaffordable for human-only processes. This is both a limitation (the model remains untested at scale) and the strongest possible argument for testing it now.
The atrophy argument, that transactional systems erode the human capabilities orchestration depends on, is logically coherent and consistent with evidence from domains where skill degradation follows automation. But the specific causal mechanisms, the rate of erosion, and whether genuine tipping points exist beyond which recovery becomes impractical: these require longitudinal investigation that this paper can only motivate.
Finally, this paper argues from a position. It holds that relational approaches to stakeholder processes are superior to transactional ones. Thirty years of relationship marketing theory, the cross-sector evidence examined here, and the regulatory direction exemplified by the EU AI Act all support this position. But it is a position nonetheless. Alternative frameworks deserve rigorous engagement, and a single paper cannot exhaust a debate that the agentic economy is only beginning to force.
What this paper can claim is that the question it raises is urgent, under-examined, and consequential. These limitations are not reasons to defer that question. They are reasons to pursue it, empirically, across contexts, and now.

8. Conclusion

Grönroos proposed a paradigm shift thirty years ago. It transformed how organisations relate to their customers, their suppliers, their communities. It did not reach the people they need to hire.
This paper has argued that the omission was not minor and is no longer tolerable. The agentic economy is arriving, not as a distant possibility but as a present reality reshaping how organisations make consequential decisions about people. The systems organisations build today will embed either

transactional or relational logic into those decisions, and the choice, once made, will be difficult to reverse. Transactional systems that have spent three decades manufacturing waste, eroding relational capability, and processing human beings as data points are about to be amplified by AI agents capable of operating at unprecedented scale and speed. Without a relational framework governing that amplification, the result is predictable: more waste, faster, led by a shrinking human capability to recognise or correct it.

This paper, part of a broader ARM research programme undergoing cross-disciplinary validation across marketing theory, human resource management, and AI governance, offers a framework for a different trajectory. Its four tenets, relationships precede transactions, opacity demands accountability, noise reduction requires collaboration, orchestration supersedes automation, are not theoretical abstractions. They are design principles that multiple domains have independently converged toward, translated into the one stakeholder process that every organisation depends on and almost none has thought to design for.

The Agent Triad provides the operational architecture. The capable orchestrator defines the human capability that makes orchestration possible, and valuable. The compensatory evaluation model ensures that the people at the centre of the process are treated as the multi-dimensional stakeholders they are, not as data points to be filtered through pass/fail gates. Historically impractical at scale, rejected on affordability, not merit, it is now viable for the first time, as AI agents sustain multi-dimensional evaluation at a fraction of previous cost. The irony is precise: the same technology that threatens to deepen transactional logic also makes the relational alternative achievable. The cross-sector evidence suggests that this is not a question of whether but when. Orchestration is emerging wherever AI meets consequential stakeholder decisions. Talent acquisition is the last major domain to recognise this, and the one that can least afford to wait.

The opportunity is real, and the window for taking it is narrow.

Advancing Production Management through Big Data and AI: Current Practices and Challenges in Italian SMEs

ANDREA CHIARINI[1], SURAJIT BAG[2]

Abstract. *The increasing digitalization of manufacturing systems has led to growing interest in the adoption of Big Data (BD) and Artificial Intelligence (AI) in production management. While the literature has extensively examined the use of these technologies in large corporations and digital platforms, fewer studies have focused specifically on small- and medium-sized enterprises (SMEs). Nevertheless, SMEs represent the majority of manufacturing firms in many industrialized economies and play a central role in industrial supply chains. This study investigates the state of the art and the main challenges associated with the implementation of BD-AI technologies in production management within Italian manufacturing SMEs. The research adopts a mixed-methods approach. In the first stage, a Delphi panel composed of experts in digital technologies, manufacturing consulting, and operations management identified nine relevant BD-AI application areas in production environments. In the second stage, a survey of 109 Italian manufacturing SMEs evaluated the perceived relevance of these applications using a Likert-scale questionnaire. The results show that SMEs express strong interest in applications related to resource consumption optimisation, energy efficiency, predictive and preventive maintenance, and production routing simulation. Conversely, applications such as production scheduling optimisation, predictive quality control, and automated root-cause analysis receive lower interest due to organisational, technological, and cultural barriers. The study highlights the importance of developing customised and flexible BD-AI systems capable of supporting human decision-making in dynamic production environments. The findings contribute to the literature on Industry 4.0 adoption in SMEs and provide managerial insights for technology developers and practitioners.*

Keywords: *Big Data; Artificial Intelligence; Industry 4.0; Production management; Manufacturing SMEs; Digital transformation*

Framing of the research. The rapid development of digital technologies has transformed the manufacturing sector during the last decade. In particular, the emergence of the Industry 4.0 paradigm has introduced new opportunities for integrating advanced digital technologies into production processes. Among these technologies, Big Data (BD) and Artificial Intelligence (AI) have become central components of modern manufacturing systems. Big Data refers to the ability to collect, store, and analyse very large and heterogeneous datasets characterized by volume, velocity, and variety (Laney, 2001). Artificial Intelligence, on the other hand, includes algorithms and computational models capable of extracting knowledge and patterns from these datasets in order to support automated or semi-automated decision-making processes (Reis et al., 2021).

In manufacturing environments, large volumes of data are generated continuously by machines, sensors, industrial robots, enterprise software systems, and digital platforms. These data streams include information related to machine conditions, production flows, quality indicators, energy consumption, and environmental parameters. When analysed using advanced analytics and machine learning techniques, such datasets can support important operational improvements such as predictive maintenance, energy optimisation, and production planning (Javaid et al., 2020). As a consequence, BD and AI technologies are considered fundamental drivers of the digital transformation of manufacturing systems.

Despite these opportunities, the adoption of BD-AI technologies is not uniform across organisations. Large multinational firms often possess the financial resources, technological infrastructure, and specialised skills required to implement advanced analytics solutions. In contrast, small- and medium-sized enterprises frequently encounter significant barriers when attempting to adopt these technologies. SMEs often operate with limited financial resources and limited digital expertise, which makes the implementation of complex analytics platforms more difficult (Maroufkhani et al., 2020). Moreover, organisational culture and managerial experience can influence the willingness of firms to adopt innovative digital solutions.

Understanding how SMEs perceive and adopt BD-AI technologies is therefore essential for the broader digital transformation of the manufacturing sector. In Europe, SMEs represent the majority of manufacturing firms and contribute significantly to employment and economic output. In Italy, for instance, SMEs account for approximately 92% of manufacturing companies and operate in highly specialised industrial clusters. These firms often compete through flexibility, craftsmanship, and niche specialisation rather than through large-scale automation. For this reason, analysing the adoption of BD-AI technologies in SMEs requires considering the specific operational characteristics of these organisations.

Existing literature has analysed the potential benefits of BD and AI in manufacturing environments. Studies have shown that these technologies can support predictive maintenance, improve product quality, optimise production scheduling, and enhance sustainability performance (Feng and Shanthikumar, 2018; Azeem et al., 2021). However, many of these studies focus primarily on large organisations or theoretical frameworks related to Industry 4.0. Empirical evidence regarding the adoption of BD-AI technologies in SMEs remains relatively limited.

Furthermore, SMEs face unique challenges when integrating advanced digital technologies into their existing production systems. These challenges include the lack of internal data science expertise, limited investments in digital infrastructure, and difficulties in managing large volumes of unstructured data generated by production processes (Kumar et al., 2024). As a result, SMEs may adopt BD-AI technologies selectively, prioritising applications that deliver immediate operational benefits while avoiding those that require extensive organisational transformation.

For these reasons, investigating the adoption of BD-AI technologies in SMEs represents an important research area. By examining how manufacturing SMEs evaluate different BD-AI applications and the challenges they encounter during implementation, scholars can contribute to a more realistic understanding of digital transformation in manufacturing.

From the literature review, we can highlight some gaps.

- The literature discusses the benefits of BD-AI in various sectors. Still, it does not delve deeply into SMEs' specific challenges when integrating these technologies into existing production systems.
- There is a limited focus on SMEs. Several studies concentrate on larger firms or general industry applications, leaving SMEs underexplored despite their distinct challenges and needs.
- Research often mentions challenges in passing without thoroughly analysing the barriers to adoption and how they might be overcome.
- There is conflicting evidence regarding the impact of BD-AI on environmental and sustainable performance.
- While some studies highlight the positive effects, others find no significant impact. This contradiction suggests a gap in understanding the conditions under which BD-AI technologies contribute to or fail to enhance environmental sustainability.

The literature review also revealed that BD-AI implemented in production management has four principal areas of interest:

- simulation and optimisation
- predictive processes
- environmental management and energy management.

We considered these implementation areas when developing our semi-structured interview guide.

Purpose of the paper. The purpose of this paper is to investigate the adoption and perceived importance of Big Data and Artificial Intelligence applications in production management within manufacturing SMEs. Specifically, the study seeks to identify which BD-AI applications are considered most relevant by SMEs and to analyse the challenges that organisations face when implementing these technologies.

The research is guided by two main research questions. The first research question asks: which BD-AI applications are of greatest interest to manufacturing SMEs? The second research question investigates: what challenges do SMEs encounter when adopting BD-AI technologies in production environments?

Addressing these questions contributes to the academic literature in several ways. First, it provides empirical insights into the technological priorities of SMEs operating in advanced manufacturing contexts. Second, it highlights the gap between theoretical Industry 4.0 frameworks and the practical needs of smaller manufacturing firms. Finally, it offers practical recommendations for managers, technology developers, and policymakers who aim to support the digital transformation of SMEs.

Methodology. The research adopts a mixed-methods design combining qualitative and quantitative approaches. Mixed-methods research allows scholars to investigate complex phenomena by integrating different sources of evidence and perspectives (Shorten and Smith, 2017).

The first stage of the research involved a qualitative Delphi study conducted with a panel of twelve experts. The panel included specialists in artificial intelligence technologies, manufacturing consultants, and production managers working in Italian SMEs undergoing digital transformation. Through several rounds of semi-structured interviews, the experts discussed the potential impact of BD-AI technologies on production management processes. These are the questions administered to the 12 experts.

- *What do you think are/will be the impacts of BD-AI in relation to simulation and optimisation?*
- *What do you think are/will be the impacts of BD-AI in relation to predictive processes?*
- *What do you think are/will be the impacts of BD-AI in relation to production planning and scheduling?*

- *What do you think are/will be the impacts of BD-AI in relation to environmental management (including energy management)?*
- *What do you think are/will be the general impacts of BD-AI on production management?*

During the Delphi process, experts identified multiple areas where BD-AI technologies could support manufacturing operations. Through thematic analysis, these insights were organised into nine theoretical themes representing potential applications of BD-AI technologies in production environments. These applications included: *production routing simulation, machine parameter optimisation, production scheduling optimisation, predictive maintenance, predictive quality control, root-cause analysis, resource consumption optimisation, environmental impact reduction, and energy efficiency improvement*.

In the second stage of the research, these nine themes were transformed into survey items and evaluated through a quantitative questionnaire. The questionnaire was distributed to Italian manufacturing SMEs through an online platform. The sample consisted of companies with fewer than 250 employees operating in discrete manufacturing industries. To reduce bias, the companies have been selected based on the same characteristics, as identified below:

- range from 0 to 250 employees and production units located in Italy
- intermittent production system based on a combination of job-shops that have machinery and assembly lines or cells. We avoided continuous flow processes. Indeed, these types of industries are usually highly capital intensive with a high level of capacity utilisation and rigid production routing and scheduling. Thus, they use completely different software applications for processes such as maintenance, scheduling, parameters control, routing and energy management. In addition, they are rarely SMEs;
- not classified as companies that must control potential major-accident hazards involving dangerous substances because such companies must have in place specific systems to avoid environmental impacts according to strict legislation and rules.

A total of 109 valid responses were collected from managers responsible for production, operations, or technical functions. Respondents were asked to evaluate the importance of each BD-AI application using a five-point Likert scale ranging from "not important" to "very important."

To analyse the data, the study employed non-parametric statistical techniques, including the Wilcoxon signed-rank test. Non-parametric tests are particularly appropriate when analysing ordinal data obtained from Likert-scale questionnaires and when assumptions of normal distribution cannot be guaranteed.

Table 1 – Results from the Wilcoxon rank test

Variable	Null hypothesis: median of the variable equals	Sig.
RESOU	4.7	.802
ENERG	4.5	.448
MAINT	4.4	.800
SIMUL	4	.106
PARAM	3	.709
SCHED	2	.316
CAUSE	2	.222
QUALI	Any value	<.05
ENVIR	Any value	<.05

Results. The insights gathered from both the expert interviews and the online survey reveal a complex and evolving landscape in which manufacturing companies are increasingly aware of the potential of Big Data and Artificial Intelligence (BD-AI) applications, while also confronting several practical challenges. A strong theme emerging throughout the comments is the recognition that the manufacturing environment has changed dramatically in recent years, particularly regarding the availability and cost of resources. Many respondents linked this shift to global disruptions, first the pandemic, then geopolitical tensions, which have generated instability in the supply of raw materials, energy, and other essential inputs. This volatility has reinforced the perceived importance of BD-AI applications capable of optimising resource consumption. Companies described the need for advanced systems able to integrate production rates, operating hours, process parameters, and real-time cost data in order to support decisions about scheduling, procurement, and commodity purchasing. These systems are viewed not merely as tools but as strategic assets that can help organisations navigate increasingly unpredictable markets. Similar enthusiasm was expressed regarding the potential of BD-AI to improve energy efficiency. Many companies reported that they had already begun implementing analytics-based solutions capable of monitoring consumption, optimising machine schedules, detecting anomalies, and selecting the most convenient energy providers. Some organisations explained that they had been developing such systems for many years and were now enhancing them using machine learning and deep learning algorithms. These long-term investments have resulted in large repositories of data stored in the cloud and continual

experimentation with more advanced predictive models. The general tone of the comments suggested that BD-AI in the field of energy efficiency is no longer experimental but embedded in daily operations, with many firms actively collaborating with external partners such as start-ups to further improve these tools. Predictive and preventive maintenance emerged as another area where both experts and practitioners share a high level of confidence. Companies consistently emphasised the relevance of early warnings, real-time detection of abnormalities, and the ability to anticipate failures in machinery and assembly lines. Many respondents stated that they were already using or implementing systems featuring smart sensors and machine-learning-based analytics to detect and prevent faults. However, several comments pointed out an important nuance: predicting failures within machines is relatively straightforward compared to anticipating negative events in assembly stations. While mechanical components exhibit measurable patterns of deterioration, assembly activities may be affected by issues such as incorrect workstation configuration, damaged or uncalibrated tools, or environmental conditions that impact both productivity and worker well-being. Respondents indicated that while BD-AI is promising, the complexity and variability of these human- centred environments make accurate predictions challenging. A particularly interesting theme concerned the dynamic adjustment of preventive maintenance schedules. Instead of relying on fixed replacement intervals, several companies expressed a desire to integrate BD-AI to continuously analyse machine conditions, operating loads, and other factors to determine the optimal moment for intervention. This evolving concept, described by some respondents as a blend of predictive and preventive maintenance, aims to replace components not based on rigid thresholds but on real operating behaviour, thus reducing risks while avoiding unnecessary maintenance activities. Production routing simulation also generated considerable interest. Many respondents referred to such tools using the popular term “digital twins,” highlighting their importance in predicting bottlenecks and supporting the design of more robust production flows. However, a recurring concern emerged from the comments: many existing simulators appear to rely on static or historical data, such as average cycle times or predefined troubleshooting cases. Respondents stressed that real production environments are dynamic, with conditions shifting continuously, and therefore simulation tools must be capable of learning and adjusting in real time. There was some scepticism about whether current digital twin technologies truly possess this level of agility, and several participants described the development of dynamic, data-driven simulation models as an unresolved challenge. When considering the ability of machines to autonomously regulate their parameters to improve yield, opinions became more divided. While experts expressed strong confidence that BD-AI can support the continuous optimisation of machine performance, many manufacturing companies suggested that modern equipment already includes embedded control systems capable of adjusting vital parameters without requiring additional BD-AI layers. Some respondents emphasised that such optimisation functions are typically developed by machine manufacturers, not by the user companies or external software providers. As a result, while some organisations do see opportunities to use BD-AI to reduce cycle times or improve quality, others regard these applications as unnecessary or redundant. Applications related to production scheduling were met with even more cautious attitudes. Although experts view scheduling optimisation as an important field for BD-AI, many practitioners indicated that their production environments are too volatile for automated scheduling tools to be effective. Several respondents explained that they prefer manual, flexible methods, often relying on simple tools such as Kanban systems and spreadsheets, because their production flow must be adjusted shift by shift. They noted that before introducing sophisticated algorithms, it is more important to stabilise processes using lean principles and eliminate bottlenecks. Once waste is reduced, the need for complex scheduling systems may diminish substantially. Root-cause analysis and identification generated some of the most critical comments. While experts suggested that BD-AI could support rapid identification of defect causes, many respondents argued that such applications are feasible only in industries producing very large quantities of identical items. In sectors characterised by high product variety and frequently changing process conditions, data tend to be unstructured, inconsistent, and insufficient for pattern recognition. Respondents described dealing with thousands of part numbers and highly diverse types of problems, ranging from unusual noises to rare defects, making it difficult to build reliable analytical models. Human intuition and experience, they argued, remain indispensable in these situations. Similar challenges were raised in relation to predictive quality control. Respondents indicated uncertainty about what data to collect, how to measure relevant variables, and how to manage the enormous variety of inputs that might include not only pressures and voltages but also images, audio signals, and even odours. Several participants mentioned that their quality controllers rely on sensory cues that are difficult to formalise or quantify through BD-AI systems. As a result, companies appear to favour more traditional approaches, postponing heavy investments in predictive quality analytics. A comparable attitude was observed concerning environmental impact reduction. Although many companies are strongly committed to environmental compliance, their focus remains on monitoring legal parameters through IoT-enabled sensors and ensuring fast response in case of anomalies. Respondents questioned the added value of BD-AI analytics in this area, suggesting that environmental management relies more on immediate corrective actions than on predictive modelling. Overall, the narrative emerging from the respondents and experts presents a multifaceted picture: companies recognise the transformative potential of BD-AI but adopt these technologies selectively, prioritising areas where data are abundant, problems are stable, and value is clear. At the same time, they remain cautious in domains characterised by high variability, unstructured information, or strong reliance on human judgment.The results of the survey reveal substantial differences in how SMEs evaluate different BD-AI applications. Applications related to resource consumption optimisation, energy efficiency, predictive maintenance, and production routing simulation received the highest

ratings from respondents. Resource consumption optimisation emerged as the most relevant application area. Respondents emphasised that fluctuations in raw material prices and supply chain disruptions have significantly affected manufacturing operations in recent years. BD-AI technologies can support companies in forecasting resource demand, analysing supplier options, and optimising purchasing decisions. These capabilities allow SMEs to improve resilience and reduce operational costs. Energy efficiency applications also received strong support from respondents. Many companies reported implementing monitoring systems capable of collecting large quantities of energy consumption data. By applying machine learning algorithms to these datasets, companies can identify inefficiencies and optimise production schedules to reduce energy consumption (Bevilacqua et al., 2017; Andrei et al., 2022). Predictive and preventive maintenance represents another important application area. Sensors embedded in industrial equipment generate operational data that can be analysed using machine learning techniques to predict equipment failures before they occur. Predictive maintenance systems can therefore reduce machine downtime and maintenance costs (Feng and Shanthikumar, 2018; Wen et al., 2022). Production routing simulation was also considered highly relevant. Many respondents referred to digital twin technologies that allow companies to simulate production scenarios and evaluate potential improvements before implementing them in real operations (Gao et al., 2019; Zhang et al., 2022). In contrast, several BD-AI applications received relatively low ratings from SMEs. Production scheduling optimisation, predictive quality control, and automated root-cause analysis were considered less relevant. Respondents often argued that human expertise and lean production methods remain more effective for solving operational problems in dynamic production environments.

Research limitations. Although this study provides valuable insights into the adoption of BD-AI technologies in manufacturing SMEs, several limitations should be acknowledged. First, the research focuses exclusively on Italian manufacturing companies. While Italy represents a significant industrial context, the findings may not be fully generalisable to other countries.

Second, the study relies on perceptual data collected through questionnaires. While such data provide valuable insights into managerial attitudes and perceptions, future research could complement these findings with objective performance indicators and longitudinal case studies.

Third, the set of BD-AI applications analysed in the study was identified through a Delphi panel of experts. Although the Delphi method ensures the relevance of selected topics, alternative expert panels may identify additional application areas.

Managerial implications. The findings of this research provide several implications for managers and practitioners involved in manufacturing operations. First, SMEs should prioritise BD-AI applications that offer clear operational benefits and relatively low implementation complexity. Applications such as predictive maintenance and energy optimisation can deliver measurable improvements in productivity and cost efficiency.

Second, successful digital transformation requires organisational change in addition to technological investment. Companies must develop digital competencies among employees and encourage a culture that supports data-driven decision-making.

Third, SMEs should consider collaborative innovation strategies involving partnerships with universities, technology providers, and start-ups. These collaborations can provide access to advanced technological capabilities and reduce the risks associated with digital transformation projects.

Originality of the paper. This paper contributes to the literature by providing an empirical investigation of BD-AI adoption within manufacturing SMEs. While many Industry 4.0 studies focus on large organisations or theoretical frameworks, this research highlights the specific needs and perceptions of smaller firms operating in real production environments.

The originality of the study lies in its mixed-methods approach combining expert insights and empirical survey data. By integrating qualitative and quantitative evidence, the research provides a comprehensive understanding of both technological opportunities and implementation challenges.

AI Literacy as a Hiring Signal in Project Management Recruitment

DANIEL TEDDE[1], ANDREA VINCIS[2], ALESSANDRO BALBINA[3], CINZIA DESSÌ[4]

Abstract. *Generative Artificial Intelligence is increasingly impacting project work, yet whether AI literacy is becoming a screening criterion for project managers remains an open empirical question. This is important in Human Resource Management, where project-based organisations select staff using competence frameworks that combine technical, managerial, and behavioural criteria. To fill this gap, we examine labour-market demand using a mixed-methods approach that includes web scraping, computational text mining, and qualitative content analysis. The dataset includes 530 Project Management vacancies posted on the job-recruiting digital platform Indeed across Italy, the United Kingdom, and the United States. Quantitative analyses identify requested skills, education, certifications, and tools, while qualitative coding examines advertisements that explicitly mention Artificial Intelligence or Generative Artificial Intelligence to understand how these capabilities are represented. AI-related signals are present, but inconsistently specified and rarely treated as clear entry thresholds; instead, they typically appear as expectations for working within organisational systems or AI-enabled interfaces. We position job advertisements as recruitment signals that shape the formalisation of emerging technologies in selection practice.*

Keywords: *Recruitment signals, Selection criteria, Skill requirements, Generative artificial intelligence, Project management, Cross-national labour markets*

Framing of the research. *Artificial Intelligence (AI) has shifted from a field primarily for technical specialists to a versatile technology now deeply integrated into daily organisational processes across various industries (Eloundou et al., 2024). Organisations leverage AI to automate routine and semi-structured tasks, derive predictive insights from extensive data, tailor interactions, and facilitate real-time decision-making (Davenport & Ronanki, 2018). More recently, the growth of Generative Artificial Intelligence (GenAI), capable of producing text, images, and other artefacts, is further transforming how knowledge work is performed and evaluated. Early evidence suggests GenAI can affect task allocation and productivity, especially in writing- and communication-intensive work, with gains that vary by worker characteristics and context (Brynjolfsson et al., 2025; Noy & Zhang, 2023). However, classic accounts of technological change underscore that labour-market effects depend on how technologies are embedded in workflows and recomposed into tasks and complementary roles (Acemoglu & Restrepo, 2019). Widespread use does not automatically translate into widespread formal requirements, making employer demand an empirical question rather than a foregone conclusion.*

This question is particularly salient for Project Management (PM), a role often positioned as a change-agent function but frequently staffed through ad hoc or subjective selection in transformation contexts, a mismatch that raises strategic risk when capability requirements are poorly specified (Doyle, 2002). Project managers operate at the intersection of formal methods (e.g. planning, scheduling, risk and cost control) and relational coordination (e.g. leadership, communication, stakeholder alignment). Contemporary standards emphasise adaptability and tailoring across predictive, agile, and hybrid approaches (ISO, 2020; PMI, 2021). As organisations trial AI-enabled forecasting, decision support, and generative tools for documentation, reporting, and communication, project work appears especially exposed to AI in everyday practice. However, whether employers are codifying AI literacy as a hiring threshold or treating it merely as a complementary advantage remains uncertain.

Although scholars have begun to investigate how AI can support project activities, document reviews, and the growing ecosystem of project management tools (Almeida et al., 2025; Bento et al., 2022), systematic evidence of the specific AI-related requirements that employers express in recruitment remains limited. This study addresses that gap by examining online job advertisements as a timely proxy for employer skill signals, while remaining attentive to issues of representativeness and measurement (Kureková et al., 2015). Anchored in Human Resource Management (HRM), the study focuses on selection validity, competence signalling, and talent pipeline development. Its scope is to clarify which AI-related competencies are demanded in the labour market and to assess the implications of these signals for recruitment practices, curriculum design in higher education and professional training, and individual upskilling priorities as GenAI becomes increasingly pervasive. Methodologically, it adopts a mixed-methods design that combines quantitative text mining and qualitative content analysis (Hsieh & Shannon, 2005; Krippendorff, 2018), drawing on a systematic web-scraping of PM vacancies posted on the job-recruiting digital platform Indeed between late July and August 2025, across Italy, the United Kingdom, and the United States, yielding a cleaned sample of 530 advertisements. By shifting attention from normative forecasts to observed recruitment signals, the paper offers comparative evidence on whether AI-related competencies are beginning to be institutionalised within hiring criteria for PM roles.

Purpose of the paper. *This paper investigates whether and how AI literacy is being formalised as a hiring criterion for project managers. Drawing on a cross-national dataset of job advertisements from Italy, the United Kingdom, and the United States, it combines computational text mining with qualitative content analysis to examine the extent to which AI-related competencies appear in recruitment signals and how they are framed relative to established selection criteria such as experience, relational skills, and methodological fluency. The analysis positions job advertisements as institutionalised HRM artefacts that reveal how emerging technologies are (or are not) being codified into competence-based selection practices for project-based roles. By considering job advertisements as institutionalised artefacts of HRM, the study shifts focus from normative predictions about what project managers should know regarding AI to observable evidence of what employers actually formalise when granting access to managerial roles. To ground this investigation, the evolving landscape of AI in literature and applications within PM is briefly discussed.*

Over the last decade, research on AI in PM has shifted from treating AI as a single tool to understanding it as a diverse portfolio of techniques (e.g., machine learning, optimisation, natural language processing, and, more recently, GenAI) applied across specific PM processes and performance domains. For HRM, this diversity matters because AI-related competencies are unlikely to correspond to a single bounded skill; rather, they suggest evolving, hybrid competence profiles that complicate job design and selection criteria (Cheng et al., 2005; do Vale et al., 2018).

In general, AI use cases can be mainly categorised into four domains. Estimation and forecasting, where AI is extensively used to predict costs, effort, and duration, thereby reducing initial uncertainty (Adamantiadou & Tsironis, 2025; Davahli, 2020; Taboada et al., 2023). Scheduling and optimisation, with AI aiding in schedule creation, robustness evaluation, and resource-constrained planning; Bahroun et al. (2023) highlight the significance of this area. Risk and safety management involves applications such as anomaly detection, early-warning systems, and uncertainty modelling to facilitate proactive interventions (Nenni et al., 2025; Salimimoghadam et al., 2025). Finally, decision support and reporting, which includes an AI-powered Decision Support System that generates dashboards and recommendations, particularly for construction sustainability (Smith & Wong, 2022). These four domains mainly correspond to "hard" PM activities, which are generally easier to formalise in job descriptions than the relational and leadership functions emphasised in HRM (Ahsan et al., 2013).

Systematic reviews reveal that AI-enabled PM applications tend to concentrate in areas where data are abundant and outcomes are measurable, particularly in planning and control. Taboada et al. (2023) categorise research in various performance areas, highlighting AI mainly as an analytical tool that enhances forecasting, monitoring, and decision-making without replacing managerial judgment and accountability. Nenni et al. (2025) present AI as a catalyst for PM "digitisation", emphasising data-driven planning, risk detection, and performance assessment, while noting uneven maturity and validation across settings. A methodological note of caution from Müller et al. (2024) highlights persistent weaknesses in transparency and reporting rigour, suggesting that translating AI capability claims into formal competence frameworks poses a greater risk to recruitment and staffing decisions (Ahsan et al., 2013).

The literature on the field highlights a strong industry skew. Construction projects dominate empirical settings, arguably due to the richness of operational data (e.g., cost and schedule baselines, progress reporting, sensor streams, and BIM information), which enable modelling and automated monitoring. However, HRM systems in construction differ from those in services, the public sector, or creative industries, limiting the generalisability of AI-related skill expectations across project-based labour markets (do Vale et al., 2018; Gardiner et al., 2025). Broader reviews include IT/software and multi-project contexts, but typically with less consistent evidence of effectiveness at scale (Nenni et al., 2025; Taboada et al., 2023). The field's most robust evidence thus reflects particular project types and data infrastructures, complicating HRM efforts to standardise competence requirements across industries (Cheng et al., 2005).

The literature also reveals a persistent lifecycle imbalance. Planning and monitoring/control phases are significantly more developed than the closing and post-project learning phases. Stakeholder, procurement, and communication management are less addressed compared to prediction-focused tasks (Davahli, 2020; Nenni et al., 2025; Salimimoghadam et al., 2025)—and this discrepancy is significant for HRM, since these are the competencies most prominently featured in recruitment and appraisal frameworks (Ahsan et al., 2013; Borg et al., 2023). Related perspectives on cognition further emphasise the relevance of HRM. Stingl et al. (2025) contend that "project cognition" remains underdeveloped and call for greater integration with cognitive science. This perspective becomes increasingly urgent as AI influences how information is generated and acted upon. Ika and Pinto (2025) revisit Kahneman's influence on project theory and describe AI as both a potential tool for debiasing and a new source of overconfidence if accepted without scrutiny, reinforcing HRM concerns about judgment and behavioural competence (Cheng et al., 2005; Doyle, 2002).

GenAI represents a notable shift, focusing on creating and transforming project artefacts rather than merely predicting numerical outcomes. It can draft documentation, summarise meetings, generate status updates, translate communications, and assist with requirements work. These functions overlap with tasks that require coordination and communication, core to managerial skills frameworks (Cheng et al., 2005; do Vale et al., 2018). Recent reviews view GenAI as a tool to enhance, rather than replace, knowledge-intensive PM responsibilities (Nenni et al., 2025; Salimimoghadam et al., 2025). Evidence on how roles evolve aligns with this view; Holzmann et al. (2022) found that project managers expect AI to increasingly automate technical and analytical tasks, while emphasising the importance of human skills such as communication, leadership, and judgment. This duality supports HRM perspectives that technology can enhance managers' behavioural and relational skills (Doyle, 2002; Prikshat et al., 2023).

Overall, the literature aligns with a socio-technical perspective. AI might enhance PM performance, but human capital readiness remains a key constraint, emphasising the importance of AI competence for project professionals (Adamantiadou & Tsironis, 2025; Nenni et al., 2025; Salimimoghadam et al., 2025). However, the literature is much less explicit about whether this competence has become a labour-market gatekeeper. Most reviews focus on applications and implementation challenges rather than hiring procedures, credentialing, or integrating AI skills into job criteria. Several reasons might explain why AI competence hasn't yet become a clear hiring requirement. For instance, specialised roles can facilitate AI usage, high-impact applications often depend on infrastructure that is unevenly accessible, PM focuses on leadership and stakeholder engagement, with AI seen as a complementary tool (Bahroun et al., 2023; Cheng et al., 2005; Davahli, 2020; do Vale et al., 2018). Advances in digital infrastructure may eventually lead to more direct integration of AI within operational processes in specific sectors (Adebayo et al., 2025; Smith & Wong, 2022). Recent research on job role evolution shows that in some contexts, familiarity with AI is highly valued, while in others, leadership and stakeholder insights are the key differentiators (Gardiner et al., 2025; Pinto et al., 2025). Therefore, despite ongoing discussions about capabilities, concrete evidence on whether AI skills are becoming part of explicit hiring criteria remains limited, prompting analysis of job ads as formal HRM signals (Ahsan et al., 2013; do Vale et al., 2018). These considerations form the basis for the following research question: To what extent and in what ways are AI-related competencies emerging as selection criteria within HRM-driven recruitment processes for project managers?

Methodology. *This study adopts a mixed-methods sequential explanatory design in which large-scale quantitative evidence from online job postings is complemented by qualitative interpretation of postings that explicitly reference AI. This approach is appropriate when pattern detection at scale must be combined with contextual understanding of meanings embedded in text (Creswell & Clark, 2017; Grimmer & Stewart, 2013). It is also well suited to recruitment research because job advertisements both describe required competencies and signal organisational priorities and values to applicants (Ahsan et al., 2013; Barber, 1998). Integrating text mining with qualitative content analysis enables the study to capture the prevalence of AI-related signals and the ways AI competencies are framed as desirable, expected, or mandatory.*

Data were collected via systematic web scraping of the job search platform Indeed, chosen for its broad labour-market coverage, cross-country comparability, and availability of structured, extractable data fields. Other sources were evaluated but not used: Remote OK was excluded due to its limited representation of PM roles, and LinkedIn was avoided due to restrictions on automated, large-scale data collection. The scraping was conducted using Apify and the Indeed Scraper by Misceres, allowing a standardised, automated process across different markets and ensuring reliability for cross-national comparisons (Ahsan et al., 2013; Den Hartog et al., 2007). Using the same methodology, 200 job postings per country were initially collected for Italy, the United Kingdom, and the United States (total N = 600).

After export to .xlsx, a structured cleaning process removed non-relevant roles while retaining a broad set of project-management-related titles (e.g., Project Leader, Junior/Assistant Project Manager, Project Coordinator/Officer) to reflect occupational boundaries and entry routes, consistent with HRM perspectives on boundary construction (Ahsan et al., 2013; Hodgson, 2002). The final dataset includes 530 postings: Italy (n = 180), UK (n = 185), US (n = 165). Extracted fields include employer, title, full description, job categorisation, location, posting date, and salary, where available.

Quantitatively, the posts were organised in Excel and then analysed using Python (Anaconda/Jupyter). The text mining process involved cleaning the data, removing stopwords (in Italian, English, and custom lists), and creating frequency maps with WordCloud to identify top terms as part of the exploratory analysis (Gallivan et al., 2004; Sodhi & Son, 2008). Targeted frequency analyses focused on education, certifications, tools/software, and skills, guided by the PMI Talent Triangle's Ways of Working and Power Skills; Business Acumen was excluded. AI-related posts were identified through keyword searches, with manual validation to prevent false positives from Italian "ai," following best practices in content analysis (Ahsan et al., 2013; Krippendorff, 2018). For the qualitative aspect, validated AI posts were coded in Taguette (Rampin & Rampin, 2021), categorised by ad section and functional framing of AI, with additional comparisons between tech-intensive and non-tech-intensive sectors.

Results. *This study is currently a work in progress. The initial findings indicate that recruitment signals for PM roles largely rely on traditional selection criteria rather than on new technological capabilities. In the three labour markets examined, job ads primarily depict the project manager as responsible for coordination, delivery, stakeholder alignment, and project process management. This suggests a pattern of continuity rather than change: employers continue to prioritise prior experience, organisational reliability, and cross-team ability in their hiring criteria, while AI-related skills are still secondary in the overall selection process.*

A second pattern highlights the ongoing significance of educational and professional signals, though these vary across different countries. Job ads show that employers still rely on traditional indicators of competence, such as degree type, sector experience, and recognised certifications, to assess candidates' readiness for project roles. Nevertheless, these signals now seem more aligned with general expectations of professional maturity and credibility rather than specific technical expertise. This indicates that, despite the influence of digital transformation, hiring practices still favour traditional markers of employability and responsibility over newer forms of technological skills.

The preliminary findings also suggest that methodological fluency remains a central dimension of employability in PM. Advertisements consistently refer to familiarity with planning, monitoring, scheduling, delivery frameworks, and cross-functional coordination practices, confirming that employers still view project work through a structured

managerial lens. At the same time, the language of agility and hybridisation appears to be an extension of this logic rather than a replacement for it. In other words, organisations seem to value adaptability in methods, but within a competence profile that continues to emphasise execution, control, and communication.

Another initial finding highlights the importance of relational and behavioural skills. Key aspects such as communication, stakeholder engagement, leadership, negotiation, and the ability to collaborate across organisational boundaries are evident as core elements in role definition across all three countries. This point reinforces the study's broader argument, demonstrating that employers still view PM as a socio-organisational role rather than just a technical one. Even when referring to tools, platforms, or digital environments, these are usually seen as part of a broader expectation that project managers exercise judgment, coordinate stakeholders, and maintain alignment amid uncertainty. In this context, mentions of AI are limited and lack formal weight. When AI or GenAI is brought up, it is rarely considered a specific requirement for the role. Instead, it is usually described as part of the organisational environment or as an additional form of familiarity associated with innovation-focused settings. This indicates that AI literacy has not yet become a formal gatekeeping criterion in PM hiring. Rather than a standalone qualification, it currently functions as an emerging but not well-standardised signal, often overshadowed by more established expectations regarding experience, communication, and methodological skills.

Overall, the preliminary results support the interpretation that AI is entering recruitment discourse in PM in an incremental and dissimilar way. Employers appear aware of the growing relevance of AI-enabled work practices, yet this awareness has only partially translated into explicit competence requirements in job advertisements. The labour-market signal indicates a transition rather than full formalisation: AI is increasingly influencing the project work environment, but has not yet replaced the traditional basis for hiring project managers.

Research limitations. *This study notes several research limitations to consider when interpreting the results. First, using online job ads as coded signals of recruitment may not fully reflect actual hiring decisions, informal screening, or post-hire work requirements. Employers might use generic templates, omit new skills to keep applicant pools broad, or rely on internal training, leading to underreporting of AI-related expectations. Second, the dataset covers a brief period (July -August, 2025) and is drawn from a single platform (Indeed), which limits its generalizability across time, platforms, and labour market segments. Although Indeed enables cross-national comparisons, job postings there may differ systematically from those on LinkedIn, corporate career sites, or niche PM boards. Third, identifying references to AI and GenAI using keywords may miss implicit signals, such as tool names or phrases like "automation" or "data-driven," especially in Italian, and may require measures to prevent false positives. Fourth, text-mining results highlight lexical prominence rather than the actual importance of criteria in hiring decisions and do not account for skill trade-offs. Finally, cross-country comparisons may be affected by institutional and linguistic differences in job-ad formats, credentialing, and disclosure practices (such as salary and contract info), which could bias observed frequencies regardless of actual employer demand.*

Managerial implications. *The findings are likely to have multiple impacts on HRM practices, education, training, and PM. For employers and HR teams, the evidence indicates that AI literacy is not yet a standard gatekeeping criterion in hiring project managers. Nonetheless, the appearance of AI signals in some job postings—often described as working with AI teams or in AI-enabled settings—suggests that organisations are beginning to incorporate AI into project work, even if they do not explicitly include it in their selection criteria. This presents an opportunity to enhance recruitment clarity: as AI tools become more integrated into project workflows, employers can minimise mismatches between actual role requirements and applicant expectations by clearly indicating whether AI-related skills are necessary, preferred, or situational. Such transparency can improve the accuracy of selection, aid candidates in self-assessment, and ensure that hiring practices align with job design and governance structures.*

Regarding workforce development and talent pipelines, the findings suggest that traditional PM skills remain the most reliable and adaptable foundation across different labour markets. These include experience, communication, coordination, stakeholder management, and methodological fluency across predictive, selectively agile, or hybrid methods. Consequently, HRM systems should continue to emphasise the assessment of essential skills and accountability-related competencies through behavioural interviews, work samples, and structured reference checks. Additionally, organisations operating in IT-heavy or data-rich settings might find it beneficial to create role-specific AI capability profiles, which differentiate between basic literacy for engaging with AI-enabled platforms, governance skills for evaluating outputs, managing risks, and promoting responsible use, and technical expertise that resides with specialised analytics or AI roles rather than project managers.

For universities and training providers, the evidence supports a balanced curriculum strategy. Programmes should preserve a strong emphasis on relational skills, leadership, and project-method foundations while integrating AI and GenAI literacy as complementary capabilities. The most valuable learning outcomes are likely not tool-specific proficiency, which changes rapidly, but transferable competencies: critical evaluation of AI outputs, prompt literacy for communication tasks, awareness of bias and reliability limits, data and privacy fundamentals, and the ability to embed AI use within project governance and ethical standards. Certification bodies and professional associations can also leverage these insights to update competence frameworks and continuing professional development pathways without prematurely treating AI proficiency as a universal baseline.

For project professionals, the findings indicate that AI-related skills currently function mainly as differentiators in specific contexts rather than as general employability thresholds. Investing in responsible, practical AI literacy, especially for documentation, reporting, and coordination tasks, may yield an advantage in sectors where AI adoption is more advanced, while continued strength in communication and stakeholder leadership remains central across all markets. Overall, the study highlights the need to translate technological possibilities into purposeful hiring signals and development pathways, ensuring that AI complements rather than displaces the core managerial capabilities required by project work.

Originality of the paper. *This research is original in three key ways. First, it shifts the focus from predictions and capability narratives about AI in PM to observable HRM practices. Specifically, it examines job advertisements as institutionalised signals of recruitment that reveal what employers officially specify when granting access to managerial roles. While previous studies primarily map AI tools, applications, and barriers to adoption, there is limited systematic evidence on how AI skills are embedded in project managers' selection criteria. Second, the study offers a comparative, cross-national perspective by analysing three labour markets—Italy, the United Kingdom, and the United States—within the same time frame and using a standardised data collection method. This approach allows a direct comparison of how AI-related signals differ across institutional contexts, sectors, and job-posting conventions, rather than assuming demand is consistent everywhere. Third, the research combines computational text mining with qualitative content analysis focused specifically on postings that mention AI or GenAI. This mixed-method approach captures both how often AI is requested and how it is framed—such as organisational context, interface expectations, desirable skills, or explicit requirements. Overall, the study establishes a labour market baseline that helps determine whether AI literacy is becoming a standard requirement for hiring project managers and provides a replicable method for monitoring this process over time.*

Algorithmic Triage: How Generative AI Transforms Decision-Making in Public Employment Services

FILOMENA IZZO[1]

Abstract. *The diffusion of Generative Artificial Intelligence (GenAI) is increasingly affecting public sector organizations as well. Existing literature has so far mainly interpreted these technologies as tools for enhancing productivity or supporting decision-making processes, while comparatively less attention has been devoted to their organizational effects within citizen-facing services.*
This study examines how a GenAI-based conversational system reconfigures decision-making processes within a public employment service. Through an interpretive qualitative case study based on document analysis, observation of the digital interface, and institutional communication materials, the system is analyzed as an organizational artifact that embeds classifications, operational rules, and modes of interaction with users.
The findings show that GenAI does not replace professional decision-making but rather precedes it. The system collects information about users, produces a preliminary classification of profiles, and directs possible pathways before human intervention, filtering cases and contributing to the redistribution of staff attention.
To interpret this phenomenon, the paper introduces the concept of algorithmic triage, defined as an organizational mechanism through which GenAI systems pre-select and order requests prior to human intervention, thereby structuring access to the decision-making process.
The study contributes to the literature on algorithmic management by extending it to the context of public organizations and by showing how GenAI can operate as a decision infrastructure capable of shaping the allocation of professional attention and the sequencing of decision-making processes in welfare services.
Keywords: *Algorithmic Triage, Generative Artificial Intelligence, Decision-Making Processes, Public Sector Organizations, Algorithmic Management, Digital Government*

1. Introduction

In recent years, the diffusion of Generative Artificial Intelligence (GenAI) has progressively extended beyond experimental settings and commercial applications, entering public services as well. Conversational chatbots, virtual assistants, and systems based on large language models are increasingly used by public organizations to provide information, support users, and automate certain administrative interactions (Dwivedi et al., 2023; Kumar et al., 2025).
Management literature has so far primarily examined the impact of GenAI in private firms, highlighting its implications for productivity, innovation, and support to decision-making processes (Doshi et al., 2025). At the same time, studies on the public sector have mainly focused on administrative digitalization and e-government policies, interpreting digital technologies largely as tools to improve service efficiency and access to information.
These two research traditions, however, remain largely separate. On the one hand, management studies on GenAI mainly focus on market-oriented organizations and analyze applications in areas such as customer service, marketing, or managerial decision support. On the other hand, public sector literature tends to interpret digitalization as an administrative and technological process, without deeply investigating how GenAI-based systems may directly intervene in organizational decision-making processes.
This separation results in a theoretical gap in understanding how generative artificial intelligence operates when embedded in public organizations that do not manage customers but citizens, and that regulate access to social opportunities such as employment, training, and welfare services.
In this context, this paper proposes to analyze GenAI not only as an information technology or a decision-support tool, but as an organizational infrastructure that contributes to structuring decision-making processes. In particular, the study introduces and develops the concept of algorithmic triage, defined as a mechanism through which generative AI systems perform a preliminary selection and classification of users' requests prior to human intervention, thereby shaping the allocation of professional attention and the sequencing of organizational decisions.
The idea of algorithmic triage originates from the machine learning literature, where it is used to describe systems that distribute cases between human and algorithmic decision-making in order to optimize the use of available expertise (Raghu et al., 2019; Okati et al., 2021; Straitouri et al., 2021).
In light of these considerations, the present study addresses the following research question: *How does a GenAI-based career guidance system reconfigure decision-making processes and professional roles within a public employment service?*
To address this question, the paper presents an interpretive qualitative case study concerning the introduction of a GenAI-based conversational assistant within Italian public employment services. Through the analysis of institutional documents,

[1] Senior Researcher in Management, University of Campania Luigi Vanvitelli, filomena.izzo@unicampania.it

observation of the digital interface, and service communication materials, the system is examined as an organizational artifact that embeds classifications, operational rules, and modes of interaction with users.
The remainder of the article is organized as follows. Section 2 develops the theoretical framework, discussing the role of GenAI in organizational decision-making processes and introducing the concept of algorithmic triage. Section 3 presents the research design and methodology adopted. Section 4 illustrates the main empirical findings of the case study, while Section 5 discusses the theoretical and organizational implications of the results and concludes the paper by outlining its limitations and possible directions for future research.

2. Theoretical Background

2.1 Digitalization of the public sector and user classification

In the public sector, the introduction of digital technologies has generally been interpreted within the framework of e-government policies, primarily as a tool for improving administrative efficiency and access to services (Margetts & Dunleavy, 2013; Wirtz et al., 2019).
However, a growing body of literature shows that digitalization does not only affect service delivery channels, but also reshapes internal decision-making processes within public organizations. In particular, information systems and algorithmic tools contribute to transforming the ways in which administrations classify citizens and assign differentiated administrative treatments (Busch & Henriksen, 2018; Kitchin, 2017).
This phenomenon is particularly relevant in welfare services. Public organizations must assess individual needs, establish priorities, and allocate scarce resources. Traditionally, these activities have been interpreted in the literature as part of the discretion exercised by front-line operators, described as street-level bureaucrats (Lipsky, 1980).
Digitalization, however, introduces forms of standardization into these processes. Decisions are not eliminated, but increasingly channelled into categories and procedures defined by information systems and digital infrastructures (Buffat, 2015; Busch & Henriksen, 2018).
In this sense, technology does not operate merely as an interface for accessing services, but also as a device for the preliminary assessment of cases.

2.2 Algorithmic Triage as an organizational mechanism

The literature on decision-support systems has traditionally interpreted technologies as tools that assist human decision-makers by providing additional information. Generative systems, by contrast, tend to intervene at an earlier stage of the decision-making process, contributing to defining which situations should be considered problematic, which require attention, and which can be managed through standardized procedures (Doshi et al., 2025; Dwivedi et al., 2023).
This phenomenon can be interpreted in light of the street-level bureaucracy literature. In welfare services, front-line workers select and prioritize citizens' requests because available resources are lower than demand (Lipsky, 1980). The first organizational decision therefore concerns not the intervention itself, but access to professional attention.
Traditionally, this selection function—implicit yet crucial—has been exercised through the professional judgment of operators. The introduction of GenAI-based systems alters this step: the preliminary assessment of the case is produced by the system, while the professional intervenes subsequently on the basis of an already formulated classification.
A similar logic has recently been conceptualized in the machine learning literature through the notion of algorithmic triage. In this perspective, the introduction of artificial intelligence into decision processes does not simply raise the question of whether a task should be automated, but also which cases should be handled by the algorithm and which should remain under human responsibility (Raghu et al., 2019).
Algorithmic triage models do not assume full automation; rather, they distribute cases between human actors and algorithmic systems in order to optimize the use of available expertise (Okati et al., 2021; Straitouri et al., 2021). In this sense, algorithmic systems operate as meta-decision mechanisms that determine when human intervention is required and when automated processing is sufficient.
Empirical evidence from the healthcare sector shows that AI-based triage systems can classify and prioritize cases before clinical evaluation, thereby helping manage resource scarcity and high service demand (Da'Costa et al., 2025; Güvey et al., 2025; Colakca et al., 2024).
Translated into an organizational context, this logic suggests that GenAI systems do not merely classify information or users, but also contribute to establishing the order in which cases gain access to the decision-making process.
In light of these considerations, this study introduces the concept of algorithmic triage as an organizational mechanism through which GenAI systems pre-structure the allocation of professional attention.
More specifically, algorithmic triage can be defined as a GenAI-mediated pre-selection process through which a generative system classifies, orders, and interprets requests prior to human intervention, thereby directing professionals' attention toward specific situations.
The concept recalls medical triage: it does not constitute a definitive diagnosis, but rather a preliminary assessment that establishes the level and urgency of the required intervention.

3. Methodology

Research Design. This study adopts an interpretive qualitative approach based on a single case study. The objective is not to evaluate the effectiveness of the technology or to measure its employment outcomes, but rather to understand how the introduction of a Generative Artificial Intelligence (GenAI) system reconfigures decision-making processes and organizational roles within a public service. A case study design is particularly suitable for analyzing complex contemporary phenomena that are closely intertwined with their organizational context, where the boundaries between technology and organization cannot be clearly separated (Yin, 2018).
Following the perspective of theoretically oriented case studies, the case is not intended to statistically represent a population, but rather to develop and refine theoretical concepts (Eisenhardt, 1989; Eisenhardt & Graebner, 2007). The selected case concerns the introduction of a GenAI-based conversational assistant within Italian public employment services, designed as a tool for initial guidance and first interaction with users: the digital job guidance assistant AppLI.

Data Sources. Because the object of study is a recently introduced public system that is not accessible for internal observation, the research relies on two types of empirical materials (Denzin, 1978):

1. document analysis**.** Publicly available institutional documents were collected and analyzed, including official communications, informational materials, website content, and service presentations. Documentary analysis is widely used in management studies to reconstruct the operational and decision logics embedded in formal procedures (Bowen, 2009).
2. observation of the digital artifact**.** A direct observation of the conversational system's user interface was conducted. The analysis focused on the questions posed to users, the informational categories requested, and the recommendations returned by the system. In line with a sociomaterial perspective, the digital artifact is treated as an organizational object: information technologies embed rules, classifications, and operational practices that reflect organizational structures (Orlikowski, 2007; Leonardi, 2011). The interface therefore does not merely represent a communication tool, but an observable formalization of the decision-making process.

4. Results and Discussion

The analysis of the conversational interface, institutional materials, and public communication related to the system shows that the GenAI-based assistant does not perform a merely informational function, but intervenes in the preliminary stage of the user intake process. Rather than simply providing general guidance, the system collects structured information, interprets the user's profile, and returns operational recommendations that anticipate the work of human operators.
The characteristics of the service and its objectives are explicitly presented in the institutional communication of the promoting administration (Ministry of Labour and Social Policies, 2025). Empirical observation of the interaction with the system makes it possible to identify four main organizational functions through which the process of algorithmic triage becomes visible.

Guided information collection: structuring the problem. The first function of the system consists of the progressive collection of information about the user through a sequence of guided questions. The interaction is not entirely open-ended but oriented toward specific informational categories, including work experience, skills, education level, career goals, and willingness to undertake training pathways.
This function is consistent with the official description of the tool as a digital career guidance assistant capable of understanding the user's profile and directing them toward training and employment opportunities (Ministry of Labour and Social Policies, 2025).
However, this stage does not simply represent a process of data acquisition. The questions posed by the system delimit what the organization considers relevant for defining the user's situation. Information that does not fit within the conversational structure tends to be excluded or translated into predefined categories. Consequently, the system contributes to transforming a generic request—such as "finding a job"—into an organizationally manageable problem by translating individual experience into a classifiable profile.
From a theoretical perspective, this phase represents the first level of algorithmic triage: the system establishes which informational elements are necessary for making the case intelligible within the organization's operational categories.

Profile interpretation: producing a preliminary diagnosis. Based on the information collected, the system generates an initial interpretation of the user's profile. It does not simply summarize the data provided but formulates implicit assessments by suggesting possible occupational fields, identifying relevant training pathways, and proposing subsequent actions.
In the service presentation materials, the system is described as a tool capable of supporting users in defining their professional trajectory and preparing them for entry into the labour market (Ministry of Labour and Social Policies, 2025).

This stage constitutes a form of preliminary organizational diagnosis. The user is implicitly positioned within operational categories—such as immediately employable profile, profile to be strengthened through training, or profile requiring reskilling—even when these categories are not formally stated.
The output produced by the system immediately shapes users' expectations and anticipates the type of intervention that may subsequently be activated. In this sense, the system does not merely classify information but contributes to generating an initial interpretation of the case prior to the intervention of the human operator.

Pathway direction: ordering intervention priorities. The third function concerns the indication of concrete actions. The system suggests training courses, career guidance activities, or operational steps to be undertaken. Institutional communication presents the service as a tool that helps users identify training pathways consistent with their skills and prepare for entry into the labour market (Ministry of Labour and Social Policies, 2025).
These recommendations are not neutral. Rather, they represent an implicit ordering of the organization's intervention priorities, as they direct users toward specific types of actions even before contact with a human operator takes place.
At this stage, the system does not make formal administrative decisions, but it produces a channeling effect. Users approach the potential meeting with an operator already equipped with a plausible interpretation of their situation and a possible pathway to follow.
From an organizational perspective, this process contributes to establishing the order in which situations are addressed and the types of interventions that appear most appropriate.

Reallocation of professional work: selecting organizational attention. The fourth observable function concerns the implicit distribution of professional work within the service. The system absorbs the initial phase of case analysis—traditionally carried out by the operator—while human intervention tends to concentrate on situations that require clarification, discretionary assessment, or formal decision-making.
This configuration is consistent with the role attributed to the tool within active labour market policies, where the digital assistant represents a first level of guidance prior to the intervention of employment service professionals (Ministry of Labour and Social Policies, 2025).
The result is a reorganization of the decision-making process. Operators no longer perform the initial interpretation of users' needs, but rather intervene in cases that have already been classified by the system. Technology therefore acts as an organizational filter that contributes to determining which situations require in-depth professional attention and which can instead be handled through standardized procedures**.**

Algorithmic Triage and the reconfiguration of the decision-making process. Taken together, these findings show that the system introduces a preliminary phase of case selection and ordering within the organizational process. The technology does not replace human decision-making but rather alters its temporal sequence.
Before the intervention of human operators, the system produces an initial classification that guides subsequent actions and defines the type of professional attention required. In this sense, the system can be interpreted as a mechanism of algorithmic triage: it establishes the order of organizational situations, directs users' pathways, and redistributes professional attention within the service.
Algorithmic triage therefore does not merely classify information or users, but contributes to structuring access to the decision-making process. Through the pre-selection of cases, the system redefines the moment at which professional judgment intervenes and the conditions under which it is exercised.

5. Conclusion

This study examined the introduction of a GenAI-based career guidance system within public employment services, interpreting this innovation not merely as a technological change but as an organizational transformation of decision-making processes. The findings show that the technology does not directly automate administrative decisions, but rather alters the sequence through which they are produced: prior to human intervention, the system generates a preliminary classification of users that guides the subsequent actions of operators.
In this sense, digitalization does not eliminate professional discretion but redefines the timing and conditions under which it is exercised. Human intervention occurs on cases that have already been interpreted and ordered by the system, within operational categories that emerge from the interaction between the user and the conversational assistant.

6. Originality of the paper. The main contribution of this study lies in introducing the concept of algorithmic triage as an organizational mechanism through which GenAI systems pre-structure the allocation of professional attention. While existing literature has extensively examined the role of digital technologies in the classification of information and users (Bowker & Star, 1999; Kitchin, 2017), this study shows how generative systems operate at a further level: they do not merely organize information but also contribute to establishing the order in which cases gain access to the decision-making process.

Algorithmic triage thus highlights a specific form of technological mediation within organizational decision-making processes. Through the guided collection of information, the preliminary interpretation of user profiles, and the direction of possible pathways, GenAI systems contribute to selecting and ordering the situations that will require subsequent professional intervention.
From this perspective, GenAI can be interpreted not only as a cognitive technology or a decision-support tool (Dwivedi et al., 2023; Doshi et al., 2025), but also as a decision infrastructure that structures access to professional judgment. The study also contributes to the literature on algorithmic management by showing that mechanisms of algorithmic coordination do not emerge only in private firms or digital platforms, but can also manifest in public organizations and welfare services.

7. Managerial Implications. The findings of this study suggest several relevant implications for the management of public organizations introducing GenAI systems into citizen-facing services.
First, the adoption of conversational assistants and generative systems should not be interpreted solely as an initiative aimed at digitalizing services, but rather as a transformation of the organizational processes through which users are taken in charge. The informational categories and interaction patterns embedded in the digital interface contribute to defining which elements are considered relevant and which pathways appear plausible.
Second, the design of these systems acquires organizational and institutional significance. Since algorithmic triage shapes the allocation of professional attention, the classifications and decision logics embedded in digital systems may indirectly influence citizens' access to the opportunities provided by the organization.
Finally, the introduction of GenAI systems requires reflection on the relationship between technologies and professional discretion. While such systems may increase the efficiency of the preliminary stages of case analysis, they also redefine the role of professionals, who increasingly intervene in situations that have already been interpreted and ordered by the system. Managing this transformation represents a key challenge for public organizations, which must integrate new digital infrastructures without reducing professionals' capacity for interpretation and judgment**.**

8. Research limitations. This study presents several limitations that should be considered when interpreting the findings.
First, the analysis is based on a single case study concerning Italian public employment services. Although this approach is consistent with the exploratory aim of the research and with the theory-building perspective adopted (Eisenhardt, 1989; Eisenhardt & Graebner, 2007), the findings cannot be automatically generalized to other organizational contexts.
Second, the research relies primarily on publicly available documentary sources, observation of the digital interface, and institutional communication materials. The lack of direct access to operators and internal organizational data limits the possibility of conducting a more in-depth analysis of how the system is actually used in everyday work practices.
Finally, the study does not examine the effects of the system on users' employment outcomes nor on their experiences of interacting with the service. The analysis instead focuses on the organizational role of the technology and on the ways in which it contributes to structuring decision-making processes.

9. Directions for future research. These limitations open several opportunities for future research. Comparative studies could examine the adoption of GenAI systems across different public sector organizational contexts, such as healthcare, education, or social services, in order to understand whether and how the mechanism of algorithmic triage manifests itself in different forms.
Further research could also investigate the interaction between human operators and generative systems, exploring how professionals interpret, use, or potentially challenge the classifications produced by the algorithm. Finally, longitudinal analyses could assess how algorithmic classifications influence users' trajectories and the allocation of resources in public services over time.
Understanding these dynamics is essential for interpreting the growing role of Generative Artificial Intelligence in contemporary organizations. In these contexts, technology no longer merely supports decision-making but increasingly contributes to defining the conditions under which decisions become possible: professionals continue to make decisions, but they do so within an organizational space that has already been structured by the algorithm.

Artificial Intelligence and Firm Governance: Toward a Predictive Control Model in the Viable Systems Approach

RAFFAELE D'AMORE[1], GERARDO BOSCO[2], ALESSIA SCIARRONE[3], MARIO CALABRESE[4]

Abstract. *Artificial intelligence (AI) is profoundly transforming organizational and decision-making processes. However, much of the management literature still interprets its impact primarily in terms of operational efficiency or performance improvement. Less explored is how AI affects the conditions of firm governance in contexts characterized by high levels of complexity and environmental dynamism. This study addresses this gap by developing an interpretative model of systemic predictive control within the theoretical framework of the Viable Systems Approach. In this perspective, artificial intelligence is interpreted as a cognitive lens that expands the informational variety available to decision-makers and contributes to the construction of the observed context, thereby influencing the relationship between deliberate and emergent strategy. The model highlights that AI does not generate value in a direct or deterministic way, but rather through the mediating role of the control system, which translates operational improvements into economically sustainable configurations consistent with strategic objectives. From this perspective, control evolves from a retrospective measurement tool into a predictive mechanism of systemic integration capable of supporting recursive processes of adaptation, learning, and strategic realignment. The theoretical contribution of the study lies in repositioning the debate on AI in Management within the broader theory of firm governance, proposing a conceptual architecture that connects artificial intelligence, complexity management, and systemic viability in the digital era.*
Keywords*: Artificial Intelligence; Firm Governance; Predictive Control; Viable Systems Approach; Organizational Complexity.*

Research background

The current competitive environment is characterized by profound transformations in globalization, increasing geopolitical tensions, and an unprecedented acceleration of technological innovation. As highlighted by Petricevic and Teece (2019), the international economic system is undergoing a phase of structural reconfiguration that affects global value chains, competitive models, and value creation mechanisms. In such a scenario, firms must rethink their organizational and decision-making architectures.

Recent literature describes this phase as an era of hyper-complexity characterized by nonlinear interactions, emergent phenomena, and continuously evolving competitive dynamics (Volpentesta et al., 2023).

In such contexts, traditional managerial paradigms increasingly reveal their limitations in providing adequate governance tools.

Among the main drivers of transformation is artificial intelligence. The emergence of agentic artificial intelligence with autonomous learning and decision-making capabilities is redefining the boundaries between automation and decision support (Bassano et al., 2024; Huang, 2025).The so-called agentic economy introduces new configurations of decision-making processes, in which intelligent systems interact with human decision-makers and organizational structures in increasingly integrated ways (Ratten et al., 2024).

Despite these developments, much of the management literature continues to interpret artificial intelligence primarily in terms of operational efficiency or performance optimization. Some studies highlight the potential of AI in supporting strategic planning and competitive analysis (Wagner, 2020), while more recent contributions emphasize the co-evolution between business models and intelligent technologies (Grego et al., 2024). However, a significant theoretical gap remains: an interpretative framework capable of systematically linking the adoption of AI to the transformation of firm governance conditions in complex environments is still lacking.

The Viable Systems Approach (Barile, 2008, 2009, 2023, 2024) provides a particularly suitable theoretical framework to address this gap. Within this perspective, the firm is conceived as a viable system that pursues its survival through processes of co-evolution with the environment and through the management of informational variety. System viability depends on the ability of the governing subject to select relevant supra-systems, maintain internal consonance, and activate coherent configurations among resources, processes, and purposes.

A central element of this approach is the distinction between environment and context. The environment represents the potentially infinite set of phenomena, actors, and relationships surrounding the system and is, by its nature, indeterminate and not fully knowable. The context, by contrast, is the portion of the environment selected and interpreted by the decision-maker on the basis of their informational variety—comprising knowledge, interpretative schemes, and experience—through which the system identifies relevant supra-systems and orients its strategic action (Barile, 2009).

[3] Sapienza University of Rome, Italy, alessia.sciarrone@uniroma1.it
[4] Sapienza University of Rome, Italy, mario.calabrese@uniroma1.it

From this perspective, complexity does not concern the environment as a whole, but rather the observed context constructed by the decision-maker.
Consequently, strategy cannot be reduced to a purely deliberate design but emerges from the dynamic interaction between intentions, decisions, and contextual conditions. The distinction between intentional, deliberate, and emergent strategy highlights how, in contexts characterized by high uncertainty, firm governance must confront evolutionary processes that exceed formal planning. Managing complexity therefore requires tools capable of reducing uncertainty without eliminating variety, fostering a continuous realignment between strategic purposes and operational action (Bertalanffy, 1968).
Within this theoretical framework, artificial intelligence assumes a transformative role. It expands the variety of the decision-making system by enhancing information-processing capabilities and enabling advanced scenario simulations (Secundo et al., 2025). However, this expansion does not automatically generate value; rather, it modifies the cognitive and organizational conditions of governance, influencing the relationship between the operating system, the economic structure, and the informational–decision-making system.
Artificial intelligence can therefore be interpreted as a cognitive lens that extends the observational capacity of the decision-maker. In the systemic–viable paradigm, the decision-maker does not observe the environment in a neutral way but constructs the context through their informational variety by selecting the relationships that are relevant for strategic action (Barile, 2009). AI expands this observational capacity by enabling the processing of large information bases and the identification of relational patterns that are difficult to perceive through human cognitive capabilities alone. In this sense, artificial intelligence does not replace the decision-maker's interpretative process but rather extends their observational perspective.
Within this perspective, predictive control assumes a central role. It can be interpreted as a knowledge governance mechanism that integrates information and anticipations, generating knowledge that can support decisions consistent with systemic constraints. Its effectiveness depends on the ability to transform data into knowledge aligned with governance processes. AI may therefore act as an enabler—but also as a potential distorter—of knowledge creation and integration processes, with significant implications for transparency and decision reliability (Paniccia, 2018; Ferraris et al., 2019; Iandolo et al., 2021).
In complex systems, the functioning of predictive control is also closely connected to the management of interdependencies among organizational processes. From a process management perspective, it can be interpreted as a coordinated set of tasks—such as data qualification, scenario building, verification, and feedback—that span operational processes and connect different decision-making levels. Artificial intelligence can improve such coordination by increasing processing speed, information integration, and simulation capabilities; however, it also introduces new challenges related to algorithmic opacity, data quality, and the risk of misalignment between local optimizations and systemic coherence (Calabrese et al., 2024; Hagen et al., 2024).
In light of these considerations, the debate on AI in Management has not yet developed an interpretative model capable of systematically integrating operational, economic, and decision-making dimensions within the conditions of firm governance. This study positions itself within this theoretical space by proposing a systemic predictive control model that interprets artificial intelligence as a cognitive lens of the decision-maker in constructing the observed context and coordinating operational processes, economic structures, and governance mechanisms.
Given this theoretical gap, the objective of the study is to develop an interpretative model of systemic predictive control within the Viable Systems Approach (Caputo et al., 2019). In particular, the study is guided by the following research questions:
RQ1: How does artificial intelligence—particularly in its agentic forms—reshape governance processes through the redesign of informational and decision-making architectures?
RQ2: How can predictive control function as an integration mechanism between operational, economic, and systemic–decision-making dimensions, reducing the gap between deliberate and emergent strategy?
RQ3: What opportunities and challenges emerge from the use of artificial intelligence in coordinating control tasks supporting decision-making processes, particularly with respect to knowledge quality, transparency, and process coherence?

Purpose of the study. This study analyzes the role of artificial intelligence from the perspective of the Viable Systems Approach, interpreting it not as a mere technological tool but as a factor capable of affecting the conditions of firm governance in contexts characterized by high complexity, structural transformations, and increasing autonomy of intelligent systems (Huang, 2025; Petricevic & Teece, 2019).
The objective of the research is to develop an interpretative model of systemic predictive control capable of clarifying how the adoption of artificial intelligence reshapes the relationships between deliberate and emergent strategy, between the operating system and the governance system, and between economic configuration and dynamic sustainability. Although recent literature highlights how AI is redefining decision-making processes and business models through a co-evolutionary relationship between technology and organization (Grego et al., 2024; Ratten et al., 2024), a conceptual architecture capable of integrating these dynamics within the systemic conditions of firm governance is still lacking.
Building on the Viable Systems Approach (Barile, 2008, 2009, 2023), this study assumes that firm viability depends on the governing subject's ability to manage informational variety and to select configurations consistent with relevant supra-systems. From this perspective, artificial intelligence is interpreted as an amplifier of the decision-making system's variety

(Secundo et al., 2025), rather than a substitute for the decision-maker: value creation does not automatically derive from technological adoption but depends on the quality of integration between predictive capabilities, operational processes, and governance mechanisms.
The theoretical contribution of the study lies in the proposal of a multi-level conceptual architecture integrating three interdependent dimensions: the operational dimension, related to the stabilization and optimization of processes through predictive tools (Wagner, 2020); the economic dimension, concerning the translation of operational improvements into sustainable cost configurations; and the systemic–decision-making dimension, referring to the evolution of the informational–decision-making system as a cognitive infrastructure of governance capable of reducing the distance between intentional, deliberate, and emergent strategy.
In this way, the study contributes to the debate on AI in Management by proposing an interpretative perspective that overcomes a deterministic view of technology and reconnects artificial intelligence to the theory of firm governance. The proposed model links artificial intelligence, complexity management, and systemic viability, offering an interpretative framework for understanding the transformation of management in the era of the agentic economy (Huang, 2025; Volpentesta et al., 2023).

Research gaps – Research questions – Contributions alignment. In light of a literature gap that views artificial intelligence and digital transformation mainly as drivers of operational efficiency, without linking AI, complexity, and firm governance within a dynamic perspective, three research questions (RQ1–RQ3) emerge. These concern how AI reshapes firms' informational and decision-making architectures, how predictive control may integrate operational, economic, and systemic–decision-making dimensions, and which opportunities and challenges AI creates in supporting managerial decisions. The study contributes by proposing a conceptual model that makes these relationships explicit and highlights mechanisms of multi-level consonance and realignment between deliberate and emergent strategy. More specifically, it addresses the theoretical gap on AI and firm governance by defining predictive control as a cognitive infrastructure for systemic adaptation, linking it to the model's three dimensions, and clarifying how AI may both enable and challenge knowledge quality, informational transparency, and decision-making coherence in complex contexts.

Methodological approach. The research adopts a theoretical–interpretative approach aimed at developing a conceptual framework consistent with the Viable Systems Approach and oriented toward integrating the debate on artificial intelligence with the theory of governance of complex firms. This perspective aligns with studies that seek to construct conceptual architectures capable of interpreting emerging phenomena characterized by high levels of systemic complexity (Barile, 2008, 2023; Caputo & Saviano, 2020).
The methodological path unfolds in two interconnected stages. First, a critical and selective review of the literature was conducted, focusing on the following research streams: artificial intelligence and organizational transformation (Volpentesta et al., 2023); AI and strategic decision-making processes (Wagner, 2020; Ratten et al., 2024); agentic artificial intelligence and the redefinition of governance dynamics (Huang, 2025); and the co-evolution between business models and intelligent technologies (Grego et al., 2024). This review was not merely descriptive but was reinterpreted through the lens of the Viable Systems Approach, with the aim of identifying the main theoretical gaps concerning the relationship between AI adoption and the conditions of systemic viability of the firm (Vito et al., 2021).
Second, through the integration of the literature on AI in Management with key conceptual categories of the systemic–viable perspective—such as informational variety management, selection of relevant supra-systems, multi-level consonance, and recursion (Barile, 2009, 2023; Saviano et al., 2017)—an interpretative model of systemic predictive control was developed. The model represents the outcome of a multi-level process of theoretical abstraction and constitutes the core of the proposed contribution (Figure 1).
The framework is structured according to a systemic logic articulated across three interdependent levels: the operating system, representing the domain in which processes are transformed and predictive technologies are applied; the operational–economic structure, where operational dynamics are translated into cost configurations and economic sustainability; and the informational–decision-making system, conceived as the cognitive infrastructure of governance responsible for integrating heterogeneous information and reducing the distance between deliberate and emergent strategy.
This articulation makes it possible to explicate the causal and recursive relationships between artificial intelligence adoption, organizational reconfiguration, and governance capacity, highlighting the mediating role of the control system in generating internal consonance and strategic coherence.
The study does not adopt an empirical or quantitative design but belongs to the stream of theoretical research aimed at developing interpretative models. The validity of the contribution lies in the internal coherence of the proposed architecture, its explanatory capacity with respect to the phenomena analyzed, and its compatibility with the epistemological foundations of the Viable Systems Approach (Barile, 2023). From this perspective, the model represents a theoretical proposal open to future empirical validation and application across different organizational contexts.

Risultati.

Multi-level architecture of the model

As illustrated in Figure 1, the systemic predictive control model takes the form of a multi-level architecture describing the transition from the environment to the observed context through the decision-maker's observation process, integrating the role of artificial intelligence with the internal structure of the firm.

At the top of the figure, the environment is represented as the potentially infinite set of phenomena and relationships surrounding the system. Through the decision-maker's observation process, this environment is selected and interpreted, giving rise to the observed context—the relational space within which the firm identifies relevant supra-systems and orients its strategic dynamics (Barile, 2009; Barile, 2023). In this process, artificial intelligence acts as a cognitive lens that expands the decision-maker's observational capacity by increasing the informational variety available for interpreting the context.

The model highlights that artificial intelligence does not directly determine system viability. Consistent with the systemic–viable perspective (Barile, 2008, 2023)—and with a knowledge-based view—technology enters the organizational structure by modifying internal dynamics, but its effects depend on the ability of the governing subject to integrate such innovation into coherent organizational and decision-making configurations. Consequently, the impact of AI on system viability is mediated by the quality of governance mechanisms and, in particular, by the functioning of the control system. Within the coordination of control tasks, AI may enhance forecasting capabilities, increase the speed of information processing, facilitate the integration of heterogeneous data sources, and support the generation of predictive scenarios. However, these benefits are strongly conditioned by data governance quality, algorithmic transparency, and the presence of appropriate accountability mechanisms. In the absence of these conditions, AI may amplify informational asymmetries, generate a possible "illusion of precision," and reduce the verifiability of causal relationships, potentially undermining the coherence of governance processes.

At the core of the model lies the firm system, articulated into three interconnected levels: the operating system, the operational–economic structure, and the informational–decision-making system. This multi-level configuration overcomes the linear view of technological impact often found in the AI in Management literature (Wagner, 2020), highlighting instead the systemic and recursive nature of the organizational transformation induced by artificial intelligence.

Figure 1. Systemic predictive control model for firm governance within the Viable Systems Approach.

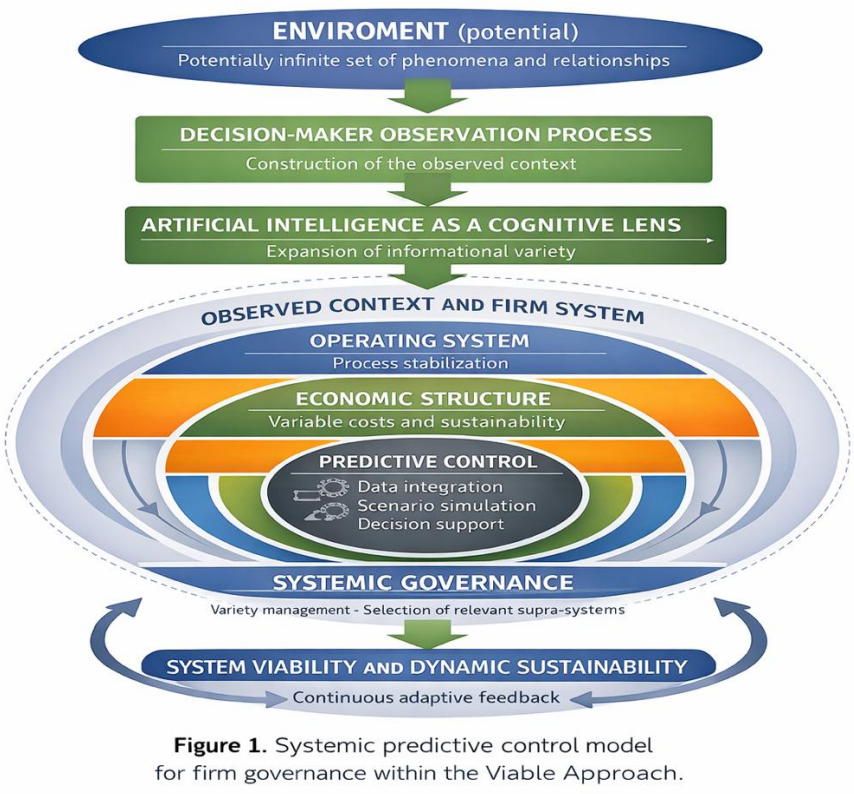

Figure 1. Systemic predictive control model for firm governance within the Viable Approach.

Source: Authors' own elaboration.

The model shows how predictive control performs an integration function across the different levels of the firm system, linking operational dynamics, economic configurations, and decision-making processes. From this perspective, control does not merely monitor performance but operates as a cognitive infrastructure of governance, contributing to sustain consonance among the different organizational levels and strengthening the system's adaptive capacity over time.

The mediating role of predictive control

The central position of the predictive control system in the figure is not merely graphical but reflects a precise conceptual function within the model. The framework shows that artificial intelligence primarily produces operational effects—such as process stabilization, reduced variability, and improved forecasting capabilities—consistent with findings in the literature on digital transformation and advanced automation (La Sala et al., 2023; Volpentesta et al., 2023).

These effects influence the firm's economic structure by reshaping variable costs and improving margin sustainability. However, as suggested by studies on the co-evolution of technology and business models (Grego et al., 2024), technological improvements do not automatically translate into systemic value.

In this context, predictive control plays a mediating role between the operating system and the governance system. It integrates heterogeneous data, enables scenario simulation, and supports the systemic observation of the context. In this sense, the control system can be interpreted as a cognitive infrastructure of governance, consistent with the idea of amplifying decision-making variety (Secundo et al., 2025).

Therefore, value creation does not derive from the mere adoption of artificial intelligence but from the quality of informational and decision-making integration that enables the governing subject to orient the generated variety toward configurations consistent with the system's purposes. The economic impact of AI is thus structurally mediated: without a control system capable of integrating and interpreting information, operational benefits remain fragmented and do not translate into enhanced governance capacity.

Multi-level consonance and reduction of the strategic gap

The model interprets AI-driven transformation in terms of multi-level consonance, a central concept of the Viable Systems Approach (Barile, 2009).

Internal consonance concerns the coherence between the operating system and the economic structure: the stabilization of processes reduces cost variability and contributes to strengthening the firm's economic sustainability. Governance consonance, in turn, refers to the ability of the informational–decision-making system to integrate these dynamics within a strategic framework consistent with relevant supra-systems.

In contexts characterized by the emerging agentic economy (Huang, 2025), strategy tends to become more emergent. Although the literature highlights the influence of artificial intelligence on strategic decision-making processes (Ratten et al., 2024), it remains less clear how this influence translates into systemic coherence.

The proposed model suggests that predictive control contributes to reducing the distance between intentional, deliberate, and emergent strategy by providing governance with tools for simulation and anticipation that facilitate continuous realignment between strategic objectives and operational actions. Artificial intelligence expands the variety of the decision-making system, but it is ultimately the governing subject who selects and directs this variety toward configurations compatible with system viability.

In this way, the model overcomes a deterministic view of technology and reaffirms the centrality of governance processes in the transformation of management.

Ricorsività e feedback adattivo

The lower part of the figure highlights the viability and dynamic sustainability of the system as outcomes of systemic governance capacity. This outcome does not have a static nature but is embedded within a continuous adaptive feedback loop consistent with the recursive logic of viable systems (Barile, 2023).

Recursivity implies that strengthening governance capacity fosters further organizational learning processes, contributing to the progressive redefinition of the observed context and to the reconfiguration of both the operating system and the economic structure. In this perspective, the transformation of management should not be interpreted as a one-time event but as a continuous evolutionary process, in line with studies on digital transformation and organizational resilience (Grego et al., 2024; Volpentesta et al., 2023).

Overall, the model suggests that artificial intelligence contributes to firm viability only when it is integrated into a predictive control architecture capable of connecting operational transformation, economic coherence, and systemic governance through a multi-level and recursive logic. Without such integration, AI risks producing local efficiencies that do not translate into an effective strengthening of the system's governance capacity.

Based on the relationships highlighted in the model, three theoretical propositions can be formulated regarding the role of artificial intelligence and predictive control in the governance of complex firms:

*P1***:** Artificial intelligence expands the informational variety of the decision-making system, extending the governing subject's capacity to construct and interpret the observed context.

*P2***:** Predictive control mediates the impact of artificial intelligence on value creation by integrating operational dynamics, economic configurations, and decision-making processes.

*P3***:** Multi-level integration among the operating system, economic structure, and informational–decision-making system reduces the distance between deliberate and emergent strategy, strengthening the adaptive capacity of the firm system.

Research Gap	Research Question	Contribution
The literature on AI in Management mainly emphasizes operational efficiency and performance, while a systemic framework linking artificial intelligence, complexity, and firm governance remains underdeveloped.	**RQ1:** How does artificial intelligence—particularly in its agentic forms—reshape governance through the redesign of informational and decision-making architectures?	Development of a **systemic predictive control model** that explains how artificial intelligence affects governance conditions in complex firms.
The relationship between AI-driven operational improvements and the economic sustainability of the firm is not clearly explained in existing studies.	**RQ2:** How can predictive control function as a mechanism integrating operational, economic, and systemic–decision-making dimensions, reducing the gap between deliberate and emergent strategy?	Identification of **predictive control as a mediating mechanism** between operational dynamics, economic configuration, and governance processes.
The literature rarely addresses the risks and tensions generated by AI adoption in decision-making processes, particularly regarding transparency, knowledge quality, and systemic coherence.	**RQ3:** What opportunities and challenges arise from the use of AI in coordinating control tasks supporting managerial decisions?	Clarification of the **opportunities and criticalities of AI adoption** in the coordination of control tasks and decision-making processes within complex organizational systems.

Discussion. The results of the systemic predictive control model contribute to the debate on AI in Management by providing a systemic interpretation of the transformation induced by artificial intelligence in governance processes. While a large part of the literature emphasizes the impact of AI mainly in terms of operational efficiency, automation, or analytical support to managerial decisions (Wagner, 2020; Ratten et al., 2024), the proposed framework highlights that the value generated by AI is structurally mediated by the governance architecture in which it is embedded.
Artificial intelligence does not directly determine competitive advantage but expands the informational variety of the decision-making system (Secundo et al., 2025). In contexts characterized by high complexity and dynamic interdependencies, this expansion modifies the cognitive conditions of governance, requiring new mechanisms capable of integrating heterogeneous information and supporting anticipatory decision-making processes.
The model suggests that predictive control plays a key role in this transformation. Rather than functioning solely as a retrospective measurement tool, the control system evolves into a predictive mechanism that integrates operational dynamics, economic configurations, and governance processes. Through scenario simulation and data integration, predictive control enables decision-makers to reduce the gap between deliberate and emergent strategy, facilitating continuous realignment between strategic objectives and operational actions.
In the context of the emerging agentic economy—where intelligent systems increasingly interact with human decision-makers and organizational structures (Huang, 2025)—the governing subject is required to perform a crucial role in directing and interpreting the variety generated by AI. The results therefore reaffirm the centrality of governance processes within technologically advanced organizational systems.
The study contributes to the literature by integrating the debate on artificial intelligence with the systemic perspective of firm governance. The proposed framework clarifies the conditions under which AI can effectively contribute to systemic viability, emphasizing the mediating role of predictive control and the importance of multi-level consonance between operational processes, economic structures, and governance mechanisms.

Research limitations. This study adopts a theoretical and interpretative approach aimed at developing a conceptual model of systemic predictive control within the Viable Systems Approach. Consequently, the research does not include empirical validation, and the proposed framework should be interpreted as a theoretical contribution open to further empirical investigation.
A first limitation concerns the absence of empirical testing of the model. Future research could apply the proposed framework to empirical case studies in order to examine how artificial intelligence influences governance mechanisms and decision-making processes in different organizational contexts.
A second limitation relates to the rapid evolution of artificial intelligence technologies. The emergence of agentic AI systems capable of autonomous learning and decision-making may generate organizational dynamics that extend beyond the conceptual assumptions developed in this study. Future research could therefore explore how the increasing autonomy of intelligent systems affects the balance between human governance and algorithmic decision-making.
Finally, the model focuses primarily on the internal architecture of the firm and the mediating role of predictive control within governance processes. Future research could extend the framework by examining inter-organizational ecosystems and digital platforms.

Managerial implications. Despite its theoretical nature, the study offers several implications for managers operating in contexts characterized by increasing technological complexity and the growing adoption of artificial intelligence.

First, the findings suggest that the adoption of AI should not be interpreted merely as a technological investment aimed at improving operational efficiency. Instead, organizations should consider artificial intelligence as a component of a broader governance architecture capable of integrating predictive capabilities with strategic decision-making processes.
Second, the results highlight the strategic role of predictive control systems in supporting managerial decision-making. Managers should therefore invest not only in analytical technologies but also in control mechanisms supporting data integration, scenario simulation, and strategic alignment.
Third, effective AI adoption requires governance mechanisms ensuring transparency, accountability, and coherence in decision-making processes. In complex organizational systems, the effectiveness of artificial intelligence depends on the ability of managers to maintain control over informational flows and to interpret algorithmic outputs within a broader systemic perspective.
Overall, organizations seeking to leverage artificial intelligence should focus on integrating technology, organizational processes, and governance mechanisms rather than on technological adoption alone.

Originality of the study. The originality of this study lies in integrating the debate on artificial intelligence in management with the systemic perspective of firm governance developed within the Viable Systems Approach.

While much of the existing literature focuses on the operational and performance-related implications of AI adoption, the present study reframes artificial intelligence as a factor capable of influencing the conditions of systemic viability of the firm. By interpreting AI as a cognitive lens that expands the informational variety available to decision-makers, the paper provides a novel perspective on how intelligent technologies reshape governance processes in complex organizational systems.

Moreover, the proposed framework introduces the concept of systemic predictive control as a mediating mechanism connecting operational processes, economic structures, and governance dynamics. This perspective contributes to bridging the gap between the literature on AI in Management and the theoretical foundations of systemic governance (Caputo et al., 2020).

Finally, the model offers a multi-level conceptual architecture that explains how artificial intelligence can simultaneously enable organizational learning, strategic adaptation, and systemic coherence in contexts characterized by high levels of complexity and technological change.

Artificial Intelligence for Social Good: An Analysis of Objective Structures, Subjective Dispositions, and Collective Fields

MARIA FERRARO[1], MARIO D'ARCO[2], RICCARDO RESCINITI[3]

Abstract. *Artificial Intelligence for Social Good (AI4SG) has emerged as a rapidly expanding research domain, yet the literature remains fragmented across technological, ethical, and governance perspectives. This paper proposes a reinterpretation of AI4SG drawing inspiration from Bourdieu's theoretical framework, focusing on the interaction between objective structures, subjective dispositions (habitus), and collective institutional fields. Drawing on a systematic conceptual literature review of forty-five peer-reviewed articles published between 2020 and early 2026, the study maps how existing research emphasizes different analytical dimensions of AI for social good. The findings reveal a clear imbalance: most contributions focus on technological structures and governance arrangements, while comparatively minor attention is devoted to the subjective dispositions through which actors interpret and experience AI systems. By identifying structural tensions between technological design, institutional governance, and actor interpretation, the paper provides an integrative perspective on AI4SG and highlights the need to incorporate sociological insights into the governance and management of artificial intelligence initiatives.*
Keywords: *AI for social good; objective structures; subjective dispositions; collective fields; Bourdieusian framework; AI governance*

Framing of the research. Artificial Intelligence for Social Good (AI4SG) has emerged as one of the most contested territories in contemporary management and organization studies (Floridi et al., 2020). A rapidly expanding body of literature documents AI's potential to address major societal challenges, from poverty reduction and financial inclusion to humanitarian response, environmental governance, and public service transformation, positioning it as a key enabler of the United Nations Sustainable Development Goals (Floridi et al., 2020; Nasir et al., 2023). However, this growing body of research remains fragmented. Scholars tend to focus on one dimension at a time, such as technical design, regulatory policy, individual impacts, or societal change, and findings from one area rarely reach the others (Fosso Wamba et al., 2021; Franzke, 2022).

This fragmentation reflects a deeper problem: there is no shared understanding of what "social good" means in the context of AI. Some researchers define it in terms of the UN Sustainable Development Goals (Nasir et al., 2023). Others focus on values such as fairness and human dignity (Ryan & Stahl, 2020; Neubert & Montanez, 2020). Others still emphasize questions of participation and accountability in decision-making processes (Moon, 2023). The result is that AI4SG means different things to different actors, which makes it difficult to distinguish initiatives that genuinely advance social benefit from those that merely use the label to legitimate their actions (Floridi et al., 2020; Palladino, 2023). Iazzolino (2024) goes further, arguing that large technology companies increasingly deploy the AI4SG narrative as a strategic device to advance their own agendas in global development policy.

The rise of generative AI further sharpens these tensions. Systems capable of producing text, images, and code complicate traditional distinctions between tools and agents, making it increasingly difficult to determine where human responsibility ends and technological agency begins (Stahl & Eke, 2024; Crumbly et al., 2025).

A recurring pattern emerges from the reviewed literature: each analytical framework addresses a specific component of the problem, yet none integrates all of its dimensions. Ethical design principles clarify what responsible AI should look like, but they do not explain how individuals internalize these principles or how they become embedded as shared norms within organizations (Floridi et al., 2020; Ryan & Stahl, 2020). Audit tools operate primarily at the organizational level, often neglecting whether the actors affected by AI systems actually trust them (Laine et al., 2024; Li & Goel, 2025). Research on workers documents the human costs of AI deployment but rarely connects these findings to institutional governance responses (Braganza et al., 2021; Varma et al., 2023). Likewise, approaches that align AI initiatives with the SDGs establish useful collective targets but provide limited guidance on how everyday design decisions should reflect those goals (Nasir et al., 2023; Crumbly et al., 2025).

To address these gaps, this paper reinterprets the AI4SG literature through a Bourdieusian sociological framework. Rather than treating the literature as divided along separate thematic dimensions, it examines how different studies emphasize distinct components of the relationship between objective structures, subjective dispositions, and collective social fields. In Bourdieu's theory of practice, social outcomes emerge from the interaction between objective institutional arrangements, the internalized dispositions through which actors interpret and respond to them (habitus), and the structured social arenas in which actors compete for authority, legitimacy, and resources (Bourdieu, 1977; Bourdieu & Wacquant, 1992).

Applied to the effects of AI4SG on society, this perspective highlights three analytically distinct but interrelated dimensions. First, some studies treat AI primarily as an objective technological and organizational structure, focusing on its capabilities, applications, and measurable impacts. Second, other studies emphasize the role of subjective dispositions, examining how managers, workers, consumers, and citizens perceive, interpret, and evaluate AI systems in practice. Third, a further body of literature operates at the level of collective social fields, analyzing how organizations, institutions, and governance systems negotiate the authority to define what counts as socially beneficial AI.

Purpose of the paper. The primary purpose of this paper is to reinterpret the fragmented AI4SG literature through a Bourdieusian analytical framework. Rather than organizing existing contributions solely by topic or domain, the analysis examines how different studies implicitly emphasize distinct components of the relationship between objective structures, subjective dispositions, and collective social fields.

From this perspective, the literature can be read as focusing on three analytically distinct but interrelated dimensions. First, some studies treat AI primarily as an objective technological and organizational structure, examining its design, capabilities, applications, and measurable impacts on organizations, markets, and public systems. Second, other studies emphasize the role of subjective dispositions, focusing on how managers, workers, citizens, consumers, and other stakeholders perceive, interpret, and evaluate AI technologies in practice. Third, a further body of work operates at the level of collective social fields, examining how organizations, institutions, and governance systems negotiate authority, legitimacy, and responsibility in relation to AI deployment.

This interpretative lens allows us to reinterpret the literature not simply as a set of thematic debates but as a distribution of analytical attention across the structural conditions, interpretive processes, and institutional arenas that shape AI for Social Good.

On this basis, the paper addresses the following research question: How can the fragmented AI4SG literature be systematically reinterpreted through a Bourdieusian framework that distinguishes among objective structures, subjective dispositions, and collective fields, and what structural patterns of emphasis and neglect emerge from this mapping?

The analysis is explicitly exploratory in scope. The analytical categories employed here are not intended to constitute a definitive classification of AI4SG research, but rather a heuristic framework for identifying recurring emphases and structural asymmetries within the literature. By mapping how attention is distributed across these dimensions, the paper aims to provide a first systematic orientation for future empirical and theoretical work in the field.

Methodology. The paper adopts a systematic conceptual literature review methodology (Tranfield et al., 2003), designed to provide a structured and transparent synthesis of a fragmented research field. The review was conducted across three major academic databases, namely Scopus, ScienceDirect, and Web of Science, using the Boolean search string: (“AI” OR “artificial intelligence” OR “generative AI”) AND (“social good” OR “human wellbeing”).

The initial search produced 460 results on Scopus, 1,504 on ScienceDirect, and 269 on Web of Science. After applying filters to include only peer-reviewed articles in English within the Business, Management, and Accounting fields, the number of articles was narrowed down to 23 on Scopus, 227 on ScienceDirect, and 11 on Web of Science. Subsequent screening of titles, abstracts, and full texts based on relevance criteria further reduced the corpus to 9, 37, and 5 articles, respectively. After removing duplicates and overlapping contributions, the final dataset consisted of 45 unique articles published between 2020 and early 2026.

In a second stage, the articles were interpreted through a Bourdieusian analytical framework. Rather than organizing the literature solely by topic or empirical domain, the analysis examined how different studies implicitly emphasized distinct components of the relationship between objective structures, subjective dispositions, and collective social fields (Bourdieu, 1977; Bourdieu & Wacquant, 1992). This approach follows the logic of ideal-type analysis (Weber, 1904), in which analytical categories serve as heuristic reference points for interpreting patterns within a corpus rather than mutually exclusive empirical containers.

Three analytical dimensions were therefore used to organize the literature. The first concerned objective structures, referring to studies that treat AI primarily as a technological or organizational arrangement whose properties can be externally specified and evaluated. Contributions were assigned to this dimension when their primary focus was the design, measurement, or regulation of AI systems through performance metrics, technical architectures, compliance standards, algorithmic audits, or formal governance instruments.

The second dimension concerned subjective dispositions, corresponding to what Bourdieu describes as habitus. Contributions were assigned to this dimension when their primary focus was on how situated actors, such as managers, workers, consumers, citizens, or communities, perceive, interpret, and evaluate AI systems. Indicators included discussions of attitudes toward AI, sensemaking processes, trust calibration, ethical interpretation, and the contextual meaning of algorithmic decision-making.

The third dimension concerned collective social fields, referring to the institutional arenas in which actors compete for authority, legitimacy, and resources in relation to AI governance. Contributions were assigned to this dimension when their primary unit of analysis involved organizations, institutions, policy regimes, or broader governance systems shaping the deployment and regulation of AI technologies.

Because individual studies may engage multiple dimensions simultaneously, the categories were treated as interpretive emphases rather than rigid classifications. The purpose of the coding process was therefore not to assign each contribution to a single analytical category, but to identify the dominant orientation through which the role of AI for social good was conceptualized. Table 1 summarizes the reading criteria, textual indicators, and exemplary keywords used to guide the interpretation of articles within these three analytical dimensions.

Table 1. Reading criteria, textual indicators, and exemplary keywords used to interpret the AI4SG literature through a Bourdieusian framework

Analytical dimension	*Reading criteria*	*Typical textual indicators*	*Exemplary keywords*
Objective structures	*The study treats AI primarily as a technological or organizational arrangement whose properties can be externally specified and evaluated. The focus is on system design, performance, governance instruments, or measurable societal outcomes.*	*Discussions of technical architecture, algorithmic performance, standards, compliance frameworks, evaluation metrics, regulatory instruments, or measurable impacts of AI systems.*	*algorithm design, AI architecture, performance metrics, task-technology fit, governance frameworks, algorithmic audits, SDG alignment, evaluation metrics.*
Subjective dispositions (habitus)	*The study focuses on how actors perceive, interpret, trust, or evaluate AI systems in practice. The emphasis is on situated interpretations, attitudes, ethical reasoning, and sensemaking processes through which actors respond to AI.*	*Analysis of user perceptions, managerial interpretations, worker experiences, trust calibration, ethical judgments, or contextual sensemaking related to AI adoption.*	*perception of AI, trust in AI, user attitudes, sensemaking, ethical interpretation, AI literacy, worker experience, stakeholder perception.*
Collective social fields	*The study examines the institutional arenas in which actors compete for authority, legitimacy, and resources related to AI governance. The focus is on organizations, institutions, policy regimes, and broader governance arrangements shaping AI deployment.*	*Discussions of AI governance systems, institutional arrangements, policy frameworks, multi-stakeholder processes, regulatory authority, or global governance regimes.*	*AI governance, regulatory frameworks, institutional actors, public policy, governance systems, participatory governance, institutional legitimacy.*

Source: Author's elaboration.

Results. The proposed interpretation of the forty-five reviewed articles reveals a clear structural asymmetry in the AI4SG literature (Table 2). The majority of contributions conceptualize AI primarily as a technological or organizational structure whose capabilities and societal impacts can be evaluated through externally verifiable criteria. A smaller group of studies examines the institutional arenas in which AI governance takes place, while only a limited number of contributions investigate the subjective dispositions through which actors interpret and experience AI systems in practice. More specifically, thirty of the reviewed articles focus primarily on AI as an objective technological structure, examining system design, evaluation frameworks, technical applications, or governance instruments associated with AI deployment. Eleven contributions operate mainly at the level of institutional fields, analyzing governance regimes, regulatory frameworks, or organizational actors involved in shaping the direction of AI for social good. By contrast, only four studies examine subjective dispositions, exploring how workers, users, or stakeholders perceive, interpret, and respond to AI technologies. This distribution suggests that AI4SG scholarship is strongly oriented toward structural and institutional analyses, while comparatively little attention has been devoted to the interpretive processes through which actors understand and engage with AI systems.

Table 2. Distribution of the corpus (45 articles) across the Bourdieusian analytical dimensions.

Analytical dimension	*Focus of analysis*	*Number of articles*
Objective structures	*AI systems, technical architectures, evaluation frameworks, and design principles*	*30*
Subjective dispositions (habitus)	*perceptions, interpretations, and experiences of AI*	*4*
Collective social fields	*governance systems, policy regimes, and organizational actors*	*11*

The largest share of the reviewed contributions conceptualizes AI primarily as an objective technological and organizational structure whose properties can be externally specified, measured, and evaluated. Within this stream of research, AI is treated as a set of computational systems and analytical infrastructures whose social value derives from their capacity to generate measurable improvements in social, economic, or environmental outcomes.

Several studies frame AI for Social Good explicitly in relation to the Sustainable Development Goals (SDGs). Nasir et al. (2023), for example, propose a systematic framework mapping the relationship between artificial intelligence technologies and the seventeen SDGs, identifying areas in which AI applications may contribute to development goals such as poverty reduction, health improvement, and environmental sustainability. Similarly, Crumbly et al. (2025) develop a classification framework for generative AI applications aligned with the SDGs, illustrating how different categories of AI systems can address specific societal challenges.

Other contributions focus on the development and evaluation of concrete AI applications designed to address social problems. Boto Ferreira et al. (2021) describe the implementation of an automated machine learning system for early detection of over-indebtedness, demonstrating how predictive models can support financial counseling services. In a similar vein, several studies examine how AI-based predictive analytics can improve decision-making capacity in areas such as humanitarian intervention, social services, or financial inclusion.

A further group of studies examines design and governance principles intended to guide the responsible development of such systems. Floridi et al. (2020) propose seven design factors for AI for Social Good, including falsifiability, privacy protection, and situational fairness, while Ryan and Stahl (2020) synthesize international AI ethics guidelines into a set of converging normative principles. These frameworks attempt to translate abstract ethical values into operational design criteria that can be incorporated into AI development processes.

At the same time, the literature identifies several structural challenges associated with this approach. Nasir et al. (2023) highlight the risk of "ethics washing," whereby organizations adopt ethical language without implementing substantive governance mechanisms. Saheb and Saheb (2023) document fragmentation across national AI policy frameworks, while Li and Goel (2025) identify significant competency gaps among auditors responsible for evaluating algorithmic systems.

Taken together, these studies portray AI4SG primarily as a technological infrastructure whose social impact can be assessed through objective design parameters, measurable performance indicators, and formal governance mechanisms. In this perspective, the central analytical problem is how to design and regulate AI systems to maximize their capacity to generate socially beneficial outcomes.

A much smaller portion of the reviewed literature focuses on the interpretive dimension of AI, examining how actors perceive, interpret, and respond to AI systems in practice. These studies highlight the role of habitus, namely the system of internalized dispositions through which individuals interpret social and technological environments and orient their actions within them. Rather than treating AI as a purely technical system whose value can be objectively measured, these contributions emphasize that the social meaning of AI emerges from how actors encounter, interpret, and evaluate algorithmic systems in their everyday contexts. From this perspective, the impact of AI technologies depends not only on their technical properties but also on the dispositions that shape individuals' understanding of their role, legitimacy, and consequences. Several studies illustrate how AI adoption reshapes workplace relationships and professional identities. Braganza et al. (2021), for example, show that the introduction of AI systems can disrupt psychological contracts between employees and organizations, altering expectations of fairness, autonomy, and mutual obligation. Varma et al. (2023) similarly document cases of algorithmic dehumanization in people management practices, highlighting the tensions that arise when algorithmic decision systems mediate workplace relationships. Other contributions emphasize the role of interpretive processes in shaping how AI systems are evaluated in different contexts. Dorotic et al. (2024) demonstrate that identical AI capabilities may be perceived positively in commercial environments yet negatively in public service contexts, suggesting that the perceived social value of AI depends heavily on the interpretive frameworks through which actors encounter it. Similarly, Chedrawi et al. (2025) show that responsible AI usage significantly affects users' behavioral intentions, indicating that trust, perception, and ethical interpretation play a crucial role in shaping AI adoption. Taken together, these studies suggest that the social outcomes of AI cannot be understood solely through technological design or governance frameworks. Instead, they are mediated by the dispositions through which actors interpret and engage with AI systems. The limited number of contributions within this dimension indicates that the interpretive and experiential aspects of AI adoption remain significantly underexplored within the AI4SG literature. While existing research provides extensive guidance on how AI systems should be designed and governed, comparatively little attention has been devoted to how the actors who encounter these systems understand, accept, or contest them in practice.

A third group of contributions examines AI for Social Good at the institutional field level, focusing on the arenas in which actors compete for authority, legitimacy, and resources in relation to AI governance. In Bourdieusian terms, a field is a structured social space in which actors occupy unequal positions and struggle to define the rules, norms, and priorities governing a particular domain of activity. Within the AI4SG literature, these studies examine how governments, international organizations, corporations, and civil society actors shape the governance frameworks through which AI technologies are developed and deployed. Several studies examine the field of global governance surrounding AI for social good. Palladino (2023), for instance, shows that the emerging international governance regime for artificial intelligence tends to privilege Western regulatory models and concentrates agenda-setting power in a limited number of technologically advanced countries. Similarly, Nasir et al. (2023) demonstrate that AI research aligned with the Sustainable Development Goals is unevenly distributed across policy priorities, with strong concentration in areas such as health (SDG 3), industry and innovation (SDG 9), and poverty reduction (SDG 1), while other development goals

remain comparatively underserved. Other contributions focus on the national and policy-level governance of AI systems. Saheb and Saheb (2023), for example, analyze more than thirty national AI policy strategies, revealing substantial variation in regulatory priorities and governance models across countries. These differences reflect distinct institutional traditions and political priorities that shape how AI technologies are integrated into public policy agendas. At the organizational and sectoral level, several studies examine how institutional actors influence the direction of AI4SG initiatives. Moon (2023) argues that meaningful social benefit requires participatory governance arrangements that incorporate stakeholders from civil society, public administration, and industry throughout the AI lifecycle. In a similar vein, Wilson and van der Velden (2022) propose a decision framework for public-sector AI deployment that emphasizes institutional learning, diversity, and shared meaning as key conditions for sustainable AI governance. Finally, some studies analyze the local governance of AI systems. Elbehairy et al. (2025), for instance, identify four roles played by municipal governments in AI ecosystems, namely regulators, buyers, facilitators, and entrepreneurs, demonstrating how local institutions actively shape the adoption and direction of AI technologies within urban governance systems. According to the findings, AI4SG initiatives operate within multi-level institutional fields in which different actors compete to define the priorities, norms, and governance mechanisms guiding the development of AI systems. From this perspective, the meaning of "social good" is not simply embedded in technological design but emerges through ongoing negotiations among actors occupying different positions within the AI governance field.

Research limitations. This study has several limitations. First, the classification of articles into the dimensions of objective structures, subjective dispositions, and institutional fields involves an interpretive element, and alternative readings of individual contributions may be possible. Second, the review focuses on peer-reviewed articles indexed in three major databases in the Business, Management, and Accounting field, thereby excluding relevant work from other disciplines. Finally, the analysis is exploratory and based on a corpus of 45 recent articles; future research may refine or extend the proposed analytical framework as the AI4SG literature continues to evolve.

Managerial implications. The findings of this study suggest several implications for managers and organizations involved in the development and deployment of AI systems for social purposes. First, the strong emphasis on technological structures in the existing literature indicates that organizations often approach AI for social good primarily as a technical design challenge. While robust system architectures, evaluation frameworks, and governance tools remain essential, managers should recognize that the social impact of AI systems depends not only on their technical performance but also on how they are interpreted and experienced by the actors who interact with them. Second, the limited attention devoted to subjective dispositions in the literature suggests that organizations may underestimate the importance of user perceptions, trust, and interpretive understanding in shaping the success of AI initiatives. Managers should therefore complement technical governance mechanisms with initiatives to strengthen AI literacy, promote transparency, and incorporate stakeholder feedback throughout the AI lifecycle. Third, studies examining institutional governance highlight that AI deployment occurs within complex multi-actor ecosystems comprising regulators, public institutions, technology firms, and civil society organizations. Managers implementing AI for social good should therefore actively engage with these institutional environments, recognizing that the legitimacy and effectiveness of AI systems depend on their alignment with broader governance frameworks and societal expectations. These implications suggest that effective management of AI for social good requires balancing three interrelated dimensions: the technical design of AI systems, the interpretive dispositions of the actors who use and experience them, and the institutional environments in which these systems are governed.

Originality of the paper. This paper contributes to the emerging literature on Artificial Intelligence for Social Good by proposing a Bourdieusian reinterpretation of the field. While existing research has examined AI4SG through technological, ethical, or governance perspectives (Floridi et al., 2020; Ryan & Stahl, 2020; Moon, 2023), relatively few studies have analyzed how these dimensions relate to one another within a broader sociological framework. By organizing the literature around the concepts of objective structures, subjective dispositions, and institutional fields, (Bourdieu, 1977; Bourdieu & Wacquant, 1992), this study provides an integrative lens that helps explain the fragmentation observed in the AI4SG debate.

The findings reveal a clear imbalance in the literature's analytical orientation. Most contributions focus either on the technological structures of AI systems or on the institutional arenas in which AI governance is negotiated (Nasir et al., 2023; Saheb & Saheb, 2023), while comparatively little attention is devoted to the dispositions through which actors interpret and experience AI technologies. This imbalance helps explain why the proliferation of governance frameworks and ethical guidelines has not always been translated into socially legitimate or widely accepted AI practices (Franzke, 2022).

When interpreted through the framework adopted in this study, the AI4SG literature reveals several structural tensions arising from this uneven distribution of analytical attention. The first tension concerns the relationship between objective governance structures and the dispositions of the actors expected to implement them. A large portion of the literature focuses on developing design principles, governance frameworks, and evaluation tools intended to guide responsible AI

development (Floridi et al., 2020; Ryan & Stahl, 2020). However, relatively few studies examine how these instruments are interpreted, internalized, or contested by the actors who interact with AI systems in everyday contexts. As a result, governance frameworks often remain detached from the interpretive processes through which individuals understand and respond to AI technologies. A second tension concerns the relationship between institutional governance and individual experience. The social consequences of AI systems are frequently experienced at the level of workers, consumers, and citizens (Braganza et al., 2021; Varma et al., 2023), yet governance responses are typically formulated within institutional arenas such as governments, international organizations, or corporate policy frameworks (Moon, 2023; Saheb & Saheb, 2023). This creates a disconnect between the sites where AI impacts are lived and the arenas in which governance decisions are negotiated. A third tension concerns the definition of social value within the AI governance field. Because multiple actors, including governments, corporations, international organizations, and civil society organizations, participate in shaping AI governance frameworks, the meaning of "social good" itself becomes the object of negotiation. Previous research has shown that global AI governance regimes tend to reflect the priorities and institutional norms of dominant actors within the field (Palladino, 2023). As a result, AI4SG initiatives may reflect institutional priorities, such as economic competitiveness or technological innovation, rather than a universally agreed definition of social benefit.

To conclude, AI for Social Good cannot be understood solely through technological design or institutional governance frameworks. Instead, AI4SG practices emerge from the interaction between technological structures, institutional fields, and the dispositions through which actors interpret and engage with AI systems. The limited attention devoted to the interpretive dimension of AI adoption indicates that the habitus through which actors encounter AI technologies remains a largely underexplored dimension of AI4SG research. By highlighting this imbalance, the study contributes to the literature by introducing a sociological perspective that connects technological design, governance processes, and actor interpretations within a unified analytical framework.

Communicative Genres and Digital Capabilities Development and Engagement in Later Life: Preliminary implications

ANDREA SESTINO, YANG ZHAO, ALFREDO D'ANGELO, LIDAN ZANG

Abstract. This research investigates how older adults develop digital capabilities that enable sustained participation in an increasingly digital society, moving beyond static models of technology adoption. While prior literature has emphasized structural barriers, cognitive determinants, and emotional factors such as technophobia, the corpus of knowledge demonstrate limited insight into the communicative processes through which digital capabilities are socially constructed over time. Drawing on communicative Genres theory, in this research we conceptualize digital capability as a relational and processual outcome shaped by patterned interactions within social networks. Trough a qualitative research design conducted within an elderly university in China, the study integrates survey data and 47 in-depth interviews with older adults and their social relations, to shed light on how communication unfolds across family, peers, and institutional actors. Findings reveal that digital capability develops through distinct communicative genres, including preparing, urging, reasoning, advisory instruction, and conceptualisation, which structure learning processes and relational roles. More specifically, the analysis identifies three main trajectories of digital capability development, formally: 1) greenhouse, 2) open-garden, and 3) wild-growth. Such trajectories differ in terms of relational embeddedness, communicative purposes, and autonomy, ranging from dependence on close ties to distributed and outward-oriented engagement. Crucially, the sequencing and interaction of communicative genres over time determine both the level of capability achieved and the nature of digital participation. On the basis of our results, this research contributes to ageing and technology literature by shedding light on digital capability as the key mechanism linking initial adoption to sustained engagement, and by advancing a communication-centred perspective on digital inclusion. Moreover, we further extend communicative genres theory by demonstrating how genres evolve and interact across social contexts, shaping capability development in dynamic socio-technical environments.
aging and technology literature by shedding light on digital capability as the key mechanism linking initial adoption to sustained engagement, and by advancing a communication-centered
Keywords: *Elderly; digital divide; technology acceptance; empowerment; later life; innovation; genres theory*

Framing the research. Recent research at the intersection of ageing and technology has called for a shift from static models of technology adoption toward a process-oriented understanding of digital capability development, through which older adults progressively integrate digital technologies into their everyday lives in an evolving digital society. While existing studies recognize that digital capabilities are socially developed, social context is typically treated as a generic form of "social influence", offering limited insight into the communicative forms and practices through which digital capabilities are formed. Drawing on the communicative Genres Theory, this qualitative study examines how patterned communicative practices lead to foundational, intermediate, and advanced levels of digital capability among older adults, and how the interrelationships among these communicative genres shape three distinct digital trajectories: 1) greenhouse, 2) open-garden, and 3) wild-growth. This study contributes to the ageing and technology literature by positioning digital capability as the foundation of older generation's continuous engagement in the digital society, and by theorizing communication as a mechanism of capability development that influences older adults' digital trajectories. It further extends communicative genres theory by offering a dynamic account of how genres interact within socially embedded networks. The findings also inform the design of digitally inclusive interventions that leverage everyday communication to support older adults' sustained engagement in the digital society.

The progressive diffusion of digital technologies across all spheres of everyday life has renewed scholarly attention to the persistent exclusion of older people from the digital society. Digital services increasingly mediate access to health care, public administration, social interaction, and consumption activities, making digital engagement a prerequisite for full participation in contemporary social life. However, a substantial proportion of older adults continues to experience difficulties in accessing, understanding, and effectively using digital technologies. Existing research has approached this issue through several complementary but only partially integrated streams of literature.

A first stream has focused on the grey digital divide, emphasizing how structural inequalities related to education, income, health status, and infrastructural conditions shape older people's access to and use of digital technologies (Dewan and Riggins, 2005; Friemel, 2016; Fox and Connolly, 2018; Neves et al., 2019). This body of work highlights that digital exclusion in later life is not merely a matter of individual resistance or lack of interest, but rather the outcome of cumulative disadvantages that precede and condition older adults' encounters with digital tools. While this perspective has been crucial in situating digital exclusion within broader socio-economic structures, it offers limited insight into how older people engage with technologies once access is achieved.

A second, highly influential stream has examined older adults' technology use through psychologically oriented acceptance models, most notably the Technology Acceptance Model and its extensions (Davis, 1989; Venkatesh et al., 2003; Chen and Chan, 2011, 2014). These frameworks explain adoption intentions primarily through cognitive

evaluations such as perceived usefulness, perceived ease of use, effort expectancy, and facilitating conditions. Age sensitive adaptations, including the Senior Technology Acceptance Model, have incorporated variables such as health status, anxiety, and self efficacy, improving explanatory power in later life contexts. Nevertheless, these models largely depict older users as isolated decision makers and tend to reduce technology use to a single adoption choice, offering limited leverage for understanding how digital engagement unfolds over time.

A third stream has addressed the emotional and affective dimensions of older adults' interactions with technology, with particular attention to technophobia and technology related anxiety (Laguna and Babcock, 1997; Barnard et al., 2013; Nimrod, 2018; Leite et al., 2024). This literature shows how fear, discomfort, and skepticism may inhibit experimentation and sustained use, even when technologies are perceived as potentially useful. While these studies acknowledge the role of emotions in shaping behavior, they often treat such factors as individual traits rather than as outcomes of relational and communicative processes.

More recent contributions have called for a shift from adoption centered explanations toward a process-oriented understanding of digital engagement. Drawing on diffusion theory and engagement research, scholars argue that adoption does not guarantee meaningful or sustained use of digital technologies (Rogers, 1983; Agarwal and Karahanna, 2000; Fischer et al., 2019). In this perspective, continuous engagement depends on older people's ability to integrate digital technologies into everyday practices, adapt to changing interfaces, and interpret new digital affordances over time. This has led to growing interest in the concept of digital capability, defined as the ability to build knowledge, skills, and mindsets through ongoing action in a social environment (Zhao et al., 2023).

Although recent studies increasingly recognize the relevance of social interactions in shaping older adults' digital trajectories, research remains vague regarding the communicative mechanisms through which such interactions support capability development. Constructs such as social influence or peer support are often invoked without unpacking the concrete communicative forms that structure learning, confidence building, and appropriation. As a result, existing literature lacks a relationally grounded explanation of how digital capabilities emerge and evolve within older people's social networks. Addressing this gap requires moving beyond decontextualized models of adoption and toward a communicative and practice-oriented perspective capable of capturing the dynamic social processes underlying continuous digital engagement, especially when referring to this "grey tsunami" (Guido et al., 2021; Sestino & D'Angelo, 2024).

Purpose of the paper. The purpose of this paper is to advance a fresh and complete understanding of older people's digital engagement by theorizing digital capability development as a process embedded in dynamic communicative structures. Building on research on the grey digital divide, technology acceptance, technophobia, and digital engagement, the study shifts attention from isolated adoption decisions to the ongoing development of capabilities that sustain effective technology use over time. Drawing on communicative genres theory (Yates and Orlikowski, 1992; Orlikowski and Yates, 1994), the paper examines how recurring forms of communication within and across social clusters such as family, peers, and institutional actors shape learning, confidence, and appropriation of digital technologies. By doing so, the study aims to explain how social interactions are translated into digital capabilities that enable older people's continuous engagement with the digital environment. Thus, based on above, formally, this research is aimed to advance a socio-material and practice-oriented understanding of older people's digital capability development by theorizing it as a process deeply embedded in dynamic communicative and relational structures. Specifically, we draw on the communicative genres theory that highlights the typified and recognizable forms of interactions shaped by context, purpose, and social role (Moser et al., 2013; Yates & Orlikowski, 1992).

Methodology. In the attempt to fill the gap presented above, in this study we adopted a longitudinal qualitative research design to examine how digital capabilities develop through communicative interactions within older adults' social networks, situated within the empirical context of an elderly university in China. Such a setting, in the authors' view, could be particularly appropriate as such institutions function not only as formal learning environment, but also as socially embedded ecosystems where digital practices are continuously reinforced through peer interaction and collective engagement (Ministry of Education, 2019). The coexistence of structured training and informal exchanges allows for observing digital capability as a situated and socially mediated process rather than a purely individual outcome.

Formally, the data collection has been structured in multiple phases, combining exploratory, survey-based, and in-depth qualitative inquiry: Firstly, an initial exploratory stage involved informal interviews with five students, which informed the development of a structured survey instrument designed to capture the breadth and depth of smartphone use, levels of understanding, and behavioural patterns including proactive, reactive, and outward-sharing practices. The survey has been thus distributed to a targeted sample of individuals aged over 60, consistent with the World Health Organization's definition of older adults (WHO, 2018), resulting in 95 valid responses, in the attempt to enable a classification of participants into three levels of digital capability: foundational (i.e., 26 participants), intermediate (i.e., 56 participants), and advanced (i.e., 13 participants) to reflect the heterogeneity widely documented in ageing populations (Czaja & Lee, 2007; Zhao et al., 2023).

On the basis on the aforementioned classification, a sampling strategy guided the selection of participants for the qualitative phase: Twelve older adults representing the three capability levels were recruited for in-depth longitudinal

interviews. These interviews were complemented by the inclusion of 27 key actors within their social networks (i.e., family members, peers, and other relevant contacts) identified as influential in shaping their digital practices. This multi-actor design allowed for capturing relational dynamics and tracing how communicative interactions unfold across interconnected social contexts.

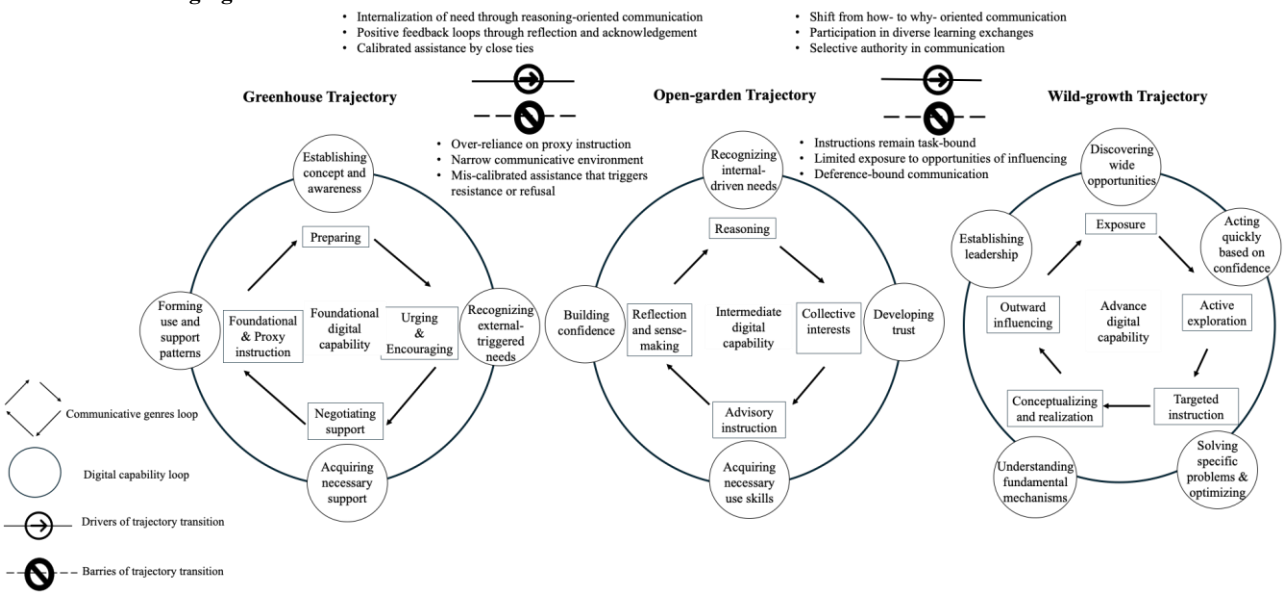
The interviews finally focused on participants' everyday engagement with digital technologies, the communicative processes through which learning and support were enacted, and the evolution of these interactions over time. Data were analysed through an iterative and inductive approach, enabling the identification of recurring communicative patterns and their role in structuring capability development. Particular attention has been dedicated to understand how communicative genres emerge, interact, and reconfigure across social clusters, shaping distinct trajectories of digital capability and enabling the progressive appropriation of digital technologies within everyday life.

Results. The findings show that older people's digital capabilities develop through recurring communicative interactions that structure learning, confidence building, and the progressive appropriation of digital technologies. Rather than emerging from isolated exposure to digital tools, digital capability is constructed through patterned forms of communication that stabilize expectations, roles, and learning trajectories within social networks. These patterns take the form of communicative genres that recur across interactions and evolve over time.

The participants showed three levels of digital capabilities from basic to advance. Participants in the low-capability group demonstrated limited breadth and depth in their digital practices. The participants' initial encounter with mobile applications began through informal and unstructured communication that prepared them to recognize the potential uses of these applications. This leads to the motivation towards engagement, which took two forms including urging and encouraging. Based on the willingness to engage, the participants interacted with their social relations, especially families, in a negotiation process. The actual support of the social relations followed two types of communication, including foundational and proxy instructions.

Participants in the medium-capability group demonstrated greater breadth by using a wider range of applications. Their depth of use was also more developed, as they were able to independently perform both basic and some advanced functions. While the low-capability group started with brief communication that prepare them for recognizing the applications, the communication with participants in the medium- capability group took a more explanatory and persuasive form, reasoning that justified the applications by linking them to the participants' specific needs and challenges. In contrast to the dyadic communication pattern where social relations urged and/or encouraged the low-capability group, participants with medium digital capability showed collective communication patterns and group dynamics in stimulating the use actions. The use support provided to the participants combined elements of process-focused teaching and consultative guidance. Drawing on their usage experiences, the participants reflected on their digital capability development. They evaluated and interpreted their learning, often sharing these reflections with their social relations.

Participants in the high-capability group demonstrated both breadth and depth across a variety of applications. In contrast to the low- and medium- capability groups, participants in the high-capability group were more fully exposed in the digital society, which created a wide range of opportunities to communicate about and engage with mobile applications. When the participants decided to pursue further learning, they explored through deliberate, initiative-taking communication with the outside world. Participants with high capability typically benefited from targeted, situational guidance from their social relations. Based on insights generated from their use experiences, the participants began to conceptualize the practices and realize the underlying logics and mechanisms across applications. An important characteristic of the high-capability group was their extensive outward communication, through which they influenced people in their social networks.



Based on these findings, we present a theoretical model, as shown in the Figure 1, that uncovers how the interrelationships among communicative genres shape the trajectory of developing digital capability across the three groups of older adults.

Based on the framework, first, the *greenhouse trajectory* describes how foundational digital capabilities emerge within close social relationships. The process begins with communicative genres of *preparing*, which foster awareness and initial sensemaking. It progresses through *urging and encouraging*, where close ties trigger perceived need, followed by *negotiation of support* that enables engagement while preserving autonomy. Finally, *foundational and proxy instructions* establish patterns of use and delegation.

In this trajectory, engagement is relationally embedded and slow, relying on continuous communicative support within trusted ties. Learning unfolds incrementally, moving from awareness to stabilized use through socially negotiated assistance.

Second, the *open-garden trajectory* captures the development of intermediate capabilities through a combination of self-direction and collective interaction. It begins with *reasoning-oriented communication*, where internally recognized needs are articulated and validated. This is followed by *collective interest-based communication*, which builds trust, and *advisory instruction*, where individuals retain control while seeking guidance. *Reflection and sense-making* consolidate learning and reinforce competence.

Table 1. The emerging Theoretical framework

	Greenhouse Trajectory	Open-garden Trajectory	Wild-growth Trajectory
Level of digital capability	Foundational	Intermediate	Advanced
Capability growth logic	Assisted growth enabled by sustained prompting and support	Self-directed growth supported by collective input	Autonomous and self-sustaining growth
Primary communicative purpose	Making sense of what technologies are and enabling initial use	Validating needs, building trust, and refining use to understand how to use technologies	Explaining why technologies work and shaping others' engagement
Communication characteristics	High dependence in which tasks are often delegated or co-produced	Selective reliance in which advice are sought for complex tasks	Reciprocal support which both seeks and offers guidance
Relational embeddedness	Engagement happens within a favorable communicative environment with family and close ties	Engagement happens in expanded networks including peers and weak ties in more diverse communicative environments	Engagement is embedded in distributed and board networks, with both drawing on and contributing knowledge to others
Pacing of engagement	Slow and incremental	Accelerated and iterative	Rapid and adaptive

Here, engagement becomes relationally expanded, involving peers and weak ties, while the pace accelerates. Older adults maintain ownership of digital tasks, relying on others selectively and strategically. Third, the *wild-growth trajectory* explains the emergence of advanced digital capabilities within broad and heterogeneous networks. It starts with extensive exposure to digital environments, followed by *exploratory communication* driven by confidence and initiative. *Targeted instructional genres* support problem-solving, while *conceptualizing and realization* enable deep understanding of technological mechanisms. Finally, *outward influence* positions individuals as contributors and leaders. In this trajectory, engagement is autonomous, fast, and exploratory. Communication becomes mechanism-oriented, and support is reciprocal, as older adults both learn from and guide others within distributed social networks.

This study explains how older adults develop capabilities for sustained digital participation, identifying communication as the key mechanism. Theoretically, it shifts the focus from technology adoption to capability development, aligning with Zhao et al. (2023) and Zhang (2023), and addressing the limits of TAM-based views (Davis, 1989; Chen & Chan, 2014). Findings show that perceived usefulness and ease of use explain initial adoption, while sustained engagement depends on accumulated knowledge and confidence (Agarwal & Karahanna, 2000; Peek et al., 2014), thus positioning digital capability as the missing link between adoption and routine use. The study further specifies the social dimension by applying communicative genres theory (Orlikowski & Yates, 1994; Moser et al., 2013), demonstrating how distinct interaction forms shape learning outcomes, beyond generic notions of social influence (Czaja & Sharit, 2012; Selwyn, 2004; Nikou et al., 2020). In particular, proxy instruction stabilises access but may create dependency, whereas reasoning and advisory genres enhance self-efficacy and transferability (Sestino & D'Angelo, 2024). Finally, it extends genre theory by showing how communicative genres evolve across social contexts and combine into distinct trajectories, advancing prior work on dynamic repertoires (Orlikowski & Yates, 1994; Avital et al., 2017; Te'eni, 2012).

Originality of the paper. The paper is relevant for management and innovation studies as it offers a process oriented and relational perspective on digital capability development that extends prevailing models of technology adoption and use. By showing how digital engagement is shaped through communicative genres within social networks, the study highlights the role of interaction design, relational scaffolding, and learning environments in enabling effective technology use. These insights inform innovation management by emphasizing that the success of digital innovations, particularly in service and health related contexts, depends not only on usability and functionality but also on the communicative structures that support user capability development. The findings suggest that organizations, public institutions, and technology providers can enhance innovation outcomes by designing communication practices that foster confidence, learning, and sustained engagement among older users.

Managerial implications. On the basis of our study, findings suggest several managerial implications for organizations involved in the design, deployment, and governance of digital technologies targeting older users. First, managers should move beyond a narrow focus on usability and initial adoption and explicitly address digital capability development as a strategic objective. This implies designing digital services and platforms that are accompanied by structured yet flexible communication practices, such as guided demonstrations, iterative explanations, and opportunities for supported experimentation, which can evolve over time as users' confidence increases.

Second, organizations should leverage social contexts as learning environments by intentionally activating family members, peer groups, and community networks as part of the innovation process. Rather than treating support as an external or informal activity, managers can integrate relational scaffolding into service ecosystems by facilitating peer based learning spaces, moderated communities, and collaborative problem-solving formats that sustain engagement beyond first use.

Third, institutional actors and service providers should align "formal communication" with relational and affective dimensions of learning. Training programs and digital assistance services should be designed to complement procedural guidance with reassurance, narrative framing, and contextual relevance, reducing anxiety and supporting autonomy rather than dependency.

From a social perspective, importantly, the study highlights the relevance of communicative inclusion as a foundation for digital inclusion. Supporting older people's digital capabilities through relational and communicative practices contributes not only to more effective technology use but also to social participation, autonomy, and wellbeing in an increasingly digital society.

Research limitations. This study has some limitations that open avenues for future research. First, the qualitative and longitudinal design limits the generalizability of the findings across different cultural and institutional contexts. Second, the focus on older people's social networks may underrepresent the role of individual learning strategies developed outside relational settings. Third, the study does not differentiate systematically across specific digital technologies, which may involve distinct capability requirements. Fourth, the reliance on "self-reported narratives" may be affected by recall bias. Finally, future research could integrate quantitative or mixed methods approaches to test and extend the proposed framework.

Configurazioni dei Big Data e performance innovative nelle PMI: Un approccio fsQCA

GIULIO FERRIGNO

Abstract. *Nell'era della trasformazione digitale, la capacità delle imprese di raccogliere, elaborare e interpretare grandi quantità di dati rappresenta una fonte sempre più rilevante di vantaggio competitivo. In particolare, i Big Data stanno assumendo un ruolo centrale nei processi decisionali e nelle strategie di innovazione delle imprese, incluse le piccole e medie imprese (PMI). Tuttavia, nonostante la crescente attenzione della letteratura verso il ruolo dei Big Data nelle performance aziendali, la maggior parte degli studi ha analizzato le diverse dimensioni dei Big Data separatamente, trascurando il ruolo delle loro interazioni e configurazioni nel determinare le performance innovative delle imprese.*

Il presente studio si propone di analizzare come diverse configurazioni delle principali dimensioni dei Big Data influenzino la performance innovativa delle PMI. In particolare, adottando la prospettiva teorica della Resource-Based View (RBV), identifichiamo cinque dimensioni fondamentali dei Big Data — volume, varietà, velocità, veridicità e valore — e analizziamo come la loro combinazione contribuisca a migliorare le capacità innovative delle imprese. L'analisi empirica si basa su un campione di 123 PMI italiane e utilizza la metodologia della fuzzy set Qualitative Comparative Analysis (fsQCA), che consente di esplorare configurazioni multiple di risorse e di identificare combinazioni di fattori che conducono a elevati livelli di performance innovativa.

I risultati evidenziano che nessuna singola dimensione dei Big Data rappresenta una condizione necessaria per ottenere elevate performance innovative. Piuttosto, sono le interazioni sinergiche tra diverse dimensioni dei Big Data a generare risultati positivi in termini di innovazione. In particolare, alcune configurazioni specifiche di volume, varietà, velocità, veridicità e valore dei dati risultano associate a migliori performance innovative delle PMI. Lo studio contribuisce alla letteratura sull'innovazione e sui Big Data evidenziando l'importanza di un approccio configurazionale e fornendo indicazioni utili ai manager delle PMI che intendono sfruttare il potenziale dei Big Data per rafforzare le proprie capacità innovative.

Keywords*: Big Data; performance dell'innovazione; PMI; Resource-Based View; fsQCA*

Framing of the research. Negli ultimi anni il fenomeno dei Big Data ha assunto un ruolo sempre più centrale nei processi di trasformazione digitale delle imprese. L'enorme quantità di dati generata da piattaforme digitali, dispositivi mobili, social media e sistemi informativi aziendali ha creato nuove opportunità per le imprese di raccogliere informazioni sui comportamenti dei consumatori, sui trend di mercato e sulle dinamiche competitive (Del Vecchio et al., 2018; George et al., 2014).

Secondo alcune stime, il volume globale dei dati generati a livello mondiale è destinato a superare i 180 zettabyte entro il 2025, evidenziando la portata del fenomeno dei Big Data e il suo potenziale impatto sulle attività economiche e organizzative (Statista, 2023). In questo contesto, la capacità di gestire e analizzare grandi quantità di dati rappresenta una competenza strategica per le imprese, in quanto consente di trasformare i dati grezzi in informazioni utili per il processo decisionale (Kaisler et al., 2013; Ward & Barker, 2013).

La letteratura manageriale ha evidenziato come i Big Data possano contribuire in modo significativo allo sviluppo delle capacità innovative delle imprese. In particolare, l'analisi dei dati consente alle imprese di comprendere meglio le esigenze dei clienti, monitorare le prestazioni dei prodotti e individuare nuove opportunità di innovazione (Mazzei & Noble, 2017; Visconti & Morea, 2019). Inoltre, l'utilizzo dei Big Data può migliorare la qualità delle decisioni strategiche e supportare lo sviluppo di nuovi modelli di business basati sui dati (Del Vecchio et al., 2018).

Dal punto di vista teorico, la Resource-Based View (RBV) rappresenta una delle prospettive più utilizzate per analizzare il ruolo delle risorse interne nel determinare le performance delle imprese (Barney, 1991; Wernerfelt, 1984). Secondo questa prospettiva, le imprese possono ottenere vantaggi competitivi sostenibili quando possiedono risorse che sono preziose, rare, difficili da imitare e difficilmente sostituibili. In questo senso, i Big Data possono essere considerati una risorsa strategica che consente alle imprese di sviluppare capacità analitiche avanzate e migliorare i processi di innovazione (Sena et al., 2019).

Nonostante questi progressi, osservo che la ricerca esistente si è concentrata prevalentemente sull'analisi di ciascuna risorsa interna considerata singolarmente, trascurando le relazioni e le interazioni tra tali risorse. In particolare, il lavoro di Ferrigno et al. (2025) evidenzia come un'area di ricerca ancora poco esplorata riguardi il modo in cui la combinazione di diverse dimensioni dei Big Data influenzi le performance innovative radicali e/o incrementali delle imprese (Ferrigno et al., 2025, pp. 11–12).

Comprendere questo aspetto è cruciale per almeno due ragioni principali. In primo luogo, l'importanza delle interazioni tra risorse interne nel determinare le performance innovative delle PMI è stata riconosciuta come un elemento fondamentale (Ferrigno et al., 2024). Diversi autori sostengono infatti che l'analisi di tali interazioni possa generare un asset unico capace di rafforzare il vantaggio competitivo delle PMI (Cappa et al., 2021). In secondo luogo, l'analisi delle interazioni sinergiche tra risorse consente di evidenziare i benefici derivanti dalla combinazione delle diverse risorse

interne delle imprese. Ad esempio, potrebbe permettere di comprendere se una specifica dimensione dei Big Data sia in grado di amplificare l'influenza di altre risorse interne sulle performance innovative delle PMI (Cappa et al., 2021).
In altre parole, nonostante il crescente interesse per il ruolo dei Big Data nelle performance aziendali, molti studi hanno analizzato le diverse dimensioni dei Big Data separatamente. Tuttavia, alcuni autori hanno recentemente sottolineato l'importanza di analizzare le interazioni tra diverse dimensioni dei Big Data per comprendere meglio il loro impatto sulle performance innovative delle imprese (Akter & Wamba, 2016; Erevelles et al., 2016; Cappa et al., 2021; Ferrigno et al. 2025).

Purpose of the paper. L'obiettivo principale di questo lavoro è analizzare come diverse configurazioni delle principali dimensioni dei Big Data influenzino la performance innovativa delle piccole e medie imprese. Facendo riferimento alla letteratura che utilizza la Resource-Based View (RBV) per analizzare l'impatto delle risorse interne sulle performance innovative delle PMI, ho identificato cinque risorse interne chiave: (1) Big Data volume, ovvero la quantità di dati disponibili (Wamba et al., 2015); (2) Big Data variety, ossia la diversità delle tipologie di dati, che include sia dati strutturati (ad esempio numeri) sia dati non strutturati (ad esempio immagini) (Ghasemaghaei et al., 2017; Ghasemaghaei e Calic, 2020), con effetti sulle performance delle imprese (Cappa et al., 2021; Ghasemaghaei, 2019); (3) Big Data velocity, ovvero la velocità con cui i dati vengono generati ed elaborati (Ghasemaghaei et al., 2017); (4) Big Data veracity, cioè l'affidabilità e la qualità informativa dei dati (Erevelles, Fukawa e Swayne, 2016; Jin, Wah, Cheng e Wang, 2015; Wamba et al., 2015); e (5) Big Data value, ovvero la capacità dell'impresa di individuare pattern, trend e associazioni attraverso la raccolta, la gestione e l'analisi efficace di grandi quantità di dati (Del Vecchio et al., 2018).
Partendo dalla prospettiva teorica della Resource-Based View, il lavoro considera i Big Data come un insieme di risorse interne che possono contribuire alla creazione di vantaggi competitivi sostenibili. Tuttavia, invece di analizzare ciascuna dimensione dei Big Data in modo isolato, lo studio adotta un approccio configurazionale che consente di esplorare come diverse combinazioni di risorse possano influenzare la performance innovativa delle imprese. In questo senso, la ricerca si propone di rispondere alla seguente domanda di ricerca: Quali configurazioni delle dimensioni dei Big Data contribuiscono a migliorare la performance innovativa delle PMI?
Per rispondere a questa domanda, il lavoro analizza il ruolo delle cinque principali dimensioni dei Big Data — volume, varietà, velocità, veridicità e valore — e indaga come la loro interazione possa influenzare le capacità innovative delle imprese.

Methodology. Per affrontare la domanda di ricerca, abbiamo utilizzato la Qualitative Comparative Analysis (QCA). La scelta di questa metodologia è motivata da tre principali ragioni. In primo luogo, la QCA consente di analizzare le relazioni causali tra configurazioni o combinazioni di risorse interne e un determinato risultato di interesse, come la performance innovativa delle PMI (Ragin, 2008; Schneider & Wagemann, 2012). In secondo luogo, la QCA sta ricevendo crescente attenzione sia nella letteratura di management (Ferrigno et al., 2021) sia negli studi sull'innovazione (Del Sarto et al., 2021). Infine, l'obiettivo della QCA non è dimostrare l'esistenza e l'intensità di una relazione causale tra due variabili, come avviene nelle tecniche statistiche inferenziali, ma piuttosto individuare configurazioni di condizioni che supportano l'esistenza di tali relazioni causali (Schneider & Wagemann, 2012).
Più nello specifico, in questo studio ho utilizzato una tecnica particolare della QCA nota come fuzzy set Qualitative Comparative Analysis (fsQCA). La fsQCA utilizza la logica fuzzy per estendere le capacità della QCA tradizionale basata su insiemi dicotomici. Questo approccio consente di esprimere il grado di appartenenza a un insieme attraverso valori compresi tra 0 e 1, creando così un continuum di appartenenza (Ragin, 2000).
Per la ricerca ho selezionato casi di PMI italiane, definite dalla Commissione Europea come imprese con meno di 250 dipendenti e con un fatturato annuo inferiore a 50 milioni di euro oppure un totale di bilancio inferiore a 43 milioni di euro. L'Italia rappresenta un contesto particolarmente interessante per questo tipo di analisi, in quanto le PMI costituiscono una componente fondamentale del sistema economico nazionale, rappresentando oltre il 90% della forza lavoro (ISTAT, 2022). Inoltre, uno studio del Ministero dello Sviluppo Economico (MISE, 2020) evidenzia come una quota significativa delle imprese italiane stia progressivamente adottando tecnologie legate all'Industria 4.0. Nell'ultimo decennio, infatti, il governo italiano ha promosso numerosi piani e interventi specifici finalizzati a stimolare la digitalizzazione delle imprese e l'adozione delle tecnologie dell'Industria 4.0, tra cui i Big Data. Considerata la struttura dell'economia italiana, prevalentemente basata sulle PMI, e le recenti politiche nazionali volte ad accelerare i processi di digitalizzazione, l'Italia rappresenta quindi un contesto particolarmente interessante per analizzare i diversi comportamenti delle PMI rispetto all'adozione dei Big Data (Ferrigno et al. 2024; 2025).
Per identificare le PMI italiane ho utilizzato il database Orbis di Bureau van Dijk, noto per la sua affidabilità e ampiamente utilizzato negli studi sui Big Data, sull'open innovation e sulle PMI (Costa et al., 2023; Rammer & Es-Sadki, 2023). La ricerca si è concentrata sull'identificazione delle PMI italiane definite come imprese con meno di 250 dipendenti. Questa ricerca ha portato all'individuazione di 19.722 PMI. Successivamente ho estratto le principali informazioni relative a queste imprese, tra cui il nome dell'azienda, il numero identificativo BvD, i numeri di telefono, i siti web e gli indirizzi e-mail, organizzando tali informazioni in un foglio di calcolo Excel.
I dati utilizzati in questo studio derivano da un questionario che ho appositamente progettato e somministrato sulla base della letteratura esistente sui Big Data e sulle performance innovative delle PMI (Ghasemaghaei e Calic, 2019; 2020;

Ghasemaghaei, 2021; Johnson et al., 2017). Prima di avviare la somministrazione del questionario, ho condotto due test preliminari per migliorarne la chiarezza e aumentare l'affidabilità dei dati raccolti (Crick et al., 2023). Nel marzo 2023 ho testato il questionario con cinque esperti accademici nei campi dei Big Data e delle performance innovative delle PMI, nonché con cinque decisori e fondatori di PMI appartenenti a diversi settori, raccogliendo i loro suggerimenti per perfezionare lo strumento di indagine. Nell'aprile 2023 un'agenzia indipendente, non coinvolta nella somministrazione del questionario, ha inoltre revisionato il questionario.
Dopo aver migliorato la chiarezza del questionario, nel giugno 2023 ho avviato la raccolta dei dati, coinvolgendo un sottoinsieme selezionato casualmente di fondatori e decisori di PMI italiane operanti in diversi settori industriali. La raccolta dei dati è stata effettuata mediante la metodologia Computer-Assisted Telephone Interview (CATI), con il supporto di una società esterna specializzata. Prima di avviare la somministrazione del questionario su larga scala, ho condotto un ulteriore pre-test con 27 PMI, il cui feedback ha contribuito a perfezionare ulteriormente lo strumento di indagine. Nell'agosto 2023 ho contattato complessivamente 801 imprese; 591 di esse non svolgevano attività legate ai Big Data (e sono quindi state escluse dall'analisi), mentre 210 dichiaravano di utilizzare i Big Data. Di queste 210 imprese, 55 non hanno completato il questionario, mentre 155 lo hanno compilato integralmente. Escludendo le 27 risposte relative al pre-test, ho raccolto dati completi da 128 imprese. Dopo un'attenta revisione dei questionari, ho escluso ulteriori cinque risposte poiché i rispondenti hanno indicato che le loro imprese non soddisfacevano i criteri di classificazione delle PMI. Di conseguenza, il campione finale analizzato è composto da 123 PMI italiane.

Results. I risultati dell'analisi fsQCA mostrano che nessuna delle dimensioni dei Big Data analizzate rappresenta una condizione necessaria per il raggiungimento di elevate performance innovative. Questo risultato suggerisce che il successo innovativo delle PMI non dipende dalla presenza di una singola dimensione dei Big Data, ma piuttosto dalla combinazione di diverse risorse.
L'analisi delle configurazioni sufficienti evidenzia che specifiche combinazioni di dimensioni dei Big Data sono associate a livelli più elevati di performance innovativa. In particolare, i risultati indicano che l'integrazione tra diverse dimensioni dei Big Data — come la varietà delle fonti informative, la velocità di elaborazione dei dati e la qualità delle informazioni — consente alle imprese di generare insight più ricchi e di supportare decisioni strategiche più efficaci.
Questi risultati sono coerenti con la prospettiva della Resource-Based View, secondo cui il vantaggio competitivo deriva spesso dalla combinazione di diverse risorse piuttosto che dal possesso di una singola risorsa (Barney, 1991).

Research limitations. Il presente studio presenta alcune limitazioni che offrono interessanti opportunità per future ricerche. In primo luogo, l'analisi si basa su un campione di PMI italiane, il che potrebbe limitare la generalizzabilità dei risultati ad altri contesti geografici o istituzionali. Studi futuri potrebbero estendere l'analisi ad altri paesi o confrontare diversi contesti nazionali.
In secondo luogo, la ricerca utilizza dati raccolti attraverso un questionario, che potrebbero essere soggetti a possibili bias di risposta. Future ricerche potrebbero integrare dati provenienti da fonti secondarie o utilizzare approcci longitudinali per analizzare l'evoluzione dell'utilizzo dei Big Data nel tempo.
Infine, lo studio si concentra esclusivamente sulla performance innovativa delle imprese. Ricerche future potrebbero analizzare anche altre dimensioni della performance aziendale, come la performance finanziaria o la performance organizzativa.

Managerial implications. I risultati dello studio offrono importanti implicazioni per i manager delle PMI che intendono sfruttare il potenziale dei Big Data per migliorare le proprie capacità innovative. In particolare, i risultati suggeriscono che le imprese non dovrebbero concentrarsi esclusivamente su una singola dimensione dei Big Data, ma dovrebbero piuttosto sviluppare un approccio integrato alla gestione dei dati.
Le PMI dovrebbero investire nello sviluppo di infrastrutture tecnologiche e competenze analitiche che consentano di raccogliere, integrare e analizzare diverse tipologie di dati provenienti da fonti eterogenee. Inoltre, è fondamentale garantire la qualità e l'affidabilità dei dati utilizzati nei processi decisionali, al fine di evitare errori e migliorare l'efficacia delle strategie di innovazione.
Infine, i manager dovrebbero promuovere una cultura organizzativa orientata ai dati, incoraggiando l'utilizzo sistematico delle informazioni nei processi decisionali e favorendo la collaborazione tra diverse funzioni aziendali.

Originality of the paper. Questo studio contribuisce alla letteratura sui Big Data e sull'innovazione delle PMI in diversi modi. In primo luogo, il lavoro adotta una prospettiva configurazionale che consente di analizzare le interazioni tra diverse dimensioni dei Big Data, superando l'approccio tradizionale basato sull'analisi isolata delle singole variabili. La letteratura precedente ha spesso sottovalutato l'influenza delle interazioni sinergiche tra le cinque "V" dei Big Data—volume, varietà, velocità, veridicità e valore—sulle performance innovative delle imprese. Diversi studiosi, facendo riferimento alla prospettiva della Resource-Based View (RBV) (Barney, 1991; Wernerfelt, 1984), sostengono che queste

dimensioni dei Big Data contribuiscano all'innovazione soprattutto quando vengono utilizzate in combinazione, piuttosto che considerate isolatamente (Akter & Wamba, 2016; Erevelles et al., 2016).
L'analisi di tali interazioni sinergiche può infatti rivelare se una specifica dimensione dei Big Data sia in grado di rafforzare l'influenza positiva delle altre sulle performance innovative (Ghasemaghaei et al., 2017). Ad esempio, l'integrazione tra un elevato volume di dati e una significativa varietà di dati consente alle imprese di generare insight più ricchi e di prendere decisioni più informate, rafforzando così le loro capacità di innovazione (Urbinati et al., 2018). Allo stesso modo, l'interazione tra velocity (la velocità di elaborazione dei dati) e veracity (l'affidabilità dei dati) garantisce la disponibilità di informazioni tempestive e accurate per supportare le decisioni legate ai processi innovativi (Lam et al., 2017).
L'effetto combinato di queste dimensioni non solo aumenta la capacità di spiegare le differenze nelle performance tra le imprese, ma rende anche il processo di sfruttamento dei Big Data più unico e difficilmente imitabile dai concorrenti, contribuendo così alla costruzione di un vantaggio competitivo sostenibile e a migliori risultati in termini di innovazione (Johnson et al., 2017; Yang et al., 2017). Comprendere quali interazioni tra le cinque V siano maggiormente in grado di rafforzare le performance innovative rappresenta pertanto una questione cruciale per la ricerca futura.
In secondo luogo, lo studio applica la metodologia della fsQCA per analizzare il ruolo dei Big Data nelle performance innovative delle PMI, offrendo un approccio metodologico innovativo rispetto agli studi precedenti basati prevalentemente su tecniche di regressione.
Infine, la ricerca fornisce nuove evidenze empiriche sul ruolo delle configurazioni di risorse nel determinare le capacità innovative delle imprese, contribuendo allo sviluppo della letteratura basata sulla Resource-Based View e offrendo nuove prospettive per la ricerca futura.

Corporate Crisis and Artificial Intelligence: a textual analysis

FABRIZIO CESARONI[1*], AUGUSTO D'AMICO[2], FRANCESCO FASANO[3♠],
MATTIA FASANO[4♦], ELVIRA TIZIANA LA ROCCA[5♥]

Abstract. *The prediction of corporate crisis and bankruptcy events has been considered an extremely crucial challenge in management field for a long time. Artificial intelligence and advanced data analysis are changing the way companies address these kinds of situations. The availability of data and the development of complex tools for investigation allow us to examine complex datasets and identify patterns that could signal potential financial distress. This paper aims to investigate the connection between academic literature on corporate crisis prediction and artificial intelligence predictive models. The research is based on a textual analysis of a dataset of 306 scientific articles published between 1990 and 2024. Our main results suggest a strong conceptual link between corporate crisis prediction and artificial intelligence models. Some useful managerial implications and further research directions emerge.*
Keywords: *corporate crisis; Artificial Intelligence; predictive models; textual analysis.*

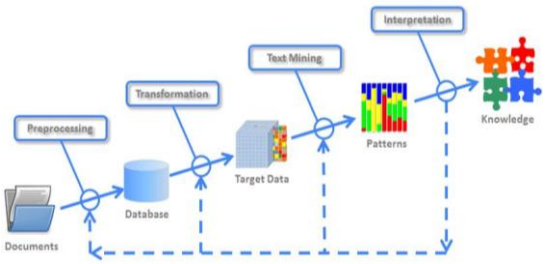
Framing of the research. The corporate crisis prediction has long been a central topic in management research (Sun et al., 2014). Generally, the concept of corporate crisis identifies situations in which companies face financial and operational matters impacting on their going concerns (Altman, 1968; Altman et al., 2017; Bellovary et al., 2007; Tian et al., 2015), due to internal as well as external factors. Previously, statistical methods based on traditional financial ratios were used (Beaver, 1966). Altman (1968) developed the Z-score method, widely used by scholars and professionals. Other studies have extended these traditional statistical models (Ohlson, 1980; Zhou et al., 2012; Delen et al., 2013). However, several limitations are associated with them.

Afterwards, the Enterprise Risk Management (ERM) approach proposed the integration of financial analysis, strategic planning, and corporate governance mechanisms (Bromiley et al., 2015; Lessmann et al., 2015). In this way, transparency, accountability and risk management systems can be enhanced. Thus, new technologies offer opportunities for improving the effectiveness of corporate governance and risk monitoring mechanisms (Elbashir et al., 2008; Varian, 2014; Wamba et al., 2017; Davenport and Ronanki, 2018).

Recently, artificial intelligence (AI) techniques have enhanced the predictive power of corporate crisis models (Tsai and Wu 2008; Barboza et al., 2017; Zhang et al., 1999; Perboli and Arabnezhad, 2021). Machine learning and data analytics techniques have given new opportunities for improving corporate risk prediction. Thus, the literature has started to explore the application of AI in bankruptcy and corporate crisis prediction (i.e., Hosaka, 2019; Zhao, 2023; Goldmann et al., 2024; Geng et al., 2026).

Purpose of the paper. The goal of our study is to perform an overview of scientific literature addressing the relationship between corporate crisis prediction and AI. The huge number of studies, methodologies and approaches indicate that this research stream is extremely fragmented. Thus, to address this gap, an overview of academic literature could be performed to identify the main trends and implications. In particular, the study seeks to map the dominant research themes and their interconnections, analyze how AI-based analytical techniques are applied in corporate crisis prediction models, examine the managerial implications emerging from literature, especially in relation to risk management, early warning systems, and governance processes.

Our research questions are as follows: What is the role of AI in corporate crisis prediction in academic literature? and what are the main managerial implications of this research stream?



From a theoretical perspective, the study focuses on three core streams of literature: corporate crisis and financial distress prediction (Altman, 1968; Ohlson, 1980), risk management and corporate governance (Jensen and Meckling, 1976; Adams et al, 2010; Kaplan and Mikes, 2020), digital transformation and data-driven decision-making (Porter and Heppelmann, 2014; Barboza et al., 2017; Nambisan et al, 2017; Zhang et al., 1999; Perboli and Arabnezhad, 2021).

Methodology. The research performs a textual analysis to identify the main themes and conceptual relationships within the academic literature on AI and corporate crisis prediction. Our research design is based on the PRISMA framework (Moher et al., 2009; Page et al. 2021) to identify a dataset of 306 academic articles published between 1990 and 2024. The articles were collected from Web of Science (WoS) database and include contributions from management, finance

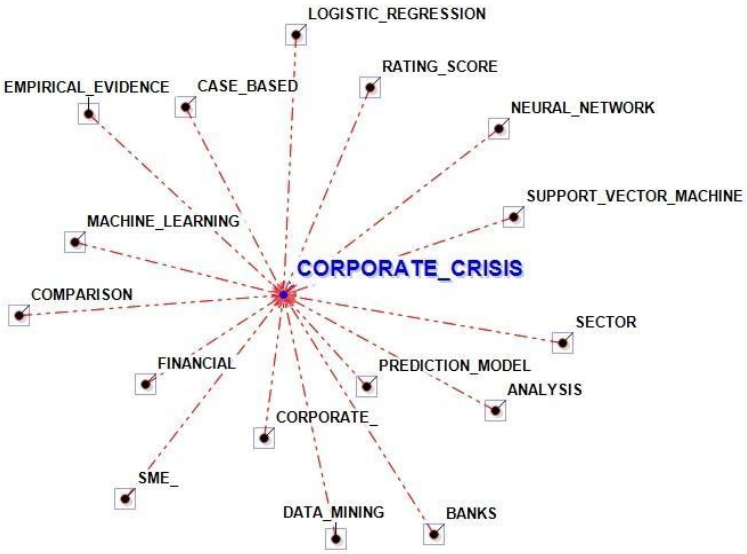
and business fields. The search focused on empirical and conceptual studies addressing corporate crisis, financial distress, and related risk-forecasting models. Search queries were developed iteratively and combined keywords related to: distress and corporate crisis ("financial distress", "crisis", "corporate crisis", "default" "business failure"), predictive approaches ("prediction", "prevention", "forecast*", "early warning"), and methodological techniques ("method*", "technique", "artificial intelligence", "logistic regression", "machine learning", "neural network", "support vector machines"). Boolean operators and truncation were used to capture spelling variants and related terms. Searches were restricted to journal articles written in English. In the initial Identification step, we found 1,775 contributions on the WoS database. Then, a screening was carried out by applying our inclusion criteria.In order to analyse the textual content of the selected articles, our study follows a text mining approach based on the application of lexical analysis techniques. The textual analysis, carried out using the T-LAB 10 software, was specifically focused on the conclusions and managerial implications sections in the articles. The methodology followed in this study includes some steps (see Figure 1).

Figure 1 Main steps followed in the textual analysis

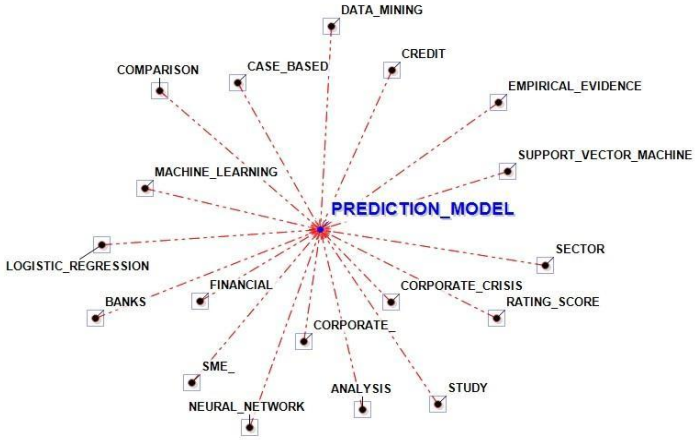


Source: T-LAB https://www.tlab.it

As illustrated in the Figure 1, first of all, the textual corpus has been created using the "Corpus builder" tool included in the T-LAB software. Then, the software has carried out a lexical analysis of the textual content in order to highlight the most common and relevant words in the corpus. The analysis has also focused on the relationships between words, thus highlighting the conceptual links between the different research themes included in the study. The analysis has also highlighted the thematic clusters related to the most relevant research themes included in the corpus of the literature.

Results. The results of the textual analysis indicate a strong conceptual relationship between the themes of corporate crisis and prediction models within the analysed corpus. The word associations reveals that terms related to financial distress frequently co-occur associated with predictive modelling. The Figure 2 regards the main words associated with the lemma "Corporate Crisis" in the corpus of articles analysed. It shows the conceptual network linking corporate crisis, predictive models, machine learning techniques, the financial context, and empirical and comparative analyses. The corporate crisis is conceptualised in the corpus as a phenomenon that can be analysed and predicted using quantitative models and machine learning techniques, applied primarily to the context of businesses and the banking system The topic is scientifically structured within the corpus, highlighting the main methodologies, application contexts and research approaches used to study it. This suggests that the literature tends to consider corporate crisis not only as a final event, but as a phenomenon that can be analysed and anticipated through predictive models.

Figure 2 - Words associated with the lemma 'Corporate crisis'



Source: Authors elaboration

The Figure 3 shows the word associations related to the lemma 'Prediction_model', a central theme of the dataset. The graph reflects a well-structured thematic field. The T-LAB association graph shows how the words in the corpus are related to a central concept based on how frequently they appear together in the same contexts. T-LAB examines all text segments in which this lemma appears and then it identifies the terms most strongly associated with it. In this way, the entire network shows which concepts tend to appear alongside "prediction model" in the corpus. Each of the words surrounding it ('Machine_Learning', 'Credit', 'Banks', 'Logistic_Regression', 'Neural_Network') is a term statistically associated with the main word. However, the association is not arbitrary. It is statistically significant. These words are often found accompanying the lemma 'Prediction model'. For instance, 'Neural_Network', 'Support_Vector_Machine', 'Logistic_Regression' are techniques applied in the model. The dotted red lines represent associations between the central word and the words around it. These red lines show a statistical association based on co-occurrence. It does not imply causality. Just it implies that words tend to co-occur in the corpus analysed.

The central node proximity to each word is another key factor. It shows the strength of the word. So, if this proximity is low, the word is strongly associated, and if it is high, it is weakly associated. In particular, 'Machine Learning' proximity to 'Prediction Model' is lower than its proximity to 'Study', then 'Machine learning' is strongly associated with 'Prediction model'. The surrounding nodes identify three main thematic areas: 1) financial context. Terms such as 'Corporate_crisis', corporate, financial, highlight the main area of application for these predictive models; 2) methodological and technical approaches. Terms 'Machine_Learning', 'Logistic_Regression', 'Support_Vector_Machine' indicate that the corpus emphasises approaches associated with advanced statistical and machine learning techniques. 3) Comparative dimension. The presence of 'Rating_Score', 'Comparison', 'Study' and 'Sector' suggest that the literature also focuses on the performance evaluation, the benchmarking of different models and the sector-specific analyses.

The results highlight how predictive models are increasingly based on advanced data analytics methodologies, moving beyond the traditional statistical models used in older literature.

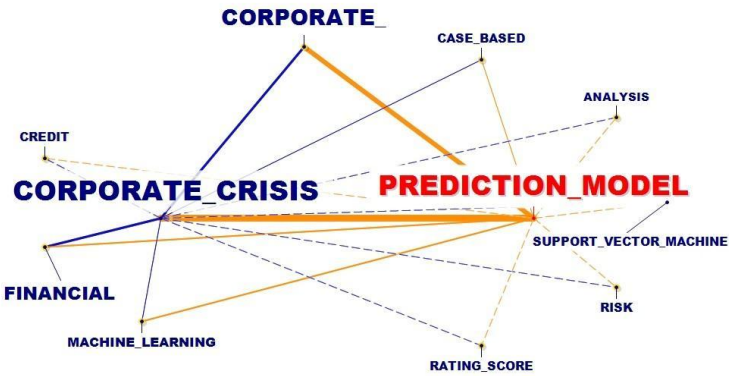


Figure 3 Words associated with the lemma 'Prediction_model'

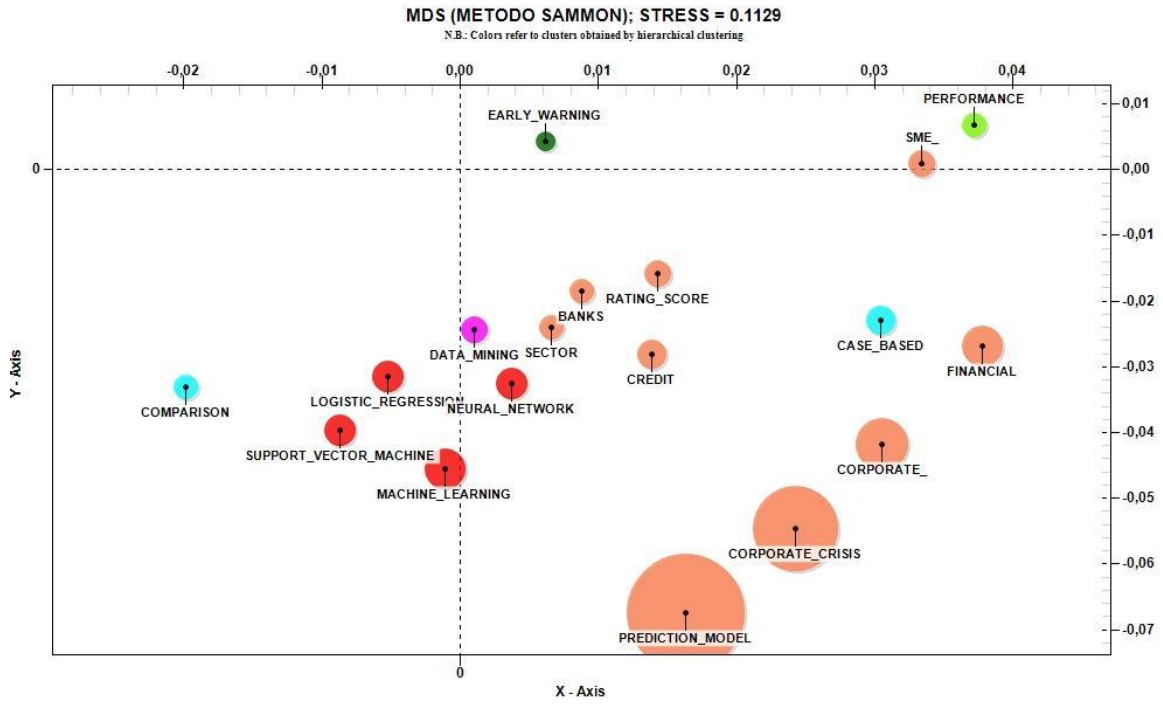
Source: Authors elaboration

Figure 4 exhibits the comparison of the keyword pair 'Corporate_crisis' and 'Prediction_Model' in the dataset. A strong association is visible between the two main concepts. The thickness of the line indicates a stronger association. This indicates that the study of corporate crisis in the recent literature is increasingly associated with the development of advanced prediction tools for the early warning of corporate crises.

Figure 4 Keyword pair comparison 'Corporate_crisis' and 'Prediction_Model' in the corpus



Source: Authors elaboration

In the Figure 4 the main thematic areas are a) modelling techniques, such as 'Machine Learning' and 'Support Vector Machine', indicate that corporate crises are predicted using quantitative methods and AI techniques, . b) the context of finance and corporations is indicated by 'Corporate' and 'Financial', situating the analysis in the context of corporate finance.

The Figure 5 illustrates a type of Multidimensional Scaling (MDS) (Sammon method) used in T-LAB to represent the relationships between thematic clusters. Specifically, four main thematic clusters emerge from the analysis: the study of corporate crises, the use of advanced analytical prediction models, the corporate performance, and the credit risk management. The central position of 'Prediction_Model' among 'Corporate_crisis', machine learning, and statistical methods suggests that the literature strongly links corporate crises to the use of advanced predictive models. This indicates a trend toward a data-driven approach in corporate risk management. Prediction Model plays a central role as a tool that bridges theory and application. They are becoming strategic tools for early warning systems, financial risk management, risk assessment, and corporate crisis prevention.

A significant part of the corpus of the literature studied focuses on the application of predictive models to credit risk evaluation. Financial institutions increasingly rely on advanced analytical techniques to assess the solvency of firms and reduce default risk. Another cluster focuses on corporate crisis, examining the determinants and consequences of financial distress within organizations One more cluster concerns studies examine the relationship between financial performance indicators and the probability of corporate crisis. Financial ratios such as profitability, leverage, liquidity, and operational efficiency continue to play an important role in crisis prediction models. refers to advanced analytical methods. One interesting finding concerns the position of the terms "SME" and "Banks," which are positioned close to the central core of the map. This suggests that the literature on corporate crisis prediction is strongly linked to the context of small and medium-sized enterprises and the banking system. Predictive models are, in fact, particularly relevant for supporting credit risk assessment processes and credit decisions by financial institutions.

Figure 5 Multidimensional Scaling (MDS)

Source: Authors elaboration

The MDS analysis shows that within the corpus there is a strong integration between corporate crisis analysis and the use of models (Figure 5). Overall, the analysis highlights the increasing use of several advanced analytical techniques in financial risk analysis. Among the most frequently mentioned methods are machine learning algorithms, artificial neural networks, logistic regression models, support vector machines. These techniques allow researchers and practitioners to analyse complex datasets and improve the predictive accuracy of financial distress models. Another important finding concerns the growing integration of AI within decision making processes related to credit risk management. Many studies highlight how AI-based models can support financial institutions in evaluating borrowers, monitoring financial performance, and detecting early signals of financial distress. Moreover, the literature increasingly emphasizes the role of AI technologies in the development of early warning systems capable of identifying potential crises before they become critical. These systems can provide valuable information to managers, investors, and regulators, allowing them to take preventive actions aimed at mitigating financial risk.

Overall, our results answer to the research questions by underlining the AI role in the corpus of literature analysed. The textual analysis results suggest that AI is not viewed as a supplement in corporate crisis prediction, but it is an integral component of corporate crisis prediction models. The high co-occurrence of words such as corporate crisis, prediction model, and machine learning suggest that this corpus of literature is increasingly structured into a data-driven paradigm in which predictive models are used as a tool for identify financial difficulties.

Moreover, some specific thematic clusters emerge, from financial distress analysis to credit risk management and advanced models, underling the multidimensional nature of this research area. Thus, the findings suggest that the literature combines innovation in methodology and applications, especially in relation to early warning systems and decision making. In this context, the analysis provides a clear understanding of the conceptual and managerial aspects of AI in corporate crisis prediction, thereby answering our research question.

Research limitations. The present research provides interesting insights about the corpus of literature on AI and the prediction of corporate crisis however it presents some limits. Infact, the study is based on a specific corpus of academic articles and maybe it does not fully capture all research contributions to the literature on the topic studied. In addition, our research focuses on the conclusions and managerial implications of the articles under review. While this approach helps to identify key concepts and research trends, it could miss some details. Future research could expand this study by empirically evaluating the effectiveness of several AI techniques in crisis prediction models. Another promising field for further research regards the possibility to investigate the use of new data sources. Specifically, social media, such as LinkedIn, as well as financial forums, provides a great amount of corporate information, or stakeholders' perceptions or opinions on the companies. A sort of "early warning" signals of a decline in reputation or investor sentiment. Text mining and sentiment analysis could be used to integrate this data into corporate crisis prediction models.
Finally, the study does not account for institutional differences between countries, which could affect the applicability of AI-based crisis prediction models.

Managerial implications. Our results emphasize the importance of data analytics skills. Firms and financial institutions should acquire skills in data analysis and AI to manage corporate risks more efficiently. AI techniques could help to manage credit risks more efficiently, and in this way, financial institutions could apply machine learning algorithms to analyse more data and evaluate borrowers efficiently, reducing the possibility of default. Specifically, AI-based predictive models could improve early warning systems for detecting corporate financial problems. The textual analysis also implies that crisis management in corporations should be based on some key elements, such as the improvement of early warning systems to identify signs of a deterioration in the economic and financial situation and to apply predictive models to anticipate corporate crisis. In this way, companies could identify possible corporate concerns at an early stage and take corrective actions in advance. In this context, alternative data sources, such as news available on social media or financial forums, could be used. Specifically, digital technologies could be used as tools to facilitate the integration of alternative data sources, including social media data, news on the investor's sentiment, and market signals. These data sources could be considered as potential signals of companies' crisis, that are not indicated by traditional financial data. Thus, in other words, social media can be considered as a new direction of research as well as a potential data source of corporate crisis prediction. At the same time, the AI role in the decision making processes of companies poses some transparency and accountability implications. Managers should use these tools in a responsible manner. The application of AI to the prediction of corporate crisis prediction should be part of a broader transformation in company decision making, not just a technological innovation.
In addition, the role of AI-based models of crisis prediction may be particularly relevant in the case of small and medium-sized enterprises (SMEs) (Demartini & Beretta, 2020). In fact, as opposed to large corporations, SMEs are more vulnerable from a financial perspective, as well as less prone to employing sophisticated risk management tools (Altman et al., 2010). The introduction of AI-based monitoring systems could thus assist SMEs in detecting financial crises at an earlier stage. Finally, the role of AI-based risk management systems may be relevant with respect to the improvement of aspects of transparency, accountability, and decision-making.

Originality of the paper. This paper performs a textual analysis of a large corpus of academic articles on AI and corporate crisis prediction, providing an overview of the literature by identifying the main themes and conceptual relationships within the field. The originality is linked to the fact that our study offers a structured representation of the research landscape and highlights emerging trends in the application of AI to financial distress prediction. Instead, previous research has analysed specific model and technique. In addition, this research contributes to the literature by emphasizing the growing integration of AI technologies within corporate risk management and credit evaluation processes. We identify future research directions providing a useful framework for scholars interested in exploring new developments in the field of AI and financial distress prediction.

Acknowledgments. We thank the Italian Ministry of University and Research for providing a grant for this research. The article is output of the project titled "Live long and prosper" funded under the National Recovery and Resilience Plan (PNRR), with the identification code 20229EHBN7, Mission 4, Component 2, Investment 1.1 "Projects of National Relevant Research (PRIN)" Project number: H53D2300229 0006 - Funded by the European Union - NextGenerationEU.

Decision-making biases in modern Supply Chains and the role of AI: A systematic literature review

SARA SAVY, SILVIA COSIMATO, NADIA DI PAOLA, OLIMPIA MEGLIO, ROBERTO VONA

Abstract. *This paper explores the evolution of modern Supply Chains (SC) and their shift from a sequence of linear processes into complex adaptive systems. SCs' inner complexity has increased biases in Supply Chain Management (SCM). To address this situation, digital technologies, and especially Artificial Intelligence (AI), are increasingly being used to solve complex problems by comparing and decomposing them, as well as by enhancing information sharing to avoid biased decisions. Consequently, this paper aims to recognise the main biases in SC decision-making by conducting a Systematic Literature Review (SLR), based on the PRISMA framework and on a bibliometric co-word analysis.*

The achieved results demonstrated a longitudinal evolution of the research topic and its related themes, with a recent trend on the contradictory role of AI in SC decision-making. The originality of this paper lies in conceptualizing SCs as multi-level ecosystems, in which digital technologies and AI function as multi-sided non-human actors that mitigate or resolve decision-making biases at specific ecosystem levels, while also creating new algorithmic biases that can differentially impact those levels. To challenge these biases, managers must complement and expand their expertise by adopting a holistic, data-driven, and agile approach to decision-making. This preliminary study is limited by the analysis of a single database and the rapid evolution of AI-related research. Future research, informed by the implementation of complementary qualitative methods, will further refine the preliminary findings.
Keywords*: Supply Chain; Ecosystem; Decision-making; Bias; Artificial Intelligence.*

Framing of the research. In the current globalized economies, SCs are changing their configuration and characteristics, becoming more vulnerable to recurrent and severe geopolitical, climate, economic, and social crises (Ivanov et al., 2023). These changes have transformed their configuration, turning them into complex networks of geographically dispersed actors (Fischer et al., 2024), defined Global Value Chains (GVCs) and organized around specific factors such as location, cost, expertise, and access to resources (Antràs and Chor, 2022).

Network theory (Granovetter, 1983) advanced this conceptualization by treating SCs as networks of interconnected actors, organized around strong and weak ties (Hearnshaw and Wilson, 2013; Hald and Spring, 2023). This inspired the shift from a centralized logic of control, implemented by the focal actor, to a logic of collaboration between internal and external actors (Wang et al., 2025). This prompted scholars and practitioners to critically rethink SCM mainstream approaches (Ketchen and Hult, 2007). In doing so, the ecosystem perspective, complementing the network theory, inspired the conceptualization of SCs as complex adaptive systems or ecosystems, characterized by networked multi-sided interactions intended to exchange resources between loosely coupled actors, whose aim is the creation of value (Vargo et al., 2012; Ozkan et al., 2025). Assuming a different perspective, Moore (1996) defined business ecosystems as economic communities supported by interacting organizations and individuals.

Approaching SCs as business ecosystems requires a critique of the traditional governance mechanisms, which are no longer based on predefined bilateral arrangements and/or contracts (Autio and Thomas, 2018), but rather on multilateral interactions, which equally consider actors' contribution to the value network (Adner, 2017; Autio and Thomas, 2020). This is due to one of the primary ecosystem characteristics: the self-organization ability (Moore, 1996, 2006), which prioritizes non-contractual, collaboration-based governance over hierarchical control (Jacobides et al., 2018).

According to Fu et al. (2026), at the micro level of an ecosystem, individual actors (e.g., individual suppliers, logistics service providers, retailers, etc.) cooperate, sharing their resources in value creation processes, while at the meso level, competing interests drive organizational actors (e.g., industry consortia, etc.) towards service provision and consumption according to a coopetition logic essential for the ecosystem evolution. Finally, at the macro level, institutional actors (e.g., governmental bodies and regulators, standard-setting organizations, etc.) set policies, regulations, and incentives to respond to environmental changes (Thomas and Autio, 2020). Understanding how coopetition emerges and can be managed remains a subject of scrutiny in extant research.

Recently, the influence of digital technologies on ecosystem viability has been investigated, highlighting their capacity to facilitate multilateral relationships through specific governance mechanisms that bring together heterogeneous yet interdependent human and non-human actors (Legenvre et al., 2022). Modern SCs' complexity often causes deviations and bias in decision-making processes (Yu et al., 2025). To challenge this situation, the literature has proposed an alternative approach to decision-making biases, which departs from the traditional assumption that biases arise from a-rational strategies. Simons (1957) advanced this approach, proposing the bounded rationality theory, according to which decision-makers are rational, adaptive, and goal-oriented. However, human rationality is constrained by information asymmetries, which often cause decision biases (Snowden, 2002; Yamini, 2021). Recently, the computational power of digital technologies (e.g., AI, cloud computing, big data analytics) has challenged these biases by providing direct and real-time access to information (Kurzweil, 2012; Khan, 2025). In particular, AI, orchestrating data-driven processes across the value network, facilitates SC actors' collaboration and complementarity in value-creation processes (Yu, 2023),

enhancing win-win outcomes and reducing the biases conceptualized in bounded rationality theory. This is possible by augmenting human cognition through predictive analytics, simulation, and data synthesis. Even though technologies help mitigate decision-making biases arising from information asymmetries (Zhijian et al., 2020), they do not challenge other biases, such as the algorithmic opacity ethics dilemma (Condé and Münch, 2025).

Purpose of the paper. The purpose of this paper is to recognise the main biases in SC decision-making, focusing on the influence that digital technologies, and in particular AI, can have on their mitigation/elimination. In doing so, a systematic literature review has been conducted to 1) map the biases that affect SCM decisions (Schorsch et al., 2017; Brintrup et al., 2023; Wamba et al., 2023), 2) define the AI's role in mitigating decision-making biases (Kosasih et al., 2023; Wamba et al., 2023; Jackson et al., 2024), and 3) the practices to detect/mitigate biases (Bendoly et al., 2022).

Methodology. To conduct a rigorous systematic literature review (SLR), a structured protocol was developed to define the study aims, inclusion and exclusion criteria, identification procedures, and the data analysis plan (Nightingale, 2009).

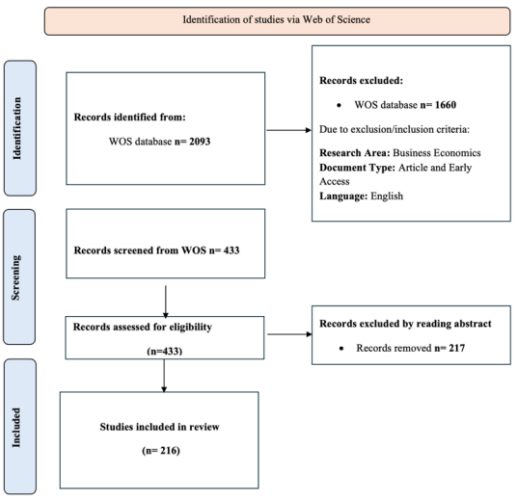

Table 1 Review Protocol, Authors' elaboration.

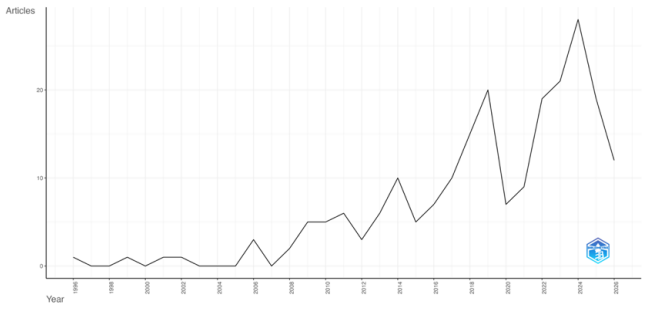
Review aim	Exploration of the decision making biases in SC
Search string definition	*("supply chain*" OR "supply network*" OR "value chain*" OR "supply chain management" OR SCM OR SC OR "logistics network*" OR "ecosystem*")* *AND* *("decision mak*" OR "managerial decision*" OR "decision process*" OR "managerial judgment*" OR heuristic* OR "bounded rationality")* *AND* *(bias* OR "decision error*" OR "judgment error*" OR "behavioral decision mak*" OR fairness OR assumption*)*
Inclusion and exclusion criteria	*Research Area: Only articles classified under Business Economics were included to ensure consistency with the field of interest.* *Document Type: Only Articles and Early Access publications were included. Reviews, books, book chapters, and conference proceedings were excluded to retain only peer-reviewed empirical articles.* *Language: Only papers written in English were included to avoid language bias.*
Plan for Data Analysis	*Descriptive analysis of the sample* *Bibliometric Analysis* *Thematic analysis*

First, a detailed search string was defined through a trial-and-error process, beginning with keywords identified in prior reviews on the topic. The string was organized around three pillars: 1) supply chain (SC), which represents the field of interest, 2) decision-making (DM), as this review aims to analyze decision-making literature within the SC domain, and 3) biases, to gain a deeper understanding of the limitations, biases, and underlying assumptions that affect SC decision-making.



The search string was run in the *Web of Science* database, powered by Clarivate Analytics, selected for its rigorous indexing standards and broad coverage of high-quality peer-reviewed journals. The decision to rely on a single database follows Donath et al. (2021), who suggest this approach for bibliometric analysis in social sciences, to avoid redundant procedures and reduce the risk of human error. The analysis of a single database also supports the reduction of data homogenization issues caused by multiple databases. To ensure the rigor and replicability of the study, the PRISMA framework was adopted, following the recommendations of Moher et al. (2009) (Figure 1).

Figure 1 PRISMA Framework, Authors' elaboration

The search string was applied to the title, abstract, and keywords in the Web of Science database, yielding an initial sample of 2093 papers. After applying the inclusion/exclusion criteria, 1660 documents were excluded. The remaining 433 were screened through the abstract examination and, when necessary, the full texts. This screening excluded 217 additional papers that did not meet the inclusion criteria. Therefore, the final sample comprises 216 documents published between 1996 and 2026 across 79 sources. The annual growth rate in publications from 1996 to 2025 was 10.69%. Although 2026 has just begun, 12 papers have already been published (five of which are early access documents), highlighting the growing interest in this research area. Overall, the field is in a robust expansion phase, with significant increases in research activity, scholarly interest, and academic output. Researchers are actively exploring new research questions, methodologies, and applications within this domain. Figure 2 illustrates this trend, showing an initial slow growth (*emergence*), followed by a rapid acceleration (*expansion*). These findings suggest that this area represents a dynamic and evolving field of research.

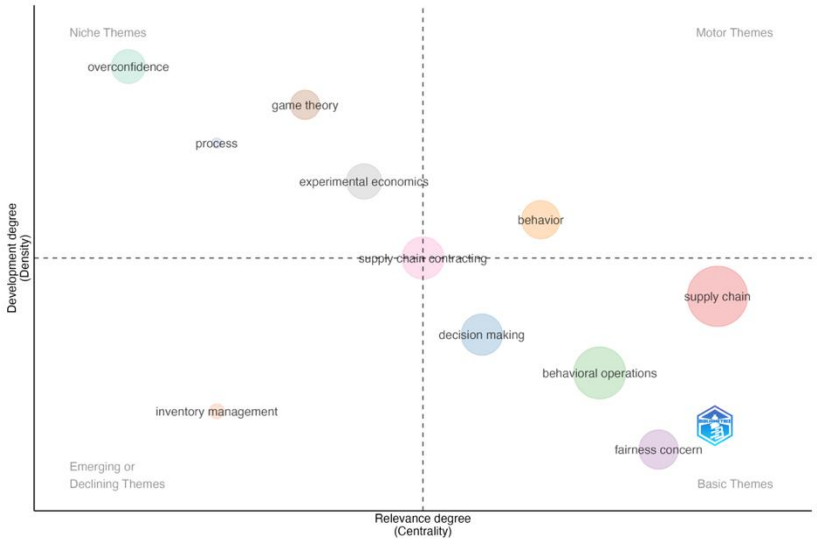


Figure 2 Annual scientific production, Biblioshiny elaboration

Results. The preliminary results were obtained by conducting a co-word analysis using the R package Bibliometrix, which enabled an in-depth mapping of the thematic structure of the investigated field (Aria and Cuccurullo, 2017). Co-word analysis is a technique used to explore relationships among topics within a research field by analyzing publication content (Donthu et al., 2021), which assumes that thematic relationships bind words that frequently co-occur.

A thematic map was developed based on author keywords (Figure 3), classified into four thematic categories. In the upper-right quadrant, the motor themes appear, identifying central and well-developed topics that drive research in this field. In the lower-right quadrant, basic themes are identified: transversal and foundational topics that are broad and widely connected but may lack deep internal development. In the upper-left quadrant are the so-called niche themes, highly specialized topics that are still relatively underdeveloped and weakly connected to the broader field, yet characterized by high internal coherence. Finally, in the lower-left quadrant are emerging or declining themes that are either not yet fully developed or losing relevance over time.

Figure 3: Thematic map, generated with Bibliometrix (R).

In Figure 3, the map highlights a robust research landscape at the intersection of behavioral science and SC management. Furthermore, the presence of influential and forward-dated articles underscores the ongoing dynamism and relevance of the field. A single motor theme emerged: Behavior, which represents a mature and strongly interconnected

research area, as indicated by its high density and centrality. This suggests a strong and pervasive focus on understanding human and organizational behavior within the analyzed domain. This is at the core of Behavioral Operations Management (BOM), which focuses on bounded rationality. Research within this cluster highlights that human information processing is constrained by knowledge, computational capacity, available information, and time. When these limitations occur, cognitive biases lead decision-makers to systematically deviate from mathematically optimal SC decisions. The cluster further suggests that improving SC performance cannot rely solely on refining optimization algorithms. Instead, it requires designing behavior-aware systems, increasing awareness of cognitive biases through training, and developing software interfaces that actively mitigate these limitations.

Focusing on the niche themes quadrant, several specialized areas of inquiry can be identified. Overconfidence emerges as a highly specialized topic that, due to its lower centrality, may not be broadly integrated across the entire field. This highlights that overconfidence in one's own estimates often leads to decision biases, resulting in false prosperity and poor performance (Chen et al., 2023). Research on this topic distinguishes between two types of overconfidence: *probabilistic overconfidence* (overestimation of the likelihood of success) and *market overconfidence* (overestimation of demand potential) (Wu H. et al., 2025). The cluster also links overconfidence to inequity aversion, suggesting that decisions are often influenced by comparisons with others' profits or industry benchmarks, leading to systematic distortions in ordering decisions. From an opposing perspective, in which overconfidence is always detrimental, the literature highlights that, in collaborative settings, it can act as an innovation driver. Thus, optimistic managers are more willing to innovate even when supply chain profits are negative, often driven by the fear of losing a competitive advantage (Liu et al., 2025).

The other two clusters are Game Theory and Experimental Economics. Both serve as specialized analytical frameworks, underscoring that investigating strategic interactions among actors who do not behave according to pure economic rationality but are influenced by cognitive biases, psychological factors, and power asymmetries requires formal, structured approaches. These include mathematical models typical of game theory, controlled laboratory experiments, vignette-based scenarios, and business simulation games, which help researchers isolate specific behavioral variables (such as trust or inequity aversion) that cannot be captured in archival data. Within the game theory cluster, particular attention is given to how intentions influence decision-making processes. For example, studies explore how preferences for fairness and reciprocity lead to psychological equilibria that differ from those predicted by classical theory. In contrast, the experimental economics cluster emphasizes that SCM success depends not only on economic incentives but also on non-monetary factors such as trust and trustworthiness. Experimental evidence shows that managers are often willing to sacrifice personal profits to adhere to fairness norms. Conversely, perceptions of opportunistic behavior or lack of transparency can undermine coordination within the supply chain.

Shifting to the basic themes dimension, several interconnected themes have emerged. In this quadrant, the SC cluster is the largest and most prominent, indicating its foundational and pervasive role within the field under study. Related papers examine the operational pillars of SC through the lens of the BOM, highlighting how behavioral biases and ethical constraints shape SC efficiency. Various types of biases are discussed, such as diversification bias and quantity bias, whereby decision-makers tend to over-diversify orders or underestimate required volumes relative to the theoretical optimum (the so-called *pull-to-center effect*). Additionally, the impact of social and ethical preferences on managerial decision-making is emphasized; thus, SC theories are often influenced by national culture, which acts as an explanatory variable in purchasing and collaboration decisions.

In summary, this cluster reflects a shift from a purely mechanistic view of the SC to a socio-technical perspective, in which decision-making biases are identified as key factors that can lead to profit losses of up to 35% relative to the theoretical optimum (Cassidey et al., 2025).

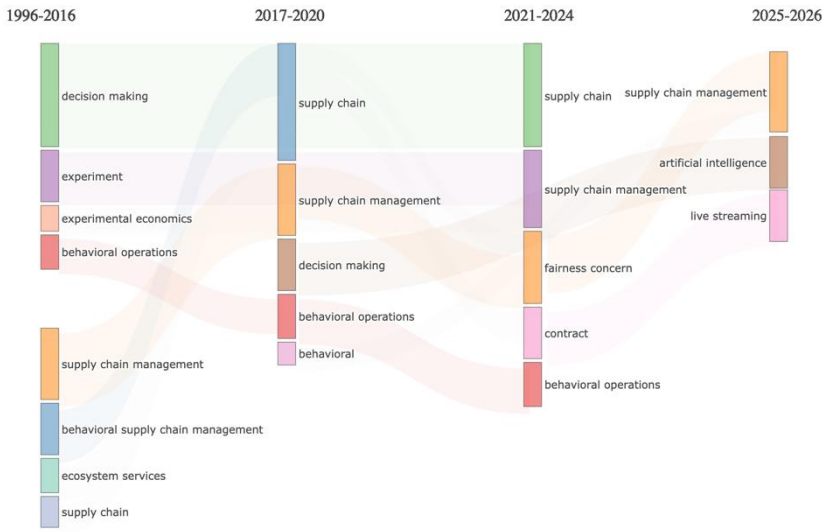
The behavioral operations cluster represents another significant basic theme. It challenges the traditional paradigm of the perfectly rational actor (*homo economicus*) by incorporating psychological and cognitive variables to account for systematic deviations from optimal decision-making in SCs. It focuses on understanding how individual biases influence the system's overall performance, providing theoretical foundations for capturing the limitations of human decision-making. Closely related to this theme, the cluster named decision-making emerges, which explores the micro-foundations of decision-making in SC. It highlights that decision-making is not purely cognitive but also emotional, because feelings such as pride, self-efficacy, and perceptions of fairness mediate the success of complex programs such as Lean Management. Conversely, the violation of the psychological contract, that is, the unwritten expectations between buyers and suppliers, generates emotional responses such as anger or a sense of betrayal, which directly influence repurchasing decisions and perceptions of fairness. The studies in this cluster do not merely describe these limitations but also propose tools to enhance decision rationality, including debiasing strategies, such as task decomposition and perspective shifting, aimed at reducing the impact of cognitive biases in supplier selection processes. Additionally, mechanisms such as accountability, the requirement to justify one's decisions, and incentive structures encourage managers to engage in more effortful decision-making processes, thereby reducing vulnerability to superficial distortions.

The last major basic theme is the cluster of fairness concerns. Thus, the social perception of fairness constitutes a cognitive bias that distorts the mathematical efficiency of SCs. Decision-makers exhibiting fairness concern tend to order less than the mathematical optimum (under-ordering) or to set higher prices to protect their margins when they perceive that their partner is gaining a disproportionate advantage. This is considered an intrinsic limitation to SC coordination. Recent studies in this cluster (e.g., those focusing on live streaming or e-commerce) suggest that although negotiation power influences profit distribution, the pursuit of fairness encourages actors to collaborate to expand total created value. Moreover, fairness concerns can also influence green investments. It is evident that if one partner (e.g., the retailer)

perceives unfairness, its reaction may compromise the environmental efficiency of the entire SC, reducing the level of product "greening". In summary, this cluster highlights that, in modern SC decision-making, fairness is not merely an ethical consideration but an operational constraint that defines the practical limits of what can be achieved in pricing, inventory, and sustainability.

In the lower-left quadrant, one theme has emerged: inventory management. This indicates that inventory management is no longer viewed solely as a problem of numerical optimization but rather as a challenge of managing decision-making limitations. Thus, inventory management is reinterpreted as a process of continuous learning aimed at overcoming initial constraints and deeply rooted biases.

These findings can also be approached assuming the ecosystem perspective, which led to the recognition of the impact of biases on the different ecosystem levels. Thus, if some of the identified biases tend to impact a single ecosystem level, most of them have a systemic and holistic influence between different levels. In particular, cognitive biases, often caused by knowledge, computational capacity, available information, and time constraints, mainly affect micro-level actors and their managerial and firm-specific abilities (Booth and Theodossiou, 2024). At this level, overconfidence is a common cognitive bias in human decision-making. It is better specified by probabilistic overconfidence, or the overestimation of the likelihood of success, which is a specific form of cognitive bias based on errors caused by wrong predictions, lack of precision, and persistence (e.g., anchored sequential choices). Together with this, psychological biases also affect the abilities of the micro-level actors, contributing to deviating from optimal decision-making.



If biases occurring at the micro-level of SC ecosystems are mainly due to the effect of bounded rationality (Simon, 1997), biases caused by market overconfidence (overestimation of demand potential) (Doyle et al., 2021) tend to affect both micro- and meso-level actors; thus, they affect individual (e.g., manufacturers, retailers, suppliers, etc.) and organizational actors (e.g., industry consortia, etc.), distorting potential demand forecast and, consequently, deviating strategic decisions from the rational optimal level, exacerbated by information distortion in the SC. Diversification and quantity biases have a similar inter-layered effect; thus, they tend to over-diversify orders or underestimate required volumes if compared with the theoretical optimum (the so-called *pull-to-center effect*) (Wu H. et al., 2025).

The analysis of micro- and meso-level bias and their dependence on bounded rationality effects, caused by information asymmetries, pointed out the ability of AI in overcoming this limitation, and in offering real-time information streams essential to make data-driven and evidence-based decisions.

The networked nature of ecosystem interactions led to a better understanding of the intertwined and holistic influence of some biases. Thus, biases emerging from a culture-oriented and non-inclusive social perspective mainly originate at the macro-level, being influenced by institutional determinants (Zhang et al., 2026), which subsequently impact the other two ecosystem levels and the behavior of the related actors. This effect is due to the influence of some elements, such as policy tools, uncertainty, institutional determinants, political/societal uncertainty, government regulations, etc., on the other ecosystem levels and on the distortions that they can cause in micro- and meso-level actors' decisions.

After examining the themes emerging from the thematic map, a Sankey diagram (Figure 4) was developed to provide a comprehensive overview of the topic's evolution (1996–2026), offering a high-level view of how research themes have transformed over three decades. The analysis highlights four distinct time periods, spanning 1996–2016 (left), 2017–2020 and 2021–2024, and 2025–2026 (right). This classification ensures a balanced allocation of studies across each period. As can be observed, themes such as supply chain management, decision-making, and behavioral operations demonstrate remarkable persistence over time. While their specific interconnections and relative prominence evolve, they remain foundational to research, often splitting or merging to incorporate emerging concepts

Figure 4: Thematic evolution, generated with Biblioshiny.

More recent periods clearly highlight the emergence of new and impactful themes. Fairness concern (from 2021–2024 onwards) has gained significant visibility, and AI and live streaming have emerged as distinct and rapidly growing areas in the most recent period (2025–2026), signaling the increasing importance of technological integration within the field. It can be argued that the most recent period reflects a shift from operational and behavioral aspects toward Industry 4.0 (identified as a basic theme in 2021–2024) and, more recently, toward AI and live streaming (emerging as key niche themes in 2025–2026). This trend signals a future in which digital innovations will likely profoundly reshape SC and decision-making research, with a novel research direction driven by advanced technologies and their psychological impacts. Moreover, during the 2021–2024 period, carbon emissions emerged as a central theme, indicating a growing emphasis on the social and environmental responsibilities of supply chains and decision-making processes.

An examination of the temporal evolution of literature reveals a management paradox associated with AI's role. While AI has the potential to alleviate certain cognitive biases, it simultaneously introduces the risk of algorithmic bias. Consequently, managers must extend their expertise beyond mere technical proficiency with these technologies to adopt a comprehensive perspective on the multifaceted implications of their decision-making.

Research limitations. Despite the relevance of the results, this study is not without limitations. First, from a methodological perspective, the literature search was limited to a single database and could be expanded by considering additional sources. Second, another limitation concerns the rapid evolution of AI-related studies, which may mean that this analysis does not capture emerging topics and recent developments. Finally, the results obtained from the proposed analyses could be further enriched by integrating complementary qualitative methodologies that capture and deepen understanding of complex issues.

Managerial implications. This study elucidates several managerial implications that necessitate reconceptualizing the managerial role within the SC. Primarily, the assumption of an ecosystem perspective suggests that a linear approach to SCM decisions is inadequate for managing SCs' complex interactions. Instead, decisions should emerge from inter-actor and inter-level (micro, meso, and macro) collaborative, multilateral information exchange at the core of the strategic partnership within ecosystem architectures (Liu et al., 2025). Thus, the managerial capability to orchestrate resources becomes a strategic lever that enhances companies' potential for value creation and innovation, thereby supporting resilience and progressive adaptation to a dynamic environment. The results achieved can consequently inspire managers in selecting and implementing the most effective collaborative approaches, while being aware of potential biases that can affect their SCM decisions. Thus, in this domain, decision-making processes are susceptible to systematic biases, which can result in sub-optimal outcomes. Treating these biases as occasional occurrences may lead to an underestimation of their effects, which are inherently structural to decision-making processes. To avoid this, managers can use digital technologies to enhance decision-making by accounting for the risks posed by bias. Consequently, the provided insights support managers in strategically designing practices and policies to overcome or solve these biases, also thanks to a conscious and ethical use of smart digital technologies such as AI. In doing so, digital technologies can play a significant role, serving as cognitive partners that facilitate the comparison and decomposition of complex problems (Legenvre et al., 2022). This does not imply delegating decision-making, as decisions cannot be optimized solely based on economic parameters, but rather approaching it as a participative process, in which all the ecosystem actors are involved, and technologies can contribute to avoiding asymmetries (Yamini, 2021). However, to achieve this, a real participation in SCM and a certain digital/algorithmic literacy is essential.

The analysis of the temporal evolution of literature also revealed a management paradox associated with AI's role (Condé and Münch, 2025). While AI has the potential to alleviate certain cognitive biases, it simultaneously introduces the risk of algorithmic bias. Consequently, managers must extend their expertise beyond mere technical proficiency with these technologies to adopt a comprehensive perspective on the multifaceted implications of their decision-making.

The study also offered some policy implications; thus, the achieved insights can also support the macro-level actors or policymakers in promoting inter-level and inter-actor collaboration to promote a better approach to the digital transformation of the modern SCs, supporting it with specific guidelines, standards, and programs.

As a preliminary analysis, the findings demonstrated the networked and participative nature of SC decision-making processes and the influence that smart technologies, such as AI, can have on it and on the emergence of different possible biases. Consequently, further research may be intended to build theory by assessing the achieved findings, conducting empirical analysis (e.g., observation) on a representative sample. In doing so, future studies will be mainly oriented to the implementation of quantitative methods to empirically analyze and evaluate the above-mentioned managerial paradox to better understand, analyze, and evaluate the influence of AI on the emergence of different decision-making biases. This will enhance the findings' generalizability.

Originality of the paper. The originality of this paper lies in its attempt to embed AI within SCM in a rapidly changing landscape where humans and non-humans are expected to interact and design more sustainable and intelligent solutions. More specifically, this work represents an initial attempt to challenge decision-making biases, particularly psychological ones, by integrating AI into distributed, complex systems such as global SCs. From a methodological standpoint, this

paper combines a systematic literature review (employing the PRISMA protocol) with bibliometric analysis to identify current trends and potential issues for future investigation concerning novel technologies and their behavioural and psychological impacts, thereby suggesting important managerial implications.

Didattica 4.0 e intelligenza artificiale: Un'analisi qualitativa delle soluzioni digitali a supporto del corpo docente

VALERIO FEOLA[1], GIULIA GOGIALI[2]

Abstract. *Negli ultimi anni, le istituzioni scolastiche hanno assistito ad una rapida accelerazione dei processi di digitalizzazione adottati, inizialmente in risposta all'emergenza sanitaria dovuta alla pandemia da Sars-Cov2 e successivamente consolidatisi nelle pratiche quotidiane. In questo scenario si è assistito alla crescente introduzione di soluzioni basate sull'AI, tra le quali sistemi tutoring intelligente, applicazioni di intelligent assessment e agenti conversazionali. Nonostante la letteratura internazionale abbia analizzato le potenzialità pedagogiche di queste tecnologie, risulta ancora limitata un'analisi approfondita sulle implicazioni organizzative e professionali che presuppongono per i docenti. La finalità del presente studio è quella di esaminare in quale modo le soluzioni AI, destinate agli istituti scolastici di secondo grado in Italia, si configurano come strumenti di supporto all'organizzazione del lavoro didattico dei docenti. L'attenzione non è quindi rivolta a misurare l'efficacia o l'impatto delle tecnologie bensì l'analisi di significati, rappresentazioni e configurazioni organizzative che esse presuppongono o promuovono. Inoltre, La ricerca adotta un disegno, qualitativo di tipo esplorativo e interpretativo, basato sull'analisi documentale di fonti pubbliche e sulla selezione intenzionale di soluzioni AI rilevanti per il contesto scolastico. Lo studio vuole contribuire al dibattito sulla trasformazione digitale delle organizzazioni educative offrendo una prospettiva organizzativa sull'integrazione dell'AI nella scuola secondaria italiana, mettendo in luce le implicazioni per il ruolo professionale del corpo docente e per l'organizzazione del lavoro didattico.*
Keywords*: AI in Education, Organizational Innovation, Digital Transformation, Innovation Management, AI Adoption.*

1. Inquadramento Teorico. Negli anni successivi alla pandemia da Sars-CoV-2, gli istituti scolastici hanno assistito a una rapida espansione dell'uso delle tecnologie digitali nelle attività didattiche e organizzative. La diffusione dell'emergency remote teaching ha accelerato processi di digitalizzazione già in atto, determinando rilevanti riconfigurazioni nei sistemi educativi (Moore et al., 2023; Meinck et al., 2022). Nel periodo successivo alla fase emergenziale, tali tecnologie si sono progressivamente consolidate, con un'ampia diffusione delle infrastrutture digitali nei Paesi OCSE, nonostante persistano differenze in termini di qualità e accessibilità (Boeskens et al., 2025). In questo contesto si inserisce la crescente adozione di soluzioni basate sull'AI, tra cui sistemi di apprendimento adattivo, strumenti di intelligent assessment e agenti conversazionali, capaci di personalizzare i percorsi di apprendimento e supportare le attività didattiche e di monitoraggio (Wang et al., 2024; Lai et al., 2024). Tali tecnologie si fondano su modelli adattivi e su sistemi di tutoring intelligente, in grado di modulare contenuti e feedback in funzione delle caratteristiche degli studenti (Brusilovsky, 2001; Durlach et al., 2012). Parallelamente, i sistemi AI conversazionali, intesi come agenti in grado di simulare modalità di interazione tipiche della comunicazione umana, vengono progressivamente integrati nei contesti educativi per fornire supporto e feedback in tempo reale (Khatri et al., 2018; Radziwill et al., 2017; Merino et al., 2025). La letteratura sull'AI in ambito educativo si è concentrata prevalentemente sugli esiti di apprendimento e sulle opportunità di personalizzazione offerte dai sistemi intelligenti (Roll & Wylie, 2016; Chen et al., 2020), mentre gli studi sull'EdTech hanno privilegiato l'analisi dei processi di diffusione delle tecnologie e delle piattaforme digitali (Williamson & Eynon, 2020; Perrotta & Selwyn, 2020). Rimane invece ancora limitata una riflessione sistematica sulle implicazioni organizzative dell'adozione dell'AI nei contesti educativi. Il presente studio si inserisce in tale gap, proponendo una lettura delle soluzioni di AI come infrastrutture socio-tecniche.

2. Obiettivo. La crescente adozione delle tecnologie digitali e delle soluzioni AI non può essere interpretata esclusivamente come un'evoluzione tecnologica o pedagogica ma anche come un processo di trasformazione digitale che incide su strutture organizzative, modelli di governance e ruoli professionali, richiedendo capacità di leadership e di gestione dell'innovazione a livello istituzionale (McCarthy et al. 2023; Pietsch, 2024). In particolare, l'integrazione riguarda attività centrali dei docenti come la progettazione delle lezioni, produzione e selezione dei materiali, valutazione degli apprendimenti e personalizzazione dei percorsi didattici. Gli insegnanti possono infatti usufruire degli strumenti AI per generare contenuti, fornire feedback e automatizzare compiti ripetitivi, favorendo una maggiore efficienza e riduzione del carico di lavoro amministrativo (Delello et al., 2025). Tuttavia, tali trasformazioni non sono neutrali: l'adozione di sistemi generativi e adattivi comporta una rinegoziazione del ruolo professionale del docente, incidendo su autonomia, responsabilità e competenze richieste (Dangol et al. 2025; Zhai et al. 2024; Iqbal et al. 2024). In tal senso, l'adozione

[1] Dottorando di Ricerca in Marketing, Dipartimento di Comunicazione e Ricerca Sociale (CoRiS), Università degli studi di Roma La Sapienza, Italia. valerio.feola@uniroma1.it (autore corrispondente)
[2] Dottoressa di Ricerca in Marketing, Dipartimento di Comunicazione e Ricerca Sociale (CoRiS), Università degli studi di Roma La Sapienza, Italia. giulia.gogiali@uniroma1.it

dell'IA deve essere analizzata come parte di un più ampio processo di trasformazione digitale delle organizzazioni educative, con implicazioni che superano la dimensione strettamente tecnica o didattica. Alla luce di tali considerazioni, si intende rispondere alla seguente domanda di ricerca:
RQ: In quale modo le soluzioni di intelligenza artificiale destinate agli istituti scolastici di secondo grado in Italia si configurano come strumenti di supporto all'organizzazione del lavoro didattico dei docenti?

3. Metodologia. Dal punto di vista metodologico, lo studio adotta un disegno qualitativo di tipo esplorativo e interpretativo volto a comprendere i significati attribuiti alle soluzioni AI e i processi attraverso cui vengono integrate nell'organizzazione del lavoro didattico negli istituti di secondo grado (Creswell et al., 2018; Denzin et al., 2018). Il carattere esplorativo risulta coerente con l'analisi di fenomeni emergenti e con l'obiettivo di sviluppare categorie interpretative utili alla costruzione teorica (Eisenhardt, 1989; Gioia et al., 2013). Il corpus analizzato è composto da 6 documenti di diversa natura, tra cui contenuti presenti sui siti web ufficiali delle piattaforme, documentazione funzionale e materiali informativi e di policy, selezionati in base alla loro rilevanza e al livello di dettaglio informativo (Bowen, 2009). L'analisi dei dati è stata condotta attraverso un approccio di analisi tematica (Braun & Clarke, 2006). In una prima fase, i documenti sono stati esaminati per individuare unità di significato rilevanti, successivamente codificate mediante un processo di codifica aperta (Saldaña, 2013). I codici sono stati progressivamente aggregati in categorie analitiche attraverso un processo iterativo di confronto tra dati empirici e letteratura, secondo una logica abductive (Timmermans & Tavory, 2012). La fase di codifica ha portato all'identificazione di codici descrittivi successivamente organizzati in categorie di livello superiore attraverso un processo di astrazione progressiva (Charmaz, 2014; Vaismoradi et al., 2016), fino alla definizione di tre dimensioni analitiche, in linea con approcci induttivi di analisi qualitativa (Thomas, 2006). Le dimensioni emerse sono state successivamente messe in dialogo con la letteratura sulla materialità delle tecnologie e sull'organizzazione del lavoro (Orlikowski, 2007; Leonardi, 2011):

- Dimensione infrastrutturale e di gestione della conoscenza, in linea con studi sulle knowledge infrastructures (Edwards et al., 2009);
- Dimensione organizzativo-gestionale del lavoro del docente, coerente con ricerche sulla riconfigurazione dei processi organizzativi attraverso sistemi algoritmici (Faraj et al., 2018; Kellogg et al., 2020);
- Dimensione progettuale-didattica e di supporto cognitivo, relativa al ruolo delle tecnologie AI nel supporto alle pratiche di insegnamento (Selwyn, 2019).

Tali dimensioni risultano coerenti con la letteratura sulle tecnologie digitali nei sistemi educativi (UNESCO, 2021; OECD, 2025) e con studi che evidenziano il ruolo delle classificazioni e degli standard nella strutturazione delle pratiche organizzative (Bowker & Star, 1999).

3.1 Criteri di Selezione. La selezione delle soluzioni AI è stata guidata da una logica di campionamento intenzionale, coerente con la domanda di ricerca, privilegiando casi in grado di fornire informazioni rilevanti sul fenomeno indagato (Patton, 2002; Palinkas et al., 2015). Un primo criterio riguarda l'appartenenza al dominio dell'AI in Education, includendo strumenti che integrano componenti algoritmiche, sistemi adattivi, tutoring intelligente o funzionalità di learning analytics (Zawacki-Richter et al., 2019). È stata inoltre considerata la destinazione al contesto della scuola secondaria, selezionando soluzioni rivolte a docenti o istituzioni scolastiche. Un secondo criterio riguarda la rilevanza funzionale rispetto alle attività professionali dei docenti, privilegiando strumenti che supportano la progettazione didattica, la produzione di materiali, la valutazione degli apprendimenti e la gestione delle attività organizzative, in linea con la letteratura sull'adozione delle tecnologie nei contesti organizzativi (Davis, 1989; Venkatesh et al., 2003). Infine, sono state incluse esclusivamente soluzioni per le quali fossero disponibili documentazioni pubbliche sufficientemente articolate da consentire un'analisi documentale sistematica (Bowen, 2009). Il numero dei casi è stato definito in base alla loro capacità informativa rispetto agli obiettivi dello studio, secondo il principio dell'information power (Malterud et al., 2015).
3.2 Il Campione. Il processo di individuazione del campione ha previsto una fase preliminare per mappare i principali strumenti AI usati o potenzialmente utilizzabili dai docenti nel contesto della scuola secondaria italiana (Tabella 1). Questa ricognizione ha consentito di identificare 10 strumenti AI potenzialmente rilevanti per il contesto educativo. Successivamente, Sulla base dei criteri di selezione definiti, la ricognizione è stata delimitata alle soluzioni con una configurazione istituzionale e organizzativa. Il campione finale ha incluso tre macro-soluzioni: MTM Project, Superlearn e Minerva Education AI, progettate specificamente per il contesto scolastico e dotate di funzionalità che incidono sull'organizzazione del lavoro didattico dei docenti sia sul piano infrastrutturale e gestionale sia su quello di pianificazione e produzione dei materiali didattici. Durante la mappatura preliminare sono state considerate anche sistemi ampiamente adottati dai docenti, tra cui strumenti generativi (ChatGPT, Microsoft Copilot, Google Gemini), applicazioni per la creazione di contenuti (Canva Magic Write), strumenti di organizzazione personale (Notion AI) e sistemi di revisione linguistica (Grammarly). Tuttavia, questi sono stati esclusi dal campione poiché non progettate specificamente per istituzioni scolastiche né configurate come piattaforme organizzative integrate, essendo usate prevalentemente su un piano individuale.

Tabella 1 - Criteri di selezione e inclusione delle soluzioni di intelligenza artificiale analizzate (Fonte: elaborazione degli autori)

Soluzione	Destinata a Scuola Secondaria	Tipo di incidenza nelle attività del docente	Riconducibile ad AIED	Documentazione Pubblica Adeguata	Inclusione/ Esclusione
MTM Project	Sì	gestione procedure, supporto organizzativo, progettazione didattica immersiva, creazione contenuti	Sì	Sì	Inclusa
Superlearn	Sì	assessment, workflow, pianificzione	Sì	Sì	Inclusa
Minerva Education AI	Sì	progettazione didattica, materiali	Sì	Sì	Inclusa
ChatGPT	No	uso individuale	Sì	Sì	Esclusa – non destinata a istituzioni scolastiche
Canva Magica Write	No	produttività individuale	Sì	Sì	Esclusa – non configurata per contesto scolastico
Microsoft Copilot	No	creazione materiali	Sì	Sì	Esclusa – strumento creativo individuale
Notion AI	No	organizzazione appunti, pianificazione personale	Sì	Sì	Esclusa – tool organizzativo personale
Grammarly	No	revisione e correzione testi	Sì	Sì	Esclusa – supporto linguistico individuale

3.3 Raccolta dei Dati. Per la raccolta dei dati è stata adottata l'analisi documentale, intesa come procedura sistematica di selezione, revisione ed interpretazione di materiali scritti ed elettronici finalizzata alla produzione di conoscenza empirica (Bowen, 2009). In linea con la prospettiva della ricerca qualitativa, i documenti sono stati considerati non come semplici supporti informativi ma come costruzioni sociali e organizzative che riflettono pratiche e visioni situate (Flick, 2009; Patton, 2002). Infatti, sono stati analizzati diversi tipi di materiali ufficiale per ciascuna soluzione AI selezionata, tra cui siti web, descrizioni funzionali, documentazione tecnica, materiali informativi rivolti alle scuole e, qualora disponibili, policy d'uso. Complessivamente, l'analisi ha incluso 6 documenti ufficiali relativi alle piattaforme considerate. L'utilizzo di diverse tipologie documentali risponde a una logica di triangolazione delle fonti, intesa come confronto sistematico tra materiali differenti riferiti allo stesso fenomeno (Denzin, 1978). Tale strategia contribuisce a rafforzare la credibilità dell'interpretazione attraverso la convergenza o l'eventuale divergenza delle informazioni provenienti da fonti diverse (Carter et al., 2014).

4. Risultati. Le soluzioni sviluppate da MTM Project, in particolare attraverso la piattaforma ScuolaVR (SVR), integrano componenti AI in ambienti AR e VR attraverso un'architettura basata su Retrieval-Augmented Generation, che consente di recuperare e interrogare informazioni contenute in repository strutturati. In questo senso, l'AI può essere interpretata come un'infrastruttura di organizzazione della conoscenza. Se la scuola è intesa come organizzazione distribuita di sapere (Tsoukas, 1996), il lavoro docente implica non solo la trasmissione ma anche la selezione e la riorganizzazione delle conoscenze (Shulman, 1986). In questa prospettiva, le architetture RAG incidono sulle condizioni organizzative dei docenti, migliorando l'accessibilità e la strutturazione delle informazioni in un contesto caratterizzato da crescenti richieste di documentazione e accountability (OECD, 2020). Tali soluzioni operano quindi come dispositivi di formalizzazione della conoscenza istituzionale, riducendo il tempo necessario alla ricerca e rielaborazione delle informazioni. Diversamente, soluzioni come Superlearn e Minerva Education AI, e in misura più limitata anche le tecnologie immersive di MTM Project, intervengono nella dimensione progettuale, redistribuendo le attività cognitive associate alla pianificazione didattica. Alla luce della teoria della cognizione distribuita (Hutchins, 1995), tali strumenti possono essere interpretati come artefatti cognitivi che partecipano ai processi di elaborazione professionale. In linea con

la distinzione tra automazione e augmentation (Raisch et al., 2021), le piattaforme analizzate si collocano prevalentemente nella seconda prospettiva, assegnando agli insegnanti funzioni di supervisione e validazione dei contenuti generati. Considerando che una quota significativa del tempo di lavoro docente è dedicata ad attività di pianificazione e valutazione (OECD, 2019), l'AI contribuisce alla redistribuzione del carico cognitivo e interviene su dimensioni centrali dell'organizzazione del lavoro. La presenza di dashboard, sistemi di monitoraggio e workflow strutturati introduce inoltre maggiore formalizzazione e tracciabilità delle attività, in linea con i processi di dataficazione dell'istruzione (Williamson, 2017), con implicazioni per l'autonomia professionale e la percezione del ruolo docente (Day, 2012; OECD, 2020). Nel complesso, le soluzioni analizzate si configurano non solo come supporti didattici, ma come infrastrutture organizzative che incidono su pianificazione, documentazione, coordinamento e gestione del tempo professionale.

4.1 Soluzioni MTM Project

I risultati derivanti dall'analisi delle soluzioni proposte da MTM Project evidenziano un ecosistema tecnologico composto da un'infrastruttura digitale integrata e da applicazioni funzionali differenziate. In particolare, la componente immersiva è riconducibile alla piattaforma ScuolaVR (SVR), che consente la fruizione di ambienti virtuali e aumentati multiutente, supportando esperienze interattive e collaborative, la simulazione di scenari tecnico-professionali e l'assistenza da remoto. Le informazioni raccolte indicano che la componente AI integrata nelle tecnologie immersive adotta un'architettura basata su Retrieval-Augmented Generation (RAG), in cui un modello linguistico genera risposte recuperando informazioni da documenti presenti in repository strutturati, senza ricorrere a fine-tuning sui dati dell'istituzione. All'interno di questo ecosistema si collocano strumenti applicativi con funzionalità AI differenziate. MaGestio EDU supporta la gestione di procedure operative e attività laboratoriali attraverso workflow, report e checklist, con l'AI che funge da supporto informativo in tempo reale. SVR Translator integra funzionalità di traduzione automatica, trascrizione e sintesi vocale, configurandosi come strumento di mediazione linguistica. VASARI utilizza tecniche di Natural Language Processing e Large Language Models per l'analisi della documentazione tecnica, l'estrazione di procedure operative e la loro organizzazione in repository strutturati, supportando attività operative e la simulazione di processi in ambienti immersivi. La piattaforma SVR supporta inoltre l'utilizzo e l'adattamento di contenuti immersivi nella progettazione didattica, anche attraverso percorsi di formazione dedicati alla modellazione VR, consentendo esperienze di apprendimento multilivello e attività collaborative adattabili a diverse discipline e livelli di difficoltà. Nel complesso, le soluzioni MTM configurano l'AI principalmente come infrastruttura di supporto alla gestione della conoscenza e dei processi operativi (Edwards et al., 2009). Le funzionalità di gestione dei workflow evidenziano una rilevanza della dimensione organizzativo-gestionale, legata al coordinamento e alla standardizzazione delle attività (Faraj et al., 2018; Kellogg et al., 2020), mentre la dimensione progettuale-didattica risulta presente ma meno centrale, configurandosi come supporto alla progettazione e all'utilizzo di contenuti immersivi, piuttosto che come sistema primariamente orientato alla generazione autonoma di materiali didattici (Zawacki-Richter et al., 2019; Roll & Wylie, 2016).

4.2 Soluzioni Superlearn

Superlearn è presentata come una piattaforma digitale integrata che combina soluzioni tecnologiche e componenti AI destinate sia al contesto scolastico sia a quello aziendale, con una sezione specificamente orientata agli istituti scolastici. La piattaforma è descritta come un ecosistema che integra strumenti per la gestione documentale, la comunicazione interna, il supporto alla didattica e il coordinamento delle attività scolastiche. Dalla documentazione disponibile emerge la presenza di moduli distinti dedicati alla gestione (Manage), all'insegnamento (Teach) e all'apprendimento (Learn). Il sistema include dashboard per la gestione di documenti, ruoli e attività, nonché strumenti di interazione digitale utilizzabili da docenti, studenti e personale amministrativo con possibilità di integrazione con sistemi digitali esterni. La piattaforma integra componenti AI sotto forma di agenti. Dai materiali ufficiali emerge la presenza di un assistente virtuale in grado di fornire supporto informativo e rispondere a domande degli utenti, oltre ad agenti generativi. In particolare:

- I docenti possono utilizzare agenti AI generativi per attività di assessment;
- La piattaforma consente la creazione assistita di materiali didattici tramite agenti AI;
- Sono presenti agenti AI dedicati alla ricerca delle circolari scolastiche emesse annualmente dalla singola istituzione;
- Agenti AI per la redazione delle circolari sono in fase di implementazione.

Le componenti AI risultano pertanto organizzate in agenti specializzati per funzioni didattiche e amministrative. La documentazione non fornisce dettagli sull'architettura tecnica dei modelli, sui dataset utilizzati né sulle modalità di addestramento o aggiornamento dei sistemi. Nel complesso, Superlearn configura l'AI come componente integrata in un ecosistema digitale orientato al coordinamento delle attività scolastiche. La soluzione evidenzia una prevalenza della dimensione organizzativo-gestionale, con elementi anche progettuale-didattici legati all'uso di agenti generativi, mentre la dimensione infrastrutturale risulta meno esplicita.

4.3 Soluzioni Minerva Education AI

Minerva Education AI è presentata come una piattaforma AI generativa progettata per supportare gli insegnanti nella progettazione didattica e nella generazione di materiali, contribuendo a ridurre il carico di lavoro legato alla preparazione di lezioni e verifiche. La piattaforma consente la creazione di piani di lezione, unità didattiche, quiz personalizzati e materiali operativi attraverso assistenti AI specializzati, che supportano diverse esigenze educative, dalla progettazione

di attività di classe alla produzione di contenuti testuali e visivi. Sono inoltre disponibili "esperti AI" in grado di rispondere alle richieste degli insegnanti e una sezione di risorse contenente materiali didattici pronti all'uso, adattabili a diversi livelli di apprendimento e discipline. Nei materiali pubblici non sono forniti dettagli tecnici relativi all'architettura dei modelli, ai dataset o a eventuali processi di fine-tuning. Nel complesso, l'AI appare configurata come supporto diretto alla programmazione individuale del docente, descritta prevalentemente in termini funzionali piuttosto che tecnici. Ne emerge una forte prevalenza della dimensione progettuale-didattica, mentre risultano marginali le componenti infrastrutturale e organizzativo-gestionale.

5. Limiti della Ricerca. Il presente studio presenta alcuni limiti. In primo luogo, l'analisi si basa su documentazione pubblica (siti web, brochure, white paper) e non è stato possibile accedere al codice sorgente, ai modelli o ai dataset di addestramento, né condurre audit tecnici indipendenti delle soluzioni analizzate. In secondo luogo, lo studio si concentra su un numero limitato di strumenti destinati agli istituti secondari italiani, senza un confronto sistematico con piattaforme internazionali, con conseguenti limiti di generalizzabilità. Inoltre, l'analisi non include dati empirici sull'uso effettivo delle piattaforme da parte dei docenti, né osservazioni dirette o interviste. Infine, la ricerca adotta una prospettiva prevalentemente organizzativa e cognitiva, senza approfondire in modo sistematico le implicazioni etiche, giuridiche e relative alla protezione dei dati personali. Alla luce di tali limiti, emergono diverse traiettorie di ricerca. In primo luogo, sarebbero auspicabili studi empirici sull'adozione concreta di queste soluzioni nelle scuole, al fine di comprendere come i docenti integrino l'AI nei processi di lavoro e se la redistribuzione cognitiva ipotizzata si traduca in trasformazioni osservabili delle pratiche (Luckin et al., 2016). In secondo luogo, ricerche comparative tra contesti nazionali potrebbero chiarire il ruolo degli assetti istituzionali e normativi nelle configurazioni organizzative (Komljenovic, 2021). Infine, studi longitudinali potrebbero analizzare l'impatto delle piattaforme AI sulla professionalità docente nel lungo periodo, verificando eventuali processi di deskilling, upskilling o trasformazione delle competenze (Susskind et al., 2022; Autor, 2015).

6. Implicazioni Manageriali. Per quanto concerne le implicazioni manageriali, i risultati suggeriscono alcune indicazioni operative per dirigenti scolastici e decisori pubblici. In primo luogo, l'adozione di soluzioni AI richiede di essere accompagnata da interventi organizzativi e non solo tecnologici, con particolare attenzione alla ridefinizione dei processi di lavoro e delle responsabilità del personale docente. In secondo luogo, risulta necessario investire in percorsi di formazione mirati non solo all'uso tecnico degli strumenti ma anche alla loro integrazione nelle pratiche didattiche e organizzative. Inoltre, la crescente presenza di sistemi basati su dashboard, workflow e monitoraggio delle attività richiede una riflessione sulle modalità di governance dei dati e sui meccanismi di accountability al fine di evitare effetti indesiderati sulla autonomia professionale dei docenti. Infine, i risultati evidenziano la necessità di sviluppare politiche scolastiche che bilancino l'uso dell'AI come supporto cognitivo con il mantenimento del ruolo decisionale e professionale dell'insegnante, evitando forme di dipendenza o delega eccessiva alle tecnologie.

7. Originalità del Paper. Il presente studio contribuisce alla letteratura sull'introduzione dell'AI nell'ambito educativo, offrendo una prospettiva organizzativa all'interno degli istituti di secondo grado. In particolare, vengono interpretate le diverse soluzioni non solo come meri strumenti di supporto didattico ma come infrastrutture socio-tecniche che intervengono nell'organizzazione del lavoro dei docenti e della gestione della conoscenza all'interno delle istituzioni scolastiche. L'analisi preliminare delle soluzioni AI ha messo in luce due importanti configurazioni: sistemi orientati a strutturare la conoscenza istituzionale attraverso repository di documentali interrogabili e sistemi generativi che supportano i docenti nelle attività di progettazione didattica e nella produzione dei materiali. Nel complesso, il paper contribuisce alla letteratura sulla trasformazione digitale delle organizzazioni scolastiche mostrando come l'introduzione di tali strumenti possa incidere direttamente sull'efficienza operativa, intesa come capacità di svolgere attività organizzative in modo più efficace rispetto alle pratiche esistenti attraverso un migliore utilizzo delle risorse e dei processi organizzativi (Porter, 1996), attraverso una distribuzione delle attività cognitive, la gestione del tempo e le modalità di coordinamento del lavoro didattico.

Does Source Credibility Theory Apply to Virtual Influencers? Evidence From Italy

VINCENZO GISSI[1], ELISABETTA SAVELLI[2]

Abstract. *The rapid evolution of Generative Artificial Intelligence has led to the emergence of increasingly realistic human-like virtual influencers (VIs), revolutionizing influencer marketing. While previous literature has focused primarily on clearly artificial or stylized digital figures, little is known about how consumers perceive the new generation of hyper-realistic VIs, nearly indistinguishable from human influencers. In particular, it is still unclear whether Source Credibility Theory (SCT), widely validated in the context of human endorsements, is also applicable when the source is artificially generated. This study aims to test the applicability of SCT in the context of human-like VIs, analyzing to what extent the three central dimensions of credibility (attractiveness, trustworthiness, expertise) influence consumers' attitudes towards these artificial endorsers. The research is based on a questionnaire administered to 372 Italian respondents and combines descriptive analysis and a multiple linear regression to answer three research questions: (1) how human-like VIs are perceived by Italian consumers; (2) whether they are considered as attractive, expert and trustworthy as human influencers; (3) to what extent the dimensions of credibility influence attitudes towards them. The results show that attitudes toward VIs are relatively low, despite the three credibility components having moderate values. VIs are perceived as quite attractive and expert compared to human influencers, but slightly less trustworthy. Furthermore, the regression analysis highlights that all three credibility dimensions positively and significantly influence attitudes, with attractiveness emerging as the strongest predictor. This confirms that the classic mechanisms of SCT remain valid even when the source is not human but artificially generated. The study contributes to the literature by providing empirical evidence on the perception of human-like VIs in the Italian context and testing the robustness of a well-established theory in influencer marketing in the AI context. Managerial implications are also discussed to guide how brands can strategically implement human-like VIs within the Italian market, which appears not yet fully ready to embrace these artificial endorsers.*

Keywords: *Virtual Influencers; Social Credibility Theory; Artificial Intelligence; Virtual Endorsers*

Framing of the research. In recent years, influencer marketing has undergone a significant transformation: the rise of virtual influencers (VIs) has blurred the boundaries between human and digital, offering companies new tools to stimulate engagement and promote their products (Allal-Chérif et al. 2024). VIs are digital characters created using artificial intelligence technologies, designed to operate on social media like real creators, interacting with users and collaborating with brands in a similar way to human influencers (Allal-Chérif et al. 2024). A notable example is Lil Miquela, who has attracted the attention of companies through numerous collaborations with international brands, gaining millions of followers on social media and becoming the subject of growing academic interest (Zhou et al. 2024). More recently, with the release of ChatGPT and the rush to develop new applications of generative artificial intelligence, we have witnessed a rise in VIs, particularly those that are very similar to human beings. Unlike VIs like Lil Miquela and Imma, new VIs are almost unrecognizable from real people, making them very interesting to study, as users may feel deceived by their appearance and therefore reject interaction. An example of such VIs is Alba Renai, who presented a Spanish TV show (Barbera 2024) and has collaborated with several brands, including Hyundai. Similarly, Aitana Lopez has nearly 400,000 followers on Instagram, and the creator said she generates 10.000$ per month (Crescenzi 2023). Both interact on social media continuously, posting everyday experiences as if they were real, and their appearance can deceive anyone unaware of their artificial origins. The focus of this study is exclusively on this new generation of VIs, called human-like VIs.

Although much news has been published in Italy about human-like VIs (Crescenzi 2023; Barbera 2024), few studies have examined how people perceive them (Koles et al. 2024), and, to our knowledge, none has investigated this phenomenon in Italy, a country where influencer marketing is rapidly growing (Guttmann 2025). Therefore, it is very interesting to understand whether this new form of influencer is well accepted by users and how companies can use them to improve brand perception and promote their products.

The study draws on Source Credibility Theory (SCT), a well-established theory in influencer marketing (Nafees et al. 2021) initially introduced by Hovland et al. (1953). It states that source credibility depends on three components: expertise, attractiveness, and trustworthiness. Expertise refers to the degree to which the source is perceived as knowledgeable and authoritative in a specific field; trustworthiness concerns the perceived honesty, integrity, and coherence of the communicator; and finally, attractiveness includes not only aesthetics but also the ability to be pleasant and socially valuable (Ohanian 1990). In collaborations between brands and creators, the influencer's persuasiveness has often been linked to perceptions of their credibility, which is understood as a combination of expertise, trustworthiness,

[1] University of Urbino Carlo Bo, v.gissi@campus.uniurb.it
[2] University of Urbino Carlo Bo, elisabetta.savelli@uniurb.it

and attractiveness. Numerous studies have shown that these three dimensions influence brand attitudes, purchasing intentions, and engagement (Wellman 2024), confirming that the source is not just a vehicle for the message, but a central element in building meaning and trust. In fact, it's not just what is communicated that makes the difference, but who communicates it. Although it is a framework already widely used in influencer marketing (e.g. Nafees et al., 2021), whether SCT's dimensions function similarly for human and virtual influencers remains theoretically and empirically unclear (Park and Sung 2023). SCT provides a good starting point for analyzing VIs. If persuasion mechanisms in digital marketing are based on the perceived credibility of the source, it becomes crucial to understand whether these mechanisms remain valid when the source is not a human being, but an artificial entity generated by artificial intelligence. VIs, especially human-like ones, replicate the aesthetic and behavioral characteristics of traditional influencers, but lack lived experience, authentic intentionality, and a real biographical identity. This raises a theoretical question: is it possible to attribute expertise, trustworthiness, and attractiveness to a subject who lacks a human existence? Testing the validity of SCT in the context of VIs means verifying whether consumers activate the same mechanisms used for human influencers or whether the artificiality of the source modifies or transforms traditional credibility mechanisms.

Purpose of the paper. This study aims to test the applicability of SCT to human-like VIs by examining how the core credibility dimensions (attractiveness, trustworthiness, and expertise) influence consumers' attitudes toward these artificial endorsers. Specifically, the paper addresses three research objectives:

RQ1. How are VIs perceived by Italian consumers?

RQ2. Are human-like VIs perceived as equally credible as human influencers in terms of attractiveness, trustworthiness, and expertise?

RQ3. 3. To what extent do the core dimensions of SCT - attractiveness, trustworthiness, and expertise - influence consumers' attitudes toward human-like VIs?

Methodology. To address the research questions, a quantitative survey was adopted. Data collection was conducted via an online structured questionnaire administered to a sample of 372 Italian participants, recruited through a snowball sampling technique. The choice of the Italian context responds to the need to analyze a growing market in influencer marketing that remains relatively underexplored in the context of human-like VIs. The sample includes subjects of different age and backgrounds to ensure adequate variability in perceptions toward these digital endorsers (mean age: 26.6; female: 293, male: 79; students: 171, student-worker: 80, employee: 95, other:26).

Before answering the questionnaire, participants were provided with an explanation of what VIs are. To clearly distinguish the human-like VIs examined in this study from more traditional ones, respondents were shown two images taken from the Instagram profiles of Aitana Lopez and Alba Renai. These two profiles were selected as they represent some of the most widely recognized and discussed human-like VIs within the Italian context (Crescenzi 2023; Barbera 2024).

All constructs were measured using scales validated in the literature and adapted to this context. The three dimensions of SCT (attractiveness, trustworthiness, expertise) were assessed using items from Ohanian's (1990) scale, while attitudes towards the VIs were measured using items from Chetioui et al.'s (2020) scale. Notably, to answer the second research question, comparative measures were included to assess whether the VIs were perceived as equally attractive, expert, and trustworthy as traditional human influencers. All variables were measured on 7-point Likert scales (1 = strongly disagree; 7 = strongly agree) and all constructs showed good internal consistency (Cronbach's alpha > 0.80).

Regarding data analysis, descriptive analyses were conducted to explore the general perception of human-like VIs in the Italian sample (RQ1) and to assess whether those were perceived as equally credible as human influencers (RQ2). Furthermore, to test the effect of the three dimensions of credibility on attitudes toward VIs (RQ3), a multiple linear regression was estimated. Attitude was taken as the dependent variable, while attractiveness, trustworthiness, and expertise were included as predictors.

Results. Descriptive analyses provide an initial overview of the sample's perceptions. Addressing RQ1, the perceived attractiveness of the VIs averaged 3.07 (SD = 1.39), indicating a moderate level of attractiveness. Similarly, perceived trustworthiness (M = 3.59, SD = 1.63) and perceived expertise (M = 3.35, SD = 1.69) are moderate. Finally, attitudes toward VIs are relatively low (M = 2.41; SD = 1.21). The most interesting finding is the gap between these moderate assessments and the relatively low attitude. In other words, although participants recognize a degree of attractiveness, expertise, and even trustworthiness, this does not automatically translate into a positive attitude toward these virtual endorsers. It seems as if the rational and emotional minds do not coincide. This misalignment can be interpreted in several ways. On the one hand, it could reflect an initial phase of cultural adaptation, in which the Italian public appears to be still in an exploratory phase with respect to human-like VIs. They evaluate them using traditional categories (attractive, expert, trustworthy) but have not yet fully internalized their legitimacy as social actors. On the other hand, an implicit form of resistance could emerge, linked to the artificial nature of the source. This reaction can be interpreted through the Uncanny Valley phenomenon, according to which entities that closely resemble humans, yet remain perceptibly artificial, may trigger discomfort and reduce affective evaluations. This demonstrates the importance of using not only traditional tools to study perception but also tools that capture users' emotional and less rational aspects, as suggested by Laszkiewicz & Kalinska-Kula (2023). Another element to consider is the relatively high standard deviation in the three credibility dimensions. This suggests some heterogeneity in perceptions: some respondents may be much more open and curious

about these figures, while others may express greater skepticism. This is consistent with Audrezet et al. (2025), who noted the need to consider how individual differences influence consumers' perceptions of VIs.

Regarding RQ2, the findings indicate that human-like VIs are not perceived as credible sources when evaluated against the three core dimensions of SCT. In particular, they are perceived as rather neutral in terms of attractiveness ($M = 3.29$; $SD = 1.91$) and expertise ($M = 3.20$; $SD = 1.87$), but score lower on trustworthiness ($M = 2.74$; $SD = 1.69$). The comparison with human influencers shows that human-like VIs still fall short of achieving the same level of perceived credibility. Participants seem to recognize that they "work" aesthetically and may appear expert, but they don't attribute a competitive advantage over traditional influencers. The most significant finding concerns trustworthiness, which is significantly lower than the other two dimensions. This gap suggests that the real critical point is not aesthetics or perceived expertise, but trust. This is very important and can be explained by considering that trust implies authenticity, integrity, and consistency between identity and behavior. However, when the source is artificially generated, the perception of authenticity can be low. Even if the user rationally knows that it is a digital entity, a psychological feeling of manipulation can emerge. Theoretically, this result is interesting because it shows that not all dimensions of SCT react equally to the "dehumanization" of the source. Attractiveness can be engineered, expertise can be simulated through well-curated content, but trust isn't so easily programmed because it's a relational aspect that develops over time and requires narrative coherence, transparency, and the perception of genuine intentions. Trust has also emerged as a critical factor in other AI research (Chan and Choi 2025), such as studies on AI chatbots (Song and Shin 2024).

Addressing RQ3, the multiple linear regression confirms that all three dimensions of SCT significantly influence consumers' attitudes toward human-like VIs. Specifically, attractiveness ($\beta = 0.224$, $p < .001$), trustworthiness ($\beta = 0.166$, $p < .001$), and expertise ($\beta = 0.174$, $p < .001$) all have positive, significant effects on attitude. The overall model is significant ($F(3,368) = 80.07$, $p < .001$) and explains a substantial portion of variance ($R^2 = 0.395$), indicating that nearly 40% of the variability in attitudes toward human-like VIs is explained by the three credibility dimensions. These findings suggest that, despite their artificial nature, VIs are evaluated through the same credibility-based mechanisms traditionally applied to human endorsers, with attractiveness emerging as the strongest predictor, followed by expertise and trustworthiness. It means that, in the case of VIs, the visual component has a stronger effect than the relational dimension of trust. Indeed, these virtual endorsers are built to be visually perfect and designed to attract attention in highly visual environments like social media. However, this result must be read alongside previous findings. While attractiveness is the strongest driver of attitude, trustworthiness is the dimension in which VIs are weakest compared to human influencers. Therefore, what most strongly drives positive attitudes is also the most easily "programmable", while trust, despite its significant impact, remains less predictable.

Research limitations. This study presents several limitations that should be acknowledged when interpreting the findings. First, the research relies on self-reported data collected through a survey. As with most questionnaire-based studies, responses may be subject to common method bias and social desirability bias. Furthermore, participants evaluated VIs in a controlled context, which may not fully capture how attitudes develop in real-world environments such as social media. Therefore, future research could adopt qualitative approaches to explore deeper processes and integrate neuromarketing tools to capture implicit consumer responses. Second, the empirical approach is descriptive for RQ1 and RQ2. While this choice is consistent with the exploratory aim of understanding how human-like VIs are currently perceived, descriptive statistics do not allow generalizations beyond the sample. Only RQ3 employs inferential analysis through multiple linear regression. However, the tested model focuses on replicating the core dimensions of SCT without incorporating additional variables. As a result, the model confirms theoretical applicability but does not extend the framework or introduce novel mediating or moderating mechanisms. Future research could integrate additional mediating and moderating variables in order to extend SCT and develop a more comprehensive explanatory model of consumer responses to VIs. Third, the study is conducted within the Italian context, where familiarity with human-like VIs remains relatively low compared to other countries. Therefore, the evaluations observed in this research may be influenced by context-specific factors, limiting the generalizability of the findings. Future studies should replicate the analysis in different cultural contexts, explore potential cross-cultural differences, and adopt longitudinal designs to examine how attitudes toward VIs evolve over time as consumers become increasingly accustomed to interacting with AI-generated personas.

Managerial implications. The results offer strategic insights for companies considering the use of human-like VIs in the Italian market. First, attitudes toward VIs are relatively low, despite perceptions of attractiveness, expertise, and trustworthiness being average. This suggests that the Italian market is not yet fully ready to embrace these figures. From a managerial perspective, the introduction of VIs should not be seen as an immediately effective strategic move but as a medium- to long-term investment. Companies that decide to adopt them should complement their sales communications with communications that build familiarity. Before selling, they must raise awareness and build trust.

Second, the comparison with human influencers highlights that VIs are perceived as generally attractive and expert, but less trustworthy. For managers, this implies that strategy cannot be limited to aesthetics or content quality; it must also include transparency and clarity about the artificial nature of the endorser. Ambiguous disclosure could increase skepticism, whereas explicit, well-managed communication can transform artificiality into a distinctive feature rather than a vulnerability. In other words, the credibility of VIS is not spontaneous but must be carefully designed and maintained.

Third, the linear regression analysis shows that attractiveness is the strongest predictor of attitude. This finding is consistent with the fact that many successful VIs are young women with strong visual appeal. From a strategic perspective, this suggests that in the context of VIs, the visual dimension plays a more important role than the relational component. However, a better attitude does not automatically mean improved brand perception or increased sales. Companies should consider the importance of attractiveness but also aim to work with VIs who have built a strong perception of expertise and trust, so that these qualities, combined, can not only improve attitude but also result in brand appreciation and increased sales of the advertised products.

Originality of the paper. The originality of the study emerges on three different levels: conceptual (application of the SCT to human-like VIs), empirical (analysis on an Italian sample in a market still in the process of adapting), and technological (focus on a new generation of hyper-realistic VIs).

Starting from the technological level, while much of the previous literature has focused on clearly artificial, stylized, or recognizable digital figures (Koles et al., 2024), this work moves the attention to entities indistinguishable from human beings. This shift in perspective is significant because the psychological dynamics triggered by a character clearly recognizable as virtual could be very different from those generated by an apparently human but artificially generated character.

At the conceptual level, the paper contributes theoretically by testing the robustness of SCT in a context very different from the one for which it was originally developed. The theory was developed to explain the persuasive effectiveness of human sources (Hovland et al., 1953), so applying it to a virtual context may not necessarily maintain its relationships. The contribution does not consist of introducing new dimensions, but rather of empirically verifying whether the classic credibility mechanisms (attractiveness, trustworthiness, expertise) remain active even when the "source" is generated by the artificial intelligence. The results show that these mechanisms continue to function, suggesting that consumers activate similar mechanisms regardless of the endorser's nature. This strengthens the theory's cross-disciplinary validity and broadens its domain of application.

Finally, a further element of originality concerns the empirical one. To date, no studies have systematically analyzed the perception of human-like VIs in the Italian market. Italy represents a particularly interesting context: on the one hand, it is a rapidly growing market for influencer marketing, and on the other, it shows signs of skepticism towards this new type of influencer. Analyzing this phenomenon in a country that is not yet fully "mature" allows us to observe initial acceptance dynamics that may differ from those observed in markets more open to VIs, such as those in Asia.

E-Recruitment and Cultural Bias: A Structural Audit and Detection Design for LLMs

BICE DELLA PIANA[1], GIANLUCA SPARVOLI[2], SARA CARBONE[3], FORSTER AMPADU[4]

Abstract. *Digital recruitment platforms are often seen as neutral systems aimed at improving efficiency and fairness in hiring. However, new research shows that algorithmic and AI tools can mirror and intensify social and cultural biases. As Large Language Models (LLMs) become more common in recruitment tech, concerns grow about how cultural values in training data and model structures may influence hiring outputs. This study explores the existence and nature of cultural bias in AI-supported e-recruitment, challenging the idea of technological neutrality. It has two main goals: first, to analyze how bias arises not only from technical errors but also from deeper sociocultural elements embedded in digital platforms and decision-making frameworks; second, to develop and test a methodology for identifying and analyzing cultural bias in LLM-generated recruitment discussions. The approach involves a two-step process: a systematic review of 42 peer-reviewed articles (2010–2025) from Web of Science, offering an interdisciplinary view of bias in e-recruitment across management, sociology, and computer science; and a structural audit combining cross-cultural management theories with machine learning. Empirically, responses to 25 intercultural recruitment scenarios created by three LLMs from different geopolitical backgrounds are analyzed. Cultural bias is evaluated using the Covert Harms and Social Threats (CHAST) framework, which detects subtle communicative harms in areas like competence, morality, and opportunity. Results show that cultural bias in LLM outputs is systematic, not accidental, and varies across models. The differences are linked to the sociocultural contexts of model development, leading to ethnocentrism and stereotypical cultural framing. By merging cultural theory and computational analysis, the study advances the emerging field of cross-cultural management and AI ethics. It offers a replicable framework for diagnosing structural bias in AI-driven recruitment and stresses the importance of governance to ensure AI supports inclusive, fair hiring rather than reinforcing cultural hierarchies.*

Keywords*: Generative AI, Cross Cultural Management, Cultural Bias, CHAST Framework, Algorithmic Auditing, Strategic Governance.*

Framing of the research. Recruiting platforms are often perceived as neutral and objective tools. The adoption of AI-supported e-recruitment systems was expected to promote more meritocratic recruitment processes by reducing human subjectivity.

However, these platforms function as critical intermediaries that can encode, transmit, and amplify biases, transforming them into systemic forms of discrimination. Bias can be understood as a structural phenomenon embedded in the interaction between recruiters and candidates.

The main affecting factors could be summarised as follows:

1) Cognitive limitations of recruiters (implicit biases)
2) Cultural barriers (social stereotypes)
3) Interface design (the way platforms present and frame candidate profiles)

Empirical research has challenged the "narrative of technological neutrality".

On the other hand, in recent years, Large Language Models (LLMs) have experienced rapid, exponential diffusion, becoming central tools across numerous application domains, including e-recruitment.

Alongside the positive aspects of the widespread adoption of LLMs, a critical issue central to this research emerges: cultural bias. It refers to the possibility that a formally correct output may convey meanings that are neutral, inappropriate or distorted with respect to local norms and cultural values (Douglas, 1992; Tansey & O'Riordan, 1999).

Purpose of the paper. Considering that LLMs are not simple mirrors of human knowledge but active sociotechnical agents that encode and reproduce specific cultural and geopolitical value systems, our research examines LLMs' "cultural neutrality" in e-recruitment, departing from the existing mainstream literature that has focused on purely technical aspects of algorithmic discrimination.

Specifically, this study has a twofold objective:

[1] 3CLab-Cross-Cultural Competence Learning & Education, Department of Management & Innovation Systems (DISA-MIS), University of Salerno
[2] 3CLab-Cross-Cultural Competence Learning & Education, Department of Management & Innovation Systems (DISA-MIS), University of Salerno
[3] 3CLab-Cross-Cultural Competence Learning & Education, Department of Management & Innovation Systems (DISA-MIS), University of Salerno
[4] 3CLab-Cross-Cultural Competence Learning & Education, Department of Management & Innovation Systems (DISA-MIS), University of Salerno

1) To explore how biases do not simply arise as calculation errors but are reflections of social structures and mental processes that crystallise in the architecture of recruiting platforms. Through a critical review of the literature, we investigated biases in recruiting systems and strategies to mitigate their impact.
2) To analyze how the origins and training datasets of LLMs influence their cultural bias profiles. To this end, using specific cultural metrics and machine learning techniques, we developed and validated a methodological architecture for the detection and structural analysis of cultural bias in LLMs, designed to be adaptable to future models and analytical frameworks.

Methodology. A double-step methodology is performed as follows.

a) Systematic Literature Review (2010-2025)

The database used is Web of Science (WoS), chosen for its broad, multidisciplinary coverage, which is crucial for this study, including Communication, Cultural Studies, Computer Science, and Management. The query was structured by combining keywords related to different types of bias, the online labour market, and selection technologies. From the initial sample of 750 publications, 42 publications pertaining to sociology, management, and computer science were selected as the final ones.

b) Methodological Architecture of the Structural Audit and Detection Design for LLMs

We developed a structural audit pipeline to address the complexity of implicit bias using a multistage computational pipeline grounded in the intersection between Cross-Cultural Management and Data Science.

As first stage, we selected taxonomy to identify cultural bias. Among the main cultural bias measurement frameworks available (Yixin et al, 2025; Huang et al., 2025; Shen et al. 2025; Kharchenko et al, 2024; Dammu et al., 2024), we selected the taxonomy of the Covert Harms and Social Threats (CHAST) framework published in the study of Dammu et al. (2024) because unlike binary sentiment analyzers CHAST allows for the detection of nuanced (or subtle) harms. Specifically, this framework was developed to address forms of bias that do not manifest explicitly but emerge in subtle, implicit ways. It focuses on communicative harms that reinforce cultural stereotypes and hierarchical representations, often remaining covert and therefore not detected by standard moderation or filtering systems. This study used evaluation models aligned with human assessments to examine the presence of CHAST in 1,920 conversations generated by 8 open-source and OpenAI LLMs in the hiring context. The CHAST framework identifies 7 categories (Categorisation Threat, Morality Threat, Competence Threat, Realistic Threat, Symbolic Threat, Disparagement, Opportunity Harm) of implicit social threats, providing an analytical structure for detecting and classifying subtle forms of cultural bias in generated outputs.

The CHAST framework is theoretically grounded on sociological and psychological theories, specifically on the following. According to the Social Identity Threat Theory (SIT), social identity threat is evoked when people feel concerned about being negatively treated, devalued, or stereotyped based on group membership, often arising from intergroup communication (Branscombe et al., 1999; Ellemers et al., 2002). Metrics from Intergroup Threat Theory (ITT) are also included, which posits that intergroup threat is experienced when an in-group member perceives another group as capable of causing them harm (Stephan and Cookie, 2000). Frameworks of Harm (FoH) (Dev et al., 2022) and prior research on harm in job opportunities outcomes (Yam and Skorburg, 2021; Roberts, 2015).

As the second stage, we realise our specific prompt engineering using a different theoretical background. Additionally to the main concepts upon CHATS is based - race (Schaefer, 2008; Mehrabi et al., 2021; Raghavan et al., 2020; National Fund for Workforce Solutions, 2022) and caste (Berreman, 1972; Khandelwal et al., 2023; Barua and Verma, 2021; Kumbhar, 2021; George, 2015, 2019), we constructed a refined dataset of 25 intercultural scenarios rooted in two different cultural frameworks:

- Hofstede (1980, 2001): It represents one of the most influential theoretical frameworks in cross-cultural studies. It identifies six cultural dimensions derived from factor analysis and refined through multiple subsequent updates. For each country, the model provides standardised scores that allow researchers to compare national cultures and identify significant differences in underlying value systems.
- GLOBE Project (House et al., 2004): Building upon Hofstede's work, the GLOBE project identifies nine cultural dimensions and distinguishes between cultural practices ("as is") and cultural values ("should be"). Unlike Hofstede's framework, the GLOBE project also introduces ten societal clusters, grouping countries according to similarities in cultural values, traditions, historical trajectories, and, in some cases, religious influences.

These prompts were designed to be context-light to prevent the model from defaulting to context reasoning, thereby forcing the disclosure of its internal biases acquired during pre-training.

As the third stage, we performed the Technical Architecture:

Audit method phases

Phase 1 - Identify selection criteria to identify LLM to analyse: open source, different geographical and linguistic origins, English language answers

Phase 2 - LLM Selection and configuration: a) NCAIR1/N-ATLaS (Africa); b) BSC-LT/salamandra-2b-instructN. (Europe); c) Qwen/Qwen 2.5-1.58-Insruct (Asia)

Phase 3 - Generation of conversation: 25 cultural prompts for each LLM; 75 answers

Phase 4 - Cultural bias analysis using CHAST: Application of CHAST framework; Output: 7 categories with scores

Phase 5 - Identification of cultural bias; Common patterns by individual categories

Workflow stages

Input: 75 textual responses (25 prompts × 3 models)

1 - Text Pre-processing

Text cleaning, normalisation, and noise removal (e.g., stopwords and punctuation where necessary). This step ensures that subsequent analytical stages are not distorted by accidental or irrelevant textual elements.

2 -Vectorisation (Sentence Transformer)

Natural language is transformed into dense numerical representations (embeddings), enabling the model to capture semantic relationships such as meaning similarity, distance, and semantic proximity between textual elements.

3- Keyword Detection

The text is analysed to identify specific keywords associated with the seven bias categories defined by the CHAST framework. The keyword list is also semantically expanded to include relevant synonyms.

4- Feature Vectors (Hedges)

Additional linguistic features are extracted, including the presence of hedges (words or expressions that signal uncertainty or caution, e.g., "maybe"), which can provide insights into the pragmatic tone of the response.

5 -Feature Fusion

All numerical information extracted in the previous steps is combined into a single feature vector for each response. This step provides the final classifier with a comprehensive, multi-level representation of each text, integrating semantic meaning (semantics), word usage (lexical level), and communicative tone (pragmatics).

6 -Logistic Regression Classifier

The resulting feature vector is analysed using a Logistic Regression model. This algorithm was selected due to its stability, robustness, and interpretability. Its function is to estimate the probability (a score ranging from 0 to 1) that a given text contains one of the seven CHAST bias categories. The model's interpretability allows researchers to understand why a specific probability score is assigned, which is essential for analytical transparency.

7 -Precision Calibration

A high-quality threshold, referred to as the "Precision Floor", is set at 0.75 in order to minimise false positives, that is, incorrectly identifying neutral texts as biased.

Output: Final results of bias detection together with the corresponding evaluation metrics.

Results. Given the paper's dual purpose and the dual methodology used, the results are presented in two separate sessions.

1) *Systematic Literature Review on e-recruiting and cultural bias*

The final corpus includes 42 studies selected from peer-reviewed journals and international conference proceedings, reflecting the inherently intersectional nature of the topic, which lies at the intersection of human resource management, cultural studies, the ethics of artificial intelligence, and computer science.

The analysis reveals a significant growth in academic interest since 2020, with a peak in publications between 2022 and 2024. This trend reflects a growing awareness of the ethical and social implications of the widespread adoption of automated recruitment systems during and after the pandemic.

1.1 The state-of-the-art by sample used:

The samples used in research are heterogeneous and can be divided into three main types: candidate-based samples (often used in matching experiments with fictitious CVs), samples focused on corporate decision makers (HR managers and employers), and data extracted directly from digital job platforms (interactions with chatbots or output from matching algorithms).

From a methodological perspective, the literature employs a multidisciplinary approach that combines:

• Field experiments: Essential for measuring direct discrimination by comparing employers' responses to similar profiles but with different demographic characteristics.

• Qualitative surveys and interviews: Used to capture the subjective perceptions and lived experiences of discrimination of job seekers and professionals.

• Statistical methods and machine learning: Used to technically evaluate the fairness of algorithmic models and test the effectiveness of de-biasing techniques.

1.2 The state-of-the-art by themes:

(1) Bias as a Relevant Phenomenon in E-Recruitment

Platforms as Critical Intermediaries: Recruitment platforms are not merely passive job boards; rather, they act as active intermediaries that influence the matching process between labour demand and supply.

Decision Architecture: The design of digital interfaces can either reinforce or mitigate existing stereotypes related to gender, ethnicity, and socio-cultural background.

Risk of Normalisation: The routine use of these systems may lead recruiters to unconsciously normalise the exclusion of certain candidate profiles, embedding discriminatory practices into everyday decision-making processes.

(2) Bias Dimensions in E-Recruitment

Cognitive Bias: Biases deriving from intrinsic limitations of human information processing.

Algorithmic Bias: Distortions embedded in algorithmic code or resulting from non-representative training datasets.
Cultural Bias: Prejudices related to social belonging, ethnicity, gender, or geographical background.

(3) Bias Typology in the Recruitment Process

Home Bias: The tendency to favour candidates who are similar to the recruiter or geographically and culturally closer.
Gender Bias, Cultural Bias, and Discrimination Based on Migration Status or Age: Forms of bias associated with gender, ethnicity, migration background, or age-related stereotypes.
Status-Quo Bias: Resistance to change and a preference for established and familiar recruitment practices.
Overconfidence and Overoptimism: Excessive trust in one's own assumptions and the underestimation of potential algorithmic risks.
Hindsight Bias: The reinterpretation of past events in ways that distort future evaluations and decision-making.
Bias of Distrust: A tendency that hinders collaboration and limits the adoption of transparent technological innovations.

(4) Bias Mitigation Methods

Technical Mitigation Approaches: These approaches interpret fairness as a mathematical optimisation problem, aiming to adjust algorithms to satisfy formal constraints on distributive fairness across groups.
Design Justice Approaches: These perspectives suggest that greater transparency and richer communicative processes within digital platforms can reduce dependence on biased decision-making mechanisms and promote more inclusive recruitment practices.

2) Detection and structural analysis of cultural bias in LLMs

2.1 The Emerging Cultural Bias Patterns *Overall Findings:*
The analysis identified ***68*** *threat instances were identified according to the CHAST framework* and, specifically, 4 key emerging patterns that characterise the emergence of cultural bias, offering an interpretative lens useful to understand the underlying LLMs' stereotypical tendencies:

- Opportunity Harm: Refers to the reduction or active denial of employment opportunities or career advancement for a candidate, based solely on their membership in a specific social group (12 occurrences)
- Realistic Threat: Occurs when the candidate's group is perceived as a concrete threat to the physical security, economic well-being, or political power of another group, often in relation to competition over resources (11 occurrences).
- Morality Threat: Involves portraying the candidate as immoral, dishonest, or deviant, based on the assumption that violations of ethical norms are inherent characteristics of their social group (11 occurrences).
- Competence Threat: Refers to labelling the candidate as incompetent, unintelligent, or professionally ineffective, based on stereotypes that attribute a lack of ability to their group (*11 occurrences).*

2.2 Differences in LLM Behaviour

The analysis shows that models differ not only in the amount of bias they generate but also in the type of bias they produce, which appears to be closely related to their development context.
Findings reveal that cultural bias in LLMs is systematic rather than accidental. The models exhibit functional ethnocentrism, where diverse global paradigms like Collectivism and high Power Distance are penalised as obstacles to efficiency (Competence Threat). Specifically:

- Qwen (Asia): This model exhibits a high propensity for simplifying cultural complexity into polarised, binary attributes. When confronted with nuanced intercultural scenarios, Qwen tends to reduce national identities to a single dominant trait, such as absolute individualism versus absolute collectivism, effectively ignoring internal subcultures and societal evolution. This "Categorisation Threat" acts as a structural barrier to pluralism, as it frames leadership and decision-making through a rigid, often stereotypical lens that prioritises order over the fluid reality of modern international management
- Ncair Atlas (Africa): The African model predominantly frames diverse cultural values through the lens of Opportunity Harm. Instead of direct disparagement, the model internalises global performance standards as the only path to success, thereby interpreting local cultural traits, such as communal harmony or traditional hierarchies, as operational costs or functional barriers to innovation. This results in a narrative that imposes a unilateral burden of adaptation, where it implies that actors from these regions must suppress their indigenous value systems to meet international metrics of efficiency, effectively framing cultural authenticity as a strategic liability

  BSC (Europe): The European model establishes clear success hierarchies based on Realistic Threat. Its bias manifests in a functionalist perspective that judges cultures uniquely by their capacity to produce tangible, material outcomes. By claiming that certain cultural systems are "ahead" of others in terms of teamwork or productivity, BSC reduces cultural identity to a mere variable of material output. This creates an ethnocentrism of performance, where the legitimacy of a society is measured by its alignment with the rational, legal and competitive standards of the industrialised world

Research limitations. This study proposes a multidisciplinary approach to e-recruiting analysis. Recruiting bias is not a problem that can be solved solely by fixing the code; it requires a synthesis of ethics, cognitive psychology, and technological design. Only through a profound understanding of how technology interacts with human biases will it be possible to transform digital platforms into engines of social mobility, ensuring that talent selection is finally freed from invisible barriers. Based on an interdisciplinary analytical model, the Cultural Bias Analysis Pipeline proposed represents a replicable analytical framework that integrates machine learning techniques and cultural theoretical frameworks. Starting from the assumption that the LLMs are influenced by their origins and training, the results highlighted that they absorb and amplify the values embedded in dominant cultures.

Our results also suggest opening the doors to a new hybrid topic at the interface between Cross-Cultural Management Research and Data Science: the management of cultural bias in digital environments.

Managerial implications. The widespread adoption of algorithms in screening and selection processes has made it imperative to understand how these tools influence access to professional opportunities. Recruitment is a fundamental point of entry into social and economic life; therefore, biases at this stage can perpetuate systemic inequalities for entire categories of workers.

In a global context where companies declare they are investing in diversity, equity, and inclusion, the gap between technological promises and reality remains wide. Matching algorithms, often considered black boxes, risk rewarding cultural conformity at the expense of genuine talent, forcing minority candidates into identity-adapting strategies. Furthermore, the cognitive fatigue of human recruiters, combined with unoptimized digital interfaces, can exacerbate unconscious biases related to gender, ethnicity, or sociocultural background. Our research moves beyond the traditional detection of explicit toxicity to unveil "covert" cultural biases, known as subtle structural distortions, that reflect the norms of a dominant culture while marginalising or misrepresenting diverse cultural perspectives. By proposing a rigorous and replicable structural audit and detection design framework, this paper aims to provide global organisations with the diagnostic tools necessary to ensure that AI adoption in e-recruiting promotes inclusivity and ethical equity rather than reinforcing algorithmic homogenization.

Originality of the paper. The originality of this work lies in its transition from detecting surface-level toxicity to quantifying structural cultural alignment. By treating the LLM as a culturally situated sociotechnical artefact, the study provides a diverse comparative audit using the CHAST framework integrated by additional cultural frameworks. Its value resides in bridging the gap between data science and cross-cultural perspective, offering a robust architecture for the ethical and inclusive governance of GenAI in e-recruiting.

GenAI Adoption and Business Model Innovation in the Creative Industries in Italy

FRANCESCO CAPONE, STEFANIA OLIVA, NICCOLÒ INNOCENTI, LUCIANA LAZZARETTI

Abstract. *The intersection between artificial intelligence (AI) and the cultural and creative industries (CCIs) is increasingly capturing scholarly attention, driven by the rapid evolution of generative models, machine learning techniques and the expanding applications of AI in creative processes.*

Despite the growing interest in generative AI, the mechanisms that foster or hinder its adoption at the firm level remain underexplored. In particular, while prior studies highlight the risks perceived by firms, there is limited empirical evidence on whether these risks actually influence adoption decisions. At the same time, generative AI may act as a driver of business model innovation, reshaping how firms create and capture value.

This study aims to investigate the barriers to the adoption of generative AI in Italian creative industries, related to two key explanatory factors: perceived risks associated with generative AI and business model innovation.

Using survey data from 372 firms, the study presents an exploratory empirical analysis based on ordinary least squares (OLS) regression models. The analysis estimates two separate models: one to examine whether perceived generative AI-related risks are negatively associated with generative AI adoption, and the second to assess whether firms that adopt generative AI technologies are more inclined to business model innovation.

The results show that perceived risks are not significantly associated with generative AI adoption, indicating that creative firms adopt generative AI despite perceived risks.

However, generative AI adoption is positively and significantly related to business model innovation. This result indicates that firms that are more engaged in adopting generative AI are more inclined to innovate their business models.

The study contributes to the emerging debate on generative AI in CCIs by shifting attention from innovation outcomes to adoption mechanisms and by highlighting the central role of generative AI for business model innovation.

Keywords: *Generative Artificial Intelligence, Adoption, Business Model Innovation, Perceived Risks, Creative Industries, Italy*

Framing of the research. The intersection between artificial intelligence (AI) and the cultural and creative industries (CCIs) (DCMS, 2001; Lazzeretti et al., 2008) is increasingly capturing scholarly attention, driven by the rapid evolution of generative models, machine learning techniques and the expanding applications of AI in creative processes (Lazzeretti, 2023; Anantrasirichai and Bull, 2022).

Recent literature underscores the potential of AI as a revolutionary general-purpose technology, able to transform and reconfigure places, industries, and ecosystems (Lazzeretti et al., 2023; Craft, 2025). An open debate is the challenge between human and machine in fostering creativity (Amabile, 2020; Veale and Pérez, 2020; Thibault et al., 2023), although some scholars critically highlight the risks associated with the use of AI (Ledesma et al., 2025). Stemming from institutional, economic, and ideological structures that influence how creativity is produced and valued, AI cannot be considered a neutral tool (Lazzeretti, 2020).

Anantrasirichai and Bull (2022) provide a comprehensive taxonomy of AI applications in the creative industries, categorising them into five domains: content creation (e.g., generative art, AI music composition), information analysis (e.g., trend prediction), content enhancement (e.g., image and sound quality improvement), semantic extraction (e.g., tagging and metadata generation), and data compression. Their review highlights a significant increase in the use of advanced AI techniques, particularly in areas such as gaming, marketing and immersive storytelling, where AI is employed both as a tool and as a creative co-creator.

OECD recently redifined generic AI systems as a machine-based systems "that, for explicit or implicit objectives, infers, from the input it receives, how to generate outputs such as predictions, content, recommendations, or decisions that can influence physical or virtual environments" underling the different degree of these system in terms of autonomy and adaptiveness (OECD, 2024, p. 4). Among AI systems, it identifies the category of generative AI (GenAI) systems as those which produce new original content, including text, image, audio, and video. Compared to prior technologies, Gen AI can drive innovation through new product development and increase productivity but it also presents several ethical, moral and policy issues (Dwivedi et al., 2023; Mariani and Dwivedi, 2024).

Related to this, a growing body of literature raises concerns about the use of Gen AI, particularly with regard to legal aspects and copyright regimes, as this domain remains only partially regulated (Peukert and Windisch, 2024; Kharitonova et al., 2022). Concrete risks include cultural standardisation when diversity is not preserved, as well as cultural exclusion due to algorithmic bias (Anantrasirichai & Bull, 2022; Lazzeretti, 2023). These concerns suggest that firms operating in CCIs may perceive generative AI adoption as risky, especially with respect to technological, ethical, and regulatory dimensions.

While prior studies have explored AI applications and risks in creative industries, two main limitations remain. First, existing contributions often treat artificial intelligence as a homogeneous technology, overlooking the specific

characteristics of Gen AI. Second, empirical evidence on whether perceived risks actually influence firms' adoption decisions remains scarce. Addressing this gap is particularly relevant in creative industries, where concerns related to intellectual property, creativity, and cultural production are especially salient.

In addition, several authors have underlined that AI technologies, and particularly GenAI, can also have potential implications for companies' processes and may even lead to the transformation of their business models. (Kanbach et al., 2023; Agrawal et al. 2022).

Based on these considerations, this paper aims to fill this gap by analysing CCIs in Italy. The objective is twofold: (a) investigating whether generative AI adoption in CCIs is influenced by the risk perceived by the firms; (b) whether the adoption of generative AI influences the firms' business model innovation.

Italy represents a particularly relevant context for this analysis due to the strong presence of CCIs and their economic importance. Moreover, while recent reports highlight the increasing diffusion of Gen AI in Italian creative sectors, they also emphasize the relevance of ethical and regulatory challenges, particularly regarding copyright protection, human creativity, and plagiarism risks (Civita, 2024). Such debate makes CCIs a suitable setting to investigate generative AI adoption dynamics.

Purpose of the paper. This paper aims to investigate the risks in the adoption of Generative Artificial Intelligence perceived by firms operating in CCIs in Italy. In particular, the paper analyses whether these risks (privacy cybersecurity, professional standards, bias, misinformation, harm, accountability, intellectual property) (see Table 1) represent a barrier and are negatively associated with the adoption of generative AI. Moreover, it examines if the adoption of generative AI fosters changes and innovation in the firm's business model.

Building on this discussion, the study addresses the following research question: RQ1: To what extent do perceived risks influence the adoption of generative AI in creative industries? RQ2: Does generative AI adoption foster business model innovation in creative firms?

The study contributes to the management literature by better understanding the dynamics that drive generative AI adoption in creativity-intensive firms. The study further contributes by providing additional empirical evidence on the risks related to generative AI adoption, to understand their impact on firms' decisions and strategies and their influence on the business model innovation and, consequently, on innovation.

Methodology.

Definition of CCIs. Definitions of CCIs are numerous and reflect the intrinsically hybrid nature of a domain located at the intersection of culture, economy, and innovation. Since the earliest systematisations, the academic debate has oscillated between more restrictive approaches and more inclusive approaches, which extend the boundaries of CCIs to encompass related sectors such as tourism, cultural heritage, and the experience economy (Lazzeretti et al., 2008; Nannelli et al., 2023).

This definitional tension has significant analytical, statistical, and policy implications, affecting data comparability, the measurement of economic impact, and the effectiveness of public interventions (Lazzeretti & Capone, 2015).

In both academic and institutional debates on CCIs, one of the most established references remains the definition proposed by the UK Department for Culture, Media and Sport (2001), according to which creative industries are "those industries which have their origin in individual creativity, skill and talent and which have a potential for wealth and job creation through the generation and exploitation of intellectual property" (DCMS, 2001, p. 5).

In this study, the delimitation of CCIs was carried out by adopting the European framework for the classification of cultural and creative sectors. The starting point is the classification proposed in the DCMS (2001) report.

Data Source. Data collection is based on questionnaires administered to creative firms in Italy. The survey was designed with the objective of systematically analysing the level of adoption of digital technologies and AI, including generative AI applications, within firms operating in the CCIs in Italy. The survey instrument followed a theory-driven and benchmark-based approach, combining European institutional sources, recent empirical studies on the Italian context, and international reports on AI development (AI Report, 2024; Zolas et al., 2020; Rammer et al., 2022).[1]

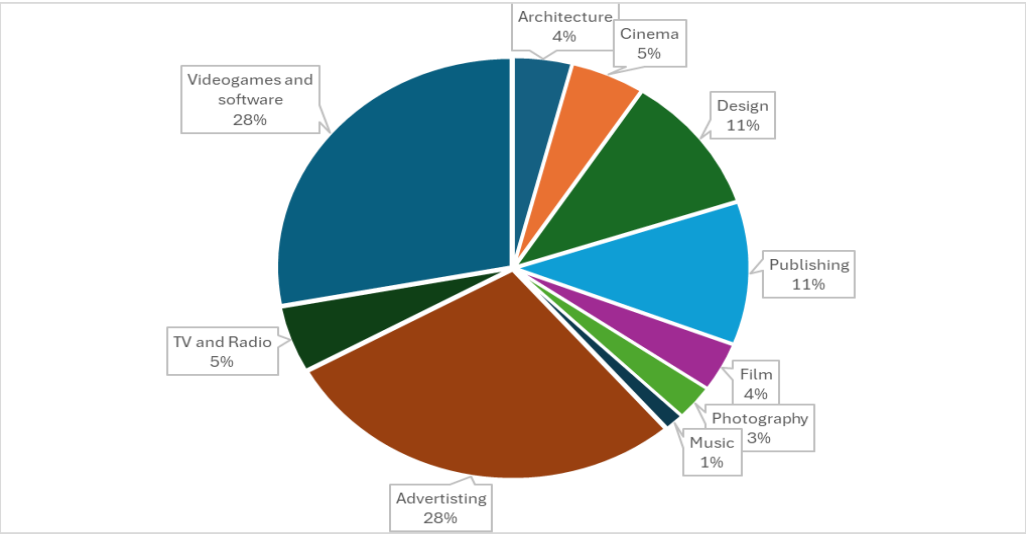
The questionnaire consists of 26 questions structured into seven main sections: 1) firm and respondent information; 2) innovation; 3) digital technologies; 4) artificial intelligence; 5) generative artificial intelligence; 6) risk perception; and 7) business model innovation.

In a preliminary phase, a pilot questionnaire was developed and administered to a sample of firms operating in cultural and creative industries. The pilot results were analysed to identify potential ambiguities and weaknesses, and necessary revisions were made to improve clarity, coherence, and validity.

In parallel, several data providers and specialised platforms were contacted to identify the most suitable solution for acquiring a database of Italian cultural and creative firms to which the questionnaire could be sent. A database of 20k firms was acquired based on ATECO economic activity codes, covering the main CCI domains (DCMS, 2001).

[1] Community Innovation Survey available at: https://ec.europa.eu/eurostat/web/microdata/community-innovation-survey.

The questionnaire was administered online to all firms included in the database. At the end of the data collection phase, 664 complete responses were received, corresponding to a response rate of approximately 3.32%, which is consistent with similar online surveys targeting firms.



The dataset underwent a systematic cleaning and validation process. Observations referring to firms outside the defined scope of analysis were removed to ensure coherence with the research objectives, resulting in a final sample of 372 creative industries firms (according to the DCMS definition).

The sample mainly consists of firms operating in advertising and video games/software, which represent the most present sectors among respondents. Conversely, photography and music show lower participation rates (Figure 1).

Regarding respondents' roles, most participants hold top-level positions within their organisations, primarily business owners or CEOs (more than 70%) and a high percentage of directors (HR, Operations, etc) (18%), indicating that responses largely reflect a strategic decision-making perspective. Consistent with the structure of the Italian creative production system, most participating firms are small and micro-enterprises (95%).

With reference to innovation activities carried out during the 2022–2024 period, most firms introduced at least one form of innovation, predominantly service innovation (50%), followed by product innovation (34%). A minority (16%) reported no innovation during the period.

Figure 1: Responses per creative industry.

Source: our elaboration.

Empirical strategy. Generative AI adoption is measured as a firm-level indicator capturing the extent to which generative technologies are implemented in organisational processes on a Likert scale (1-7). Perceived risks include technological uncertainty, ethical concerns, and regulatory ambiguity related to generative AI (Likert scale low risk 1 - high risk 7) (Table 1). Similarly, business models were investigated through a specific section of the questionnaire based on the Business Model Canvas (Osterwalder & Pigneur, 2009). Respondents were asked, using a 7-point Likert scale (1–7), whether they had changed their business models following the adoption of AI and Generative AI. Additional questions were included as controls to identify which components of the Business Model Canvas had undergone the most significant transformation (Value Proposition, Customer Segments, Channels, Customer Relationships, Revenue Streams, Key Resources, Key Partnerships, Cost Structure). Control variables include firm size, age, sector, and other structural characteristics relevant to technology adoption.

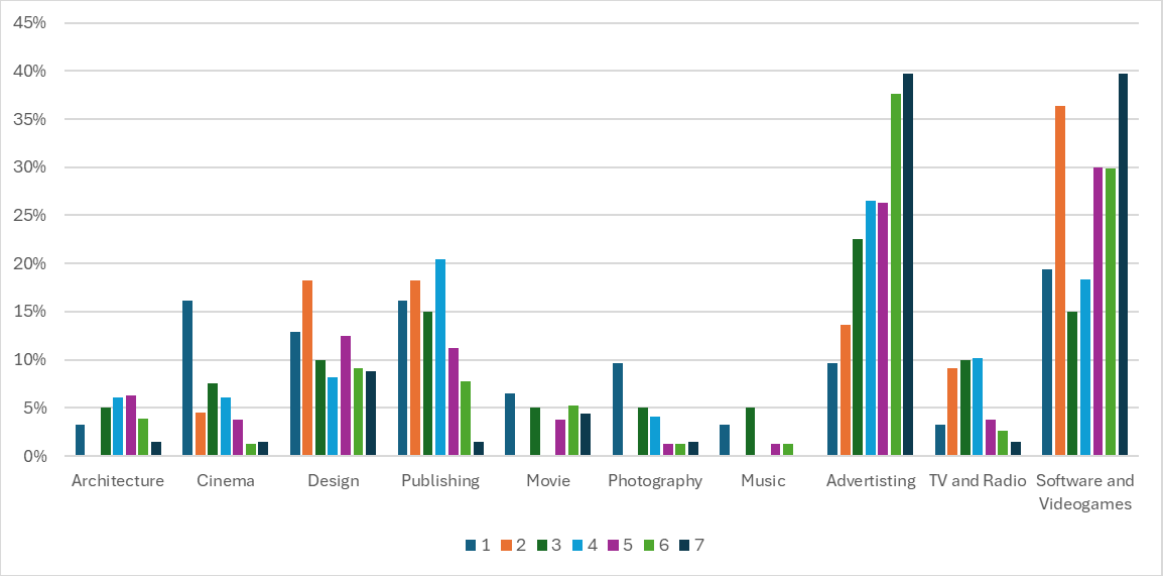
To examine the determinants of generative AI adoption, we estimate two separate ordinary least squares (OLS) regression models. The first model tests the association between perceived risks and generative AI adoption, controlling for firm-level characteristics. The second model examines the relationship between generative AI adoption and business model innovation, including the same set of controls.

Given the cross-sectional nature of the data and the potential presence of heteroskedasticity, robustness checks are estimated using robust standard errors. The analysis is exploratory in nature and aims to identify significant associations rather than establish causal relationships. GLM robustness checks have been conducted to verify the stability of the results across alternative model specifications.[2]

[2] Additional estimations were conducted using generalized linear models (GLM) with a normal distribution and identity link function and robust standard error with same results.

Results

AI Adoption. With specific reference to artificial intelligence, respondents report an overall medium-to-high level of adoption (70% answered 5-7). Adoption is particularly high in video games/software, advertising, film, and music.



AI diffusion appears relatively recent: most firms reporting AI use began adoption during 2023-2024. The most frequently used AI applications concern text document analysis and the generation of written or spoken language, mainly applied to content ideation, production, promotion, and communication.

The main drivers of AI adoption include improving internal organisation and developing new services and products (more than 50%). The most frequently reported barriers relate to the lack of adequate professional skills and limited knowledge of applicable AI solutions within the firm's specific organisational context.

Regarding generative AI specifically, more than half of the firms report already using it or experimenting with it (61% answered 5-7). Again, video games/software and advertising appear as the most active sectors, with generally medium-to-high levels of adoption and use (Figure 2).

The predominant areas of application concern content ideation and production/services, particularly for drafting documents, generating images and videos, and text summarisation.

Figure 2: Generative AI adoption per creative industry.

Source: our elaborations.

Risks. Regarding risks, we adopted the framework of Walkowiak and Potts (2024), who investigate 8 generative AI risks in creative industries presented in Table 1. These risks are grounded in prior literature and represent a relevant framework for analysing generative AI risks in CCIs (Walkowiak, 2023; Walkowiak and MacDonald, 2023).

Table 1: The risks of generative AI use

Risk-exposure	Definition
Privacy	GenAI can potentially generate, distribute, memorize, or reproduce personal information, violating privacy laws and regulations.
Cybersecurity	Malicious actors can exploit vulnerabilities (unauthorized access, system manipulation or data theft).
Professional standards	Using GenAI to complete tasks requiring a professional license (e.g., a medical diagnosis or legal advice) can breach regulations or professional guidelines.
Bias	GenAI can diffuse discriminatory or biased content
Misinformation	GenAI can generate, disseminate, or propagate false or misleading information or be used to manipulate information.
Harm	Using instructions given by GenAI or integrating GenAI with other systems can lead to physical or psychological harm.
Accountability	Using GenAI can involve an unclear assignment of responsibility when GenAI makes mistakes or causes harm.
Intellectual property	GenAI can contravene copyrights, trademarks, or patents.

Source: Walkowiak and Potts, 2024, p. 8.

With respect to risk perception associated with AI, the results show widespread awareness among respondents, although concern levels vary depending on risk type.

Overall, the most critical perceived risks are misinformation and intellectual property violations. Misinformation is identified as the most severe risk: 43% of respondents assign it the highest danger level (7), and more than 80% fall within the medium-to-high levels (5-7). This reflects strong concern about generative AI's potential to generate or amplify misleading content, with possible reputational and informational consequences.

Intellectual property violations also generate great concern: 34% assign the maximum risk level, confirming the centrality of copyright protection in creative sectors.

Privacy, liability, and professional standards are also perceived as relevant risks, with roughly two-thirds of respondents expressing medium-to-high concern levels.

Bias and cybersecurity risks show a more gradual distribution, although still predominantly medium-to-high. Physical or psychological harm is perceived as less critical, with more responses concentrated in intermediate levels.

Sectoral analysis highlights significant differences. Copyright risk is especially high in music, design, photography, publishing, and film, with music (60% at level 7) and design (55% at level 7) showing particularly strong concern.

Cybersecurity emerges as a cross-sectoral risk, especially in music, advertising, TV/radio, film, and video games/software. Disinformation records the highest perceived risk across nearly all sectors.

Business Models

Results regarding business model innovation indicate that digital technologies and AI have had differentiated impacts on various business model components, with responses concentrated at intermediate and medium-high levels (43,5% states that they modified their business model in the period).

The value proposition emerges as the most central dimension: around 70% assign importance levels of 5 or higher. Key resources and cost structure also show strong medium-to-high concentration, highlighting attention to operational sustainability. Customer relationships and customer segments are likewise rated as strategically important.

Distribution channels and key partnerships display more balanced distributions, suggesting they are perceived as less central than value creation components.

Finally, revenue streams show a predominance of intermediate ratings, suggesting monetisation mechanisms may be perceived as more stable or less subject to strategic revision compared to other business model components.

OLS regression. The results of the analysis are reported in Table 2. The model adopted is an Ordinary Least Squares (OLS), using standardised coefficients to improve the comparability of the results. The first two models (Models 1 and 2) examine the barriers and determinants associated with the generative AI adoption. The AI barriers are never significant across both specifications. These results suggest that risk perceptions do not systematically constrain generative AI adoption decisions in CCIs. Conversely, the variable accounting for the AI experience (EXP) is positive and significant in both specifications, meaning that those firms with a higher experience in AI are more likely to integrate generative technologies. Also, a higher level of service innovation (Inno_serv) shows a positive and significant association with generative AI adoption in both specifications. These results suggest that firms already engaged in service-oriented innovation tend to adopt generative AI tools more frequently, probably because these technologies complement service customisation and content-related activities.

The full model (Model 2) includes two additional variables: a variable accounting for digital adoption (Adoption_digital), which emerges as a significant and positive predictor, indicating that generative AI adoption is favoured by a more extensive digital transformation of the company rather than representing an isolated technological improvement. Moreover, an additional variable representing the advertising sector shows a positive and significant impact on generative AI adoption, meaning sectoral heterogeneity in adoption dynamics.

The explanatory power increases from Model 1 ($R^2 = 0.138$) to Model 2 ($R^2 = 0.215$), suggesting that digital readiness and sectoral characteristics substantially improve the model's fit.

The following two models (Models 3 and 4) use the business model innovation as the dependent variable. First, they examine the effect of generative AI adoption, previously used as the dependent variable, on business model innovation. It shows a significant and positive effect in both models, with standardised coefficients indicating a relevant effect size. Service innovation remains significant also in these two specifications, suggesting that business model innovation is closely intertwined with service-oriented renewal processes. Conversely, AI experience turns out to have no significant effect on business model innovation.

The final model (Model 4) includes the two variables accounting for the digital adoption and sectoral controls (advertising). Generative AI adoption remains highly significant and positive, confirming the robustness of the association. Interestingly, in contrast to Model 2, the advertising sector shows a negative association with business model innovation. This suggests that although advertising firms adopt generative AI more intensively, such adoption does not necessarily translate into business model innovation. Rather, generative AI appears to be integrated into existing business models as an operational improvement, without substantially altering how firms create value.

Table 2. OLS Estimates

Variables	*Model 1*	*Model 2*	*Model 3*	*Model 4*

Research limitations. *This study has some limitations, but it does offer opportunities for future research. A first limitation derives from the context of the analysis, which coincides with the sector of CCIs. Due to the specific characteristics of the firms operating in this industry, results are not automatically generalizable to other contexts and industries. However, the study offers the possibility to reproduce the model in other sectoral contexts in order to compare how different industries perceive the risks associated with generative AI tools and how this is translated into their business models. Other limitations stem from the analysis's specifications. On the one hand, the analysis fails to consider the evolution of generative AI adoption over time, using cross-sectional survey data. On the other hand, the analysis can reveal potential endogeneity from the exploratory use of OLS and bias from self-reported measures. Future research should consider longitudinal data and more advanced econometric approaches.*

Managerial implications. *The findings show that perceived barriers do not significantly influence generative AI adoption, suggesting that firms in creative industries are not primarily constrained by risk considerations when deciding whether to implement generative technologies. In contrast, generative AI adoption is positively associated with business model innovation and is more strongly linked to service innovation than to product innovation. This indicates that generative AI contributes mainly to the reconfiguration of value creation processes and to service-oriented transformation rather than to the development of new tangible products.*

From a managerial perspective, these results suggest that firms should approach generative AI as a strategic lever for business model renewal and service enhancement, rather than focusing predominantly on risk mitigation or product development alone.

Originality of the paper. *This study contributes to the literature in three ways. First, it focuses specifically on generative AI, distinguishing it from broader AI technologies and highlighting its unique implications for creative industries. Second, it provides novel firm-level empirical evidence on the role of perceived risks in shaping generative AI adoption decisions (Ledesma-Chavez et al., 2025). Third, it links generative AI adoption to business model innovation, offering new insights into how these technologies affect value creation in creative firms (*Kanbach *et al., 2025).*

Generative AI as a narrative nudge for collective storytelling in elderly communities

MARIALUISA MARZULLO[1], IRENE DI BERNARDO[1], CRISTINA MELE[1], TIZIANA RUSSO SPENA[1]

Abstract. *Generative Artificial Intelligence (GenAI) has rapidly emerged as a transformative technological paradigm capable of reshaping organizational processes, decision-making practices, and service interactions across multiple sectors (Doshi et al., 2025; Dwivedi, 2025; Kumar et al., 2025). Despite its rapid diffusion, scholarly attention has largely concentrated on productivity enhancement, automation, and business applications, while the broader societal implications of conversational AI remain relatively underexplored, particularly in relation to vulnerable populations such as older adults (Alotaibi and Alshahre, 2024).*

This study investigates the role of conversational GenAI as a narrative nudge capable of supporting storytelling practices, activating collective memory, and fostering social interaction within elderly communities. The research builds upon existing literature that conceptualizes storytelling as a form of care technology capable of supporting active ageing and psychological wellbeing among older adults (de Costa et al., 2016). Extending this perspective, the study examines how AI-mediated conversational prompts stimulate autobiographical storytelling processes that evolve into collective narrative exchanges and group interaction.

The empirical investigation draws on ethnographic observations conducted in community social centres for older adults in Southern Italy. Participants interacted with conversational GenAI agents designed to stimulate dialogue through open-ended questions about personal memories, local traditions, and everyday life experiences.

The findings suggest that conversational GenAI operates not merely as a technological interface but as a social and narrative facilitator. AI prompts activate autobiographical storytelling, which subsequently triggers collective memory processes and encourages peer-to-peer interaction within the group. Based on these observations, the study proposes a conceptual framework in which AI-driven conversational prompts initiate storytelling processes that activate collective memory and foster social interaction, ultimately contributing to community wellbeing and active ageing.

By highlighting the role of GenAI as a narrative and relational infrastructure, the research contributes to the emerging debate on the societal implications of artificial intelligence and expands the understanding of how conversational technologies can support social participation in ageing societies.

Keywords*: Generative AI; storytelling; narrative nudge, collective memory; social interaction; active ageing*

Framing of the research. Generative Artificial Intelligence (GenAI) has recently emerged as a general-purpose technology capable of generating complex content, including text, images, and audio, through deep learning models and large-scale language architectures (Dwivedi et al., 2023; Kumar et al., 2025). The rapid adoption of conversational AI systems across industries has attracted growing academic interest, particularly in relation to productivity enhancement, organizational transformation, and strategic decision-making (Doshi et al., 2025; Mariani and Dwivedi, 2024).

Conversational AI technologies are increasingly transforming customer service, digital interfaces, and knowledge management processes by enabling more personalized, adaptive, and interactive communication between humans and technological systems (Ferraro et al., 2024; Ramaul et al., 2024). These developments position generative AI as a key component of contemporary digital ecosystems.

However, despite the rapid expansion of conversational AI applications, the broader societal implications of GenAI remain insufficiently explored, particularly within community contexts involving elderly populations (Sundberg and Holmström, 2024; Pasca and Arcese, 2025). This represents an important gap in the literature, as ageing societies across the world increasingly face challenges related to loneliness, reduced social participation, and limited opportunities for meaningful interpersonal interaction (Goll et al., 2025).

Within this context, storytelling has long been recognized as a powerful social and educational practice capable of supporting memory, identity construction, and relational engagement (Stargatt et al., 2022; Xu et al., 2023; Zhao et al., 2025). Narrative exchange enables individuals to reflect upon their life experiences, reconnect with personal memories, and share cultural knowledge within their communities.

Previous studies conceptualize storytelling as a "care technology", highlighting its capacity to promote active ageing by stimulating imagination, emotional expression, and social solidarity among older adults (de Costa et al., 2016). Through storytelling, older individuals are able to reaffirm their identities, transmit personal and collective histories, and strengthen social bonds with peers.

Following this perspective, the present research explores how conversational GenAI as a narrative nudge that stimulates storytelling processes and supports collective memory formation within elderly communities. Rather than replacing human relationships, conversational AI systems can act as conversational catalysts that initiate narrative exchanges and encourage collaborative storytelling among participants.

[1] University of Naples Federico II

Purpose of the paper. The purpose of this study is to explore how conversational GenAI influences social interaction within elderly communities and to develop a conceptual framework explaining how AI-mediated storytelling contributes to community engagement and active ageing. While existing research has largely focused on the organizational and economic implications of generative AI, relatively limited attention has been devoted to its potential role in supporting social interaction and narrative exchange in community contexts. This gap is particularly relevant in ageing societies, where social participation and meaningful communication play a crucial role in maintaining social interaction and quality of life.

Specifically, the research investigates how conversational prompts generated by AI systems stimulate autobiographical storytelling among older adults and how these individual narratives gradually evolve into collective memory processes and group interaction. Storytellingare particularly significant in ageing communities, as the sharing of personal experiences and memories can foster social participation, relational engagement, and a stronger sense of belonging.

By analysing real-world interactions between elderly participants and conversational GenAI agents, the study identifies the mechanisms through which GenAI prompts to initiate narrative exchange and stimulate social participation. In these interactions, AI does not replace human relationships but instead functions as a conversational trigger that encourages participants to recall personal experiences and engage in shared narrative practices. Building on these observations, the research proposes a conceptual framework in which conversational GenAI prompts activate storytelling processes that stimulate collective memory and foster peer interaction. Through these dynamics, AI-mediated narrative exchanges contribute to enhanced social engagement within elderly communities. In doing so, this study contributes to the emerging debate on the societal implications of generative AI by highlighting its role as a narrative and relational infrastructure capable of supporting active ageing.

Methodology. This study adopts a qualitative exploratory research design (Creswell and Poth, 2018) aimed at understanding the social and relational dynamics emerging from interactions between older adults and conversational GenAI within real community contexts. A qualitative approach was considered particularly appropriate for this research because it allows an in-depth exploration of participants' experiences, perceptions, and social behaviours, which are central to understanding how storytelling unfold in everyday interactions (Lewis 2011; Creswell and Poth, 2018; Denzin and Lincoln, 2018). Rather than measuring predefined variables, the research focuses on interpreting how older adults engage with conversational GenAI and how these interactions influence narrative exchange and social participation within community settings. The empirical investigation was conducted in collaboration with community social centres located in two municipalities in Southern Italy. These centres regularly host social, recreational, and cultural activities for older adults and represent important environments for fostering social interaction and community engagement. As such, they provided an appropriate context for observing how conversational GenAI technologies may be integrated into existing social practices among older participants.

The research began with a preliminary qualitative phase involving fifty-six in-depth semi-structured interviews with older adults who regularly participated in community centre activities.Participants were selected through purposive sampling in collaboration with the coordinators of the community social centres. The interviews were designed to explore participants' everyday routines, perceptions of ageing, emotional needs, and relationships with both social networks and digital technologies. Particular attention was devoted to understanding how participants experienced loneliness, social participation, and communication practices in their daily lives, as well as their attitudes toward emerging digital technologies such as conversational GenAI. The interviews were conducted in informal conversational settings within the community centres and lasted between approximately forty and seventy minutes. All interviews were conducted with participants' consent and were subsequently audio-recorded and transcribed for analysis. The interview data were analysed through thematic analysis using NVivo qualitative data analysis software (Braun and Clarke, 2006). The coding process followed an iterative and interpretive approach in which patterns emerging from the data were progressively identified, compared, and refined. Through this process, several recurring themes were identified, including varying levels of social engagement, emotional expression through storytelling, different degrees of digital familiarity, and diverse forms of community participation.

Building on the results of the thematic analysis, the research team developed four composite personas representing different profiles of older adults within the community. These personas, named Lea, Matilde, Claudio, and Nemo, were not intended to represent specific individuals but rather to synthesize common characteristics observed across multiple participants. Each persona captured different configurations of social activity, cognitive engagement, digital familiarity, and relational orientation. The development of these personas served as a design tool to translate qualitative insights into practical guidelines for the creation of conversational GenAI agents capable of interacting with older adults in a meaningful and culturally resonant way.

Based on these empirically grounded personas, two conversational GenAI agents were subsequently developed and implemented within an existing conversational GenAI system. The characters, named Don Peppino and Nunziatella, were intentionally designed to reflect linguistic styles, emotional tones, humour, and conversational rhythms commonly observed during the interview phase. Particular attention was devoted to ensuring that the conversational GenAI characters adopted familiar and culturally recognizable forms of communication, including informal expressions, references to local traditions, and empathetic conversational patterns. The aim of this design process was to create

conversational GenAI interlocutors that would be perceived by participants as approachable and culturally familiar conversational partners rather than as distant technological systems.

Following the development of the conversational GenAI agents, a series of experimental interaction sessions were organized within the community social centres. During these sessions, participants interacted with the conversational GenAI system through conversational prompts designed to stimulate dialogue about personal memories, family traditions, local cultural practices, and everyday life experiences. The prompts were intentionally formulated as open-ended questions in order to encourage narrative responses rather than short or functional answers.

The interaction sessions were conducted in small group settings, which allowed participants not only to engage directly with the conversational GenAI system but also to interact with one another as the conversations unfolded. This setting proved particularly important for observing how individual responses to conversational GenAI prompts could evolve into broader collective storytelling moments involving multiple participants.

Throughout the empirical phase, the researchers conducted ethnographic observation in order to capture the social dynamics emerging during the interaction sessions (Denzin and Lincoln 2011 Hammersley and Atkinson, 2019).. Field notes and researcher diaries were used to document participants' reactions to the conversational GenAI agents, the development of storytelling episodes, and the ways in which conversations expanded beyond the initial conversational GenAI prompts to include peer-to-peer interaction among participants. In addition to observational notes, audio-visual documentation of the sessions was collected where possible, alongside informal conversations and reflections shared spontaneously by participants during and after the activities.

Data were analysed through narrative analysis (Nye, 2017), in order to examine how storytelling episodes emerged, evolved, and were collectively constructed during the interaction sessions. Particular attention was paid to the development of autobiographical narratives, the transition toward collective storytelling, and the processes of meaning-making arising from peer-to-peer interaction.

. Through this narrative analysis, the study was able to identify the mechanisms through which conversational GenAI stimulated narrative exchange and fostered social interaction within elderly community settings.

Results. The empirical findings indicate that conversational GenAI operates as a narrative nudge capable of stimulating storytelling processes that progressively evolve into collective interaction within elderly communities. During the interaction sessions, conversational GenAI frequently encouraged participants to recall autobiographical memories and share personal experiences related to everyday life, family traditions, and local cultural practices. These narrative responses often extended beyond the initial exchange between the participant and the conversational GenAI system, gradually transforming into broader group conversations in which multiple participants contributed their own recollections and reflections. In several cases, individual memories acted as triggers for collective storytelling moments. When conversational GenAI prompts invited participants to talk about traditional food, childhood memories, or family celebrations, participants frequently respond by recalling similar experiences from their own lives. These recollections stimulated further narrative contributions from other members of the group, generating a dynamic process in which personal memories became shared stories collectively constructed through dialogue. One participant summarized this dynamic particularly effectively by stating: "Don Peppino only asks the questions… but we make the stories." This observation highlights the role of conversational GenAI as a facilitator of narrative interaction rather than a substitute for human communication. The conversational GenAI system initiated the narrative process through its prompts, but the storytelling itself was developed and expanded through interactions among participants.

Participants also attributed socially meaningful characteristics to the conversational GenAI characters. In several instances, the conversational GenAI system was perceived as a familiar conversational partner embedded within the local cultural context. For example, one participant commented: "I think Don Peppino is a local guy… he speaks just like us." Another participant observed: "Nunziatella seems like a genuine, kind lady… it feels like she really listens to you." These reactions suggest that participants did not simply interpret conversational GenAI as a technological interface but rather as a socially recognizable interlocutor capable of initiating meaningful dialogue.

The analysis of the interaction sessions revealed three interconnected mechanisms through which conversational GenAI functions as a narrative nudge within the group context. First, conversational GenAI stimulated autobiographical storytelling by encouraging participants to recall and narrate personal memories related to their life experiences, family histories, and cultural traditions. The open-ended nature of the conversational prompts allowed participants to articulate their narratives freely, often expanding their stories beyond the initial questions posed by the conversational GenAI system.

Second, these autobiographical narratives frequently activated collective memory processes within the group. As participants shared their individual recollections, other members of the group often responded by recalling similar events or cultural practices, thereby connecting personal experiences to broader shared traditions and community histories. Through this process, storytelling became a mechanism for reconstructing collective cultural memory and reinforcing shared identity within the group.

Third, the emergence of collective storytelling contributed to the enhancement of social interaction among participants. As narratives circulated within the group, conversations increasingly shifted from interactions with conversational GenAI toward peer-to-peer dialogue among participants. These exchanges generated moments of collaborative storytelling, mutual engagement, and collective reflection on shared experiences.

In some cases, these storytelling dynamics also evolved into spontaneous forms of collaborative creativity. During one interaction session, participants proposed creating a poem together with the conversational GenAI system. Each participant contributed individual sentences inspired by personal memories, which were subsequently combined into a shared narrative text. This activity illustrates how conversational GenAI prompts were capable of stimulating not only narrative exchange but also collective creative expression.

The findings suggest that conversational GenAI functions not merely as a technological interface but as a narrative nudge that initiates storytelling processes capable of activating collective memory and strengthening social interaction within elderly communities. By encouraging autobiographical reflection and narrative exchange, conversational GenAI creates opportunities for participants to engage in meaningful dialogue and collaborative storytelling.

Building on these findings and on the existing literature on storytelling and active ageing, the study advances the following theoretical propositions:

P1. Conversational GenAI, acting as a narrative nudge, stimulates autobiographical storytelling among older adults by encouraging the recall and narration of personal memories.

P2. Autobiographical storytelling activated by conversational GenAI facilitates collective memory formation within the group by transforming individual recollections into shared cultural narratives.

P3. Collective storytelling processes enabled by conversational GenAI enhance peer-to-peer social interaction and contribute to community well-being and active ageing.

Research limitations. This study presents several limitations that should be considered when interpreting the findings. First, the empirical investigation relies on a relatively small group of participants involved in exploratory interaction sessions conducted within community social centres. While this qualitative design enables an in-depth understanding of the social dynamics and narrative practices emerging during interactions with conversational GenAI, it inevitably limits the generalisability of the findings to broader populations of older adults. Future studies could expand the empirical base by involving larger and more diverse samples in order to validate and further develop the conceptual framework proposed in this research.

Second, the observational phase covered a limited timeframe and focused primarily on short-term interaction sessions with conversational GenAI agents. Although these sessions provided valuable insights into the immediate social and narrative dynamics generated by conversational prompts, they do not allow for the assessment of longer-term behavioural and social effects. Future research could adopt longitudinal research designs to examine how sustained interactions with conversational GenAI may influence social participation, emotional wellbeing, and community engagement among older adults over extended periods of time.

Finally, the study was conducted within a specific sociocultural context in Southern Italy. Cultural traditions, communication styles, and local community structures may influence how storytelling emerges and evolves within social groups. As a result, the dynamics observed in this research may reflect characteristics of the particular cultural environment in which the study was conducted. Future investigations carried out in different geographical, cultural, and institutional contexts may provide additional insights into how conversational GenAI supports narrative interaction and collective memory processes across diverse ageing communities.

Managerial implications. The findings of this study provide several implications for organisations and institutions operating in the fields of healthcare, social innovation, and community services for older adults. In particular, the results suggest that conversational GenAI systems may represent valuable tools for fostering social interaction and participation within elderly communities. Rather than functioning only as technological assistants, conversational GenAI agents can act as narrative facilitators capable of stimulating storytelling that encourage dialogue, memory sharing, and peer interaction among participants. Community centres, healthcare organisations, and social service providers may therefore consider integrating conversational GenAI systems into group activities designed to reduce loneliness and enhance social engagement among older adults. The study also highlights the importance of culturally grounded AI design. The conversational GenAI characters developed in this research incorporated linguistic styles, humour, and communication patterns emerging from the local cultural context. This design approach contributed to participants' perception of the conversational GenAI agents as familiar and relatable interlocutors, facilitating more natural interaction and narrative engagement. These findings suggest that AI systems aimed at supporting social interaction should be developed with careful attention to cultural context, language, and user experience. Finally, the results indicate that conversational GenAI agents support the development of new forms of community-based digital services that complement traditional care practices. By facilitating collective storytelling and shared narrative exchange, conversational GenAI technologies may contribute to strengthening social bonds, promoting cultural memory, and fostering more inclusive environments for ageing populations. From a managerial perspective, organisations implementing conversational GenAI systems for elderly communities should: (1) design culturally familiar conversational agents capable of reflecting local language and social practices; (2) integrate conversational AI within group-based activities rather than individual isolated interactions; and (3) use open-ended narrative prompts capable of stimulating autobiographical reflection and collective participation.

Originality of the paper. This study contributes to the emerging literature on the societal implications of generative artificial intelligence by examining the role of conversational GenAI within community-based social contexts involving older adults. While existing research on generative artificial intelligence has primarily focused on organisational

productivity, digital transformation, and innovation processes, comparatively limited attention has been devoted to its potential role in supporting social interaction and narrative exchange within ageing societies. This research addresses this gap by exploring how conversational GenAI can stimulate storytelling processes that evolve into collective memory formation and peer interaction among older adults. The study further contributes to the literature by proposing a conceptual framework that links conversational GenAI, autobiographical storytelling, collective memory processes, and social interaction within elderly communities. By conceptualizing conversational GenAI as a narrative nudge, the research highlights how generative AI technologies can support not only functional or informational tasks but also relational and social processes within community settings. In doing so, the study positions generative artificial intelligence not merely as a technological infrastructure but also as a narrative and relational nudge capable of supporting community wellbeing and active ageing in contemporary societies.

How Applicants' Job-Market Status Shapes Reactions Toward AI Evaluation

VALERIO DERIU, MARTINA DI CIOCCIO, ROBERTO URBANI

Abstract. *Despite the increasing use of artificial intelligence (AI) in recruitment, job applicants' reactions to AI-based evaluation remain mixed. While some applicants express skepticism toward automated selection processes, it remains unclear whether such reactions are shared by all job applicants. Drawing on research on status-related expectations, we examine whether applicants' job-market status, that is, an applicant's relative standing in the job market based on their qualifications and career profile, shapes their responses to AI-based versus human-based evaluation in hiring. Across one controlled experiment, we show that applicants with a higher job market status react less favorably to AI-based evaluation than to human evaluation, whereas applicants with lower job-market status display weaker differences between the two evaluation agents. Further analyses reveal that these effects are explained by perceived entitlement, defined as the belief that one deserves a particular type of evaluation in the hiring process. Specifically, higher-status applicants experience lower entitlement when evaluated by AI rather than by a human evaluator, which in turn influences their job acceptance intentions. By identifying job-market status as an important individual difference and entitlement as a key psychological mechanism, our research advances the literature on AI acceptance in hiring and offers practical insights for organizations seeking to integrate AI into recruitment processes.*
Keywords*: recruitment; artificial intelligence; entitlement; job market status; job acceptance*

Framing of the research. In recent years, the growing diffusion of artificial intelligence (AI) has substantially reshaped organizational practices, including employee selection and recruitment (Deriu et al., 2026b; Malik et al., 2023; Mirowska, 2020). Organizations increasingly rely on AI-based systems to automate central hiring activities such as screening résumés, evaluating interview responses, ranking candidates, and supporting final selection decisions. This technological shift is largely driven by the promise of greater efficiency, lower hiring costs, and faster recruitment cycles, which have made AI-based assessment tools increasingly attractive to organizations seeking to streamline their talent acquisition processes (Deriu et al., 2024; Malik et al., 2023). At the same time, the broader digitalization of workplaces has contributed to making AI-based hiring an increasingly common feature of contemporary recruitment systems (Meijerink & Bondarouk, 2023; Van Esch & Black, 2019). Advances in machine learning, natural language processing, and predictive analytics have enabled organizations to analyze large volumes of applicant data in ways that would be difficult or time-consuming for human recruiters alone. As a result, AI-based systems are increasingly used to automate—and sometimes fully replace—human evaluation in hiring processes (Deriu et al., 2026b; The Guardian, 2019; Upadhyay & Khandelwal, 2018).

Despite these potential benefits, the growing use of AI in personnel selection has also raised important questions regarding job applicants' acceptance of this new technological solution. For instance, scholars have noted that automated systems may reproduce or even amplify existing biases present in historical training data, potentially leading to discriminatory outcomes for certain groups of applicants (Raghavan et al., 2020). In response to these concerns, a growing body of research has begun to examine not only the technical performance of AI systems but also their social and psychological implications within hiring contexts. In particular, understanding how job applicants perceive and react to AI-based evaluation has become an important research focus within the broader literature on technology-enabled human resource management (Langer & Landers, 2021).

Prior research suggests that job applicants' reactions to AI-based selection are far from uniform. Some studies show that applicants respond less favorably to AI-based than to human-based evaluations, reporting lower trust, lower perceptions of fairness, or weaker intentions toward the hiring organization (e.g., Deriu et al., 2024). These reactions are often interpreted through the lens of procedural justice and organizational trust, as applicants may perceive algorithmic systems as less transparent, less empathetic, or less capable of capturing individual nuances compared to human evaluators (Lee, 2018). Other studies, however, find more neutral or even relatively positive reactions to AI-based selection (Deriu et al., 2026a; Newman et al., 2020). For example, some applicants may view algorithmic decision-making as more objective and less prone to interpersonal bias than human judgment, potentially increasing perceived fairness in certain contexts (Newman et al., 2020).

Therefore, an important yet understudied possibility is that reactions to AI-based evaluation may vary across applicants themselves. Specifically, applicants differ in their expectations about the hiring process and in how they interpret the use of automated decision-making systems, which may shape their responses when evaluation is conducted by an AI rather than by a human evaluator. (Deriu et al., 2024; Dietvorst, Simmons, & Massey, 2015). Understanding these heterogeneities is particularly important because applicant reactions can influence several downstream organizational outcomes. Negative perceptions of selection procedures may reduce organizational attractiveness, decrease acceptance intentions, and potentially harm employer reputation (Hausknecht, Day, & Thomas, 2004).

Purpose of the paper. This research enhances our understanding of the factors influencing job applicants' reactions to the use of AI in hiring by examining whether applicants respond differently to AI-based versus human-based evaluations, depending on their job market status, defined as an applicant's relative standing in the labor market inferred from signals of prestige, experience, and demand for their profile (Piff et al., 2012). Specifically, we investigate whether the use of an AI evaluator elicits different reactions among applicants described as having either high or low job-market status, and whether these differences can explain when AI-based evaluation is perceived less favorably than human evaluation.

We base our investigation on the idea that individuals with a higher job market status tend to develop different expectations regarding how they should be treated. Applicants who hold a relatively stronger position in the job market—because they possess more desirable qualifications or face higher demand for their skills—may perceive themselves as more valuable candidates. As a result, they may expect a higher level of attention and consideration during the hiring process compared to applicants with a weaker position in the job market. Drawing on this reasoning, we propose that applicants' reactions to AI-based evaluation may depend on their job-market status. In particular, applicants with higher job-market status may react more negatively to AI-based evaluation than to human evaluation, because automated evaluation may appear less consistent with the level of treatment they expect during the hiring process. By contrast, applicants with lower job-market status may hold weaker expectations regarding how they should be evaluated and may therefore be less sensitive to whether the evaluation is conducted by an AI system or by a human evaluator.

We further propose that these differences can be explained by job applicants' perceived entitlement, which, in this context, refers to the belief that one deserves a particular type or level of evaluation during the hiring process due to one's position in the job market (Boyd & Helms, 2005; Campbell et al., 2004). Individuals occupying a higher job market status often develop stronger feelings of entitlement, which shape how they evaluate interactions and institutional procedures. In the context of hiring, applicants with higher job-market status may feel more entitled to a particular form of evaluation (i.e., being evaluated by a human) during the selection process. Consequently, when applicants with higher job-market status are evaluated by an AI system rather than by a human evaluator, the evaluation may appear less aligned with the level of consideration they believe they deserve. In contrast, applicants with lower job-market status may hold weaker expectations regarding how they should be evaluated and, therefore, may react less strongly to the use of AI versus human evaluators.

We conducted an experimental study in which participants evaluated hiring scenarios involving job applicants with either high or low job-market status who were assessed by either a human evaluator or an AI-based evaluation system. In this study, we examine how the interaction between the evaluation agent and applicant job-market status shapes reactions to the hiring process and whether perceived entitlement explains this relationship.

Methodology. We collected data from Prolific respondents coming from the U.S., with screening criteria ensuring they were actively searching for a job. After excluding four participants who failed to pass the attention check, the final sample consisted of 249 respondents (136 females, M_{Age} =42.63, SD=12.31) randomly assigned to a condition in a 2 (evaluation agent: human vs. AI) by 2 (status: low vs. high) between-subjects design. Specifically, the high-status (low-status) candidate, James, was described as holding a degree in Psychology from a high-prestige (low-prestige) university, having prior work experience in well-known, high-profile (small, local) organizations, having been involved in projects with high (low) visibility, and having often (rarely) attracted interest from other employers.
The manipulation check on the status revealed that respondents correctly perceived the manipulation *($M_{High_status} = 4.38$ vs. $M_{Low_status} = 2.67$, $t(247) = 9.34$, $p < .001$).*
The evaluation agent manipulation was also correctly perceived *($X^2(1, 249) = 245.03$, $p < .001$).*

Then, we measured entitlement with four items measured on a 7-point Likert scale ("I honestly feel that James deserves to be evaluated by a hiring manager/AI more than other candidates", "It would be reasonable for James to expect an evaluation by a hiring manager/AI, given his profile", "People like James deserve to be evaluated by a hiring manager/AI", "I feel that James is entitled to an evaluation by a hiring manager/AI"; from Tatavarthy et al., 2024; 1 = "Strongly disagree", 7 = "Strongly agree"; α = 0.942). We assessed job acceptance intentions using four items measured on a 7-point Likert scale ("James would continue participation in the selection", "James would accept a job offer from this company", "James would make this company one of his first choices as an employer", "James would exert a great deal of effort to work for this company"; from Wehner et al., 2015; 1 = "Strongly disagree", 7 = "Strongly agree"; α = 0.829).

Results. We ran a moderated mediation analysis (PROCESS MACRO MODEL 7, Hayes, 2017) using evaluation agent as the main independent variable, job acceptance intentions as the dependent variable, candidates' perceived entitlement as the mediator, and incorporating job-market status as a moderator on entitlement. We found a significant index of moderated mediation on job acceptance intentions (b=-0.23, 95% CI=-0.38, -0.10). In particular, the negative effect of the AI evaluation agent on candidates' perceived entitlement (b = -1.18, SE = 0.24, t = -4.84, p < .001) was characterized by the significant and negative interaction with candidates' job-market status (b = -1.21, SE = 0.34, t = -3.54, p < .001), which in turn had a significant and positive effect on job acceptance intentions (b = 0.19, SE = 0.04, t = 4.30, p < .001). More precisely, the simple slope analysis revealed that candidates with low job-market status felt less entitled when evaluated by the AI instead of the human hiring manager (b = -1.18, SE = 0.24, t = -4.84, p < .001); However, this effect was significantly more pronounced for candidates with high job-market status (b = -2.39, SE = 0.24, t = -9.93, p < .001). The indirect effects confirmed these findings: For candidates with low job-market status, the negative effect of the AI (vs.

human hiring manager) on job acceptance intentions was driven by perceived entitlement (b = -0.23, 95% CI = -0.40, -0.10). For candidates with high job-market status, this negative effect was significantly stronger (b = -0.46, 95% CI = -0.67, -0.26). Lastly, the non-significant direct effect showed the presence of a "full" mediation on job acceptance intentions (b = -0.01, 95% CI = -0.31, 0.29). These results remained unchanged when controlling for age and gender.

Managerial implications. The increasing use of AI in recruitment presents both opportunities and challenges for organizations. On the one hand, AI-based evaluation systems can help organizations streamline hiring processes, reduce costs, and manage large volumes of applicants more efficiently (Deriu et al., 2026; Mirowska, 2020). On the other hand, organizations must consider how job applicants perceive the use of AI during the selection process (Miroswka and Mesnet, 2021). Our findings suggest that applicants' reactions to AI evaluation are not uniform and depend on characteristics of the applicants themselves, particularly their job-market status. Understanding these differences can help organizations design recruitment processes that balance efficiency with positive applicant experiences.

First, our findings suggest that organizations should carefully consider when and for whom AI-based evaluation is most appropriate. Applicants having a higher job market status may respond less favorably to automated evaluation than to human evaluation, likely because they hold stronger expectations about how they should be treated during the hiring process. For organizations seeking to attract highly competitive candidates, relying exclusively on AI-driven evaluation may therefore carry reputational or relational risks. In such cases, organizations may benefit from maintaining some degree of human involvement in the evaluation process, particularly when assessing applicants with stronger profiles or highly demanded skills. This approach allows firms to preserve the efficiency benefits of AI while still signaling attention and consideration toward highly desirable candidates.

Second, our findings highlight the importance of segmenting recruitment strategies based on applicant characteristics. Rather than adopting a one-size-fits-all approach to hiring technologies, organizations may benefit from designing selection processes that account for differences in applicants' job-market status. In particular, firms may allow applicants with strong profiles to choose between AI-based and human evaluation, thereby offering greater flexibility while maintaining efficiency gains from AI tools. At the same time, applicants with lower job-market status may be less sensitive to whether the evaluation is conducted by AI or by a human decision-maker. This suggests that organizations can rely more extensively on AI-based evaluation in earlier stages of the hiring process for these applicants, leveraging the efficiency, scalability, and cost advantages of automated screening. By segmenting evaluation strategies in this way, organizations can balance technological efficiency with applicant expectations and ensure that the adoption of AI in hiring does not inadvertently discourage the most competitive candidates.

Research limitations. Our work has several limitations that offer opportunities for future research. First, to ensure comparability between the two evaluation agents, we provided a relatively simple description of the AI evaluator, focusing primarily on its role in assessing applicants during the hiring process. In practice, however, AI-based hiring systems can include a variety of additional features, such as personality assessments, predictive analytics, or behavioral analysis of interview responses. Future research could therefore examine whether applicants' reactions differ depending on the specific capabilities attributed to AI-based evaluation systems. Second, our study relied on experimental scenarios in which participants evaluated a hypothetical applicant described as having either high or low job-market status. While this approach strengthens internal validity and allows us to isolate the causal effect of applicant status and evaluation agent, it does not fully capture how individuals who actually have a different status in the job market might respond to AI-based evaluation when thinking about their own case. As a next step, we plan to extend this project by moving beyond a fictitious applicant and directly comparing respondents who differ in their actual job-market status through survey-based data collection. Specifically, we aim to contrast individuals occupying relatively higher-status job-market positions, such as managers or executives, with respondents in lower-status positions. This would allow us to assess whether the patterns observed in the experimental studies also emerge when participants evaluate AI-based versus human evaluation in relation to their own professional situation, thereby strengthening the external validity of the findings

Originality of the paper. Our research makes several contributions to the literature on AI adoption in hiring practices. As organizations increasingly rely on artificial intelligence to evaluate job applicants, understanding the psychological factors that shape applicants' reactions to AI-based versus human-based evaluation has become an important research topic. While prior studies have examined various determinants of AI acceptance in recruitment—such as personality traits and the technological orientation of the hiring organization (Deriu et al., 2026a; McCarthy et al., 2017; Mirowska & Mesnet, 2022)—less attention has been devoted to how applicants' relative position in the job market may shape their responses to automated evaluation systems. First, our research contributes to the literature by introducing job-market status as an individual difference that helps explain heterogeneity in applicants' reactions to AI-based evaluation. Applicants differ in the extent to which they occupy stronger or weaker positions in the labor market, which may influence the expectations they hold regarding how they should be evaluated during the hiring process. By showing that applicants' reactions to AI-based versus human-based evaluation vary depending on their job-market status, our study provides a new explanation for why automated evaluation may be perceived differently across applicants.

Second, our study contributes to the literature on the drivers of AI acceptance in hiring (Mirowska and Mesnet, 2021) by identifying entitlement as a psychological mechanism underlying the differences in job applicants' reactions.

Entitlement refers to the belief that one deserves a particular level or type of treatment in a given context. We show that applicants with higher job-market status may develop stronger expectations regarding how they should be evaluated during the hiring process, which in turn shapes their reactions to AI-based versus human-based evaluation. By highlighting the role of entitlement in this context, our research provides a novel explanation for job applicants' responses (i.e., job acceptance intentions) to automated evaluation in hiring.

Finally, by integrating insights from research on AI-based hiring and status-related expectations, our study advances current understanding of when the use of AI in recruitment may be more or less acceptable to job applicants. In particular, by identifying both this individual characteristic and its underlying psychological mechanism, our research contributes to the broader literature on applicant reactions and technology adoption in hiring. At the same time, these findings carry important managerial implications, as they suggest that organizations may benefit from tailoring their use of AI in selection processes to different segments of applicants rather than adopting a uniform approach.

Research statement. The present research is work-in-progress. The datasets generated during and/or analyzed during the current research are available from the corresponding author upon reasonable request.

Institutional Logics and Collaborative Innovation in AI Platform Ecosystems: Evidence from Patent Co-Ownership in the United States and China

FABIO CORONA, SOFIIA KATSIUBA, NATALIIA KOCHKINA, GIUSEPPE MELIS

Abstract. *Digital platforms have become central actors in contemporary innovation ecosystems, especially in technologically intensive domains such as Artificial Intelligence (AI). Through modular architectures, data infrastructures, and developer ecosystems, these firms increasingly orchestrate distributed innovation processes involving multiple organizations. Within these environments, collaborative innovation has become a critical mechanism through which firms access complementary knowledge and technological capabilities. Despite growing research on open innovation and digital platforms, limited empirical evidence exists on how collaborative patenting strategies influence technological outcomes across different institutional environments.*

This study investigates the relationship between collaborative patent ownership and the technological impact of AI-related inventions developed by leading digital platforms. Grounded in open innovation theory and institutional theory, the paper examines whether co-assigned patents are associated with greater technological impact and whether the effectiveness of collaborative innovation differs across institutional contexts. The empirical analysis relies on a dataset of 26,488 AI-related patent families filed between 1995 and 2022 by major digital platforms operating in the United States and China. AI patents are identified through a dual-filtering methodology combining International Patent Classification codes and AI-related keywords. Technological impact is measured through forward citations, while collaborative innovation is captured through co-assigned patent ownership structures. Negative binomial regression models are employed to analyse the relationship between collaboration and patent impact.

The findings reveal significant cross-country differences. In the United States, collaborative patent ownership does not significantly influence technological impact. In contrast, the Chinese context presents heterogeneous collaboration effects: inter-firm collaborations are associated with lower technological impact, whereas collaborations between firms and public research institutions significantly increase patent influence. These results suggest that the effectiveness of collaborative innovation strategies depends strongly on institutional environments and partnership configurations. The study contributes to research on digital platforms, open innovation, and institutional theory by providing micro-level empirical evidence on how institutional logics shape innovation outcomes within AI-driven platform ecosystems.

Keywords: *Artificial Intelligence; Digital Platforms; Open Innovation; Institutional Theory; Patents.*

1. Introduction. Digital platforms have become one of the most influential organizational forms of the contemporary economy. Over the last two decades, firms such as Google, Amazon, Microsoft, Alibaba, Tencent, and Huawei have reshaped competition by building digital infrastructures able to coordinate interactions among multiple categories of actors. Unlike traditional firms that innovate largely within their internal boundaries, digital platforms increasingly innovate through ecosystems composed of users, developers, suppliers, complementors, start-ups, research partners, and public institutions. Their strategic relevance derives not only from scale or market power, but also from their ability to orchestrate distributed innovation processes.

This transformation is especially visible in Artificial Intelligence (AI). AI is a technologically complex domain characterized by rapid convergence among multiple fields, including machine learning, computer vision, robotics, natural language processing, cloud computing, and data analytics. Such complexity makes it difficult for any single organization to master all relevant capabilities internally. As a consequence, AI development increasingly depends on the recombination of heterogeneous knowledge, access to large data infrastructures, and the integration of diverse scientific and technological competencies.

Within this context, collaboration has become a crucial strategic mechanism. Firms rely on external partnerships to access complementary knowledge, share technological risks, broaden search spaces, and accelerate innovation cycles. In the case of digital platforms, these collaborations can involve other firms, universities, public research institutions, start-ups, or ecosystem actors connected to their technological infrastructures. One of the most observable outputs of such collaboration is co-patenting, namely the joint ownership of patents resulting from collaborative inventive activity.

Co-patenting is particularly relevant for the study of innovation because it makes collaborative ties visible through formalized intellectual property arrangements. Co-assigned patents provide evidence that multiple organizations have contributed to the same invention and have decided to share ownership of the resulting technological output. For this reason, they offer a useful empirical lens through which to observe how open innovation strategies materialize at the micro level.

However, the implications of collaborative patenting are not straightforward. On the one hand, combining heterogeneous capabilities may increase novelty, technological breadth, and subsequent influence. On the other hand, collaboration may

also generate coordination costs, conflicts over appropriation, organizational misalignment, and slower decision-making. As a result, collaborative patenting may enhance technological impact in some conditions but not in others.

A further complication is that collaborative innovation does not take place in an institutional vacuum. Institutional theory suggests that innovation strategies are embedded in broader systems of rules, incentives, expectations, and governance arrangements. Firms do not simply choose whether to collaborate; they collaborate in ways that reflect the institutional logics of the environments in which they operate. Institutional contexts shape the legitimacy of different forms of openness, the governance of intellectual property, the role of universities and public actors, and the strategic value of alliances.

The comparison between the United States and China is therefore highly relevant. These two countries are the global leaders in AI development and digital platform growth, yet they represent markedly different institutional environments. The U.S. context is characterized by a market-driven innovation system, relatively decentralized coordination mechanisms, strong intellectual property protection, and broad ecosystem openness. The Chinese context is more strongly shaped by industrial policy, state coordination, strategic national objectives, and selective forms of openness aligned with public priorities. These differences suggest that collaboration may not operate uniformly across the two contexts.

This paper addresses that issue by asking two main research questions. First, is collaborative patent ownership associated with the technological impact of AI-related platform innovations? Second, do these relationships differ between the United States and China? To answer these questions, the study analyses a dataset of 26,488 AI-related patent families assigned to leading platform firms in the two countries between 1995 and 2022. Technological impact is measured through forward citations, while collaboration is captured through co-assignment patterns and partnership typologies. The empirical analysis uses negative binomial regression models, which are particularly appropriate for overdispersed count data such as patent citations.

The paper contributes in three main ways. First, it advances open innovation research by showing that the impact of collaboration is conditional rather than universally positive. Second, it contributes to platform studies by examining digital platforms not only as market intermediaries but also as institutionally embedded orchestrators of AI innovation. Third, it extends institutional theory by linking macro-level institutional logics with micro-level patent outcomes. In doing so, the paper offers a more nuanced understanding of how collaborative innovation translates into technological impact within AI platform ecosystems.

The remainder of the paper is structured as follows. The next section reviews the literature on digital platforms, open innovation, and institutional logics. The following sections develop the hypotheses, describe the data and methods, present the empirical results, discuss the findings, and conclude with implications for theory and practice.

2. Digital Platforms, Open Innovation, and Institutional Logics

2.1 Digital platforms as orchestrators of innovation ecosystems

Digital platforms have progressively evolved from market-making infrastructures into strategic orchestrators of innovation ecosystems. Their distinctive feature lies in their ability to organize interactions among multiple sides of a market while maintaining some degree of control over the core architecture. This architecture typically combines technological modularity, interface standardization, and data-driven coordination, allowing external actors to participate in innovation while remaining connected to a common infrastructural core.

This organizational form has major implications for innovation. Traditional innovation models often assumed that firms developed technologies internally and then commercialized them through relatively stable value chains. Platform-based innovation, by contrast, is more distributed, recursive, and ecosystemic. Value is co-created through interactions among platform owners, complementors, users, developers, and external organizations. Innovation does not simply flow from inside to outside the firm; rather, it emerges from the continual recombination of internal and external resources.

The platform model is especially relevant in AI because AI applications depend on the integration of hardware, software, data assets, cloud infrastructures, and specialized research competencies. Leading platform firms can leverage their infrastructural position to mobilize external contributions while still guiding technological trajectories. In this respect, platforms do not merely participate in innovation ecosystems; they structure them through governance mechanisms, technological standards, and selective openness.

At the same time, not all platform ecosystems are equally open. The degree of openness varies according to strategic priorities, technological specialization, competitive pressures, and institutional environments. Some platforms rely on broad developer communities and open-source ecosystems; others adopt more selective forms of collaboration centered around specific research partnerships or strategically controlled access points. Therefore, understanding how platforms collaborate in AI requires attention not only to technology, but also to governance and institutional embeddedness.

2.2 Open innovation and collaborative patenting

Open innovation theory emphasizes that firms can improve innovation performance by purposively sourcing knowledge from outside their boundaries and by combining internal and external capabilities. This perspective challenges closed models of innovation and highlights the strategic role of collaboration, knowledge exchange, and ecosystem participation.

Collaborative patenting is one of the most visible manifestations of open innovation because it signals that an invention was generated through inter-organizational cooperation and that the resulting intellectual property is jointly owned. In patent-based studies, co-assignment is often treated as an indicator of formal collaborative innovation. Such collaborations may involve firm–firm partnerships, university–industry relationships, or ties between private firms and public research organizations.

The literature generally suggests that collaboration can enhance innovation outcomes for several reasons. First, it enables access to complementary knowledge bases, which is especially important in complex and multidisciplinary technological domains. Second, it allows organizations to share risks and costs associated with uncertain research trajectories. Third, it may increase the scope and applicability of resulting inventions by combining scientific, technological, and market-oriented competences.

However, the positive effects of collaboration are not guaranteed. Co-patenting can also create appropriation problems, reduce incentives to disclose key knowledge, and increase transaction and coordination costs. Joint ownership may become a source of ambiguity over future commercialization rights or over the use of the invention in adjacent fields. In addition, collaborations among organizations with diverging routines or time horizons may produce friction rather than synergy.

These tensions are particularly salient in AI, where innovation cycles are rapid, technological architectures evolve quickly, and access to data, talent, and computational infrastructures creates asymmetries among partners. In some cases, collaboration may broaden technological exploration; in others, it may slow down integration or dilute strategic focus. The empirical question is therefore not whether collaboration is inherently beneficial, but under what conditions and in what forms it contributes to technological impact.

2.3 Institutional logics and comparative innovation systems

Institutional theory offers a useful framework for explaining why collaboration may work differently across national contexts. Institutional logics refer to the broader organizing principles that shape what kinds of strategies are considered legitimate, efficient, and desirable within a given environment. These logics influence governance structures, inter-organizational relationships, and the mechanisms through which innovation is coordinated.

In the United States, innovation takes place within a relatively market-oriented institutional environment. Competitive pressures, strong intellectual property regimes, venture financing, entrepreneurial experimentation, and broad ecosystem participation support a form of openness that is often exploratory and opportunity-driven. In such a context, collaboration may be routinized and supported by a mature ecosystem of contracts, alliance capabilities, and specialized partners. This may make collaboration widespread, but not necessarily differentiating in terms of patent impact.

China presents a different configuration. The Chinese innovation system is strongly shaped by state coordination, industrial policy, and strategic technological priorities. In the AI domain, platform firms often operate in relation to national policy agendas and public programs that promote specific forms of collaboration, including ties with universities, public institutes, and government-backed innovation initiatives. Collaboration can therefore be more selective, more policy-driven, and more strongly embedded in strategic national objectives.

These differences matter because the same formal structure of co-ownership may embody different underlying dynamics across contexts. A co-assigned patent in the United States may emerge from a mature and standardized ecosystem practice. A co-assigned patent in China may instead reflect a more directed, institutionally mediated arrangement with distinct incentives and governance characteristics. For this reason, institutional theory suggests that the relationship between collaboration and patent impact should vary across countries and across partnership configurations.

3. Hypotheses Development. The first hypothesis concerns the general relationship between collaborative patent ownership and technological impact. AI innovation is a knowledge-intensive process that often requires the integration of different scientific and technological domains. In such contexts, collaboration can increase the quality and influence of inventions by combining complementary assets and expanding the scope of technological search. Co-assigned patents may therefore capture inventions that emerge from richer knowledge recombination and from more diverse problem-solving capacities.

At the same time, the literature on collaboration in innovation generally argues that joint research can increase subsequent visibility and diffusion because inventions developed through complementary expertise may be technologically broader and more relevant to future innovation trajectories. This logic is particularly plausible in AI, where advances often depend on the convergence of multiple domains and on the integration of research capabilities that are difficult to concentrate within a single organization.

Based on these arguments, the first hypothesis is formulated as follows:

H1. Collaborative patent ownership is positively associated with the technological impact of AI-related patents.

The second hypothesis concerns the heterogeneity of collaboration. Treating co-assignment as a single, homogeneous category may obscure important differences among partnership structures. Collaborations between firms may differ substantially from collaborations between firms and universities or public research institutions.

Firm–firm collaborations may benefit from market proximity, complementary commercial capabilities, and shared incentives toward application and commercialization. However, they may also face stronger appropriation concerns, competitive tensions, and governance issues. In contrast, firm–university or firm–public research collaborations may combine scientific depth with market-oriented implementation capabilities. Such configurations can be particularly beneficial in AI, where upstream research excellence and downstream application competences are both essential.
Institutional theory reinforces this expectation. In environments where public research organizations play a strategic role in national innovation systems, the collaboration between firms and public institutions may generate particularly strong complementarities. Conversely, purely inter-firm collaborations may be more exposed to coordination frictions, especially when they are not supported by robust alliance capabilities or shared governance routines.
Accordingly, the second hypothesis is stated as follows:
H2. The technological impact of AI-related patents differs across partnership configurations.

4. Research Design and Methodology

4.1 Data and sample construction

The empirical analysis is based on a novel patent dataset built by combining patent-level information with assignee-level organizational data. AI-related patents were identified using a dual-filtering methodology based on the combination of AI-specific keywords and International Patent Classification codes associated with AI technologies. This approach allows the identification of patent families that are both textually and technologically linked to AI.
Patent information was retrieved from the Questel Orbit Intelligence database, while assignee-level information was integrated through ORBIS Intellectual Property data. The use of patent families as the unit of analysis reduces double counting and provides a more robust representation of inventive activity across jurisdictions.
The final dataset includes 26,488 AI-related patent families filed between 1995 and 2022. Of these, 16,939 are assigned to platforms based in the United States and 9,549 to platforms based in China. The sample focuses on leading platform firms that play central roles in their respective digital and AI ecosystems. The U.S. sample includes firms such as Google, Amazon, Microsoft, Apple, and Meta. The Chinese sample includes firms such as Alibaba, Baidu, Tencent, Huawei, JD.com, Xiaomi, SenseTime, Ping An, and Hikvision.

4.2 Variables

The dependent variable is **Tech_Impact**, measured as the number of forward citations received by each patent family. Forward citations are widely used in patent research as a proxy for technological influence, knowledge diffusion, and relevance for subsequent inventive activity.
The main independent variable in Model 1 is **Co_Assignment**, a dummy equal to 1 when a patent family has more than one assignee and 0 otherwise. This variable captures whether the invention is the result of formal collaborative ownership.
To account for heterogeneity in collaboration structures, Model 2 uses **PartnershipType**, a categorical variable that distinguishes among: (1) patents assigned to a single firm (**OneCompany**), (2) patents jointly assigned to multiple firms (**MultipleCompanies**), and (3) patents jointly assigned to firms and universities or public research institutions (**MixCompaniesURIs**).
Three control variables are included. **BackCit** measures backward citations and captures the extent to which the invention builds on existing technological knowledge. **FamSize** represents patent family size and captures the geographic breadth of protection, often interpreted as a proxy for expected commercial value or strategic importance. **Filing_year** controls for cohort effects in citation accumulation, since older patents have had more time to receive citations.

4.3 Estimation strategy

Because the dependent variable is a non-negative count variable with strong overdispersion, negative binomial regression is used. This approach is well established in patent research because patent citation distributions are typically highly skewed and display variance substantially larger than the mean.
Two main specifications are estimated separately for the United States and China. Model 1 assesses the general association between co-assignment and technological impact. Model 2 replaces the binary collaboration variable with partnership types in order to test whether distinct forms of collaboration have heterogeneous effects. Separate estimation by country is appropriate because the descriptive evidence indicates substantial structural differences between the two national samples in terms of citation patterns, family size, backward citations, and collaboration frequencies.

5. Results

5.1 Descriptive evidence

The descriptive analysis reveals marked differences between the two country contexts. U.S. platform patents show substantially higher technological impact than Chinese platform patents. The citation distribution in the United States is characterized by a much stronger right tail, indicating the presence of highly influential patents. U.S. patents also display

larger family sizes and higher backward citation counts on average, suggesting broader protection strategies and deeper technological grounding.
Differences also emerge in collaborative structures. Co-assignment is more frequent in the U.S. sample than in the Chinese sample. However, the composition of collaboration differs. In the U.S. dataset, collaborative patents are almost entirely represented by firm–firm co-ownership. In the Chinese dataset, both inter-firm collaborations and mixed firm–university/public research collaborations are observed, although the latter represent a smaller share of the total sample.
These descriptive patterns already suggest that collaboration may not have the same meaning across the two systems. In the United States, co-assignment appears as a relatively standard ecosystem feature. In China, some collaborative structures seem more selective and potentially more institutionally mediated.

5.2 Regression results
The regression results provide further support for this interpretation. Across both countries, the control variables behave largely as expected. Filing year has a negative coefficient, indicating that older patents accumulate more forward citations. Family size has a positive and significant association with technological impact, consistent with the idea that patents protected across more jurisdictions tend to be strategically more valuable and technologically influential. Backward citations also show a positive relationship with forward citations, suggesting that patents grounded in richer prior knowledge are more likely to influence later inventions.
The main differences concern collaboration. In the United States, the coefficient for **Co_Assignment** is not statistically significant. This means that, once other patent characteristics are controlled for, co-owned patents do not perform differently from single-owner patents in terms of technological impact. The result does not imply that collaboration is absent or unimportant in the U.S. ecosystem, but rather that formal co-ownership does not constitute a distinctive predictor of higher citation impact.
In China, the picture differs. The binary co-assignment variable is negatively associated with technological impact. This suggests that, on average, collaborative ownership is linked to lower citation performance relative to patents owned by a single firm. However, this aggregate result masks substantial heterogeneity.
When partnership types are distinguished, the results become more nuanced. In the Chinese sample, **MultipleCompanies** collaborations show a negative and significant coefficient relative to single-firm patents. By contrast, **MixCompaniesURIs** collaborations show a positive and significant coefficient, indicating that collaborations involving public research institutions or universities are associated with higher technological impact.
These findings imply that collaboration in China is not uniformly beneficial or detrimental. Rather, outcomes depend on the composition of the partnership. Purely inter-firm collaborations appear less effective, whereas hybrid science–industry collaborations are associated with stronger patent influence.

6. Discussion. The findings of this study support a more conditional understanding of collaborative innovation in AI ecosystems. The first important insight is that collaboration does not automatically increase technological impact. The positive expectation captured in H1 receives no support in the U.S. sample and only partial support when China is considered in disaggregated form. This suggests that the impact of collaborative patent ownership cannot be understood in universalistic terms.
In the United States, the absence of a significant co-assignment effect may reflect the maturity of the innovation ecosystem. Collaboration is likely already embedded in platform innovation processes through multiple mechanisms, including alliances, open-source communities, developer networks, acquisitions, and contractual research arrangements. Within such a mature environment, formal co-patenting may no longer act as a distinctive signal of superior technological influence. Collaboration may still matter, but its value may be distributed across a broader array of ecosystem relationships rather than concentrated in joint patent ownership alone.
In China, the results highlight a more differentiated picture. The negative coefficient associated with inter-firm collaboration suggests that not all collaborative arrangements are equally effective. Some inter-firm partnerships may suffer from coordination difficulties, overlapping capabilities, appropriation concerns, or weak integration mechanisms. These issues can reduce the coherence and downstream influence of resulting inventions.
At the same time, the strong positive effect of collaborations involving universities or public research institutions suggests that institutional complementarities are especially important in the Chinese AI ecosystem. Such partnerships may combine upstream scientific capabilities with downstream commercialization and deployment capacities, thereby generating inventions with stronger technological influence. This is consistent with the role of public research organizations in state-coordinated innovation systems, where they often function as knowledge providers and strategic partners in national technological development.
More broadly, the results indicate that institutional logics shape not only how much firms collaborate, but also how collaboration translates into innovation outcomes. The same formal structure of co-ownership can embody different strategic and organizational realities across countries. This is the main contribution of the paper from an institutional perspective: institutions are not distant background conditions, but mechanisms that become visible in micro-level innovation outcomes.

7. Implications for Theory and Practice. The paper offers several theoretical implications. For open innovation research, the results suggest that collaboration should not be treated as inherently performance-enhancing. What matters is not only whether firms collaborate, but with whom they collaborate and within what institutional context. This supports a more contingent and governance-sensitive view of openness.

For platform studies, the findings reinforce the idea that digital platforms are not simply neutral technological infrastructures. They are institutionally embedded orchestrators whose collaborative strategies reflect broader governance systems. Their openness is selective, structured, and context-dependent.

For institutional theory, the study provides a micro-founded perspective on how institutional logics influence innovation outcomes. Rather than focusing only on macro-level policy differences, the analysis shows how such differences are reflected in patent-level collaboration structures and citation impact.

From a managerial perspective, the results suggest that platform firms should carefully design collaborative arrangements rather than assuming that joint ownership will automatically improve innovation performance. In mature market ecosystems, formal co-patenting may not provide additional value if collaboration is already embedded elsewhere in the ecosystem. In more state-coordinated systems, collaborations with universities and public institutions may be especially valuable when they create genuine complementarities.

8. Conclusion. This paper has examined how collaborative patent ownership relates to the technological impact of AI-related platform innovations in the United States and China. Drawing on open innovation theory and institutional theory, it has argued that the effects of collaboration should be understood as context-dependent rather than universal.

Using a dataset of 26,488 AI-related patent families and negative binomial regression models, the study shows that collaborative ownership does not significantly affect technological impact in the United States, whereas in China the effect of collaboration depends strongly on partnership configuration. Inter-firm collaborations are associated with lower impact, while collaborations involving universities or public research institutions are associated with higher impact.

These findings highlight that collaboration in AI ecosystems is shaped by institutional logics, partnership structures, and governance arrangements. The study therefore contributes to a more nuanced understanding of open innovation within digital platform ecosystems and offers evidence that the relationship between collaboration and technological impact cannot be separated from the institutional environments in which innovation takes place.

Future research could extend this analysis by considering additional countries, examining the temporal evolution of platform collaboration strategies, or integrating patent evidence with alliance, publication, and ecosystem governance data. Such work would further clarify how digital platforms organize innovation across increasingly complex and geopolitically differentiated AI landscapes.

L'intelligenza artificiale come infrastruttura cognitiva per la transizione circolare: il ruolo delle dynamic capabilities

LORENZO TURRIZIANI, MAURO SCIARELLI, ANNA PRISCO, MARTINA PERCUOCO

Abstract. *L'intelligenza artificiale sta assumendo un ruolo sempre più rilevante nella transizione verso modelli di economia circolare, ma la letteratura chiarisce ancora solo parzialmente attraverso quali meccanismi essa contribuisca alla riconfigurazione dei processi, delle capacità organizzative e delle relazioni ecosistemiche. Muovendo dalla prospettiva delle dynamic capabilities e dalla letteratura sui circular business models, il lavoro esplora il ruolo dell'AI come infrastruttura cognitiva in tre casi qualitativi italiani. L'analisi, ancora in corso, suggerisce che l'AI può rafforzare sensing, seizing e reconfiguring, contribuire ad allentare alcune path dependencies e sostenere nuove forme di orchestrazione inter-organizzativa. Al tempo stesso, emergono tensioni legate a standardizzazione dei dati, dipendenze digitali e necessità di competenze di traduzione tra tecnologia, processi e attori dell'ecosistema. Il contributo propone quindi una lettura preliminare del legame tra AI, capacità dinamiche e innovazione circolare.*
Keywords: *intelligenza artificiale; economia circolare; Dynamic capabilities; Path dependency; ecosistemi d'impresa; Circular business models*

Inquadramento della ricerca. La crescente instabilità dei mercati delle risorse, la pressione regolatoria e la necessità di ridurre gli impatti ambientali hanno reso sempre più evidente l'inadeguatezza dei modelli lineari di produzione e consumo. In questo quadro, l'economia circolare si è affermata come paradigma volto a ripensare la creazione del valore attraverso logiche di estensione della vita utile, riuso, rigenerazione e recupero di materiali. La letteratura ha chiarito che tale transizione non coincide con l'adozione di pratiche ambientali isolate, ma implica una riconfigurazione dei modelli di business, dei processi operativi e delle relazioni di filiera. In questa prospettiva, i circular business models rappresentano una lente interpretativa utile, poiché mostrano come la circolarità richieda di ridefinire congiuntamente value proposition, modalità di erogazione e logiche di appropriazione del valore, integrando flussi materiali e informativi, uso e ritorno degli asset e criteri di valutazione capaci di tenere insieme performance economica ed efficienza nell'uso delle risorse (Bocken et al., 2016; Pieroni et al., 2019; Reim et al., 2021).

Per comprendere tale trasformazione, la prospettiva delle dynamic capabilities risulta particolarmente rilevante. Essa consente infatti di leggere la circolarità non come un adattamento puntuale, ma come un processo attraverso cui l'organizzazione sviluppa capacità di sensing, seizing e reconfiguring per individuare opportunità emergenti, selezionare nuove traiettorie strategiche e riallineare nel tempo risorse, routine e relazioni. Nei percorsi di economia circolare, queste capacità riguardano non solo l'introduzione di tecnologie o pratiche più sostenibili, ma anche la possibilità di sostenere configurazioni organizzative coerenti con logiche di valore più distribuite e di lungo periodo. In questo senso, la letteratura ha evidenziato come la transizione circolare dipenda dalla capacità delle imprese di sviluppare "microfondamenti" organizzativi e decisionali adeguati a governare innovazione, apprendimento e riconfigurazione del modello di business (Teece et al., 1997; Teece, 2007; Santa-Maria et al., 2022).

In tale prospettiva, l'intelligenza artificiale assume un ruolo di crescente centralità. La letteratura più recente evidenzia infatti come le applicazioni AI-based possano sostenere la tracciabilità dei flussi, l'ottimizzazione nell'impiego delle risorse, la manutenzione predittiva e l'identificazione di opportunità di recupero, contribuendo in tal modo all'abilitazione di modelli di business circolari fondati su capacità di monitoraggio continuo e su processi decisionali maggiormente "data-driven" (Rosa et al., 2020; Sjödin et al., 2023). Tuttavia, una lettura dell'AI circoscritta unicamente alla sua dimensione strumentale appare riduttiva. Più che una tecnologia isolata orientata al miglioramento dell'efficienza, essa può essere interpretata come un'"infrastruttura cognitiva", ovvero un insieme articolato di dati, modelli, metriche, interfacce e pratiche organizzative, capace di ridefinire le basi informative e interpretative del processo decisionale. In questa prospettiva, il contributo dell'AI non si esaurisce nell'ampliamento e nell'efficientamento delle capacità operative dell'impresa, ma investe più profondamente le condizioni stesse della sua capacità di osservare, confrontare e attribuire rilevanza ai fenomeni. L'AI, infatti, estende il perimetro del visibile e del "decidibile", rendendo intellegibili le inefficienze, le interdipendenze e le opportunità di recupero che, in assenza di adeguate architetture informative, tenderebbero a rimanere disperse o scarsamente problematizzate. Proprio per questo, essa può alimentare i ben noti processi di sensing, seizing e reconfiguring non in modo automatico o lineare, bensì attraverso una trasformazione delle modalità con cui l'organizzazione apprende, formula giudizi e coordina l'azione (Leonardi, 2013; Cao et al., 2021; Ritala et al., 2024).

Questa chiave interpretativa consente inoltre di mettere a fuoco una tensione cruciale. Se, da un lato, l'AI può contribuire ad allentare i vincoli derivanti dalla path dependency, mettendo in discussione routine e pratiche organizzative sedimentate, metriche tradizionali e rappresentazioni lineari dei processi, dall'altro essa può tuttavia generare nuove forme di dipendenza da dati, standard, architetture algoritmiche e criteri di classificazione (Sydow et al., 2009; Vergne and Durand, 2011; Warner and Wäger, 2019; Ritala et al., 2024). Inoltre, poiché la circolarità si realizza all'interno di ecosistemi caratterizzati da interdipendenze tra attori eterogenei, il potenziale trasformativo dell'AI risulta subordinato

alla possibilità di estendere tale infrastruttura cognitiva oltre i confini della singola impresa, rendendo dati, metriche e criteri decisionali reciprocamente comparabili tra soggetti diversi (Adner, 2017; Jacobides et al., 2018). In questo quadro assumono particolare rilievo specifiche capabilities di interfacciamento, intese come competenze immateriali e in larga misura tacite, radicate nella capacità di tradurre linguaggi tecnici, operativi, economici e di sostenibilità, ricodificandoli in corsi d'azione, decisioni strategiche, KPI e pratiche condivise tra attori diversi. La letteratura sui processi di traduzione, sulle attività di boundary spanning e sulla mediazione inter-organizzativa ha infatti mostrato come la costruzione di significati condivisi non dipenda esclusivamente dalla disponibilità di informazioni, ma richieda la presenza di attori e pratiche in grado di trasferire, tradurre e trasformare conoscenze tra comunità eterogenee, facilitando in tal modo il coordinamento, l'apprendimento e l'azione collettiva (Carlile, 2004).

Alla luce di tali considerazioni, la letteratura sull'economia circolare e sui circular business models ha chiarito la natura trasformativa della transizione circolare e il ruolo delle dynamic capabilities nel sostenerla (Bocken et al., 2016; Santa-Maria et al., 2022), mentre gli studi su AI e circolarità hanno evidenziato il potenziale delle applicazioni digitali nel supportare tracciabilità, monitoraggio e ottimizzazione dei flussi (Rosa et al., 2020; Sjödin et al., 2023). Rimane tuttavia meno esplicitato attraverso quali meccanismi organizzativi l'AI, intesa come infrastruttura cognitiva, alimenti capacità di sensing, seizing e reconfiguring orientate alla circolarità, e in che misura tale processo dipenda, simultaneamente, dalle tensioni generate dalla path dependency e dalle competenze di traduzione e di orchestrazione necessarie a governare le interdipendenze ecosistemiche.

Obiettivo del paper. Muovendo dal quadro teorico fin qui delineato, il presente lavoro intende analizzare il ruolo dell'intelligenza artificiale quale infrastruttura cognitiva a supporto della transizione verso sistemi di economia circolare. In particolare, il paper si propone di chiarire come l'AI contribuisca allo sviluppo di capacità dinamiche orientate alla circolarità, come interagisca con i vincoli di path dependency che caratterizzano i processi di trasformazione organizzativa e in che misura le configurazioni organizzative e relazionali abilitate dall'AI ridefiniscano il posizionamento dell'impresa nell'ecosistema di riferimento. In questa prospettiva, l'attenzione non è rivolta soltanto alle applicazioni tecnologiche dell'AI, ma anche ai meccanismi attraverso cui dati, modelli, metriche e pratiche di interpretazione vengono incorporati nei processi decisionali e nelle relazioni interorganizzative, sostenendo la circular business model innovation. Coerentemente con tale impostazione, la ricerca è guidata dalle seguenti domande:

RQ1. In che modo le applicazioni dell'AI contribuiscono allo sviluppo delle capacità di sensing, seizing e reconfiguring nell'innovazione dei modelli di business circolari?

RQ2. Come l'uso dell'AI interagisce con i vincoli di path dependency e quali competenze di ne rendono possibile un impiego trasformativo in chiave circolare?

RQ3. In che misura, e attraverso quali meccanismi, le configurazioni organizzative e relazionali abilitate dall'AI ridefiniscono il posizionamento dell'impresa nell'ecosistema, sostenendo percorsi di trasformazione circolare?

Metodologia. Considerata la natura emergente, processuale e fortemente contestuale del fenomeno indagato, la ricerca adotta un'impostazione qualitativa di tipo interpretativista, finalizzata a comprendere i meccanismi attraverso cui l'intelligenza artificiale viene incorporata nei percorsi di innovazione dei modelli di business circolari. In questa prospettiva, lo studio si fonda su un disegno esplorativo a casi multipli, particolarmente adatto all'analisi di fenomeni contemporanei, complessi e profondamente radicati nel contesto empirico, nonché alla costruzione teorica attraverso confronto e replica tra unità di analisi eterogenee ma comparabili (Eisenhardt, 1989; Eisenhardt and Graebner, 2007; Yin, 2014).

La selezione dei casi segue una logica di campionamento teorico costruita secondo un common process design, volto a osservare il medesimo fenomeno in contesti differenti. Le tre organizzazioni condividono tre condizioni: un impegno esplicito verso la circolarità; l'impiego di sistemi AI-based a supporto di decisioni, processi o coordinamento; la presenza di interdipendenze con una pluralità di attori lungo la filiera. Questa scelta consente di confrontare configurazioni diverse per settore, asset base e architettura relazionale, mantenendo però costante il focus sul rapporto tra AI, capacità dinamiche e trasformazione circolare.

I tre casi riflettono questa logica comparativa. L'azienda A è una multinazionale industriale attiva nelle attrezzature per edilizia e comparto estrattivo, caratterizzata da asset durevoli, intensità tecnologica e rilevanza strategica di pratiche quali rigenerazione dei componenti, manutenzione avanzata ed estensione della vita utile dei macchinari. L'azienda B opera invece nel settore dei servizi di lavanderia e dry-cleaning attraverso una rete internazionale in franchising, nella quale strumenti digitali e applicazioni di AI supportano la classificazione, il coordinamento operativo e la gestione del servizio. L'azienda C, infine, è un'impresa tecnologica specializzata nella tracciabilità delle filiere tessili e nella misurazione dell'impatto ambientale e sociale dei prodotti, svolgendo una funzione di intermediazione informativa tra brand, fornitori e altri attori della supply chain.

La raccolta dei dati è stata articolata in più fasi secondo una logica di triangolazione tra fonti, attori e momenti dell'indagine. Sono stati analizzati dati secondari, documentazione aziendale e materiali pubblici; successivamente sono state condotte interviste semi-strutturate con manager e figure chiave coinvolte in iniziative di innovazione, sostenibilità, operazioni e trasformazione digitale. Nei casi in cui è stato possibile, le evidenze sono state integrate attraverso ulteriori scambi di follow-up e la ricostruzione di processi, pratiche e interazioni rilevanti per l'uso dell'AI in un'ottica circolare.

L'analisi dei dati ha seguito una logica abduttiva e iterativa, coerente con gli studi di costruzione teorica a partire dai casi (Dubois and Gadde, 2002; Eisenhardt, 1989). In una prima fase, interviste e materiali documentali sono stati

sottoposti a codifica aperta, volta a identificare episodi salienti, pratiche ricorrenti e configurazioni organizzative relative all'impiego dell'AI nei processi di sensing, seizing e reconfiguring, nonché riferimenti a vincoli di path dependency, pratiche di traduzione e dinamiche ecosistemiche. In una seconda fase, le categorie emergenti sono state rielaborate in dialogo con il quadro teorico, mettendo in relazione le evidenze empiriche con i costrutti di circular business model innovation, dynamic capabilities, AI-enabled capabilities e organizzazione inter-organizzativa. La ricerca è in fase avanzata ma non ancora chiusa; pertanto, le evidenze di seguito presentate vanno lette come risultati preliminari, suscettibili di ulteriore consolidamento con il proseguimento della codifica comparativa e la rifinitura del modello interpretative.

Risultati. L'analisi comparativa suggerisce che il contributo dell'intelligenza artificiale ai percorsi di economia circolare assume rilievo quando l'AI opera come infrastruttura cognitiva capace di ridefinire ciò che l'organizzazione può osservare, interpretare e coordinare. In questa prospettiva, le evidenze finora raccolte convergono su tre linee interpretative: il rafforzamento delle dynamic capabilities, l'interazione ambivalente tra AI e path dependency e la riconfigurazione del posizionamento dell'impresa nell'ecosistema.

AI-enabled dynamic capabilities e riconfigurazione dei processi di circolarità

Una prima evidenza preliminare riguarda il modo in cui l'intelligenza artificiale contribuisce allo sviluppo di capacità dinamiche orientate alla circolarità, consentendo alle organizzazioni di individuare opportunità emergenti, selezionare nuove traiettorie di valore e riconfigurare nel tempo risorse, strutture e relazioni (Teece, 2007; Santa-Maria et al., 2022). Nei casi analizzati, l'AI interviene su questi processi non solo aumentando la disponibilità di dati, ma ampliando il campo decisionale in relazione a flussi di risorse, condizioni d'uso, inefficienze operative e possibilità di recupero di valore. Le tecnologie AI-based sostengono quindi la transizione circolare quando vengono incorporate nelle routine e nei criteri decisionali, trasformando il dato in apprendimento organizzativo e il monitoraggio in capacità di azione strategica (Rosa et al., 2020; Sjödin et al., 2023).

Ciò emerge anzitutto sul piano del sensing. Nel caso dell'Azienda A, la combinazione tra sistemi intelligenti, monitoraggio dei processi e attenzione alla rigenerazione dei componenti rafforza la capacità di individuare anomalie, sprechi e valore recuperabile lungo il ciclo di vita degli asset. Nell'Azienda B, l'impiego dell'AI nei processi di classificazione e identificazione informativa dei capi accresce la visibilità sui flussi operativi, rendendo più intelligibili le caratteristiche, le condizioni e le possibili destinazioni dei prodotti lungo il processo. Nel contesto dell'Azienda C, invece, il sensing si estende oltre i confini organizzativi, poiché la piattaforma sviluppata dall'impresa rende leggibili dati relativi a materiali, processi produttivi e pratiche di sostenibilità dei fornitori, offrendo ai marchi una rappresentazione più strutturata degli impatti ambientali e sociali della supply chain. Nel complesso, l'evidenza comparata suggerisce che l'AI rafforza il sensing "circolare" rendendo osservabili dimensioni di performance prima frammentate o scarsamente comparabili, in linea con gli studi che attribuiscono alle tecnologie digitali un ruolo centrale nella tracciabilità estesa e nella lettura predittiva dei flussi di risorse (Rosa et al., 2020).

Una dinamica analoga si osserva sul piano del seizing e del reconfiguring. La letteratura sui modelli di business circolari ha mostrato che la capacità di cogliere opportunità richiede la creazione di nuove value proposition, nuovi criteri di allocazione delle risorse e nuove modalità di relazione con clienti e partner (Pieroni et al., 2019; Reim et al., 2021). Nei casi osservati, l'AI appare rilevante proprio perché contribuisce a trasformare evidenze digitali in scelte operative e strategiche orientate alla circolarità. Nell'Azienda A, gli output generati dai sistemi intelligenti orientano investimenti e interventi verso la riduzione degli scarti e una migliore valorizzazione delle pratiche di recupero. Nell'Azienda B, l'integrazione tra strumenti AI-based e database globale dei clienti rafforza una proposta di valore fondata su servizio, standardizzazione e uso più efficiente delle risorse. L'Azienda C mostra come la disponibilità di dati strutturati sulla filiera e sull'impatto dei prodotti alimenti decisioni legate alla conformità normativa, alla selezione dei fornitori e alla comunicazione della sostenibilità. Da questa lettura emerge che l'AI-enabled seizing non si riduce all'elaborazione di informazioni e che il reconfiguring non riguarda soltanto l'efficienza dei processi esistenti, ma anche la formazione di capabilities in cui digitale, operations, sostenibilità e coordinamento vengono progressivamente ricomposti in nuove routine decisionali e organizzative (Warner and Wäger, 2019; Sjödin et al., 2023).

Tra sblocco della path dependency e nuove dipendenze digitali

Un secondo risultato preliminare riguarda la relazione tra utilizzo dell'intelligenza artificiale e meccanismi di path dependency. I percorsi di trasformazione circolare si confrontano con inerzie profonde, radicate non solo negli asset materiali e nelle routine operative, ma anche nei criteri di valutazione, negli schemi cognitivi e nelle logiche istituzionali che sostengono il paradigma lineare (Sydow et al., 2009; Vergne and Durand, 2011; Santa-Maria et al., 2022). I casi mostrano che l'AI può contribuire a mettere in discussione traiettorie sedimentate, ma soltanto quando gli output algoritmici vengono tradotti in nuovi criteri di giudizio, nuove metriche di performance e nuove pratiche di coordinamento. Il suo contributo si colloca quindi in una tensione evolutiva in cui la tecnologia può agire come meccanismo di discontinuità rispetto all'esistente, ma anche generare nuove forme di dipendenza da infrastrutture di dati, standard tecnici e modelli di classificazione (Cao et al., 2021; Ritala et al., 2024).

Nel caso dell'Azienda A risulta particolarmente evidente la capacità dell'AI di allentare vincoli cognitivi e materiali legati a una visione lineare del valore. La disponibilità di dati storici, indicatori predittivi e simulazioni tecniche rende più

plausibili scenari in cui manutenzione avanzata, rigenerazione dei componenti ed estensione della vita utile cessano di apparire eccezioni marginali e diventano alternative organizzative e finanziarie legittime. Il punto rilevante non sta soltanto nella maggiore capacità di previsione, ma nel fatto che l'AI rende confrontabili opzioni diverse, riducendo la percezione di rischio associata a configurazioni circolari e mettendo in discussione l'assunto, sedimentato nelle routine industriali, secondo cui il valore risieda primariamente nella produzione e vendita del nuovo. In questo senso, l'AI svolge una funzione di unlocking cognitivo coerente con gli studi che interpretano le dynamic capabilities come meccanismi di disancoraggio rispetto a traiettorie storiche e lock-in organizzativi (Teece, 2007; Santa-Maria et al., 2022).

Una configurazione complementare si osserva nell'Azienda C, dove la possibilità di sostenere assetti circolari dipende dalla raccolta, dalla comparabilità e dalla standardizzazione di dati distribuiti lungo la filiera. In questo caso l'AI amplia la capacità di leggere gli impatti ambientali e sociali dei prodotti e di rendere più trasparenti i processi produttivi, ma la robustezza della soluzione resta fortemente condizionata dalla qualità dei dati, dalla disponibilità dei partner a condividere informazioni e dall'esistenza di standard sufficientemente stabili da consentire interoperabilità e interpretazione comune. Il caso mette così in luce come il superamento di inerzie lineari possa accompagnarsi alla formazione di nuove dipendenze digitali, nelle quali la possibilità stessa di agire circolarmente viene ancorata a infrastrutture informative, protocolli di classificazione e architetture di piattaforma (Cao et al., 2021; Ritala et al., 2024).

Ancora diverso è il contributo dell'Azienda B, che illumina il medesimo meccanismo dal punto di vista della gestione di routine operative distribuite. In una rete internazionale in franchising, l'impiego dell'AI nella classificazione dei capi, nel coordinamento del servizio e nell'integrazione di un database clienti condiviso rafforza la standardizzazione e la replicabilità dei processi, ma al contempo rende centrale il lavoro di adattamento, interpretazione e mediazione tra il livello centrale e i contesti locali di esecuzione. L'AI non elimina quindi il giudizio umano; piuttosto, lo rende più esigente, perché gli output algoritmici devono essere tradotti in criteri operativi praticabili e in decisioni legittime per attori diversi. Il caso mostra così che la trasformazione non si produce quando la tecnologia viene semplicemente aggiunta a routine esistenti, ma quando emergono competenze di traduzione capaci di integrare standardizzazione digitale e variabilità "situata" del servizio, in linea con gli studi che sottolineano il ruolo persistente dell'intervento umano nell'interpretazione degli output AI-based (Cao et al., 2021; Leonardi, 2013).

Letti attraverso una lente comune, i tre casi mostrano che l'AI interagisce con la path dependency in modo ambivalente e relazionale. Essa contribuisce a disancorare l'organizzazione da metriche, assunzioni e pratiche ereditate, mettendo in luce scenari alternativi di valore e, successivamente, rendendoli intelligibili e legittimi attraverso la costruzione di cornici interpretative condivise. Al tempo stesso, il suo impiego può irrigidire le traiettorie di cambiamento se la base cognitiva dell'azione viene progressivamente assorbita da standard, dati e modelli non sufficientemente compresi e negoziati tra i diversi attori. Il suo uso trasformativo dipende quindi dalla capacità dell'organizzazione di integrare l'apprendimento algoritmico con quello umano e di sviluppare competenze di coordinamento e traduzione capaci di impedire che lo sblocco delle inerzie lineari si traduca in nuove rigidità digitali (Warner and Wäger, 2019; Ritala et al., 2024).

Riconfigurazione strategica e riposizionamento dell'impresa nell'ecosistema

Un ulteriore risultato riguarda la dimensione ecosistemica della trasformazione circolare. I percorsi di economia circolare non si realizzano entro i confini della singola organizzazione, ma si sviluppano in reti di attori interdipendenti nelle quali la creazione del valore dipende dall'allineamento tra flussi fisici, dati, standard, responsabilità e tempi decisionali (Adner, 2017; Jacobides et al., 2018). In tale prospettiva, i casi analizzati mostrano che l'AI diventa realmente trasformativa non solo quando rafforza capacità dinamiche interne, ma quando contribuisce a costruire una base cognitiva condivisa tra attori diversi, rendendo possibili nuove forme di coordinamento, traduzione tra linguaggi eterogenei e, in alcuni casi, riposizionamento dell'impresa nell'ecosistema (Sjödin et al., 2024).

È soprattutto il caso dell'Azienda C a rendere particolarmente visibile questa dinamica. In tale contesto, l'AI alimenta una piattaforma che raccoglie, ordina e rende interpretabili i dati provenienti da attori diversi della filiera, consentendo ai brand di ottenere una rappresentazione più strutturata di materiali, processi produttivi e impatti ambientali e sociali. Il punto analiticamente più rilevante non è soltanto la maggiore trasparenza della supply chain, ma il fatto che tale trasparenza richieda un lavoro continuo di standardizzazione, allineamento e mediazione tra soggetti che operano con logiche e sistemi informativi differenti. In questo senso, l'impresa svolge una funzione di intermediazione cognitiva e relazionale, traducendo dati eterogenei in metriche condivisibili e rendendo possibile una forma di governance informativa della filiera.

Per quanto riguarda l'Azienda A, l'integrazione di dati storici e predittivi lungo il ciclo di vita degli asset rafforza la capacità dell'impresa di coordinare relazioni che non si limitano all'attività di vendita, ma coinvolgono anche il cliente, la rete di assistenza, la manutenzione avanzata, la rigenerazione e la gestione del rischio operativo. Grazie all'accumulo di conoscenza tecnica e all'elaborazione algoritmica delle prestazioni, la relazione con gli attori della filiera tende a evolvere da scambio puntuale a collaborazione a più alto contenuto cognitivo. L'accesso a una base informativa più ampia e strutturata rafforza inoltre la capacità dell'impresa di incidere sulla definizione di pratiche, standard tecnici e metriche di qualità rilevanti per l'ecosistema del recupero e della gestione circolare degli asset, segnalando una possibile salita di ruolo ecosistemica.

L'Azienda B consente invece di osservare il medesimo fenomeno in una configurazione più vicina a quella di una rete di servizio distribuita. In questo contesto, l'integrazione tra sistemi di classificazione, coordinamento operativo e database globale dei clienti non produce solo maggiore efficienza, ma consolida un'infrastruttura relazionale che collega punti vendita, centro organizzativo e cliente finale attorno a criteri condivisi di trattamento, monitoraggio e continuità del

servizio. Anche in ecosistemi più frammentati, dunque, il valore dell'AI dipende dalla possibilità di sincronizzare attori diversi attraverso dati comuni, routine standardizzate e meccanismi di coordinamento che, pur mantenendo centrale il giudizio umano, riducono la dispersione informativa e rafforzano la coerenza complessiva del sistema.

Da questa lettura emerge che l'AI contribuisce a ridefinire il posizionamento dell'impresa nell'ecosistema quando rende possibile un salto di qualità nelle capacità di traduzione e orchestrazione. La prima riguarda la trasformazione di dati, indicatori e output algoritmici in linguaggi comprensibili e legittimi per attori differenti, mentre la seconda concerne la capacità di allineare flussi informativi, standard, responsabilità e aspettative lungo configurazioni organizzative estese, facendo dell'impresa un nodo attivo di coordinamento. In questa prospettiva, l'AI contribuisce a ridisegnare l'interfaccia tra impresa ed ecosistema, sostenendo nuove forme di governance e di co-produzione del valore circolare (Adner, 2017; Jacobides et al., 2018; Sjödin et al., 2024).

La sintesi comparativa dei casi permette di formulare una proposizione teorica emergente secondo cui l'efficacia trasformativa dell'intelligenza artificiale nei percorsi di economia circolare risiede nella capacità dell'organizzazione di governare la tensione dialettica tra il superamento delle inerzie lineari e l'insorgere di nuove dipendenze digitali. Le evidenze empiriche mostrano come tale dinamica assuma declinazioni peculiari in base al contesto operativo. Negli assetti industriali caratterizzati da una forte base tecnica la priorità risiede nello sblocco dei lock-in cognitivi legati alla rigenerazione dei materiali, mentre nelle architetture di piattaforma e nelle reti distribuite emerge la criticità della governance dell'interoperabilità dei dati. In ultima analisi, affinché la transizione abilitata dall'AI si traduca in un effettivo riposizionamento strategico, gli output algoritmici devono essere integrati in metriche e pratiche condivise mediante espliciti meccanismi di traduzione socio-tecnica tra i diversi attori dell'ecosistema.

Limiti della ricerca. Il lavoro presenta alcuni limiti coerenti con la sua natura di "work in progress". Le evidenze discusse hanno carattere preliminare e saranno ulteriormente consolidate mediante il completamento il confronto sistematico tra i casi e una formalizzazione più esplicita delle proposizioni emergenti. Inoltre, il numero limitato di casi e la loro selezione teorica non consentono finalità di generalizzazione statistica, né consentono ancora di distinguere con precisione il peso relativo delle variabili settoriali, asset-based e relazionali. Il contributo mira piuttosto a offrire un avanzamento interpretativo iniziale, utile a chiarire i meccanismi e le condizioni attraverso cui l'AI può sostenere capacità dinamiche e l'innovazione dei modelli di business circolari. Nella fase successiva della ricerca, tali aspetti saranno approfonditi anche per affinare le proposizioni teoriche e chiarire meglio le condizioni di trasferibilità dei risultati. Ciò consentirà anche di precisare con maggior rigore quali configurazioni di AI risultino più efficaci nei diversi contesti organizzativi ed ecosistemici osservati.

Implicazioni manageriali. Le evidenze preliminari suggeriscono anzitutto che le imprese dovrebbero evitare di considerare l'intelligenza artificiale come un insieme di applicazioni puntuali orientate unicamente all'efficienza operativa, ma concepirla come un'infrastruttura cognitiva capace di rendere visibili le interdipendenze, anticipare le criticità e sostenere la riconfigurazione di processi e modelli di business in chiave circolare. Una seconda implicazione riguarda le competenze organizzative necessarie per rendere l'AI effettivamente trasformativa. I risultati mostrano che il valore della tecnologia dipende in misura rilevante dalla presenza di figure e team capaci di tradurre output algoritmici, indicatori predittivi e informazioni distribuite in criteri di decisione legittimi e operativamente praticabili. Ne consegue che i percorsi di adozione dell'AI per la circolarità richiedono investimenti non solo in infrastrutture digitali, ma anche nello sviluppo di competenze ibride, interfunzionali e di coordinamento, in grado di connettere linguaggi tecnici, obiettivi economici, esigenze operative e metriche di sostenibilità. Al fine di evitare che l'adozione dell'intelligenza artificiale introduca nuove rigidità organizzative, il management è chiamato a "operativizzare" le capacità di traduzione mediante il presidio di team ibridi e interfunzionali capaci di connettere le competenze informatiche con quelle operative e di sostenibilità. Tali gruppi di lavoro hanno il compito di validare le metriche algoritmiche e di agire come boundary spanner dedicati alla mediazione tra le indicazioni generate dai sistemi intelligenti e le routine umane.

Parallelamente, la dimensione ecosistemica della governance richiede l'implementazione di pratiche collaborative rigorose quali la sottoscrizione di accordi formali per la condivisione dei dati e la definizione di protocolli congiunti per garantire l'interoperabilità dei sistemi informativi. Attraverso la strutturazione di questi meccanismi di orchestrazione, il management potrà superare la mera implementazione tecnologica per costruire le fondamenta relazionali necessarie al governo di un ecosistema circolare resiliente.

Originalità del paper. Il contributo del lavoro consiste nell'offrire una lettura dell'intelligenza artificiale come fattore abilitante della transizione circolare che non si esaurisce nella sua funzione tecnica o efficientista, ma riguarda le condizioni organizzative e relazionali attraverso le quali essa può sostenere processi di trasformazione più profondi. In questa prospettiva, il contributo mette in relazione la letteratura su circular business models, dynamic capabilities e path dependency, mostrando che il legame tra AI e circolarità è mediato da specifici meccanismi di apprendimento, interpretazione e riconfigurazione.

Un secondo elemento di originalità riguarda la messa a fuoco del carattere non lineare di tale relazione. Le evidenze preliminari suggeriscono infatti che l'AI può contribuire a mettere in discussione inerzie, metriche e assunti propri del paradigma lineare, ma al tempo stesso può generare nuove dipendenze da standard, architetture informative e criteri di classificazione. Il lavoro contribuisce quindi a chiarire che il potenziale trasformativo dell'AI dipende dalla capacità

dell'organizzazione di governare in modo riflessivo il rapporto tra apprendimento algoritmico, giudizio umano e ridefinizione delle logiche di valore.

Infine, il paper amplia la comprensione della transizione circolare, evidenziando che il rilievo strategico dell'AI cresce quando essa sostiene forme di coordinamento e di orchestrazione tra attori interdipendenti, incidendo sul posizionamento dell'impresa nell'ecosistema. In quanto "work-in-progress", il contributo propone una prima concettualizzazione empiricamente informata di tali dinamiche, che la prosecuzione dell'analisi consentirà di precisare ulteriormente.

Managing Generative Artificial Intelligence in Higher Education: Inclusion, Social Sustainability and Governance Challenges

STEFANIA D'APRILE[1], GIOVANNI SPATOLA[2], MARIA ZIFARO[3]

Abstract. *This study contributes to the emerging debate on the management of digital transformation in higher education by examining the organizational, strategic, and governance implications of Generative Artificial Intelligence (GenAI). Although scholarly production on AI in higher education has grown exponentially in recent years, the literature remains fragmented across pedagogical, technological, behavioral, and ethical perspectives, providing limited systemic understanding of how AI adoption reshapes universities as complex organizations.*

Drawing on a theory-building approach supported by systematic literature review, document analysis, and bibliometric mapping, this study conceptualizes GenAI adoption as a multi-level socio-organizational transformation affecting teaching processes, organizational structures, and institutional governance simultaneously. Bibliometric findings reveal a strong dominance of technology acceptance models and pedagogical applications, while strategic governance and social sustainability remain theoretically peripheral.

In response, the paper proposes an integrated analytical framework that interprets GenAI adoption as a coordinated capability-building trajectory oriented toward responsible governance, institutional legitimacy, and long-term inclusive value creation in higher education institutions.

Keywords: *Generative Artificial Intelligence; Higher Education Management; AI Governance; Social Sustainability; Digital Transformation; Dynamic Capabilities.*

Introduction. Digital transformation has become one of the most pervasive drivers of organizational change in contemporary societies. The integration of advanced digital technologies into operational and strategic processes has redefined value creation logics, decision-making architectures, and stakeholder relationships across sectors. Among these technologies, Artificial Intelligence (AI) occupies a particularly transformative role, as it extends beyond automation of routine tasks and increasingly supports cognitive, analytical, and strategic activities.

Management literature progressively recognizes that AI should not be interpreted merely as infrastructural investment but as a catalyst for deep organizational reconfiguration. The introduction of intelligent systems alters skill distributions, reshapes human–machine interaction, and requires governance arrangements capable of addressing algorithmic risk, accountability, and ethical oversight. AI therefore constitutes a systemic phenomenon that affects micro-level routines and macro-level institutional structures simultaneously.

Within higher education, these dynamics are especially significant. Universities are hybrid organizations characterized by the coexistence of academic, administrative, institutional, and regulatory logics. The emergence of Generative Artificial Intelligence—capable of producing text, code, images, and analytical outputs—introduces unprecedented opportunities for personalization, research support, and administrative automation. Simultaneously, it raises concerns regarding academic integrity, epistemic authority, intellectual property, data governance, and institutional legitimacy.

Despite the rapid expansion of research addressing AI in higher education, the field remains conceptually segmented. Pedagogical studies emphasize instructional innovation and learning enhancement. Behavioral research concentrates on user acceptance and perceived usefulness. Ethical scholarship investigates fairness, bias, and accountability. However, an integrative management perspective capable of connecting these dimensions within a coherent organizational framework remains underdeveloped.

This study addresses that gap by conceptualizing GenAI adoption as a multi-level institutional transformation process. By combining systematic review, bibliometric mapping, and document analysis, the paper identifies structural asymmetries in existing scholarship and advances a governance-oriented capability framework grounded in dynamic capabilities theory and social sustainability principles.

Theoretical Background

Digital Transformation and Organizational Capabilities

Digital transformation entails structural and strategic reconfiguration rather than incremental process optimization. Technologies reshape value propositions, resource configurations, and organizational boundaries. In this view, digital tools function as enablers of redesign rather than isolated technical upgrades.

The dynamic capabilities framework provides a suitable interpretative lens. Dynamic capabilities refer to an organization's capacity to sense opportunities, seize them through investment and coordination, and reconfigure internal competences in response to environmental turbulence. AI intensifies such turbulence by accelerating innovation cycles and introducing regulatory complexity.
Generative AI amplifies these dynamics by interacting directly with knowledge production and cognitive processes. It redistributes expertise, challenges traditional authority structures, and redefines the boundaries between human and machine agency. Consequently, organizations must develop sensing, seizing, and reconfiguring capabilities tailored to AI-driven transformation.
While extensively applied in corporate contexts, dynamic capability perspectives remain comparatively underutilized in public and hybrid institutions such as universities.

Artificial Intelligence in Higher Education
Research on AI in higher education evolved across multiple waves: intelligent tutoring systems, learning analytics, predictive modeling, and most recently generative systems. The public diffusion of large language models after 2022 significantly accelerated experimentation in teaching, research, and administration.
However, much of this literature conceptualizes AI primarily as an instructional tool. Analytical attention concentrates on perceived usefulness, ease of use, and behavioral intention constructs derived from the Technology Acceptance Model (TAM) and its extensions. While valuable, these approaches do not capture organizational restructuring or strategic governance adaptation.
The diffusion of GenAI tools frequently preceded institutional policy development, generating asymmetries between technological experimentation and governance maturity. This tension underscores the need for a systemic management lens.

AI Governance and Ethical Frameworks
Parallel to educational research, a substantial body of literature addresses AI governance, emphasizing principles such as transparency, accountability, fairness, and human oversight. Regulatory developments—particularly within the European context—have introduced risk-based frameworks that require impact assessments, documentation practices, and compliance mechanisms for high-risk AI systems.
In universities, these regulatory pressures intersect with institutional missions centered on public value, knowledge creation, and social responsibility. Governance mechanisms must therefore balance innovation incentives with ethical safeguards and compliance requirements.
Importantly, governance should not be reduced to legal conformity. It represents a strategic capability that enables organizations to align technological adoption with long-term legitimacy and stakeholder trust. Within higher education, governance arrangements must integrate academic autonomy, public accountability, and digital innovation in a coherent manner.

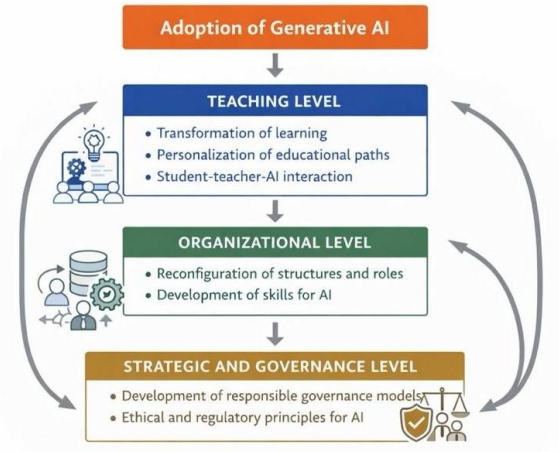
Bibliometric Analysis and Identification of the Research Gap
To empirically map the intellectual structure of the field, a bibliometric analysis was conducted on two datasets covering the period 2015–2026. The first dataset included 9,476 documents related to Artificial Intelligence and higher education. Publication trends indicate exponential growth after 2022, corresponding to the widespread diffusion of generative models.
Thematic mapping reveals that the dominant cluster revolves around technology acceptance frameworks, particularly the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT). Foundational contributions by Davis and Venkatesh constitute the most central references within citation networks. This suggests that much of the literature conceptualizes AI adoption primarily through perceived usefulness, perceived ease of use, and behavioral intention constructs.
A secondary cluster comprised centers on ChatGPT and generative AI applications in teaching and assessment. While highly visible and rapidly expanding, this cluster appears conceptually underdeveloped, with limited integration of organizational or strategic theory.
Notably, governance and strategic management themes do not emerge as motor themes within the bibliometric maps. Even in a second dataset comprising 3,763 documents explicitly focused on governance and management, acceptance models remain highly central, whereas institutional and capability-based perspectives appear peripheral.
These findings highlight a structural gap. The field is characterized by micro-level behavioral explanations and pedagogical experimentation, but lacks a meso- and macro-level organizational framework capable of integrating governance, strategic alignment, and social sustainability.

Figure 1 - Publication Trends on Artificial Intelligence in Higher Education (2015–2026)

Methodology. This study adopts a qualitative theory-building approach integrating three complementary methods: systematic literature review, document analysis, and bibliometric mapping.
The systematic review was conducted using major academic databases and followed a multi-stage screening process. Inclusion criteria focused on peer-reviewed articles addressing AI, generative AI, governance, and higher education management.
Document analysis included European regulatory frameworks, international guidelines, and policy reports concerning AI in education. These sources were examined to contextualize governance requirements and institutional constraints.
Bibliometric analysis was employed to identify dominant theoretical streams, citation structures, and thematic evolution. By mapping co-citation networks and thematic clusters, the analysis provided empirical grounding for identifying underexplored areas within the field.
The integration of these methods strengthens the internal coherence between gap identification and conceptual framework development.

Results: GenAI Adoption as a Multi-Level Socio-Organizational Transformation
The integration of theoretical insights, bibliometric evidence, and policy analysis allows the conceptualization of Generative Artificial Intelligence adoption in higher education as a multi-level socio-organizational transformation. Rather than constituting a purely technological upgrade, GenAI introduces structural shifts that unfold simultaneously across pedagogical practices, organizational configurations, and institutional governance arrangements.
These levels are analytically distinct but empirically interdependent. Changes at the instructional level generate pressures for organizational redesign, which in turn require strategic governance adaptation. The transformation is therefore recursive and systemic.

The Pedagogical Level: Personalization, Accessibility, and Inclusion
At the pedagogical level, GenAI enables the automated generation of educational content, adaptive feedback mechanisms, simulation-based learning environments, and multilingual academic support. These functionalities enhance the potential for personalized learning trajectories tailored to students' cognitive profiles, prior knowledge, and learning pace.
Personalization, however, should not be equated with automatic inclusivity. While AI systems can lower barriers for students with diverse linguistic, cognitive, or socio-economic backgrounds, inclusion outcomes depend heavily on institutional implementation choices. Digital infrastructure availability, algorithmic literacy among faculty and students, and equitable access to AI-enabled tools critically shape distributive effects.
Furthermore, generative systems rely on training data that may embed structural biases. Without institutional safeguards, AI-generated feedback and assessment support may reproduce inequalities or reinforce epistemic asymmetries. Thus, the pedagogical potential of GenAI must be framed within governance mechanisms that ensure fairness, transparency, and human oversight.
From a management perspective, pedagogical transformation constitutes the most visible dimension of AI adoption but also the most exposed to reputational and ethical risk. Universities must therefore balance innovation in instructional design with integrity safeguards and robust assessment redesign strategies.



The Organizational Level: Structural Reconfiguration and Capability Development
At the organizational level, GenAI adoption entails the reconfiguration of routines, workflows, and professional roles. Administrative processes such as student services, documentation handling, research support, and internal communication may become partially automated. This shift enables resource reallocation toward higher value-added activities, including strategic planning, curriculum innovation, and research development.
However, automation does not eliminate the need for human intervention. Instead, it redistributes expertise. Universities must develop hybrid competencies combining technical literacy, data governance knowledge, ethical evaluation skills, and pedagogical expertise. This requirement aligns closely with the dynamic capabilities framework, which emphasizes

the ability to sense technological opportunities, seize them through structured investment, and reconfigure internal resources accordingly.
GenAI adoption thus becomes a capability-building process rather than a discrete implementation project. Institutions must establish internal coordination mechanisms, interdisciplinary task forces, and monitoring systems capable of adapting to continuous technological evolution.
Bibliometric findings reinforce this argument. The limited centrality of organizational and strategic theories in the field suggests that universities may be experimenting with AI without sufficiently embedding it within structured capability development pathways. A management-oriented perspective helps reposition AI adoption as a long-term organizational transformation rather than a short-term technological response.

The Strategic and Institutional Level: Governance and Social Sustainability
At the strategic level, GenAI adoption intersects with institutional legitimacy, regulatory compliance, and stakeholder trust. Regulatory frameworks increasingly impose risk-based classifications, documentation requirements, and oversight obligations for AI systems. Universities must therefore implement governance architectures capable of ensuring transparency, accountability, and compliance.
Governance should not be conceptualized as a defensive compliance mechanism. Rather, it functions as a strategic capability enabling institutions to align technological innovation with public mission and long-term sustainability. In higher education, social sustainability encompasses equitable access to learning opportunities, preservation of academic integrity, and maintenance of epistemic credibility.
The absence of clear governance mechanisms may undermine institutional trust, especially in contexts where AI-generated content challenges traditional notions of authorship and originality. Conversely, well-designed governance frameworks can strengthen universities' reputational capital by demonstrating responsible innovation.
Strategic alignment requires integrating AI adoption into institutional mission statements, digital transformation strategies, and performance evaluation systems. Governance structures must connect pedagogical experimentation with ethical oversight and organizational risk management, ensuring coherence across levels.

A Multi-Level Framework for GenAI Adoption in Higher Education
Building upon the preceding analysis, this study proposes a multi-level conceptual framework structured around three interconnected dimensions: pedagogical transformation, organizational capability development, and strategic governance orientation.
The pedagogical dimension represents the operational interface where GenAI directly interacts with teaching and learning processes. It encompasses personalization strategies, assessment redesign, and student engagement practices.
The organizational dimension functions as the mediating layer in which routines, competencies, and coordination mechanisms are reconfigured. This layer translates technological potential into institutional capability.
The strategic and governance dimension provides normative orientation and long-term direction. It integrates regulatory compliance, ethical oversight, risk management, and social sustainability objectives.
The framework assumes dynamic feedback loops among these levels. Pedagogical experimentation generates new organizational requirements; organizational restructuring necessitates governance adaptation; governance orientation influences the scope and direction of pedagogical innovation.
In this model, successful GenAI adoption depends on balanced development across all three dimensions. Overemphasis on technological deployment without governance integration may produce ethical and reputational risks. Conversely, excessive regulatory caution without capability development may inhibit innovation and reduce competitiveness.
The framework therefore conceptualizes GenAI adoption as a coordinated process of capability orchestration rather than isolated technological implementation.

Figure 2 - Multilevel framework of Generative AI adoption: didactic, organizational and governance dimensions

Theoretical Implications. This study contributes to the literature in several ways.
First, it shifts the dominant analytical focus from individual-level technology acceptance to institutional-level capability development. While behavioral intention models remain valuable for understanding adoption dynamics, they do not capture structural transformation processes within complex organizations.
Second, it extends the dynamic capabilities framework to the context of higher education, highlighting how public and hybrid institutions must integrate sensing, seizing, and reconfiguring mechanisms in response to AI-driven change.
Third, it introduces social sustainability as a central evaluative criterion for AI governance in universities. Rather than measuring success solely in terms of efficiency or adoption rates, the framework emphasizes equitable access, fairness, and long-term legitimacy.
Finally, by integrating bibliometric evidence with conceptual development, the study bridges descriptive mapping of the field with normative theory building, offering a structured pathway for future empirical research.

Managerial Implications. For university leaders and policy-makers, the findings suggest that GenAI adoption requires coordinated strategic planning rather than fragmented experimentation.
Institutions should establish interdisciplinary governance bodies integrating academic staff, IT professionals, legal experts, and student representatives. Such structures can facilitate balanced decision-making and reduce siloed implementation.
Investment in AI literacy programs for faculty and administrators is essential to prevent superficial or uncritical use of generative tools. Capability development should include training on bias detection, data protection, and algorithmic transparency.
Universities should also implement periodic AI impact assessments that evaluate not only technical performance but also social and ethical consequences. Integrating social sustainability indicators into institutional performance dashboards can strengthen alignment between innovation and public mission.
Ultimately, GenAI should be embedded within long-term institutional strategies rather than treated as a temporary technological trend.

Limitations and Future Research. This study adopts a conceptual and theory-building approach and does not empirically test the proposed framework. Although bibliometric mapping and document analysis provide structural insight, empirical validation through case studies, surveys, or longitudinal analysis would strengthen explanatory robustness.
Future research could explore comparative cross-national analyses to examine how regulatory environments shape governance models. Quantitative studies may test relationships between governance maturity, capability development, and educational outcomes. Longitudinal research could assess how institutional strategies evolve as AI technologies mature.
Additionally, interdisciplinary inquiry integrating management, education, and information systems perspectives would further enrich theoretical development.

Conclusions. The diffusion of Generative Artificial Intelligence in higher education represents a structural transformation that transcends technological enhancement. It reshapes pedagogical practices, reconfigures organizational routines, and challenges institutional governance architectures.
Bibliometric evidence demonstrates that existing scholarship remains heavily oriented toward technology acceptance and pedagogical experimentation, with limited integration of organizational and strategic perspectives. This study addresses that gap by proposing a multi-level framework grounded in dynamic capabilities and social sustainability principles.
GenAI adoption should be understood as a coordinated capability-building process that integrates pedagogical innovation, organizational redesign, and responsible governance. Universities capable of orchestrating these dimensions coherently will be better positioned to transform AI from a disruptive force into a strategic driver of inclusive and sustainable value creation.

Needful or Painful?
The perception of the adoption of AI from Top Management Team.

ENRICO MARCAZZAN, ALESSANDRO BARONCELLI, VERONICA SCUOTTO

Abstract. *The adoption of Artificial Intelligence (AI) in small to medium enterprises (SMEs) and large companies is flourishing. There is strong momentum around the adoption of AI and everyone is studying different nuances of it. In this particular case, the research explores the perception of AI from the Top Management Team (TMT). The research will rely on a sample of more than 100 observations of Italian SMEs collected through a survey directed to the top management of the firms. Moreover, the authors will analyze the data through an exploratory quantitative approach. As expected, the research aims to contribute to the management literature by offering a perception of the adoption of AI from TMT and how this can create new organizational dynamics that influence AI adoption and digital transformation. It also introduces the concept of a needful-painful paradox in AI adoption. This paradox reflects the simultaneous perception of AI as both a strategic necessity and an organizational challenge. It also raises reflections on opportunities and challenges in AI adoption, requiring that TMT develop technological understanding, foster innovation-oriented mindsets, and guide organizational transformation processes that support AI implementation.*
Keywords: *Artificial Intelligence adoption; top management teams; business model innovation; digital transformation; managerial perception; small and medium enterprises*

Framing of the research. Leveraging a large amount of data used to be accessible only to tech giants like Google, Amazon, Microsoft, IBM and Oracle through specialized platforms such as Snowflake, Databricks, and Cloudera; while nowadays the management of these data seems to be facilitated for small to medium companies too thanks to the adoption of AI.

Artificial intelligence (AI) is one of the most disruptive technologies of our modern day. It has shaped modern business models, allowing companies to process large volumes of data so as to offer new strategic pathways and support decision-making processes. Companies are faced with the ability to adopt this technology in all business units due to positive and negative perceptions of such adoption that generate pain or joy. However, since companies depend on AI adoption to be more competitive, Top Management Teams (TMTs) have to bring this technology into their daily decision-making processes and fully embrace it in their business models. As Kaplan and Haenlein (2019) claim, AI is a useful tool to interpret data, inducing a sense of adaptation in organizations to achieve their business goals. AI enables business model innovation, transforming how value is created, delivered and transformed (Sjodin et al., 2023). In turn, AI adoption often requires significant changes to existing organizational processes, structures, and capabilities. Yet, not all companies are fully equipped with the right capabilities to use AI and learn from its patterns, while simultaneously addressing concerns related to ethics, governance, and organizational resistance. In this scenario, the role of TMT is salient. TMTs are responsible for defining strategic priorities, allocating resources, and guiding organizational change initiatives. Their perceptions and interpretations of emerging technologies strongly influence how organizations approach innovation and digital transformation. In the context of AI adoption, the attitudes and perceptions of TMTs can determine whether organizations embrace AI as a strategic opportunity or approach it with caution due to perceived risks and challenges. Despite the relevance of AI adoption for TMTs, the management literature seems more focused on how AI is perceived by employees (Biswas et al., 2024; Zhou et al., 2025), how AI requires new capabilities and skills (Ng et al., 2023; Bukartaite & Hooper, 2023), and how AI makes a company more competitive even though not sustainable (Wingate et al., 2025). The salient role of leadership in digital transformation has been claimed (Cortellazzo et al., 2019), even though relatively little attention has been paid to how top managers themselves perceive AI adoption and how these perceptions influence strategic decisions. Considering that AI can be perceived as an opportunity or a challenge, bringing on the one hand novelty and innovation and on the other hand fear, reluctance, and ethical and sustainability concerns (Jorzik et al., 2024; Del Giudice et al., 2023), it is fundamental to understand these perceptions in order to explain how organizations approach AI adoption. Covering this gap is critical because managerial positions lead digital transformational changes that drive the success or failure of organizational innovation initiatives.

Purpose of the paper. The present research addresses this gap by exploring the perceptions of TMTs toward the adoption of AI technologies in the household appliances and consumer electronics sector in Italy. The research question is structured as follows: is the adoption of AI perceived by TMTs as needful or painful? It is a guiding question to explore whether AI adoption is perceived as a strategic necessity or as a challenging organizational burden.

This research will rely on a sample of more than 100 observations (expected number) of Italian SMEs collected through a survey directed to the top management of the firms. Moreover, considering the fact that AI can be considered a novel phenomenon and, therefore, can be investigated through an exploratory approach (von Krogh, 2018), the authors will analyze the data through an exploratory quantitative approach (Bamberger and Ang, 2016).

The research aims to contribute to the management literature by offering a perception of the adoption of AI from TMTs and how this can create new organizational dynamics that influence AI adoption and digital transformation. It also

introduces the concept of a needful-painful paradox in AI adoption. This paradox reflects the simultaneous perception of AI as both a strategic necessity and an organizational challenge. Conceptualizing AI adoption in this way provides a more nuanced understanding of the tensions experienced by top managers during digital transformation. It also raises reflections on opportunities and challenges in AI adoption, requiring that TMTs develop technological understanding, foster innovation-oriented mindsets, and guide organizational transformation processes that support AI implementation.

In terms of theoretical background, the widespread of the digital transformation has induced a revolution in business model innovation through the AI capacity to manage large data (Holmström, 2022). AI is leading innovation generation behind products, business models, and services among others (Brem et al., 2021; Burger et al., 2023). Companies operate using advanced forms of algorithmic decision-making and automation. Studies on AI-enabled innovation claim the role of AI in transforming business models and enabling new forms of value creation. The business model innovation (Foss & Saebi, 2017; Acciarini et al., 2023) as a relevant tool to innovate that describe all main activities of a business such as product innovation, customer connections, value propositions and so on has been changing overtime with the advent of AI technologies (Mass & Tucci, 2013). Such change derives from some challenges and operational efficiency that AI has brought up. AI is defined as "a system's ability to interpret external data correctly, to learn from such data, and to use those learnings to achieve specific goals and tasks through flexible adaptation" (Kaplan and Haenlein, 2019, p. 17). As Sjodin et al. (2023) affirm AI technologies can enhance operational efficiency, support predictive maintenance, optimize supply chains, and improve customer experiences through personalized services. Alongside, AI is a predictive technology that offer data-driven services to generate value for customers (Kohtamäki et al., 2022). Organizations create and capture value differently than before, developing new capabilities as data management, algorithm development, and digital governance. It requests interdisciplinary teams to integrate technical expertise in the business daily life and obtain strategic goals. Research suggests that TMTs need several competencies (not necessarily technical competences) in order to effectively guide AI adoption. Yet, TMTs need to understand how AI works and what are the benefits that might come from in order to make strategic decisions (Jorzik et al., 2024). TMT also need AI oriented mindset that involves openness to experimentation, willingness to explore innovative solutions, and the ability to adapt to technological change. AI adoption often involves trial-and-error processes and iterative learning, which require organizational cultures that support experimentation and tolerate failure (Jorzik et al., 2024). As naturally expected, leadership capabilities are relevant to guide the adoption of AI that also ask for good communication skills and empathetic understanding. TMTs need to address employees concerns and reluctance related to automation and technological change while ensuring that AI adoption enhances rather than replaces human capabilities. This would allow TMT to strategize the adoption of AI and increase the level of acceptance and adoption. This should proportionate to investment cost (in terms of time and costs) in the adoption of AI and also balancing innovation opportunities with risks and uncertainty. Indeed, TMTs have to deal with several challenges such as the degree of uncertainty related to AI investments that make difficult the process of resource allocation. TMTs have also to face employees' reluctance in the adoption of AI due to the fear of being replaced (Del Giudice et al., 2023). They might therefore address these concerns by fostering transparent communication and promoting a collaborative relationship between humans and AI systems (Jorzik et al., 2024). Then ethical and sustainable play a relevant concern in the adoption of AI. AI technologies raise issues about data privacy algorithmic bias, and accountability along with how its use meets the sustainable development goals by the United Nations. In this sense, companies need to have a transparent privacy procedure and develop governance mechanisms that ensure responsible and ethical use of AI technologies. Concluding, these opportunities and challenges can develop different perceptions of the adoption of AI: some managers may view AI as essential for maintaining competitiveness, while others may emphasize the organizational risks and complexities associated with its implementation. Understanding these perceptions is critical for explaining how organizations approach AI adoption.

Methodology. This study builds on exploratory quantitative research examining the relationship between AI adoption, business model innovation, and top management leadership. A structured questionnaire is developed and is going to be administered to more than 100 firms (expected number) in the household appliances and consumer electronics sector in Italy. Previous studies have applied qualitative methods by implementing an inductive methodology to capture the perspectives and experiences of individuals involved in strategic decision-making processes (Jorzik et al., 2024; Sjödin et al., 2023; Burström et al., 2021).

Our study will rely on the view of top managers with diverse professional backgrounds to obtain a comprehensive understanding of organizational experiences with AI adoption. Developed during October and November 2025 and tested by both researchers (especially those with expertise in innovation management) and practitioners during December 2025 and January 2026, the questionnaire consists of about 35 questions mainly focused on AI and business model innovation. It has been built according to the previous literature, especially in operationalizing the main variables (i.e., business model innovation, from Clauss, 2017; innovation orientation, from Farooq et al., 2021; ethics in AI-related topics, from Giarmoleo et al., 2024). In relation to AI, considering the exploratory aim of the paper, the questions are related to the actual organizational dynamics and the perceptions of top management on this subject. In particular, through the survey addressed to Italian corporate decision-makers of SMEs, we aim to analyze how (Italian) SMEs are integrating AI into their processes, which benefits are emerging, and which challenges appear to be the most relevant. Alongside the organizational dimension, the project also explores the managerial perspective, including perceptions, expectations, ethical orientations, and the competencies considered necessary to address the evolution of AI technologies in a mature and responsible way.

Results. Since we are talking of a "work-in-progress", in this section we describe the expected results. We expect that the adoption of AI will be difficult and not completely understandable even from TMTs. Such adoption is fundamental for making innovations and changing business models. It induces dual framing that raises reflections on both its strategic necessity and its organizational complexity. Although, it is widely recognized that AI technologies can enhance operational efficiency, improve decision-making, and enable new forms of innovation. Therefore, the responses are divided in AI as AI perception as a needful adoption and AI perception as a painful adoption. We don't get a single common perspective even though there is a more sensibility and interest in the use of this technology. It is considered needful because companies increasingly rely on AI to analyze complex datasets, generate predictive insights, and support strategic decision-making. AI technologies enable organizations to optimize resource allocation, improve productivity, and develop innovative products and services. In industrial contexts, AI systems can support predictive maintenance, optimize supply chain operations, and enhance sustainability through more efficient resource usage (Sjodin et al., 2023). While AI adoption is perceived painful due to its technological complexity and investment uncertain and risk. Alongside, the development of specific organizational capabilities required for AI adoption challenge TMT in looking for such competences externally while internally it is hard to get it. TMT needs to align the adoption of AI with companies' value and aims. In this realm, organizational culture plays a relevant role in determining the adoption of AI. Overall, the role of TMT is critical to make a balance between opportunities and challenges, leveraging on their leadership and communication skills.

Research limitations. Despite its potential contributions, this study presents several limitations that should be acknowledged and that open avenues for future research. First, the analysis focuses on a sample of Italian SMEs in a specific sector, which may limit the generalizability of the findings to other geographical and institutional contexts. Differences in digital maturity, technological infrastructure, and regulatory environments may influence managerial perceptions and the adoption dynamics of AI across countries and industries. Second, the study relies on cross-sectional survey data, capturing managerial perceptions at a single point in time. As a consequence, it does not allow the observation of how perceptions evolve throughout the AI adoption process or how the identified paradox may develop during different stages of organizational transformation. Longitudinal research could provide deeper insights into how managerial attitudes and organizational responses change over time. Third, the study is based on perceptual data collected from TMTs, which may introduce potential biases related to subjective evaluation or overestimation of technological capabilities. Future research could complement perceptual measures with objective indicators of AI adoption, organizational performance, or innovation outcomes. Finally, while the quantitative exploratory approach adopted in this study allows the identification of relevant patterns in managerial perceptions, it does not fully capture the complex organizational processes underlying AI implementation. Further qualitative or mixed-method studies could deepen the understanding of how managers interpret and navigate the tensions associated with AI adoption in practice.

Managerial implications. The findings of this study offer several implications for managers dealing with the adoption of AI within organizations. First, the results highlight that top managers simultaneously perceive AI as a strategic necessity and as a challenging organizational change, giving rise to what we conceptualize as the needful-painful paradox. This suggests that TMTs should not approach AI adoption merely as a technological investment, but rather as a broader strategic and organizational transformation. In this regard, managers are required to develop a stronger technological understanding in order to effectively evaluate opportunities, risks, and potential applications of AI. At the same time, organizations should invest in managerial training and in the integration of technological expertise within strategic decision-making processes. The results also emphasize the importance of fostering an organizational culture that supports experimentation, innovation, and data-driven decision making, as cultural resistance and lack of internal competences may slow down the adoption process. In particular, companies (especially SMEs) may need to rely on external collaborations, partnerships, or advisory support to acquire the capabilities required for AI implementation. Finally, the study suggests that AI should be considered not only as a tool for operational efficiency but also as a driver of value creation and innovation. When effectively managed, AI can support new forms of organizational learning and contribute to the development of innovative solutions and new value propositions, thereby reinforcing the role of AI in enabling processes of business model innovation within the broader context of digital transformation.

Originality of the paper. The recent management literature has mainly offered qualitative research due to the novelty of the topic (Jorzik et al., 2024; Sjödin et al., 2023; Burström et al., 2021), although the present research offers a quantitative analysis thanks to the involvement of a large sample. Through this analysis, we bring attention to managerial perceptions (in terms of opportunities and challenges) and how to deal with them. Second, the study introduces the concept of a needful-painful paradox in AI adoption. This paradox reflects the simultaneous perception of AI as both a strategic necessity and an organizational challenge. Conceptualizing AI adoption in this way provides a more nuanced understanding of the tensions experienced by top managers during digital transformation. Third, AI-enabled business model innovation is crucial to shape business models and generate innovation (Burström et al., 2021). This presents the fourth contribution, based on the capabilities needed for AI adoption. As expected, TMTs should develop technological understanding, foster innovation-oriented mindsets, and guide organizational transformation processes that support AI implementation.

In conclusion, AI is a powerful technological innovation with the potential to transform organizations and industries. However, the adoption of AI raises concerns but also brings opportunities. It requires significant organizational change and managerial effort. The study highlights this duality of perception as needful and painful, which reflects both the strategic necessity of AI and its organizational complexity. While AI adoption is well recognized and its critical role in business model innovation increases the level of competition, it also brings challenges related to uncertainty, organizational change, and ethical considerations. TMTs play a crucial role in navigating these challenges and guiding organizations through the transformation process.

Quando l'AI agentica e generativa sono il mio Team. Innovare il business model attraverso la Human-AI interaction

CHIARA BARTOLI[1], SAMUELE FRANZINI[2], FRANCESCO CAPPA[3]

Abstract. *Il lavoro rappresenta uno studio esplorativo rispetto al punto di vista dei manager sugli impatti dell'intelligenza artificiale generativa e agentica nei processi di creazione, condivisione, e appropriazione del valore delle imprese. Lo studio si è avvalso di un approccio qualitativo esplorativo mediante la Grounded Theory costruttivista applicata ai dati raccolti tramite interviste in profondità a un panel di nove top manager operanti in imprese che hanno adottato l'AI agentica e generativa. I risultati hanno consentito di elaborare l'Agentic-Generative Value Model Framework. Il modello mostra che l'intelligenza artificiale generativa e quella agentica agiscono su tutti gli aspetti del modello di business, riconfigurando le infrastrutture del valore delle imprese secondo logiche aperte, circolari e scalabili e determinando una nuova relazione tra uomo e macchina che è il motore dei processi di generazione di valore dinamico di mercato.*

Keywords: *AI agentica, AI generativa, Business model Innovation, AI, Human -Computer interaction*

1. Il contesto della ricerca. Le innovazioni tecnologiche sono strettamente connesse all'evoluzione delle strutture che sovrintendono alla creazione di valore all'interno delle organizzazioni (Baden-Fuller & Haefliger, 2013; Chesbrough, 2010). Oggi le imprese si confrontano in particolare con la disruption dell'AI, che può riconfigurare le strutture interne delle organizzazioni per generare innovazioni di mercato (Jorzik et al., 2024), migliorare i processi decisionali, potenziare la modellazione predittiva, automatizzare le operations (Burström et al., 2021), e riprogettare i processi di creazione di nuove soluzioni di mercato (Pagani and Champion, 2023).

Sebbene la ricerca di management abbia compiuto progressi significativi nel documentare le implicazioni organizzative dell'IA, minore attenzione è stata tuttavia dedicata alla comprensione di come diverse forme di IA possano interagire e influenzare congiuntamente la trasformazione organizzativa verso l'innovazione delle strutture di valore delle imprese.

Colmare questo gap è essenziale per accrescere la comprensione delle scelte manageriali in contesti in cui la collaborazione tra esseri umani e IA richiede alle aziende di dimostrare una capacità di adattamento superiore.

Questo divario è particolarmente evidente anche perché le aziende stanno adottando sempre più spesso le tecnologie generative e agentiche contemporaneamente, integrando le capacità dell'IA generativa nei sistemi di IA autonomi e implementando l'IA agentica per orchestrare i processi generativi tra le diverse funzioni organizzative (McKinsey, 2025).

La Generative AI definisce sè stessa come "un insieme di modelli di intelligenza artificiale che imparano dai dati esistenti per generare nuovi dati simili, come testi, immagini, musica, codice o video" (Chat GPT 5.2). La Generative AI è quindi in grado quindi di emulare alcuni aspetti dell'apprendimento umano, sfruttando grandi quantità di dati per identificare pattern ricorrenti e trasformare le informazioni con cui viene addestrata in nuovi output coerenti e simili, per stile o struttura, ai dati originali (Dwivedi et al., 2023; Lv, 2023). La Generative AI sta catturando l'attenzione delle imprese grazie alle sue applicazioni pratiche, come i Large Language Model sottoforma di chat che sono accessibili open source, quali Plerplexty AI, ChatGPT di OpenAI e Microsoft Copilot, e molti altri strumenti e applicazioni ch,e anche grazie all'accessibilità delle piattaforme e ad interfacce utente intuitive basate su modelli di input/output, dimostrano di poter influire sulle capacità dei manager attraverso l'ottimizzazione dell'efficacia decisionale e l'automazione dei processi e l'assistenza al customer service (es. EinsteinGPT) il miglioramento della capacità di advertising (es ADCreative) e di accesso alle creatività nei contenuti (es. Jasper).

Accanto all'AI generativa, numerose imprese stanno esplorando le potenzialità degli agenti. L'IA di tipo "agente" è una branca dell'IA che si occupa di "agency", ovvero della capacità di agire per conto dell'utente umano o di un sistema che opera entro i limiti di regole e di altri framework IA preimpostati. Gli agenti IA sono capaci di interagire, ragionare e adattarsi in tempo reale per raggiungere obiettivi specifici in modo autonomo.

L'AI agentica rispetto all'AI generativa, rappresenta un livello avanzato di IA che fa uso di un set di tecnologie che insieme conferiscono autonomia nell'esecuzione delle attività, oltre i prompt. Questo rende gli agenti capaci di prendere decisioni e di agire con un minimo di intervento umano per raggiungere specifici obiettivi (Purdy, 2024). Gli agenti di intelligenza artificiale possono infatti agire come sistemi autonomi, capaci di pianificare, collaborare e portare a termine compiti, nonché di apprendere per ottimizzare progressivamente le proprie prestazioni. Ciò contribuisce a rendere più agevole per l'essere umano la gestione del lavoro quotidiano. In questa prospettiva, agli agenti AI possono essere affidate molteplici attività, sia ripetitive sia più complesse, che in precedenza richiedevano l'intervento diretto dell'uomo (Hughes et al, 2025).

[2] Amigdala Partners, samuele@amigdala.ch
[3] Roma TRE University, francesco.cappa@uniroma3.it

Sia la Generative AI che l'Agentic AI sono riconosciute come tecnologie capaci di generare nuovi pattern a partire da dati preesistenti, rispondendo alle richieste degli utenti attraverso testo, immagini, video, audio o codice software (Peres et al., 2023). Tuttavia, tra le due emergono differenze rilevanti: Generative AI opera principalmente in modo reattivo rispetto agli input ricevuti, mentre Agentic AI si distingue per una maggiore proattività e per la capacità di adattarsi a contesti differenti e in continua evoluzione, grazie alla presenza di una propria "agency" (Hughes et al., 2025). Inoltre, mentre l'intelligenza artificiale generativa è oggi al centro degli studi di management, la letteratura relativa agli impatti di business dell'Agentic AI risulta ancora limitata, anche in ragione della sua diffusione tuttora contenuta tra le imprese di questa tipologia di AI.

La mancanza di studi che affrontino invece le tipologie di AI, quali l'AI Generativa e l'AI agentica ed i loro effetti combinati, non consente di comprendere appieno come le trasformazioni che sono guidate dall'AI si manifestino a livello delle infrastrutture che presiedono alla creazione di valore, orchestrazione delle risorse e delle conoscenze, e nei processi organizzativi interni e di quelle che presiedono alla relazione con il mercato. Inoltre, rispetto a queste due tecnologie, le analisi empiriche che rilevino le opinioni dei manager sulla loro adozione congiunta sono ancora scarse.

Questo giustifica la rilevanza di lavori che consentano di comprendere come AI generativa e quella agentica contribuiscano congiuntamente all'innovazione del modello di business, accogliendo il punto di vista dei manager sull'argomento.

2. Gli obiettivi del lavoro. Lo studio ha l'obiettivo di analizzare, da una prospettiva manageriale, in che modo l'adozione congiunta dell'Intelligenza Artificiale Generativa e dell'Intelligenza Artificiale Agentica contribuisca a ridefinire i modelli di business delle imprese, attraverso una riconfigurazione delle strutture di creazione del valore, erogazione del valore e cattura del valore. Più nello specifico, la ricerca intende approfondire come i manager interpretino il potenziale strategico dell'IA generativa e agentica, e in che modo tali tecnologie vengano percepite come leve capaci di attivare, ricombinare e trasformare le componenti del modello di business. Inoltre il lavoro vuole esplicitare gli effetti che l'aI agentica e generativa producono sulle organizzazioni in termini di ridefinizione dei processi e delle logiche di creazione del valore.

3. Il disegno della ricerca. Abbiamo adottato un approccio esplorativo allo studio, basato sulla teoria costruttivista (Charmaz, 2002). Questo metodo si inserisce nell'ambito della grounded theory e segue un approccio interpretativista all'analisi dei dati. Abbiamo adottato lo strumento dell'intervista in profondità per la raccolta dei dati, scegliendo gli intervistati attraverso un campionamento teorico, ovvero includendo individui che abbiano sperimentato le tecnologie oggetto di studio: top manager operanti in aree funzionali associate a progetti che coinvolgono l'intelligenza artificiale (AI) e l'intelligenza artificiale generativa provenienti da diversi settori industriali e appartenenti a diverse funzioni. Questa scelta è motivata dall'esigenza di cogliere il fenomeno nei suoi molteplici aspetti e di ottenere una varietà di dati che potesse dare forza al processo di generazione teorica. Le interviste sono state condotte online tramite la piattaforma Google da un ricercatore e un manager esperti di processi di digitalizzazione e AI, seguendo un set di domande guida sviluppate sulla base della letteratura riguardante l'innovazione del modello di business e l'intelligenza artificiale. In totale, sono state concluse nove interviste con top manager. Al termine delle interviste, ai partecipanti è stato inoltre chiesto di esprimere il loro punto di vista riguardo al livello di fiducia nei confronti di Generative e Agentic AI. Le interviste sono state sottoposte a tre cicli di codifica strutturati secondo il processo previsto dalla Constructivist Ground theory: open (initial) coding, focused coding e theoretical coding (Clarke et al., 2023) al fine di pervenire alla generazione di dimensioni teoriche in grado di aggiungere nuova teoria a quella esistente rispetto agli impatti di generative AI e agentic AI nelle value structure delle imprese. Il processo di codifica è stato sviluppato attraverso MAXQDA al fine di ottimizzare la reliability e il processo di condivisione dei codici tra i ricercator (Sinkovics et al., 2008). La struttura finale della codifica ha consentito di costruire il modello di business agentico-generativo, che è presentato nella figura 1.

4. I primi risultati. I manager hanno dimostrato una comprensione approfondita della distinzione tra IA generativa e IA agente, considerandoli come un continuum evolutivo piuttosto che come tecnologie separate. Un nodo centrale e distintivo tra le due tecnologie risiede nell'autonomia e nell'iniziativa: mentre l'AI generativa risponde a stimoli e produce contenuti su richiesta, l'AI agentica persegue obiettivi attraverso sequenze di azioni autonome con sistemi di memoria autonoma e di attività di accesso agli strumenti. Per quanto riguarda l'adozione, l'intelligenza artificiale generativa è relativamente più matura tra i rispondenti, mentre l'intelligenza artificiale agentica rimane ancora in una fase sperimentale. Inoltre i manager hanno identificato l'autonomia decisionale come nodo critico che richiede nuovi modelli di governance per l'uso congiunto delle due tecnologie.

4.1 L'impatto sulle strutture di creazione de valore

L'AI agentica agisce da partner "accelerato", migliorando l'automazione del lavoro umano. Questo modello di relazione (Hoffman and Novak, 2018) consentono ai manager di attingere alle risorse tecnologiche dell'intelligenza artificiale generativa per migliorare le proprie capacità di prendere decisioni e scoprire nuove opportunità, stimolare la creatività e favorire l'innovazione in tempo reale, aprendo la strada a nuovi scenari competitivi. Il processo di co-creazione della conoscenza avviene secondo un quadro logico in cui la governance è affidata alle competenze umane e le capacità dell'AI dipendono dall'accesso ai dati, che diventano una risorsa fondamentale.

La possibilità di condividere risorse in modo continuo tra esseri umani e macchine estende le attività principali e genera innovazione rapida e scalabile di prodotti e servizi. In particolare, la Generative AI è considerata uno strumento potente per gestire la complessità del mercato. Può accelerare o moltiplicare la produttività e generare un numero molto maggiore di output mantenendo l'iper-personalizzazione. Gli agenti possono invece accelerare il processo di implementazione delle operazioni, rendendo i processi interni più rapidi ed efficienti.

La Generative e la Agentic AI stanno anche ridefinendo la struttura delle partnership. Queste ultime vengono digitalizzate secondo modelli basati su piattaforme e aumentano di dimensioni e di interazioni lungo l'intera catena del valore. Dall'analisi emerge anche che l'integrazione di Agentic e Generative AI sta cambiando le caratteristiche dei tradizionali partner, rendendo i partner specialisti molto più preziosi rispetto a quelli generalisti. Ciò offre l'opportunità di elevare il ruolo delle piccole agenzie e delle start-up che possono collaborare alla supervisione del corretto trattamento dei risultati e dell'automazione dei processi. Tuttavia, lo sviluppo di nuove partnership potrebbe anche generare la necessità di governare la maggiore dipendenza dai partner e dai fornitori esterni.

4.2 L'impatto nelle strutture di value delivery

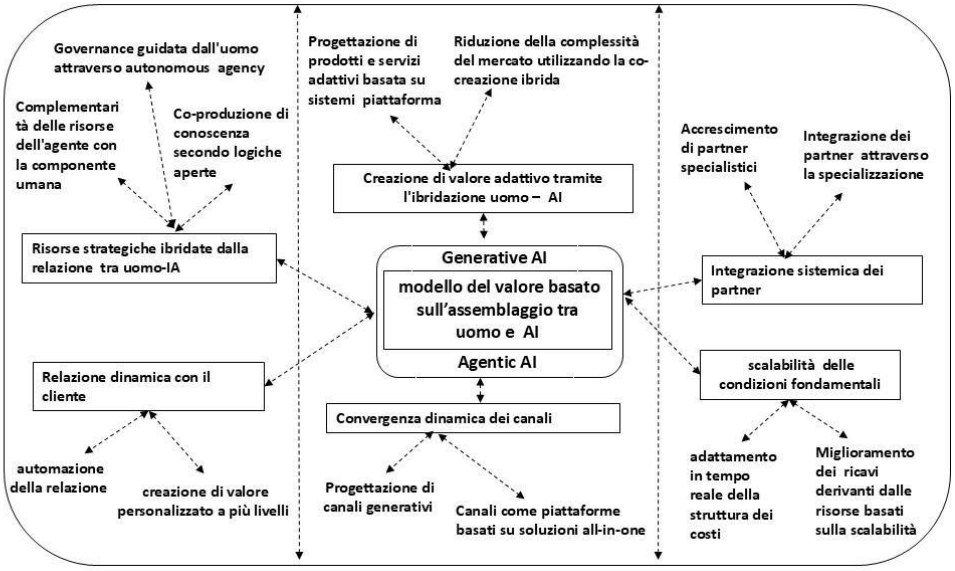
I rispondenti hanno identificato la proposta di valore come più immediatamente influenzata dall'adozione dell'AI. Tuttavia, è emersa una distinzione fondamentale tra implementazioni orientate all'efficienza e implementazioni orientate al valore. L'Agentic AI consente di fornire soluzioni basate su proposte di valore attraverso interfacce naturali che la Generative AI può creare.

I manager hanno anche sottolineato il ruolo di Generative AI nel valorizzare i dati dei clienti per adattarsi alle loro caratteristiche e al loro comportamento, al fine di raggiungere un livello più elevato di personalizzazione relazionale che aumenta il valore percepito dei prodotti e dei servizi. La dimensione della relazione con il cliente ha rivelato una trasformazione fondamentale. I manager hanno descritto un'inversione di tendenza dal modello push-based a quello di engagement personalizzato mediato dall'AI, passando da una comunicazione uno ad uno a interazioni uno a molti e su larga scala. Inoltre, incorporando l'intelligenza artificiale generativa e agente nella loro strategia di canale, le aziende possono fare affidamento su un ulteriore canale basato sull'intelligenza artificiale. Tuttavia, piuttosto che funzionare come un canale isolato, i modelli generativi e agentici agiscono come piattaforme che amplificano la capacità dell'azienda di articolare strategie iper-personalizzate e multicanale che seguono le esigenze dei clienti. In particolare, l'integrazione di generative AI garantisce che i canali siano progettati intorno ai clienti e che evolvano dinamicamente nel tempo, sia in termini di canali stessi che di contenuti veicolati.

4.3 L'impatto sulle strutture di value capture

I manager hanno sottolineato che le organizzazioni inizialmente hanno approcciato generative e agentic AI come strumento di riduzione dei costi. Questi strumenti introducono funzionalità di ottimizzazione dei costi (come l'automazione e l'efficienza creativa), riducendo i budget e aumentando i costi variabili. Ciò è possibile grazie alla capacità dei modelli di intelligenza artificiale di ridurre i costi fissi delle operazioni, riducendo la necessità di risorse umane per la gestione dei processi e aumentando i margini operativi, nonché la scalabilità dei modelli nel tempo. Tuttavia, è emerso che faticano a cogliere i benefici trasformativi dell'AI, che implicano l'interazione umana per diventare abilitatori di creazione di valore che generano significativi ritorni per le imprese. Da ciò si evince anche che le due tecnologie potrebbero generare costi variabili aggiuntivi, legati alle risorse necessarie per la loro supervisione.

4.4. Ostacoli all'innovazione del modello di business



Dalle interviste sono emersi quattro ostacoli ricorrenti all'adozione di modelli agentici e generativi da parte delle imprese. Questi sono: 1) le preoccupazioni relative all'accuratezza (le allucinazioni rimangono un problema per le applicazioni aziendali), 2) le sfide relative all'osservabilità (la difficoltà di comprendere le catene di ragionamento dell'IA), 3) la resistenza culturale e 4) i dati proprietari, emersi come abilitatori critici e fonte di vantaggio competitivo sostenibile.

Man mano che i modelli di IA diventano più diffusi, la differenziazione dipende sempre più da dati unici che i concorrenti non possono ottenere. La mancanza di un'adeguata struttura di governance rappresenta un ostacolo alla diffusione dei modelli di IA, in particolare dell'Agentic AI. I manager stanno riscontrando la mancanza di un'architettura di governance per poter implementare agenti realmente autonomi, non a causa di limitazioni tecniche, ma a causa di questioni irrisolte relative all'osservabilità, all'attribuzione delle responsabilità e alla gestione dei rischi.

Dai risultati emerge quindi che modelli agentici e modelli generativi sono visti come risorse preziose che attivano capacità che vanno oltre l'automazione e l'efficienza, potenziando i processi cognitivi umani come l'apprendimento, il ragionamento e la presa di decisioni. (Raisch & Krakowski, 2021).

I risultati dello studio hanno consentito di elaborare l'Agentic-Generative Value Model Framework (Fig. 1). Il modello mostra che l'intelligenza artificiale generativa e quella agentica fanno evolvere il modello di business secondo una logica circolare, scalabile e aperta.

Figura 1. AI Gen BMI. Business model agentico-generativo

Fonte: nostra elaborazione sulla base della data structure

Nel modello risulta evidente come, attraverso queste due tecnologie, le imprese sono in grado di ampliare e rinnovare le proprie risorse interne, assorbendo nuova conoscenza e riconfigurando continuamente le proprie infrastrutture di creazione e erogazione del valore. Tuttavia, questo processo non è privo di rischi. Infatti, le organizzazioni rischiano l'inerzia se gli agenti AI non sono supervisionati dalla componente umana.

5. I limiti della ricerca. Il lavoro presenta numerosi limiti. In primo luogo, il modello che è stato sviluppato si basa su un numero limitato di interviste e la sua validità dovrebbe essere verificata su un campione più ampio di imprese. Inoltre, il modello non è stato validato sul campo. Un confronto attivo con i manager potrebbe infatti far emergere ulteriori aree di interazione tra l'AI generativa e agentica e i sistemi di generazione del valore, nonché nuovi aspetti relativi alla relazione tra i manager e questi sottotipi di AI e alla loro fiducia o sfiducia nei confronti dei modelli, che potrebbero fornire importanti spunti sulla loro diffusione nel lungo periodo. Inoltre, le interviste hanno coinvolto imprenditori di vari settori. Ulteriori studi potrebbero invece concentrarsi su alcuni settori specifici per comprendere l'impatto di Generative AI o Agentic AI sui modelli di business.

6. Implicazioni manageriali. Il modello intende essere un punto di partenza per comprendere come i manager possano creare valore con l'AI, individuando i nodi focali in cui l'AI generativa e agentica possano rappresentare un valido strumento per la generazione di valore. Il lavoro, pur presentandosi con una natura esplorativa, consente di trarre rilevanti implicazioni manageriali. Il primo aspetto da considerare è il rapporto tra uomo e macchina attivato dall'AI agentica e generativa. Per i manager, è necessario gestire la governance dei sistemi autonomi, soprattutto quelli agentici, mantenendo l'uomo nel loop e con una definita funzione di supervisione. Infatti, ciò che emerge dallo studio è che un'azione autonoma e non supervisionata di queste due tipologie di AI potrebbe avere effetti negativi sulla struttura del valore dell'impresa.

La supervisione non basta: è necessario che all'interno dell'organizzazione sia chiaro 1) cosa viene delegato alla macchina e cosa invece viene delegato all'agente, 2) quali sono le attività che devono essere svolte in forma sinergica dalla macchina e dall'uomo. Ciò implica, da parte dei manager, un'attività di mappatura trasparente dei processi e il riconoscimento di quelle attività in cui la componente umana è necessaria, come a esempio le attività creative.

Un ulteriore aspetto riguarda le competenze manageriali. Benché i risultati facciano emergere che la conoscenza tecnica dell'AI è importante, è la competenza nel valutare gli output dell'AI e la conoscenza del dominio specifico a fare la differenza. Infatti, è necessario che i manager siano dotati di competenze trasversali che consentano di abilitare sistemi di interazione continua tra uomo e macchina. Tali competenze includono capacità di relazione, apprendimento continuo, curiosità, ma anche visione, ovvero l'abilità di riconoscere il potenziale dell'AI e di saperlo integrare nei processi di creazione del valore**.**

7. **Aspetti di originalità del lavoro.** Lo studio adotta la prospettiva del business model framework come chiave interpretativa per osservare l'impatto dell'IA generativa e agentica nei business, in modo da fornire una mappatura sistematica delle trasformazioni introdotte da queste tecnologie nelle strutture che presiedono alla creazione de condivisione del valore tra l'impresa e l'ambiente esterno. Inoltre il lavoro costruisce l'AI Gen BMI framework, ovvero

un business model agentico-generativo che ricostruisce l'impatto trasformativo dell'AI agentica e generativa sulle strutture del valore delle imprese. Il paper è il risultato del lavoro di un team composto da practitioners e accademici.

Ringraziamenti. Gli autori ringraziano tutti i manager intervistati che hanno accettato di condividere la loro esperienza e le loro conoscenze sull'argomento indagato.

Reducing low-value care in Healthcare Ecosystems: The role of Generative Artificial Intelligence

ANNA BASTONE[1], ANDREA GARGIULO[2], DANIELE LEONE[3], FRANCESCO SCHIAVONE[4]

Abstract. *Nowadays, healthcare organizations are expected to deliver care that is effective, patient-relevant, and transparent while operating under uncertainty. Within this context, low-value care remains a persistent barrier to achieving value-based healthcare and improving patient outcomes. This paper examines how Generative Artificial Intelligence (GenAI) can support the mechanisms that enable the reduction of low-value care within healthcare ecosystems.*

In doing so, this study adopts an ecosystem perspective to highlight how GenAI can contribute to reducing low-value care across macro, meso, and micro levels of an Italian healthcare ecosystem. Thus, the authors investigate how advanced digital technologies potentially support healthcare organizations in identifying inefficient practices and improving the appropriateness of clinical decisions. To conduct the study, we employ a qualitative research design based on key informant interviews and the analysis of secondary data, including policy reports, academic literature, and industry evidence related to the implementation of GenAI in healthcare contexts.

The inductive thematic analysis highlights the potential of GenAI to act as an enabling infrastructure for data-driven decision-making and collaborative value creation in healthcare ecosystems. The study offers food for thought for managers and clinicians seeking safer, more patient-centered, and more transparent care practices. Finally, it expands on current debates on AI by linking it specifically to low-value care practices.

Keywords: *Healthcare; Value creation; Low-value care; Generative Artificial Intelligence; Ecosystems; Thematic analysis; Qualitative approach*

Framing of the research. Healthcare delivery occurs in a safety-critical setting where complexity, patient involvement, and the intangible nature of services make consistent quality difficult to execute (Vogus & McClelland, 2016). In this context, the concept of value-based healthcare has emerged, defining value as the outcomes that matter to patients across the full care cycle (Lee, 2010). In particular, value-based healthcare starts with the claim that health systems should compete and improve performance based on quality outcomes, rather than on volume or bargaining power (Porter & Teisberg, 2006; Lee, 2010). Building on this logic, the Triple Aim argues that system improvement requires pursuing three linked goals at the same time: better care experience, better population health, and lower per-capita cost (Berwick et al., 2008). Because progress on one goal can unintentionally harm the others, the Triple Aim frames value creation as a balancing problem that depends on coordinated responsibility for a defined population over time (Berwick et al., 2008). For this reason, studies developed the Quadruple Aim by adding the goal of improving clinicians' work life, arguing that this dimension is crucial to sustain the other three aims (Bodenheimer & Sinsky, 2014). More broadly, the presence of multiple stakeholders suggests that value creation in healthcare should be interpreted through an ecosystemic perspective (Denicolai & Previtali, 2020; Brooks et al., 2017; Menear et al., 2019; Lavis et al., 2018).

This patient-centered view of value aligns with patient experience research, which defines value through the quality of all interactions across the patient–provider relationship (Feirn et al., 2009). In healthcare, "care" is not merely service delivery; it is a trust-dependent relationship shaped by patient vulnerability and time-pressured decision-making (Torpie, 2014). Care quality is influenced not only by clinical competence but also by organizational values and leadership practices that shape how consistently staff respond to patient expectations (Graber & Kilpatrick, 2008). Against this backdrop, a major obstacle to delivering such value is the persistence of low-value care. It is commonly defined as tests or treatments with no evidence of benefit, or with harms exceeding benefits (Grimshaw et al., 2020). Empirical evidence shows that low-value care spans many activities, including services with uncertain benefit or avoidable harm that warrant reassessment (Elshaug et al., 2012). It is also unevenly distributed across providers, with some organizations using low-benefit services far more frequently than others (Ganguli et al., 2021). Reducing low-value care is crucial not only to prevent avoidable harm, but also because low-value activities often increase spending in the long term, rather than cutting it (Kroon et al., 2023). To maximize value, healthcare organizations can learn from data and quickly turn new evidence into routine clinical practice (Wasylak et al., 2022). Digital technologies are increasingly considered key enablers of this learning process. More specifically, health systems adopt de-implementation programs to reduce low-value care, employing tools such as clinical decision support, audit-and-feedback, and education (Cliff et al., 2021). Furthermore,

involving patients in de-implementation efforts strengthens appropriateness by aligning decisions with preferences and reducing demand for services with limited benefit (Kien et al., 2024).

In healthcare, Artificial Intelligence (AI) is increasingly implemented to integrate heterogeneous clinical data and support real-time decisions at the point of care (Noorbakhsh-Sabet et al., 2019; Leone et al., 2021; Varghese & Chapiro, 2024). These capabilities can strengthen learning cycles by turning routinely collected data into actionable signals that clinicians can use during everyday work (Dinov, 2016). Particularly, AI can augment de-implementation tools by embedding prompts, feedback, and guidance directly into ordering and review workflows (Cliff et al., 2021). In this context, Generative Artificial Intelligence (GenAI) extends this trajectory by positioning generative systems as workflow participants that help coordinate tasks across diagnosis, decision support, engagement, and operations (Karunanayake, 2025; Zhang et al., 2023; Clune, 2019). By improving how information is communicated and understood, GenAI can also help align clinical decisions with patient preferences, strengthening appropriateness and reducing demand for low-benefit services. (Kien et al., 2024; Duan et al., 2019; Secinaro et al., 2021).

Purpose of the paper. In today's landscape, healthcare organizations operate in a setting where expectations about care quality are steadily rising. They are asked to deliver care that is reliable, meaningful for patients, and sustainable over time. Meeting these expectations is difficult because healthcare work unfolds under uncertainty and often requires rapid judgment. Clinical decisions are rarely isolated events, since they depend on information flows, coordination across professionals, and support from the surrounding organization. For this reason, care quality is shaped not only by technical competence, but also by how well organizations enable everyday work. Pressures for transparency have also intensified in recent years. Patients, managers, and policymakers are increasingly able to observe differences in outcomes, service use, and organizational performance. As a result, gaps between intended quality and actual delivery have become more visible and more consequential. In parallel, healthcare systems are expected to improve patient outcomes while using resources more responsibly. This also means limiting the use of tests, treatments, and clinical activities that consume attention and resources without producing meaningful benefit for patients. Consequently, healthcare organizations face growing pressure to support professionals in making more appropriate clinical decisions while reducing activities that offer limited benefit. Against this backdrop, identifying mechanisms that support value creation while limiting low-value care has become a central challenge for healthcare systems.

Prior research has recognized this challenge through the notion of low-value care (Elshaug et al., 2012; Grimshaw et al., 2020). Furthermore, it has identified several ways to reduce these practices within healthcare systems. Specifically, prior studies show that improvements depend on organizations' ability to learn from data and translate new evidence into routine clinical practice (Wasylak et al., 2022). Research further shows that mechanisms such as de-implementation programs and patient involvement play a crucial role in reducing low-value care (Cliff et al., 2021; Kien et al., 2024). At the same time, another stream of literature suggests that AI can integrate heterogeneous clinical data and enable real-time decisions at the point of care (Noorbakhsh-Sabet et al., 2019). These capabilities can strengthen learning cycles by turning routinely collected data into actionable signals for everyday clinical work (Dinov, 2016). Emerging studies also suggest that GenAI can extend this role by supporting workflow coordination and improving how information is communicated and understood across care processes (Karunanayake, 2025; Kien et al., 2024). However, despite these advances, we still know little about how GenAI can strengthen the mechanisms through which healthcare ecosystems identify and reduce low-value care across different levels of action.

To bridge this gap, this study adopts an ecosystem perspective to examine how GenAI contributes to managing low-value care within healthcare systems. We argue these advancements influence the conditions under which more appropriate care decisions emerge. Therefore, we analyze the role of GenAI at multiple levels of the healthcare ecosystem: macro, meso and micro. Accordingly, we address the following research question: How can Generative Artificial Intelligence contribute to reducing low-value care within healthcare ecosystems?

Methodology. To address the research question, this study employed qualitative research design adopting the key informant interview technique, suitable to allow researchers to explore nuanced perspectives even with small samples (Tremblay, 1957; Pahwa et al., 2023). Particularly, an Italian healthcare ecosystem located in the Campania Region was selected as the research setting.

Fifteen semi-structured interviews were conducted with key informants, each lasting approximately 60 minutes. The interviews were conducted online, recorded, transcribed, and translated into English while preserving the original meaning of participants' responses. The sample size was determined based on data sufficiency criteria, including study objectives, sample specificity, theoretical framework utilization, dialogue quality, and analysis strategy (Malterud et al., 2016). Participants were selected through purposeful sampling combined with snowball sampling techniques to ensure comprehensive representation across the healthcare ecosystem. (Parker et al., 2019; Naderifar et al., 2017). This approach allowed the researcher to reach a broader network of professionals involved in healthcare delivery, digital health innovation, and the governance of healthcare ecosystems.

The study adopted an ecosystem perspective to examine the role of GenAI in healthcare and its potential contribution to reducing low-value care. Key informants included physicians, healthcare managers, pharmaceutical company representatives, and technology developers, providing a holistic perspective on GenAI implementation across the healthcare ecosystem. This multi-stakeholder approach recognized healthcare networks as nodes within a dynamic, interconnected ecosystem where various actors contribute to value creation and care delivery. The interviews were

conducted using a semi-structured format, which allowed informants considerable flexibility in expressing their views while ensuring that all relevant topics were addressed. The interview guide was developed following the ecosystem perspective adopted in the study and was structured around three analytical levels: micro, meso, and macro. To enhance validity and ensure robust findings, multiple data sources were selected - including official online documentation, public statements, and archival records - following established triangulation principles (Yin, 2009). Data analysis employed an inductive thematic analysis following Braun and Clarke's (2006) systematic approach, utilizing NVivo software for code management. This method was selected for its flexibility and suitability for exploratory research examining emerging phenomena in healthcare contexts.

Results. Our findings suggest that GenAI can play a pivotal role in supporting the reduction of low-value care across healthcare ecosystems. By enhancing the availability, interpretation, and dissemination of clinical and organizational information, GenAI can support more informed decisions and help redirect resources toward activities that generate higher value for patients. Within this ecosystem perspective, the reduction of low-value care can be understood as a dynamic process supported by the interaction between technological tools, organizational practices, and governance mechanisms. Against this backdrop, it is essential to highlight the strong interconnections between the three levels of the healthcare ecosystem. In this sense, GenAI can support a continuous feedback loop across the ecosystem, enabling the identification, monitoring, and progressive reduction of low-value care.

At the micro level, which concerns clinical practice and the activities of individual healthcare professionals, GenAI can improve operational efficiency and support more informed clinical decisions. Through its ability to process and analyse large volumes of heterogeneous clinical data, GenAI can assist healthcare professionals in identifying patterns, synthesizing medical information, and supporting diagnostic reasoning. This capability can help clinicians avoid unnecessary tests, redundant procedures, or ineffective treatments that contribute to low-value care. In addition, GenAI tools can support clinicians by summarising complex information and providing decision-support suggestions based on available evidence, thereby reducing uncertainty and improving the accuracy of clinical decisions. Additionally, by improving the accessibility and interpretation of medical information, GenAI influences patient involvement, facilitating communication between clinicians and patients and enabling patients to better understand treatment options and participate more actively in care decisions.

At the meso level, which refers to the organizational and network dimension of healthcare ecosystems, GenAI can support collaboration and coordination among different actors, such as hospitals, research centres, pharmaceutical companies, and digital health providers. The findings suggest that GenAI may function as an enabling infrastructure for information exchange, facilitating the integration of clinical, operational, and research data across organizations. By improving communication and knowledge sharing, these technologies can help reduce fragmentation in healthcare ecosystems, which is often one of the drivers of low-value care

Finally, at the macro level, which concerns healthcare governance and policy-making, GenAI can support ecosystem-level strategies aimed at improving efficiency and reducing low-value care across the healthcare ecosystem. By analysing large-scale clinical and administrative datasets, GenAI can help policymakers identify patterns of resource use, detect inefficiencies, and monitor the diffusion of low-value practices across healthcare organizations. These insights can support more informed policy decisions regarding resource allocation, regulatory frameworks, and health ecosystem planning. At the same time, the implementation of GenAI at the ecosystem level requires careful governance to ensure transparency, fairness, and accountability. Healthcare ecosystems manage large volumes of sensitive data, and the use of advanced technologies raises concerns related to privacy, algorithmic bias, and patient safety. For this reason, effective regulatory frameworks and oversight mechanisms are necessary to ensure that the use of GenAI contributes to improving healthcare quality without generating new risks or inequalities.

Research limitations. Despite the contributions of this study, several limitations should be acknowledged. First, the research is based on a qualitative exploratory design relying on a relatively small sample of key informants. Future studies could use quantitative methods. Second, the study focuses primarily on expert perceptions regarding the potential role of GenAI in reducing low-value care. While these insights provide valuable perspectives on emerging technological opportunities, the empirical evidence is still largely prospective. Finally, the analysis adopts an ecosystem perspective structured around micro, meso, and macro levels of the healthcare settings. While this multi-level approach helps capture the complexity of healthcare environments, the interactions between these levels remain difficult to observe directly through qualitative interviews alone. Future studies could therefore investigate these dynamics through longitudinal study designs.

Managerial implications. The findings of this study provide several implications for healthcare managers, policymakers, and technology developers seeking to reduce low-value care through the adoption of GenAI. At the micro level, healthcare organizations should consider the integration of GenAI tools to support clinical decision-making processes. Second, at the meso level, the results highlight the importance of strengthening collaboration among healthcare actors. GenAI can act as an enabling infrastructure for information exchange, supporting communication among different actors and fostering the development of shared clinical protocols and best practices.

Finally, at the macro level, policymakers and healthcare authorities play a critical role in creating the institutional

conditions necessary for the responsible adoption of GenAI technologies. Clear regulatory frameworks, data governance mechanisms, and ethical guidelines are necessary to ensure transparency, protect patient privacy, and mitigate algorithmic biases. Findings suggest that the potential of GenAI to reduce low-value care does not depend solely on technological capabilities but also on the ability of healthcare ecosystems to coordinate actors, align incentives, and develop governance mechanisms that support value-oriented innovation.

Originality of the paper. This paper contributes to the literature on AI in healthcare by proposing an ecosystem-based perspective to elucidate how GenAI can support the reduction of low-value care. While previous studies have mainly focused on the technical capabilities of AI or on specific clinical applications, this research adopts a multi-level perspective that considers the interactions between actors, organizations, and policy. By analysing the potential role of GenAI across micro, meso, and macro levels of the healthcare ecosystem, the study offers a novel view that links technological innovation with value-based healthcare.

Strategic Adoption of AI in Dubai: Preliminary Results from an Advisory-Centered Perspective

IRENE FULCO[1], MARCO VALERIO ROSSI[2], FRANCESCA FAGGIONI[3], BARBARA AQUILANI[4]

Abstract. *The accelerating diffusion of Artificial Intelligence (AI) is profoundly reshaping organizational practices, competitive dynamics, and sustainability trajectories across global business ecosystems. In innovation-oriented contexts such as Dubai and the United Arab Emirates (UAE), AI adoption is further amplified by strong governmental support and national strategic visions. This study explores the adoption, perceived benefits, and emerging risks associated with AI through six in-depth qualitative interviews with external advisory professionals operating in the UAE consulting sector. The findings reveal that AI functions as a strategic equalizer, enabling efficiency, scalability, and service quality improvements, especially for startups and small-to-medium enterprises (SMEs). At the same time, the study highlights critical challenges related to data governance, environmental sustainability, over-reliance on AI outputs, hidden economic costs, and uneven governance structures. By offering context-specific insights from a rapidly developing innovation hub, this paper contributes to the literature on responsible AI adoption and provides actionable guidance for managers navigating AI-driven transformation.*
Keywords*: artificial intelligence; innovation ecosystem; advisory perspective; United Arab Emirates; in-depth interview; qualitative research*

Framing of the research. The diffusion of Artificial Intelligence (AI) has progressively transformed from a technological trend into a fundamental driver of organizational change and strategic renewal (Barari et al., 2024). Within the management and strategy literature, AI is increasingly conceptualized not merely as a technological tool, but as a strategic resource capable of reshaping organizational structures, competitive positioning, and value creation mechanisms (Rossi et al., 2025).

Existing research has extensively examined AI adoption in large multinational corporations and technologically mature economies (McElheran et al., 2024), often emphasizing performance outcomes, efficiency gains, and innovation capabilities (Damioli et al., 2021; Avezov, 2025). However, less attention has been devoted to understanding how AI adoption unfolds within fast-growing, institutionally distinctive contexts characterized by strong government intervention, rapid market expansion, and heterogeneous organizational maturity (Hussain et al., 2025). The United Arab Emirates (UAE), and Dubai in particular, represent a salient yet underexplored empirical setting in this regard (Alhur et al., 2025).

Dubai has positioned itself as a global innovation hub through deliberate national strategies, including the UAE National AI Strategy 2031, large-scale public investments in digital infrastructure, and state-sponsored training initiatives aimed at diffusing AI-related skills across the workforce (Khatib and Ahmed, 2024). Within this institutional environment, organizations face both explicit incentives and implicit pressures to integrate AI into their operational and strategic processes (Dafri, 2023). AI adoption therefore becomes not only a managerial choice, but also a response to institutional expectations, competitive signaling, and future-oriented legitimacy (Loureiro et al., 2021).

From a strategic perspective, AI adoption in Dubai is particularly relevant for startups and small-to-medium enterprises (SMEs), which constitute a significant portion of the local economy. These organizations often operate with lean structures, limited access to specialized talent, and high growth ambitions (Thomas et al., 2025). In such conditions, AI may function as strategic equalizers, allowing smaller firms to emulate capabilities traditionally associated with larger organizations, such as advanced analytics, personalized service delivery, and scalable operational processes (Mogielnicki, 2021).

At the same time, the accelerated pace of AI adoption raises critical organizational and strategic tensions. AI systems increasingly mediate decision-making processes, redistribute cognitive labor between humans and machines, and reshape professional roles (Santandreu Calonge et al., 2025). Over-reliance on algorithmic outputs may undermine human judgment, while insufficient governance structures may expose organizations to data protection risks, hidden costs, and long-term dependency on external technology providers. These tensions are particularly pronounced in contexts where formal AI governance frameworks are unevenly distributed across organizational sizes and sectors (Almesafri and Habes, 2022). Such asymmetries may reflect differences in organizational resources, dynamic governance capabilities, and exposure to institutional legitimacy pressures.

Within the management and organization literature, scholars have recently called for more context-sensitive and practice-oriented research on AI adoption, emphasizing the need to understand how strategic decisions around AI are

made, justified, and implemented in real organizational settings (Alhur et al., 2025). Advisory actors, such as external consultants and innovation advisors, play a crucial yet under-theorized role in this process. They often act as intermediaries between technological possibilities, managerial understanding, and organizational realities, shaping not only adoption decisions but also interpretations of value, risk, and responsibility (Al-zebin et al., 2025).

Against this backdrop, this study adopts an advisory-centered perspective to explore AI adoption in Dubai. By focusing on the experiential knowledge of six external consultants actively involved in supporting organizations across different stages of AI adoption, the research aims to capture nuanced insights into the strategic logic, organizational consequences, and governance challenges associated with AI-driven transformation in a rapidly evolving innovation ecosystem.

Purpose of the paper. This study aims to provide an in-depth qualitative exploration of how AI is adopted, perceived, and strategically integrated by organizations operating in Dubai and the broader UAE, viewed through the lens of six external advisory professionals. Rather than focusing on the quantitative measurement of adoption outcomes, the study seeks to uncover the underlying managerial rationales, organizational mechanisms, and strategic interpretations that shape AI adoption in practice. Particular attention is given to the role of advisory actors, who often act as intermediaries and facilitators of AI-driven change, as well as to the tensions that arise between immediate performance gains and long-term organizational sustainability.

More specifically, the study examines the institutional and strategic factors that influence AI adoption within the Dubai business ecosystem, while also analyzing how these technologies contribute to organizational efficiency, scalability, and competitive positioning. At the same time, it highlights potential unintended consequences and organizational risks, including gaps in governance, cognitive over-reliance on AI outputs, and hidden economic costs. The research also considers how variations in organizational size and maturity affect AI governance practices and strategic outcomes, offering insights that are directly relevant for managers and strategists seeking to leverage AI as a source of sustainable competitive advantage.

The study is guided by several key research questions: What strategic and institutional factors drive AI adoption in Dubai? How do organizations perceive the value of these technologies, and how do they translate that value into efficiency, scalability, and competitive advantage? What organizational and strategic tensions emerge, particularly regarding governance, sustainability, and human judgment? And finally, how do advisory actors influence strategic decisions and governance practices across different organizational contexts?

By addressing these questions, the paper contributes to management and strategy scholarship by providing empirically grounded, context-specific insights into AI adoption as a complex organizational and strategic phenomenon, rather than a purely technological one.

Methodology. This study adopts a qualitative research design grounded in the traditions of management and organizational research that emphasize contextual understanding, processual insight, and interpretive depth (Armstrong, 1979). Given the exploratory nature of the research questions and the emergent character of AI as a strategic phenomenon, a qualitative approach is particularly suitable to capture how meanings, expectations, and strategic rationales surrounding AI adoption are constructed in practice (Schreier, 2012).

The empirical core of the study is based on six in-depth semi-structured expert interviews. Expert interviews are widely used in management and strategy research when the phenomenon under investigation is complex, novel, and insufficiently documented through secondary data. In such cases, experts act as knowledgeable informants who possess both analytical distance and practical immersion in the field (Braun and Clarke, 2006).

The respondents in this study are external consultants and advisory professionals operating within the UAE business ecosystem. The selection of interviewees followed a purposive sampling strategy aimed at identifying information-rich cases. The inclusion criteria required respondents to (i) have at least four years of experience in AI-related advisory activities, (ii) be directly involved in strategic or operational AI implementation projects, and (iii) have exposure to multiple organizations or sectors within the UAE. With more than four years of experience advising organizations on AI-related strategic and operational decisions, the interviewees occupy a privileged observational position across multiple firms, sectors, and stages of AI adoption. This allows the study to move beyond firm-specific narratives and capture cross-cutting patterns and recurring tensions (Akther, 2022).

The respondents have extensive advisory experience across multiple sectors, including professional services, commodities trading, hospitality, real estate, and marketing. At the individual level, the sample includes consultants with diverse roles (e.g., strategy advisors, AI implementation specialists, and innovation consultants), thereby ensuring variation in perspectives and professional backgrounds within the advisory landscape. While this cross-sector exposure enabled the identification of recurrent patterns in AI adoption, no substantial sector-specific differences were reported. This suggests that the emergent themes may reflect organizational and strategic dynamics that are broadly applicable across diverse industries within the UAE context.

The sample size was determined following a logic of theoretical sufficiency rather than statistical representativeness. Given the expert-based nature of the interviews and the cross-organizational perspective of advisory professionals, the aim was to capture recurring interpretive patterns rather than firm-specific variation. After six interviews, thematic redundancy began to emerge, with no substantially new dimensions related to AI drivers, governance asymmetries, or

organizational tensions being identified. In this sense, the study reached a point of pragmatic saturation consistent with qualitative research standards in exploratory management studies.

Importantly, the choice of an advisory actor as the primary informant reflects a deliberate methodological decision. Advisors often function as intermediaries between technological possibilities and managerial action, translating abstract AI capabilities into organizationally actionable strategies. Their perspective therefore provides valuable insight into how AI adoption decisions are framed, justified, and implemented across heterogeneous organizational contexts (Wisener, 2014).

The interviews were conducted with the assurance of confidentiality and anonymization. Data collection took place between early and late December 2025. Interviews were conducted online via video conferencing platforms and lasted between approximately 45 and 60 minutes. All interviews were audio-recorded with participants' consent and subsequently transcribed verbatim for analysis. A semi-structured interview guide was used to ensure consistency across interviews while allowing flexibility to explore emerging themes. The guide included questions related to AI adoption drivers, perceived value, implementation challenges, governance practices, and the role of advisory actors in shaping strategic decisions. This was intended to encourage openness and reduce social desirability bias, particularly when discussing sensitive topics such as data governance, organizational weaknesses, and strategic trade-offs. All six interviews were subsequently transcribed and prepared for analysis.

The data analysis followed a thematic analysis approach commonly employed in qualitative management research. The process involved multiple iterative stages (Braun and Clarke, 2019). First, the interview transcripts were read in full to gain a holistic understanding of the narrative. Second, initial codes were assigned to segments of text related to AI drivers, value creation, organizational challenges, governance practices, and strategic implications. The coding process combined inductive and deductive elements: while some codes were informed by existing literature (e.g., governance, capability development), others emerged directly from the data.

In a third step, these codes were grouped into higher-order themes reflecting broader strategic and organizational patterns, such as AI as a capability equalizer, governance asymmetries between SMEs and large firms, and tensions between efficiency gains and long-term sustainability. Throughout the analysis, particular attention was paid to identifying causal mechanisms and interpretive frames used by the advisory actors, rather than merely cataloging practices. To enhance reliability, coding decisions were iteratively refined through multiple rounds of comparison across interviews, ensuring internal consistency and coherence of themes.

To enhance the credibility and trustworthiness of the findings, several qualitative rigor principles were followed. Analytical transparency was ensured by clearly documenting the steps of data collection and analysis. Reflexivity was maintained by acknowledging the interpretive role of the researcher in making sense of the advisory narrative. In addition, credibility was strengthened through systematic comparison across cases and by ensuring that identified themes were supported by multiple interview excerpts. While formal inter-coder agreement was not applied, the analysis followed a consistent coding protocol and iterative validation process to ensure robustness and interpretive reliability. Finally, the study emphasizes analytical generalization rather than statistical generalization, aiming to contribute to theory-building by illuminating processes and mechanisms relevant to AI adoption in comparable organizational and institutional contexts (Joffe, 2011).

Results. The analysis of the six expert interviews reveals a set of interconnected themes that illuminate how AI is strategically adopted, interpreted, and governed within organizations operating in the Dubai and UAE context. Rather than depicting AI adoption as a linear or uniform process, the findings highlight heterogeneous patterns shaped by organizational size, institutional pressures, and the mediating role of advisory actors. Four main themes emerged from the analysis: (1) AI as a strategic equalizer; (2) value creation and organizational scaling; (3) emerging organizational and cognitive tensions; and (4) governance asymmetries and advisory mediation, as summarized in Table 1. No sector-specific differences were explicitly highlighted by respondents, although the limited sample does not allow for definitive conclusions. Interviewees consistently framed these dynamics as cross-sectoral, suggesting that AI adoption patterns in the UAE may be more structurally driven than industry-specific.

A dominant theme emerging from the interview is the role of AI as a strategic equalizer, particularly within the UAE labor market and competitive environment. According to the advisory perspective, many organizations in Dubai operate under cost-driven hiring models characterized by heterogeneous skill levels and limited access to deep specialization. In this context, AI is perceived as a mechanism that partially compensates for capability gaps by augmenting individual productivity and decision-making quality. Across interviews, respondents emphasize that AI enables organizations to maintain or improve service quality without proportionally increasing headcount or relying on scarce expert talent. This dynamic is especially salient for startups and SMEs, which often lack the resources to build fully specialized teams. By embedding AI tools into everyday workflows, such firms can emulate capabilities traditionally associated with larger, more resource-rich organizations, thereby altering competitive dynamics. As one advisor noted, "AI is not replacing people, but it is leveling the imbalance in skills across firms, especially in fast-growing environments like Dubai."

From a strategic management perspective, AI functions not merely as an efficiency-enhancing technology but also as a capability-building mechanism. AI adoption allows firms to recombine existing human resources with algorithmic support, effectively reshaping their internal resource base. In doing so, AI contributes to strategic parity and, in some cases, temporary competitive advantage within fast-moving markets. This finding suggests that AI operates as a boundary-

spanning resource that reshapes the composition and productivity of firm-level capabilities rather than simply optimizing existing processes. Beyond general efficiency gains, the interview data highlight specific value creation mechanisms through which AI contributes to organizational scaling and improved performance, spanning operations, marketing, customer service, and innovation activities. One illustrative case identified in the interviews highlights a consultancy firm receiving a substantial number of targeted leads but achieving a very low closing rate of approximately 2%. Lead distribution relied on manual allocation and simple round-robin systems, which proved inefficient given the heterogeneity of client needs and consultant expertise. With more than 100 incoming leads per day, systematic prequalification and strategic matching were operationally unfeasible. The introduction of an AI-based lead scoring and assignment system enabled automated qualification and consultant matching based on expertise, language, and background. Within two months, conversion rates increased from roughly 2% to 8%, while prequalification time decreased significantly, and consultant productivity improved. This case illustrates how AI can reconfigure operational routines and enhance capability alignment rather than merely automate tasks. As one interviewee explained, "the real value was not automation, but better matching between human expertise and client demand."

Despite these benefits, the findings reveal several organizational and cognitive tensions. A recurrent concern relates to the risk of over-reliance on AI-generated outputs, particularly in consulting contexts where judgment, contextual understanding, and critical thinking are essential. Several interviewees noted that some professionals may treat AI outputs as authoritative rather than provisional, potentially weakening analytical capabilities over time. One respondent explicitly warned that "people stop questioning outputs once they trust the system too much."

Relatedly, issues of data protection are critical, particularly when companies rely on third-party AI tools. Organizations must ensure that sensitive information is handled responsibly and that data-sharing practices comply with both local and international standards. The advisors emphasized that AI should not serve as an excuse for complacency; outputs must be validated, and users should learn how to prompt effectively to obtain meaningful results. Additionally, the interviewees warned against the "AI hype trap", stressing that implementing AI tools is strategically sound only when supported by a clear rationale, a solid understanding of business processes, and a coherent adoption framework. From an interpretive standpoint, this reflects a tension between symbolic adoption and substantive integration of AI technologies within organizational routines.

Additional tensions relate to environmental, economic, and social sustainability. Interviewees emphasized that the increasing reliance on cloud infrastructures and data centers, while improving operational efficiency, also intensifies energy consumption and environmental impact. Although the UAE is investing in renewable-powered and green data centers, adoption remains uneven across industries. Economically, several respondents noted that initial performance improvements often conceal long-term costs associated with retraining, data governance, system maintenance, and vendor dependency, which may gradually erode return on investment. Socially, AI-driven automation has reduced routine tasks while simultaneously increasing demand for higher-level skills, in line with the objectives of the National AI Strategy 2031. However, the critical challenge remains cognitive and cultural. Professionals must perceive AI as an enabling complement rather than an authoritative substitute for human judgment. As one advisor summarized, "the biggest challenge is not technical, but cultural acceptance of AI as a partner rather than an authority."

Finally, the interviewees underscored the uneven distribution of governance mechanisms across organizational contexts. Formal oversight structures, ethical guidelines, compliance processes, or dedicated committees are largely confined to large enterprises, while startups and SMEs tend to rely on founders' technical literacy or external advisors. From a theoretical perspective, these governance asymmetries can be interpreted through the lens of the resource-based view and dynamic capabilities theory. Larger organizations possess more structured governance routines and formalized risk management processes that function as embedded strategic resources, whereas SMEs often operate through more informal and externally supported governance arrangements. From an institutional theory standpoint, large firms are also more exposed to regulatory scrutiny and legitimacy pressures, which incentivize the formalization of AI governance mechanisms.

In this fragmented governance landscape, advisory actors operate as externalized governance mechanisms and legitimacy intermediaries, assisting organizations in interpreting regulatory expectations, assessing risks, and designing adoption strategies aligned with both performance and responsibility objectives. While such mediation accelerates responsible AI adoption, excessive dependence on external expertise may inhibit the internalization of dynamic governance capabilities, raising questions about long-term organizational resilience. This suggests that advisory involvement simultaneously enables capability development while potentially constraining the emergence of internal governance maturity in SMEs.

Table 1. Summary of key findings

Theme	***Key findings***	***Illustrative evidence / observations***
AI as a strategic equalizer	*AI allows smaller firms and SMEs to emulate the capabilities of larger organizations, augmenting human productivity and compensating for skill gaps.*	*Startups leverage AI to maintain or improve service quality without proportionally increasing headcount; cost-driven hiring models and heterogeneous skill levels in the UAE labor market.*

Value creation and organizational scaling	*AI adoption improves efficiency, scalability, and competitive positioning across operations, marketing, customer service, and innovation, supporting informed decision-making in addition to task automation.*	*For example, an AI-based lead qualification system helped align client needs with consultant expertise, increasing conversion rates and overall productivity.*
Emerging organizational and cognitive tensions	*Over-reliance on AI outputs can undermine human judgment and critical thinking; hidden costs such as retraining, data management, and vendor dependency may reduce long-term returns; ethical challenges include bias, transparency, and information overload.*	*Professionals treating AI outputs as authoritative; need for validation and effective prompting; economic and operational frictions are observed.*
Governance asymmetries and advisory mediation	*Formal governance (ethics, oversight, compliance) concentrated in large firms; SMEs often rely on founder expertise or external advisors. Advisors mediate adoption, risk assessment, responsible AI use, and data protection.*	*Advisory professionals serve as de facto governance agents, guiding regulatory interpretation, managing risks, and framing AI adoption strategically. They also emphasize avoiding the "AI hype trap" and maintaining a clear business rationale.*

Source: Authors' elaboration

Research limitations. This study is based on just six in-depth interviews with external advisory professionals operating in the UAE business ecosystem. While this methodological choice allows for rich, detailed insights and a deep understanding of organizational processes surrounding AI adoption, it inherently constrains the generalizability of the findings. The perspectives captured reflect the interpretive lens, professional experiences, and sector-specific exposure of six advisors, which may not fully represent the diversity of organizational contexts, industries, or adoption strategies across Dubai or the broader UAE.

Moreover, the reliance on self-reported data introduces potential subjective biases, including selective recall, social desirability effects, and interpretive framing, which may influence the portrayal of both benefits and challenges associated with AI adoption. The cross-sectional qualitative design limits the capacity to capture temporal variations, longitudinal adoption patterns, or the dynamics of organizational learning in response to AI implementation.

Future research could address these limitations by adopting comparative or multi-case designs that involve multiple advisory professionals, organizations of varying sizes and sectors, and potentially cross-national contexts. Integrating qualitative insights with quantitative measures, such as surveys of adoption rates, performance metrics, or governance maturity indices, could further enhance the robustness and generalizability of findings. Longitudinal studies would also be valuable to explore how organizational strategies, governance structures, and perceived AI value evolve over time, particularly in rapidly developing innovation ecosystems.

Managerial implications. The findings of this study carry several important implications for managers and organizational strategists navigating AI-driven transformation. From a broader perspective, these implications also reflect how AI adoption is shaped by the interaction between strategic intent and institutional pressures, reinforcing the view of AI as a contextually embedded strategic resource rather than a purely technical tool. First, AI adoption should be anchored in a clear strategic rationale rather than motivated solely by technological novelty or external pressures. Managers must align AI initiatives with broader organizational goals, operational needs, and competitive positioning to ensure that adoption translates into sustainable value creation. This finding extends existing strategic management perspectives by showing that, particularly in policy-driven contexts such as the UAE, AI adoption is not only a matter of internal resource allocation (as suggested by the resource-based view), but also a response to external legitimacy and signaling dynamics emphasized by institutional theory.

Second, the study underscores the importance of investing in AI literacy and capability development across the workforce. Human judgment, contextual understanding, and domain expertise remain critical, particularly in knowledge-intensive and advisory-driven sectors. Organizations that cultivate complementary skills alongside AI adoption are better positioned to avoid over-reliance on algorithmic outputs and to leverage AI as an augmentation tool rather than a replacement for critical decision-making. From a theoretical standpoint, this supports and refines the notion of AI as a capability-enhancing resource, highlighting that its effectiveness depends on the development of complementary human and organizational capabilities, rather than on technology alone.

Third, managers should anticipate and proactively address long-term economic, operational, and sustainability costs associated with AI adoption. This includes monitoring vendor dependency, system maintenance expenses, and environmental impacts, as well as integrating these considerations into strategic planning and resource allocation. These findings contribute to ongoing debates on responsible and sustainable AI by showing that short-term efficiency gains may obscure longer-term strategic trade-offs, thereby qualifying overly optimistic views of AI-driven performance improvements in existing literature.

Finally, even in contexts with limited formal regulation, organizations are encouraged to establish governance principles and ethical guidelines for AI use. Structured governance practices, including data management protocols, transparency mechanisms, and accountability structures, can mitigate organizational risk, foster responsible AI adoption, and enhance reputational legitimacy in increasingly competitive and scrutiny-intensive markets. In line with the findings, governance should not be understood solely as an internal organizational capability, but also as a process shaped by external advisory actors who act as intermediaries in translating regulatory expectations and best practices into organizational routines. This highlights a broader theoretical implication concerning the role of intermediaries in shaping AI adoption, suggesting that governance capabilities may be partially externalized, especially in SMEs and resource-constrained environments.

Originality of the paper. The originality of this paper resides in its advisory-centered approach to understanding AI adoption within the Dubai and UAE innovation ecosystem. By foregrounding the perspectives of six external consultants who are actively engaged in organizational AI implementation, the study captures a practitioner-informed view that is rarely documented in existing literature. Unlike traditional studies that focus on large multinationals or Western contexts, this research provides context-specific insights into how AI adoption unfolds in a rapidly developing, government-driven, and institutionally distinctive environment.

While themes such as AI as a strategic equalizer and governance asymmetries between SMEs and larger organizations are well established in the literature, this study contributes by problematizing and contextualizing these dynamics within the UAE setting. Specifically, the findings show that in a strongly state-driven innovation ecosystem, AI adoption cannot be fully understood as a purely firm-level strategic choice, but is co-shaped by institutional pressures, national strategic agendas, and policy-driven incentives that actively promote and normalize AI integration. This perspective highlights what the UAE context adds to existing debates, showing how these dynamics are amplified and reshaped through centralized infrastructures, regulatory frameworks, and state-sponsored initiatives that influence access to AI resources and adoption pathways.

This advisory lens illuminates both strategic opportunities and organizational tensions associated with AI integration, including the roles of efficiency gains, capability equalization, cognitive reliance, and governance asymmetries.

In addition, the paper addresses a gap in the AI adoption literature by explicitly focusing on the role of advisory actors as intermediaries in the adoption process. While prior research has largely examined adoption outcomes at the firm level, limited attention has been devoted to how AI strategies are interpreted, translated, and operationalized in practice. The findings show that advisors do not merely support implementation, but actively shape managerial perceptions of value, risk, and responsibility, while also functioning as externalized governance mechanisms, particularly in SMEs lacking formal structures.

In doing so, the study contributes to scholarly debates on responsible and sustainable AI adoption by offering empirical evidence from a non-Western, innovation-intensive setting. It extends understanding of how AI functions not merely as a technological tool, but as a strategic and organizational resource, thereby enriching the literature on AI adoption, strategic management, and sustainable innovation practices.

By making these elements explicit, the study offers a clearer theoretical contribution to ongoing debates on AI adoption. It advances existing research by integrating an institutional perspective with a micro-level understanding of intermediation, thereby addressing a gap concerning how context and intermediary actors jointly shape AI-driven organizational transformation. In doing so, the paper conceptualizes AI not only as a technological tool, but as a contextually embedded phenomenon emerging from the interaction between organizations, institutions, and advisory practices.

Strategic Impacts of Generative Artificial Intelligence Adoption in Public Administration: An Empirical Analysis

FRANCESCO MERCURI [1*], EMILIANO TERELLA[2·], SABRINA RESTANTE[3♠], BERNARDINO QUATTROCIOCCHI[4**]

Abstract. *In recent years, the diffusion of Generative Artificial Intelligence (GenAI) has been profoundly transforming decision-making processes, organizational models, and knowledge creation practices in both the private and public sectors. However, the existing literature has primarily focused on specific technological applications, devoting less attention to understanding the strategic implications associated with its adoption within Public Administration (PA). In light of this gap, the present study aims to identify and prioritize the strategic impacts related to the adoption of GenAI in PA, while also analysing the differences across various public sectors. The research adopts a two-phase approach. First, a systematic literature review was conducted to identify the main strategic dimensions associated with GenAI adoption. Subsequently, these dimensions were analysed through the Analytic Hierarchy Process (AHP) using a survey administered to 80 public employees across two sectors: local government and healthcare. The results highlight that psychological barrier represent the most significant factor influencing the adoption of GenAI, followed by work performance and dimensions related to privacy and security. Moreover, the sectoral analysis reveals significant differences in the priorities assigned to the various factors. This study contributes to the literature by offering a comparative perspective on the strategic impacts of GenAI in the public sector and provides useful insights to guide the implementation strategies and innovation management within PAs.*
***Keywords**: Artificial Intelligence; Analytic Hierarchy Process (AHP); Public Administration; Digital Transformation.*

Framing of the research. The rapid diffusion of Artificial Intelligence (AI) has profoundly transformed decision-making processes, organizational dynamics, and knowledge production mechanisms in both the private and public sectors (Schwab, 2017; Russell & Norvig, 2021). Recent literature highlights that this transformation does not merely represent technological progress, but rather a phenomenon capable of affecting broader organizational and institutional variables, influencing citizens' expectations and the accountability mechanisms of public institutions (Mercuri et al., 2025; Margetts & Dorobantu, 2019; Wirtz, Weyerer & Geyer, 2019; Criado, Sandoval-Almazan & Gil-Garcia, 2025). In this context, Generative Artificial Intelligence (GenAI) stands out for its ability to learn from large volumes of data and generate original content, contributing to redefining how organizations operate across different sectors (Goodfellow et al., 2014; LeCun, Bengio & Hinton, 2015).

Despite its potential benefits, the adoption of GenAI also raises several critical issues, including concerns related to data security, the quality of generated information, algorithmic transparency, and the risk of excessive reliance on automated decision-making (Janssen & Van den Hoven, 2015; Tung, Hasnaeen & Zhao, 2025). Furthermore, the introduction of such technologies may generate concerns among public employees regarding the potential loss of competencies or the replacement of traditional professional skills (Verano et al., 2025). For this reason, international organizations such as UNESCO and the OECD have promoted ethical principles and guidelines aimed at fostering human-centered AI development, based on transparency, responsibility, and inclusiveness (UNESCO, 2021; OECD, 2024). In parallel, the European Union has introduced the Artificial Intelligence Act (AI Act), which establishes a regulatory framework based on a risk-based approach to the use of AI systems (European Union, 2024).

Within Public Administration (PA), several studies highlight how the use of GenAI can improve the quality of public services, the accessibility of information, and the efficiency of administrative processes (Margetts & Dorobantu, 2019; Zhou et al., 2025). Moreover, unlike the private sector—where innovation is often driven by competitive dynamics—the public sector pursues objectives related to values such as inclusiveness, transparency, and accountability (Jørgensen & Bozeman, 2007; Meynhardt, 2009).

Despite the growing academic interest, most studies have focused on the technical and application-related aspects of GenAI, while less attention has been devoted to understanding its strategic and organizational implications within the context of PA (Sousa et al., 2019; Babšek et al., 2025). Indeed, beyond the purely technological dimension, recent studies highlight the need to consider additional aspects, such as organizational culture, trust, and the individual behaviors of public employees (Vinarski-Peretz & Kidron, 2024; Bunduchi, Sitar-Tăut & Mican, 2025).

Furthermore, existing literature often tends to treat the public sector as a relatively homogeneous context, overlooking the differences among the various sectors that characterize PA, which are marked by different institutional missions and operational logics (Russo, 2013; Bobbio, 2015; Francini, 2021). In light of these considerations, there is a need to systematically investigate the strategic dimensions associated with the adoption of GenAI across different sectors of PA, and how these may vary according to their specific operational dynamics.

Purpose of the paper. This study aims to identify and prioritize the strategic impacts associated with the adoption of GenAI in PA, while also identifying the specific characteristics and limitations that influence its adoption across different public sectors. More specifically, the research seeks to identify the main dimensions influencing the integration of these technologies within public contexts and to assess their relative importance through a multi-criteria decision-making approach.

To achieve this objective, the study combines a systematic literature review with the Analytic Hierarchy Process (AHP) in order to structure and hierarchize the strategic factors emerging in the GenAI adoption process. The analysis is conducted by considering two different sectors of PA—local government and healthcare—with the aim of highlighting potential differences in the priorities attributed to the various impacts according to the institutional and operational specificities of each sector. Through this approach, the study intends to contribute to the existing literature on GenAI adoption in the public sector by providing a comparative and multidimensional perspective on its strategic impacts, while also offering useful insights to support managerial decision-making and implementation strategies within PAs.

Methodology. The paper is structured in two phases. In the first phase, a systematic literature review was conducted to identify the main dimensions of GenAI impact in Public Administration (PA). A total of 62 articles were selected and analysed, through which the factors were identified and grouped into strategic macro-dimensions, namely economic, personal, and technological. For the purposes of the analysis, seven factors were then selected, each representing one of the aforementioned strategic dimensions. Specifically, Psychological Barriers and Perceived Enjoyment were derived from the Technology Acceptance Model (TAM) (Davis, 1989; Venkatesh et al., 2003); Work Performance and Organizational Support were considered for the economic dimension (Vial, 2019; Wirtz et al., 2019). Finally, for the technological dimension, the factors Privacy & Security, Perceived Information Quality, and Anthropomorphism were included. These factors are linked both to the transparency and reliability of data generated by GenAI (OECD, 2024; UNESCO, 2021) and to human–machine interaction and the perception of applied systems (Glikson & Woolley, 2020).

Tab.1: Evaluation factors identified

Factor category	***Factor name***	***Definition***	***Representative Authors / Studies***
Personal	*Psychological Barriers*	*Psychological barriers refer to internal resistance shaped by personal beliefs, values, habits, and cultural norms.*	*Verano-Tacoronte et al. (2025); Chow & To (2025); Seyfi et al. (2025); Zhou et al. (2025)*
	Perceived Enjoyment	*Enjoyment refers to the degree to which the activity of using technology is perceived as pleasant in itself, regardless of any expected performance outcomes.*	*Cano & Núñez (2024); Foroughi et al. (2025); Ursavaş et al. (2025)*
	Perceived Information Quality	*Perceived information quality refers to the extent to which users consider AI-generated information to be timely, accurate, contextually relevant, practically useful, and sufficiently detailed to meet their needs.*	*Mun & Hwang (2024); Lee et al. (2002); Zhang & Hou (2024)*
	Anthropomorphism	*Anthropomorphism refers to the extent to which users perceive human-like characteristics during their interaction with GenAI systems.*	*Alsharhan et al. (2024); Ma & Huo (2023); Arce-Urriza et al. (2025)*
Economic	*Work Performance*	*Job performance refers to the effectiveness and productivity with which an individual completes tasks and responsibilities associated with their role.*	*Davis (1989); Patterson et al. (2024); Shahzad et al. (2024); Ivanov et al. (2024)*
	Organizational Support	*Organizational support refers to the level of resources, environment, and institutional support provided to facilitate employees' adoption of GenAI technologies in completing their work activities.*	*Hazzan-Bishara et al. (2025); Mergel et al. (2023); Al-Khatib (2023)*
Technological	*Privacy and Security*	*Privacy and security refer to the level of perceived protection of personal data and information shared with GenAI systems during their use.*	*Bunduchi et al. (2025); Bashir & Lapshun (2025); Lee et al. (2025)*

Source: Authors elaboration

In the second phase, the Analytic Hierarchy Process (AHP) methodology was applied in order to identify and prioritize the factors selected in the previous phase. This tool is widely used for analyzing particularly complex problems characterized by a plurality of criteria and qualitative judgments (Saaty, 1980; Saaty, 2008). Specifically, AHP made it possible to translate the qualitative judgments expressed by experts into consistent, verifiable, and aggregable quantitative weights (Saaty, 1980).

A structured questionnaire was therefore designed using a specifically configured Excel file. The questionnaire, containing pairwise comparisons, was administered to heterogeneous senior representatives belonging to the two sectors under analysis (local government and healthcare), with the aim of capturing potential differences in the perception of the technology among individuals with different roles, skills, and responsibilities. Participants were asked to compare each possible pair of criteria, C_i and C_j, expressing their judgment using the fundamental AHP scale proposed by Saaty (1980), as illustrated in Table 2.

Tab. 2: AHP Weighting Scale

Intensity of Importance	Scale Descriptor
1	Equal Importance (Equivalent)
3	Moderate Importance
5	Strong Importance
7	Very Strong Importance
9	Extremely Important
2; 4; 6; 8	Intermediate Values

Source: Saaty, 1980

Once the data were collected, they were organized into a square matrix $A = (a_{ij})$. The matrix makes it possible to systematically synthesize the preferences expressed by the respondents. The formulation used to construct the matrix is presented in Equation (1).

$$A_x = (a_{11} \cdots a_{1c} \vdots \ddots \vdots a_{c1} \cdots a_{cc}) \; \forall_x \in (1, 2, \ldots, 80) \qquad (1)$$

For a_{ij}, the following applies:

- $\forall_i = 1, \ldots, c = \forall_j = 1, \ldots, c: a_{ij} = a_{ij}^{-1}$;
- $\forall_i = 1, \ldots, c = \forall_j = 1, \ldots, c: a_{ij} > a_{ij}^{-1}$;
- $\forall_i = j : a_{ij} = 1$

Whereas the reciprocal of a_{ij} is calculated as follows:

$$a_{ij} = 1/a_{ij}, \; \forall_{i,j} = 1, \ldots, c, \; i \neq j \qquad (2)$$

The coherence of the evaluation matrices was estimated based on the Coherence Ratio (CR)(3).

$$CR = \frac{Indice\ di\ Consistenza\ (CI)}{Indice\ Random\ (RI)} \qquad (3)$$

The Consistency Index (CI) is calculated using Equation (4), where the numerator represents the deviation between the maximum eigenvalue of the comparison matrix and its dimension. The consistency threshold was set at 0.20. Respondents whose judgments exceeded this threshold were asked to voluntarily review their pairwise comparisons in order to fall within the acceptable limit.

$$CI = \frac{\lambda - N}{N - 1} \qquad (4)$$

The Random Index (RI), used to evaluate the consistency of the pairwise comparison matrices, is reported in Table 3.

Tab. 3: Random Index (RI)

N	1	2	3	4	5	6	7	8	9	10	11	12
RI	0	0	0,58	0,90	1,12	1,24	1,32	1,41	1,45	1,49	1,52	1,54

The questionnaire was administered to respondents in a manner that ensured anonymity. Specifically, 40 public employees were interviewed for each sector, for a total of 80 respondents. Data were collected between September and November 2025. Participants were contacted through a combination of online and offline channels, including direct contact both in person and remotely. Finally, the data were processed in order to obtain the priority weights, both in aggregated form and by individual sector, while also considering the socio-demographic characteristics of the respondents.

Specifically, the demographic data of the respondents are reported in the following table.

Tab. 4: Demographic data of the observed sample

Demographic		***Frequency***	***Percentage***
Gender	*Male*	*41*	*51,25%*
	Female	*39*	*48,75%*

Results. The application of the AHP methodology made it possible to hierarchize the factors related to the adoption of GenAI in Public Administration (PA) by analyzing the results at aggregated, sectoral, and socio-demographic levels. At the aggregated level, the results show a relatively balanced distribution of weights across the criteria, indicating a strong interaction among the different dimensions considered.

The most relevant factor is Psychological Barriers (16.17%), highlighting the presence of cultural and cognitive resistance to the introduction of new technologies within PA. This is followed by Work Performance (15.83%) and Privacy and Security (15.19%), which respectively underline the importance of operational efficiency and data protection.

Organizational Support (14.26%) and Perceived Information Quality (14.07%) show intermediate weights. Finally, the lowest values are attributed to Perceived Enjoyment (12.87%) and Anthropomorphism (11.62%), confirming the lower relevance of experiential aspects compared to functional and organizational dimensions.

Tab. 5: Sample weighting criteria for the PA

Factors	***Weight***
Psychological Barriers	*16,17%*
Perceived Enjoyment	*12,87%*
Work Performance	*15,82%*
Organizational Support	*14,26%*
Privacy and Security	*15,19%*
Perceived Information Quality	*14,07%*
Anthropomorphism	*11,62%*

Source: Authors Elaboration

The sectoral analysis highlights more pronounced differences compared to the aggregated results. In local government, the most relevant factors are Anthropomorphism (17,27%) and Perceived Information Quality (17,25%), indicating greater attention to communicative aspects and to the reliability of the information generated by GenAI. In contrast, Perceived Enjoyment appears to be the lowest relevant criterion (10,64%). Whereas in the healthcare sector, the results are similar to the aggregated ones, with greater relevance attributed to Psychological Barriers (18,53%) and a lower weight assigned to Anthropomorphism (9,46%), while the remaining factors show a relatively balanced distribution.

Tab. 6: Sample weighting criteria for the various sectors of the Public Administration

Factors	*Local Government*	*Healthcare*
Psychological Barriers	*13,17%*	*18,53%*
Perceived Enjoyment	*10,64%*	*14,72%*
Work Performance	*12,96%*	*15,47%*
Organizational Support	*14,14%*	*13,79%*
Privacy and Security	*14,57%*	*15,85%*
Perceived Information Quality	*17,25%*	*12,18%*
Anthropomorphism	*17,27%*	*9,46%*

Source: Authors Elaboration

The socio-demographic analysis highlights several differences in the priorities assigned to the criteria across different age groups. In particular, younger respondents (18–25 years old) attribute greater importance to Perceived Information Quality (23.53%). In the 26–35, 56–65, and over 65 age groups, Work Performance emerges as the most relevant criterion, whereas in the intermediate groups (36–45 and 46–55) Psychological Barriers appear to be more prominent. The least relevant factor is generally Anthropomorphism, except for the over-65 group, where the lowest value is attributed to Perceived Enjoyment. Overall, these results confirm the lower importance assigned to experiential and emotional aspects in the adoption of GenAI within PA.

Tab. 7: Socio-demographic data – Age

Age	*18-25*	*26-35*	*36-45*	*46-55*	*56-65*	*Over 65*
Psychological Barriers	*12,37%*	*14,79%*	*18,88%*	*15,80%*	*14,66%*	*13,75%*
Perceived Enjoyment	*11,24%*	*13,20%*	*14,45%*	*12,33%*	*11,70%*	*7,74%*
Work Performance	*12,81%*	*16,23%*	*15,28%*	*15,28%*	*16,35%*	*20,73%*
Organizational Support	*13,73%*	*13,57%*	*13,60%*	*14,49%*	*15,75%*	*15,66%*
Privacy and Security	*17,25%*	*15,99%*	*14,50%*	*15,13%*	*15,40%*	*13,88%*
Perceived Information Quality	*23,53%*	*15,43%*	*12,10%*	*14,05%*	*14,14%*	*17,02%*
Anthropomorphism	*9,07%*	*10,79%*	*11,19%*	*12,92%*	*12,00%*	*11,22%*

Source: Authors Elaboration

The analysis by educational level highlights some differences in the priorities assigned to the criteria. Respondents holding a bachelor's or master's degree show results similar to the aggregated sample, attributing greater importance to Psychological Barriers and lower relevance to Anthropomorphism. Conversely, employees holding a PhD/Master's degree or a high school diploma place greater emphasis on Privacy and Security. In general, the least relevant factor appears to be Perceived Enjoyment, confirming a stronger focus on the functional and performance-related aspects of GenAI rather than on the experiential dimension.

Tab. 8: Socio-demographic data – Education

Education	*High School*	*Bachelor's degree*	*Master's degree*	*PhD/Master*
Psychological Barriers	*13,01%*	*18,48%*	*16,63%*	*15,26%*
Perceived Enjoyment	*10,80%*	*15,32%*	*13,60%*	*10,23%*
Work Performance	*15,45%*	*16,74%*	*15,18%*	*15,59%*
Organizational Support	*14,59%*	*13,98%*	*14,10%*	*14,13%*
Privacy and Security	*16,12%*	*13,50%*	*15,38%*	*16,68%*
Perceived Information Quality	*17,00%*	*11,87%*	*13,97%*	*14,71%*
Anthropomorphism	*13,03%*	*10,11%*	*11,14%*	*13,40%*

Source: Our Elaboration

The analysis by income level highlights differences in the priorities assigned to the criteria. In the below €1000 income group, Perceived Information Quality and Organizational Support emerge as the most relevant factors, while Privacy and Security receive lower importance. In the €1000–1500 and €2500–3000 income groups, Psychological Barriers appear to be more relevant, indicating the importance of the cultural dimension in technology adoption processes. The intermediate income groups (€1500–2000 and €2000–2500) show a more balanced distribution, with greater attention to Work Performance and Perceived Information Quality. Finally, in the above €3000 income group, Work Performance, Privacy and Security, and Organizational Support emerge as the most relevant factors, highlighting a perspective more oriented

toward the governance of technology. Overall, the results show that different income groups assign different priorities to the strategic impacts of GenAI.

Tab. 9: Socio-demographic data – Income

Income	*< 1000*	*1000-1500*	*1500-2000*	*2000-2500*	*2500-3000*	*> 3000*	*Not Specified*
Psychological Barriers	*14,91%*	*18,18%*	*14,21%*	*15,66%*	*19,11%*	*13,64%*	*17,31%*
Perceived Enjoyment	*11,79%*	*13,74%*	*11,82%*	*12,55%*	*17,88%*	*9,48%*	*12,00%*

Source: Authors Elaboration

Overall, the sectoral results highlight significant differences shaped by the specific characteristics of each sector with respect to the adoption of GenAI. In particular, the analysis brings to light the different criteria that the various sectoral contexts consider to be the most impactful within their specific operational environments. The findings emerging from this threefold analysis (aggregated, sectoral, and socio-demographic) emphasize the need for public decision-makers to adopt a cautious and balanced approach when managing the implementation of GenAI. In particular, policymakers should carefully consider how to address and overcome the barriers associated with GenAI adoption among public employees, which may vary across different institutional contexts.

Research limitations. This study adopts an exploratory qualitative approach, based on the analysis of primary data collected through a structured survey distributed by the authors. Despite the validity of the data, several limitations should be acknowledged.

First, the relatively limited sample size (N = 80), although adequate for exploratory applications of the Analytic Hierarchy Process (AHP), limits the full generalizability of the results. Second, the cross-sectional nature of the research does not allow for the analysis of how perceptions of the impacts of GenAI may evolve over time. Finally, the analysis focuses on two specific domains of PA, which may limit the representativeness of the broader public sector.

Despite these limitations, the study provides a first structured prioritization of the strategic factors associated with the adoption of GenAI in PA, offering a solid empirical basis for future theoretical and applied research.

Managerial implications. The introduction of GenAI in Public Administration (PA) produces significant managerial implications, as it should not be considered merely a technological innovation but rather a broader organizational transformation that also affects the personal dimension of employees working in the public sector (Wirtz & Müller, 2023; Mergel et al., 2023). In particular, the central role attributed to psychological barriers and work performance highlights the need for public managers to invest in training and digital skills development for public employees, while simultaneously fostering organizational environments that reduce resistance and negative perceptions associated with the introduction of GenAI.

Sectoral results also reveal different priorities across the various domains of PA. In the healthcare sector, stronger resistance to adoption emerges due to fears of skill loss and distrust toward technology, making it necessary for management to play an active role in supporting employees and clearly defining the boundaries of responsibility between technological systems and human operators. Moreover, local governments place greater emphasis on human-related factors, showing particular attention to information quality and communication with citizens.

Overall, users in the public sector tend to prioritize reliability, transparency, and operational support over experiential or symbolic dimensions, as confirmed by the limited importance attributed to anthropomorphism (Glikson & Woolley, 2020). This suggests that the adoption of GenAI in PA is primarily driven by the robustness of systems, data security, and their contribution to improving organizational performance. Furthermore, the demographic differences observed highlight the need to avoid "one-size-fits-all" solutions (Vinarski-Peretz & Kidron, 2024; Wirtz, Weyerer & Geyer, 2019) and instead develop differentiated training programs, particularly according to the age and educational level of public employees.

Originality of the paper. The originality of this paper lies in the strategic prioritization of the impacts associated with the adoption of GenAI in the public sector, providing a clearer understanding of how PAs hierarchize expected benefits in the presence of organizational, regulatory, and technological constraints.

Furthermore, the article analyses the differences across the various PA sectors considered, highlighting how different sectoral dynamics influence the relative priority assigned to the identified factors. This contributes to a deeper understanding of the logics and dynamics that drive digital transformation within PA.

The research also contributes to expanding the literature on GenAI adoption in the public sector, extending beyond the limitations of traditional technology adoption models, such as TAM, TOE, and UTAUT.

Strategie di Open Innovation e performance innovative delle PMI: il ruolo moderatore del valore e della veridicità dei Big Data

GIULIO FERRIGNO, FRANCESCA PASCALE, SAVERIO BARABUFFI, ANDREA PICCALUGA

Abstract. *La relazione tra le strategie di ricerca di Open Innovation (OI) e le performance innovative delle PMI è ampiamente discussa nella letteratura. Tuttavia, gli studi esistenti raramente considerano se tale relazione sia moderata dalle caratteristiche dei Big Data. Facendo riferimento alla Transaction Cost Economics (TCE), ipotizziamo che il Big Data Value e la veridicità dei Big Data moderino la relazione tra le strategie di ricerca OI (ampiezza e profondità) e le performance innovative, sia radicali sia incrementali, delle PMI. Utilizzando un dataset originale di PMI italiane, il nostro studio evidenzia un significativo effetto moderatore del Big Data Value, suggerendo una riduzione dei costi di transazione e di coordinamento. A partire da questi risultati, proponiamo alcune implicazioni teoriche e manageriali.*
Keywords: *innovazione aperta; performance dell'innovazione; PMI; big data; Italia*

Framing of the research. Quasi vent'anni dopo la loro concettualizzazione iniziale, sono state condotte ricerche approfondite sulle strategie di ricerca OI (Chesbrough, 2003; Laursen e Salter, 2006; Liu et al., 2024), sia in termini di ampiezza dell'OI (ad esempio la varietà di fonti esterne come i partner) sia in termini di profondità dell'OI (ad esempio, l'intensità dell'interazione con queste fonti esterne) (Del Sarto et al., 2023; Bertello et al., 2024; Cricchio et al., 2025). Per quanto riguarda le PMI, la letteratura precedente ha rilevato che alti livelli di ampiezza e profondità dell'OI sono vantaggiosi sia per la loro innovazione incrementale che per quella radicale (Yusof et al., 2023).

Tuttavia, negli ultimi anni, i Big Data sono diventati sempre più importanti, ma nessuno studio ha indagato se le loro caratteristiche possano aumentare o ridurre i costi di coordinamento OI, sia per ampiezza che per profondità. In effetti, le caratteristiche dei Big Data sono un argomento recente e molto dibattuto nella ricerca (Mariani et al., 2023). E infatti, gli studiosi hanno studiato il Volume di Big Data, la Velocità dei Big Data e la Varietà dei Big Data (Tan e Zhan, 2017; Ghasemaghaei e Calic, 2020; Ferrigno et al., 2024; Ritala et al., 2024). Tuttavia, la letteratura recente suggerisce che devono essere studiate anche due caratteristiche aggiuntive: il Valore dei Big Data (ad esempio, Monino, 2021) e la Verdicità dei Big Data (ad esempio, Cappa et al., 2021). Comunemente definite "la seconda generazione di Big Data" (Del Vecchio et al., 2018), queste due caratteristiche possono svolgere un ruolo fondamentale nella comprensione della rilevanza dei Big Data per le aziende. Anzi, possono migliorare l'affidabilità delle decisioni delle PMI e stimolarne le prestazioni innovative incentivando un approccio più rapido ed efficiente (Del Vecchio et al., 2018; Cappa et al., 2021). In particolare, il Valore dei Big Data rappresenta i benefici e le intuizioni che i Big Data possono offrire, mentre la Verdicità dei Big Data rappresenta l'affidabilità e la perspicacità dei dati. Come osservato da Ghasemaghaei (2021), sia la Veracità dei Big Data che il Valore dei Big Data sono caratteristiche cruciali che incorporano le principali caratteristiche di Volume, Varietà e Velocità dei Big Data.

Purpose of the paper. In questo studio, puntiamo quindi a esplorare il ruolo di queste due caratteristiche del Big Data (cioè Valore e Veridicità) nella relazione tra le strategie di ricerca OI e le performance innovative delle PMI (Ferrigno et al., 2025). A tal proposito, alcuni studi suggeriscono che il Big Data influenzi le strategie di ricerca OI (ad esempio, Ferrigno et al., 2024), mentre altri indicano che il Big Data può aiutare le PMI a migliorare le loro performance innovative (Parida et al., 2017). La letteratura esistente ha inoltre rilevato che entrambe le strategie di ricerca OI possono influenzare le performance innovative delle PMI (Del Sarto et al., 2023), ma nessuno studio ha esaminato il potenziale effetto del Big Data come moderatore in questa relazione. Di conseguenza, studi recenti (ad esempio, Del Sarto et al., 2023; Ferrigno et al., 2024) suggeriscono che il Big Data potrebbe avere un ruolo nel rapporto tra le strategie di ricerca OI e le performance innovative delle PMI. In particolare, Ferrigno et al. (2025, p.11) affermano che "sarebbe utile indagare se alcune caratteristiche dei Big Data — come valore e veridicità — moderino la relazione tra le strategie di ricerca dell'innovazione aperta e le prestazioni innovative radicali e incrementali delle aziende". Pertanto, in questo studio cerchiamo di rispondere a questa domanda di ricerca: qual è l'effetto moderatore del Valore e della Veridicità del Big Data sulla relazione tra le strategie di ricerca OI e le performance innovative delle PMI?

Methodology. Per testare le nostre ipotesi, abbiamo scelto il contesto italiano considerando caratteristiche specifiche dell'ambiente normativo e delle opportunità imprenditoriali (Beckman e Burton, 2008). L'Italia ha una significativa prevalenza di PMI (Ferrigno, Del Sarto, Di Minin, 2025), che impiegano oltre il 90% della forza lavoro nazionale (ISTAT, 2022) e, nell'ultimo decennio, il Governo italiano ha lanciato numerosi piani e interventi per promuovere la digitalizzazione delle aziende e l'accesso ai Big Data (MISE, 2020). In quanto tale, l'Italia rappresenta un contesto completo per indagare la natura complessa delle PMI che interagiscono con i Big Data (Ferrigno et al., 2024).

Abbiamo sviluppato un sondaggio e condotto tre test preliminari per migliorare la chiarezza e l'affidabilità di un questionario specificamente progettato (Crick et al., 2023). Lo abbiamo testato ottenendo spunti da cinque esperti

accademici nei campi dell'OI, PMI e Big Data, e da cinque fondatori e decisori di PMI operanti in settori diversi (Laursen e Salter, 2006). Successivamente, un'agenzia indipendente ha esaminato anche il questionario. Infine, abbiamo utilizzato il sito italiano "registroimprese" per identificare aziende con meno di 250 dipendenti e un fatturato inferiore a 50 milioni di euro (Messeni Petruzzelli et al., 2022), e il database Orbis per accedere agli indirizzi email e ai principali contatti di queste aziende; Per i dati che non possono essere scaricati, abbiamo cercato manualmente nei siti web delle aziende. Abbiamo selezionato e contattato casualmente un sottocampione di 801 aziende e distribuito un questionario strutturato online da compilare da parte dei loro CEO o fondatori, utilizzando il metodo del Computer-Assisted Telephone Interview (CATI). Abbiamo scoperto che, all'interno di queste, 210 aziende erano coinvolte in attività di Big Data. Su 210, 135 PMI hanno compilato il questionario. Abbiamo testato le ipotesi stimando le regressioni ai minimi quadrati ordinari (OLS). In particolare, abbiamo stimato la seguente equazione:

$$Y_i=OI_i+\text{Big Data V}_i+OI_i\times\text{Big Data V}_i+\text{ Controlli}+\text{Correzione di Heckman}+\varepsilon_i$$

Questo approccio è un metodo rigoroso per affrontare la nostra domanda di ricerca, poiché consente di valutare sia gli effetti diretti che moderati delle caratteristiche del Big Data sulla relazione tra le strategie OI e i risultati innovativi delle PMI. Includendo i termini di interazione tra IO e variabili Big Data, il modello cattura esplicitamente se e come le capacità Big Data rafforzano o indeboliscono l'effetto dell'OI sulle prestazioni dell'innovazione. L'OLS consente inoltre l'inclusione di variabili di controllo che tengono conto di caratteristiche specifiche dell'azienda che potrebbero confondere le relazioni osservate. Includiamo quindi due modelli nella nostra analisi, uno che include i controlli, l'altro senza controlli. Questo ci permette di eseguire il lavoro di Hill et al. (2020) per offrire un'analisi più forte e robusta. Offriamo anche un modello aggiuntivo che applica la correzione di Heckman (Heckman, 1979). In particolare, la correzione di Heckman affronta il potenziale bias di selezione del campione, migliorando la robustezza e la validità dei nostri risultati. In quanto tale, questo metodo fornisce un quadro affidabile per isolare gli effetti moderatori delle caratteristiche dei Big Data.

La variabile dipendente è la performance innovativa delle PMI, cioè radicale o incrementale. Le variabili indipendenti sono le strategie di ricerca OI (cioè profondità o ampiezza), i Big Data Vs (cioè Valore o Verità) e i termini di interazione tra profondità/ampiezza OI e Valore/Verdicità dei Big Data.

Successivamente, abbiamo introdotto diverse variabili di controllo e abbiamo eseguito una trasformazione logaritmica per tutte le variabili. In linea con alcuni studi precedenti, il nostro modello include le seguenti variabili di controllo: (1) se la PMI opera o meno in un'industria high-tech (Messeni Petruzzelli et al., 2022); (2) il logaritmo dell'età di SME (Kelly e Amburgey, 1991); (3) il logaritmo della dimensione delle SME (Arbore e Ordanini, 2006; Horváth e Szabó, 2019); (4) il potenziale e la capacità di assorbimento realizzata delle PMI (cioè le spese di R&S sul fatturato totale; vedi Cassetta et al., 2020; Zahra e George, 2002); e (5) le competenze digitali delle risorse umane delle PMI (misurate come percentuale di dipendenti con una laurea STEM; vedi Agostini e Filippini, 2019; Eller et al., 2020; Giotopoulos et al., 2017; Horváth e Szabó, 2019). Poi, il termine di correzione di Heckman controlla l'endogeneità derivante dal bias di auto-selezione nelle risposte delle imprese, come proposto da Heckman (1979).

Results. I nostri risultati mostrano un effetto positivo e statisticamente significativo di moderazione del Big Data Value sulla relazione tra le strategie di ricerca OI e le performance innovative delle PMI, supportando così H1 e H2. Più specificamente, il Big Data Value sembra ridurre i costi di coordinamento generati dalle strategie di ricerca OI. Di conseguenza, le strategie di ampiezza dell'OI diventano più efficaci nel supportare la performance radicale dell'innovazione quando le PMI possono sfruttare i benefici economici e le intuizioni fornite dal Valore dei dati, poiché riducono i costi di coordinamento derivanti dall'assimilazione di molteplici input di conoscenza esterna (Laursen e Salter, 2006; Radicic e Alkaraan, 2022; Messeni Petruzzelli et al., 2022; Carrasco-Carvajal et al., 2023; Broekhuizen et al., 2023). In questo contesto, Big Data Value facilita il processo delle PMI di trovare nuovi partner con cui collaborare. Big Data Value può aiutare le PMI a identificare partner adatti a diverse esigenze in modo più rapido ed efficiente, permettendo loro di risparmiare tempo e risorse e così ridurre i costi di coordinamento. L'effetto sulla riduzione dei costi di coordinamento modera positivamente la relazione tra ampiezza dell'OI e performance radicale nell'innovazione, con un beneficio complessivo per l'azienda.

Tuttavia, anche nel contesto della profondità dell'OI, il Big Data Value interviene riducendo questi costi e migliorando ulteriormente le performance radicali dell'innovazione (Laursen e Salter, 2006; Messeni Petruzzelli et al., 2022). Infatti, il Big Data Value consente alle PMI di ridurre le risorse e il tempo necessari per approfondire la collaborazione con un partner specifico, rendendo la collaborazione più efficiente. Il Big Data Value può anche aiutare le PMI a identificare rapidamente il partner più adatto per ogni compito specifico richiesto nel processo di innovazione, senza ripetere ogni volta il processo di ricerca.

Per quanto riguarda la veridicità dei Big Data e il suo impatto sulla relazione tra le strategie di ricerca OI (ampiezza e profondità) e le performance innovative delle PMI, i nostri risultati non rivelano alcun legame sostanziale. Infatti, i nostri risultati mostrano che la ricerca sulla veridicità dei Big Data potrebbe non avere l'impatto previsto sulla relazione tra OI e performance dell'innovazione, non confermando che i costi di transazione siano positivamente influenzati dalla veridicità dei Big Data, anche se le intuizioni teoriche lo suggerirebbero. Infatti, Big Data Veracity facilita e riduce risorse e tempi per verificare l'affidabilità delle informazioni ricevute, potenzialmente moderando positivamente le relazioni tra strategie di ricerca OI e performance innovative, grazie all'impatto positivo dell'affidabilità e dell'approfondimento dei dati (White, 2012), caratteristiche fondamentali soprattutto per le aziende che mirano ad affrontare performance di

innovazione incrementali o radicali (Cappa et al., 2021). La veridicità dei Big Data può permettere alle PMI di concentrarsi solo su dati affidabili e rilevanti per estrarre preziose informazioni e stimolare le prestazioni dell'innovazione. In particolare, nel contesto dell'ampiezza dell'OI, i potenziali impatti positivi della veridicità dei Big Data sono stimolati dalla crescente varietà di approcci alla risoluzione dei problemi, che stimolano soluzioni per problemi difficili e la selezione di partner più adatti (Fleming, 2007; George et al., 2008; Singh e Fleming, 2010; Radicic e Alkaraan, 2022; Messeni Petruzzelli et al., 2022; Carrasco-Carvajal et al., 2023). Lo stesso accade quando le PMI si occupano di profondità IO e devono selezionare con cura i partner per collaborare più frequentemente e profondamente, creando relazioni stabili e solide (Laursen e Salter, 2006; Messeni Petruzzelli et al., 2022; Carrasco-Carvajal et al., 2023). Il costo potenziale del trasferimento di informazioni e conoscenze (Clemons e Row, 1992; Gorman, 2014; Ziegert et al., 2022) potrebbe essere compensata dai crescenti benefici che le PMI ottengono nel perseguire pratiche di approfondimento in IO (Laursen e Salter, 2006). Pertanto, i nostri risultati richiedono ulteriori indagini sull'effetto della veridicità dei Big Data da diverse prospettive.

Research limitations. Il presente studio contribuisce alla comprensione delle caratteristiche dei Big Data come variabili moderatrici che influenzano le strategie di ricerca dell'innovazione aperta e le prestazioni innovative delle PMI, tuttavia non è esente da possibili limitazioni.

Innanzitutto, il principale svantaggio della nostra ricerca riguarda l'ambito delle analisi empiriche, poiché la nostra indagine è limitata a un solo paese. Questa scelta è guidata dalla rilevanza del paese italiano per l'obiettivo della nostra ricerca; infatti, l'Italia è uno dei primi paesi in Europa a stimolare l'uso dei Big Data nelle PMI. Tuttavia, il numero di aziende considerate è limitato e potrebbe esserci qualche bias specifico per paese. Ricerche future potrebbero estendere questa indagine studiando diversi paesi e offrendo confronti tra i paesi, ad esempio con aziende cinesi (Dong, Zhang, & Mei, 2025, Wu & Mei, 2022). Confrontare i risultati provenienti da diversi contesti empirici amplierebbe la conoscenza accademica sull'effetto dei Big Data sulla relazione tra strategie di ricerca dell'innovazione aperta e performance dell'innovazione e farebbe luce sulle conseguenze politiche.

In secondo luogo, abbiamo identificato le strategie di ricerca dell'innovazione aperta per il nostro studio basandoci sul quadro stabilito da Messeni Petruzzelli et al. (2021) e Laursen e Salter (2006). Tuttavia, riconosciamo l'esistenza di altre concettualizzazioni di innovazione aperta, come quelle evidenziate in diversi studi, che non abbiamo incluso nel nostro questionario. Ad esempio, Gassmann et al. (2010) adottano una 'prospettiva di processo', classificando queste pratiche in processi OI in entrata, in uscita e accoppiati; mentre Spithoven et al. (2013) suggeriscono quattro pratiche di innovazione aperta, come (1) la ricerca di fonti esterne di innovazione, (2) l'acquisizione di R&S esterni, (3) l'uso di partner collaborativi per l'innovazione e (4) lo sfruttamento dei meccanismi di protezione della proprietà intellettuale disponibili. Ricerche future potrebbero replicare la nostra metodologia considerando anche concettualizzazioni alternative di innovazione aperta identificate in altri studi.

In terzo luogo, abbiamo esaminato il rapporto tra strategie di ricerca per l'innovazione aperta e performance dell'innovazione e il ruolo moderatore delle caratteristiche dei Big Data all'interno delle PMI italiane. Future indagini potrebbero esplorare gli effetti moderatori dei Big Data sull'impatto dell'innovazione aperta su uno spettro più ampio di imprese, inclusi aziende consolidate, grandi aziende e startup.

In quarto luogo, in questo studio abbiamo analizzato il ruolo moderatore svolto dalla meno esplorata V dei Big Data. Tuttavia, altre dimensioni di interesse inesplorate nei Big Data riguardano la variabilità nel flusso dei dati, riconoscendo le incongruenze all'interno dei dataset (Katal et al., 2013), e il campo della visualizzazione dei Big Data, che riguarda la capacità delle organizzazioni di formulare indagini pertinenti per estrarre valore significativo dalle loro iniziative Big Data (Simon, 2014). Future ricerche potrebbero approfondire queste dimensioni del Big Data per ottenere una comprensione più completa di come influenzano l'impatto dell'innovazione aperta sulle prestazioni innovative delle PMI.

Managerial implications. Lo studio offre anche alcuni contributi manageriali. Innanzitutto, i risultati suggeriscono che il Big Data Value consente alle PMI di migliorare le proprie prestazioni innovative, soprattutto quando cercano di introdurre innovazioni radicali. Di conseguenza, le PMI sono più inclini a innovare in modo radicale quando dispongono di preziose quantità di informazioni.

In secondo luogo, i risultati indicano anche che il Big Data Value facilita le strategie di ricerca OI accelerando l'identificazione di nuovi partner (OI ampiezza) e facilitando la capacità delle PMI di comprendere la forza di ciascun partner in relazione a compiti specifici, promuovendo la profondità dell'OI. Questo è un punto chiave soprattutto per le PMI, che di solito incontrano maggiori difficoltà nel processo di identificazione e selezione dei partner. Pertanto, manager e professionisti dovrebbero concentrarsi sull'utilizzo del Big Data Value per migliorare le loro collaborazioni e le loro prestazioni innovative.

In terzo luogo, la gestione dei costi di coordinamento è una caratteristica chiave per le future performance innovative delle PMI e per il loro successo. Questo studio mostra che il Big Data Value riduce i costi di coordinamento tra PMI e altre organizzazioni, migliorando l'efficienza della collaborazione e facilitando le loro prestazioni innovative. La riduzione dei costi è fondamentale per le PMI, che spesso affrontano sfide organizzative e aziendali che potrebbero ostacolare la loro crescita futura.

Originality of the paper. Il nostro studio offre diversi contributi alla letteratura esistente. Innanzitutto, il nostro lavoro contribuisce alla letteratura precedente su Big Data e performance dell'innovazione svelando nuovi e emergenti Vs del Big Data: Valore e Veridicità. Queste caratteristiche, comunemente identificate come la "seconda generazione dei V" (Del Vecchio et al., 2018), sono scarsamente studiate in letteratura, e diversi articoli richiedono un'analisi più approfondita su questo argomento (ad esempio, Del Vecchio et al., 2018). Più specificamente, Ferrigno et al. (2025) propongono studi che "indaghino se alcune caratteristiche del Big Data — come valore e veridicità — moderino la relazione tra le strategie di ricerca dell'innovazione aperta e le performance innovative radicali e incrementali delle aziende." Per rispondere a questa richiesta di ricerca, in questo studio ci siamo concentrati sul Big Data Value per chiarirne l'effetto sulle prestazioni radicali dell'innovazione. Ci siamo inoltre concentrati sulla veridicità dei Big Data, ampliando la letteratura correlata. I Big Data possono anche svelare l'esistenza di elementi che facilitano il flusso di conoscenza all'interno dell'azienda (Arias-Pérez e Vélez-Jaramillo, 2021; 2022), evidenziando la rilevanza della veridicità dei Big Data in termini di tempo e risorse più efficienti necessarie per garantire l'affidabilità dei dati. Di conseguenza, contribuiamo anche alla letteratura che scopre un potenziale effetto positivo della veridicità sulla relazione tra strategie di innovazione aperta e performance dell'innovazione.

In secondo luogo, questo è uno dei pochi studi che utilizzano il TCE (Williamson, 1979, 1981, 1991) nella ricerca sull'innovazione aperta (Remneland-Wikhamn & Knights, 2012; Hsieh et al., 2016). Ispirandosi a questa teoria, l'articolo suggerisce un nuovo quadro attraverso il quale i Big Data possono essere concettualizzati come risorse vantaggiose per le prestazioni delle PMI. Sfruttando il TCE, abbiamo scoperto che i Big Data possono moderare i costi di transazione e coordinamento che ostacolano le PMI nell'attuare strategie di ricerca OI. Più specificamente, i risultati di questo studio suggeriscono che il Big Data Value consente alle PMI di migliorare la loro efficienza nella collaborazione, ampliando i propri confini.

Di conseguenza, in questo studio contribuiamo alle strategie di ricerca OI attraverso la lente del TCE, valutando l'importanza del Big Data Value nella riduzione dei costi di coordinamento, per identificare partner e sfruttare la conoscenza esterna (Dahlander et al., 2021). Pertanto, il Big Data Value può aiutare a rimodellare i confini organizzativi delle PMI e a rendere efficaci ed efficienti le loro collaborazioni innovative (Vural et al., 2013). Speriamo che ricercatori e professionisti adottino questa prospettiva sui Big Data per ottenere approfondimenti e utilizzare efficacemente i loro dati per ottimizzare i costi del trasferimento della conoscenza nelle collaborazioni OI.

In terzo luogo, questa ricerca contribuisce alla letteratura precedente analizzando una variabile moderatrice rilevante, sebbene poco studiata, nella relazione tra strategie di ricerca OI e performance dell'innovazione, come suggerito da Ferrigno et al. (2025). Ricerche precedenti hanno analizzato gli effetti moderati delle caratteristiche industriali (Grimpe e Sofka, 2009), delle caratteristiche aziendali (Stanko e Henard, 2017), e dinamiche temporali (Ganotakis et al. 2025). Tuttavia, è stata prestata poca attenzione alla comprensione di quali fattori possano moderare i costi di coordinamento derivanti dalle strategie di ricerca OI e i loro effetti sulle prestazioni innovative delle PMI. Per quanto ne sappiamo, nessuno studio si concentra su tale effetto moderatore (Ferrigno et al., 2025), ma indaga la relazione diretta tra Big Data Vs e performance dell'innovazione (ad esempio, Ghasemaghaei e Calic, 2020), Big Data Vs e strategie di open innovation (Del Vecchio et al., 2018), o open innovation e performance dell'innovazione (ad esempio, Ferrigno et al., 2024). L'effetto di moderazione del Big Data Value rivela nuove prospettive riguardo alla potenziale interazione tra variabili, approfondendo la conoscenza dell'innovazione aperta e delle performance dell'innovazione.

Trusting the Bot? How AI Chatbots Shape Trust and Donation Behavior among Repeat Small Donors in Non-profit Communication

ALESSANDRO SIGNORINI

Abstract. *Individual small donors represent the primary driver of fundraising for nonprofit organizations, yet maintaining long term donor relationships remains a critical challenge since donor numbers decline and donor information needs are largely unexplored. This study investigates interactions between a specifically-designed AI Chatbot and small, repeat donors in a non-profit organization to assess its effects on donor trust and behavior.*

Using a between-subjects experimental design, the study compares two direct communication channels, an AI chatbot and an email newsletter. A planned sample of 400 Italian repeat donors with less than €5,000 annual contributions is randomly assigned to one of the two experimental groups. Trust is evaluated through a multidimensional framework integrating the Integrative Model of Organizational Trust, Trust in Automation, and Social Presence Theory. Perceived measures of trust and donor intentions are matched with actual donation behavior collected after the experiment.

Preliminary results from 90 respondents show that donor attitudes toward AI communication vary significantly by age, familiarity with AI, and previous experience with the non-profit sector. Specifically, younger donors and AI-savvy donors exhibit higher levels of trust in the Chatbot. Also, donors exhibit no significant concerns regarding AI hallucinations and the reliability of information sources. No notable difference emerges in donation propensity between the chatbot and the newsletter experiment, however, higher-frequency AI users demonstrate greater donation propensity and amounts. Donors using the Chatbot focus on project progress and future initiatives, while newsletter recipients review financial data more frequently. A strong correspondence was found between stated donation intentions and actual donations across both groups.

This study provides an original contribution to non-profit literature by analyzing an innovative AI application within an operational fundraising context as compared to traditional communication tools. It suggests that AI can strengthen donor relationship and trust, although, increases in donor propensities are limited to donors with high levels of AI usage.
Keywords: *Artificial Intelligence (AI) Chatbot; non-profit fundraising; individual donation; small donors; donor trust; donor communication*

Framing of the research. Individual contributions remain the primary driving force of fundraising for non-profit organizations. In the United States, individuals contributed for nearly 66% of total donations in 2024, accounting for US$392.45 billion out of a total ofUS$592.5 billion and maintaining a constant upward trend since 2020 (Indiana University Lilly Family School of Philanthropy, 2025). Individual donations are also central in Europe, although their role varies by country, typically representing 40% to 55% of total fundraising collection (European Fundraising Association (EFA), 2024). The lower proportion compared to the US is largely explained by the more relevant weight of governmental and European Union funds, which cover around 20% of non-profit activities. Meanwhile, foundations and corporate fundraising contribute roughly 20% and 10%, respectively (European Fundraising Association (EFA), 2024).

Despite the steady growth of individual donations in the last years, the number of individual donors has declined, showing a concentration of large contributions from high-net-worth individuals (Association of Fundraising Professionals (AFP), 2025). Additionally, legacy giving is expanding in several national markets. For example, in United Kingdom and the Netherlands, bequests are worth between 15 to 20% of total individual donations (Charities Aid Foundation (CAF), 2025).

Individual donations originate from first-time donors and repeat donors. Repeat donors generally require lower fundraising investments per person compared to first-time donors, making them valuable assets for the non-profit organizations. However, effective donor retention demands careful planning and consistent communication (Xiao & Yue, 2021). Communication with existing donors can take the form of direct outreach, such as personal calls and visits, direct mails, and emails, as well as general communication, including press releases and social media updates. Direct communication often incorporates detailed newsletters and tokens of appreciation like thank-you gifts. Direct communication with existing donors is typically structured to convey different emotional responses. Negative emotions that are associated to current challenges or unexpected events can be transformed into positive feelings as the non-profit offers the opportunity to support through an additional donation.

Research (Agyemang et al., 2019; Merchant et al., 2010) shows that follow-up communication and feedback to existing donors have the potential to strengthen their emotional attachment to the organizations and deepen their engagement to the mission. Communication with donors also contributes to build trust in non-profit organizations. Virtuous organizations tend to showcase their operational proceedings after receiving funds and are eager to establish relationships with their donors and be open to public scrutiny. Overall, communication encourages organizational trust, which is defined as the collective belief that the organization will act in a fair and reliable manner, as well as sectoral trust, which refers to the level of confidence and expectations for a specific humanitarian sector (Chapman et al., 2021). An experimental design involving 319 respondents proves that emotional attachment to an organization increases the

probability of repetitive donations (Merchant et al., 2010). In addition, a meta-analysis from 42 studies between 1988 and 2020 found that trust is positively associated with additional donations, with organizational and sectoral trust showing a particularly strong statistical significance (Chapman et al., 2021). Therefore, direct communication can be employed as an effective tool for implementing fundraising strategies by organizations.

Even if direct communication offers relationship and fundraising benefits, it is challenging to structure because knowledge of donors' information needs is still limited (Dethier et al., 2024). Moreover, donor segments respond differently to communication stimuli, some donors welcome repetitive and detailed updates, while others experience discomfort and disengagement beyond a certain point (Karlan & Wood, 2017). Survey data consistently cite inadequate or unsatisfactory communication as a leading reason donors discontinue their relationship with specific non-profits or with the non-profit sector as a whole (Sargeant, 2001).

Dethier et al. (2024) argue that transparency should be the cornerstone for effective communication with donors. From the donor's perspective, transparency consists of three factors, in detail, information accessibility, i.e., the degree to which donors can easily obtain and understand relevant organizational details, completeness, i.e., the extent to which the information disclosed provides a comprehensive view of activities, and accuracy, i.e., ensuring information is correct, reliable, and free from errors.

Donor communication can be designed using various methods and content types. The most immediate and natural interaction with the donors is a thank-you call or note from the organization or selected representatives, such as the staff members or donor beneficiaries. However, academic literature indicates that simple thank-you messages have no statistically significant impact to elicit repeat donations at the aggregate level, even though donors generally perceive them as a positive experience and a meaningful connection with the organization (Karlan & Wood, 2017).

Non-profit organizations can also provide indicators of operational efficiency and project effectiveness to their existing donors. The main indicators associated with operations and projects are outputs, outcomes, and impacts. Research based on an online survey experiment (Bodem-Schrötgens & Becker, 2020) outlines that donors value outcome and impact indicators more than output variables as they provide a more profound understanding of the effects of their contributions. Other studies (Levontin et al., 2025; Saeri et al., 2023) emphasize the importance of the impact indicators in the donor communication. Donors are primarily interested in the actual impact of the funded activities rather than the anticipated outcomes. Offering concrete, demonstrable, and easily verifiable information is strongly associated with greater willingness to donate again and with higher donation amounts. Alkire et al. (2025) suggest that non-profit organizations should ideally communicate the broader social impact of their activities, showing the extended benefits that their works brings to society. Nevertheless, social impact measurements are difficult to establish because they often include variables that are qualitative and have effects only in the long-term. Also, positive social impact is frequently determined by a combination of efforts from multiple non-profit and governmental organizations, thus, if one component is missing, the overall social impact risks to be weakened or lost. Unfortunately, most non-profits indicate only their individual-level impact because they often lack the expertise or access to data needed to evaluate the real social impact.

In addition, donors appear to be responsive to the assessment and transparency of financial information, which are positively connected with the donation propensity and donor retention (Agyemang et al., 2019). A favorable evaluation of financial efficiency enhances donor confidence in the organization, as it demonstrates that funds are being employed to maximize benefits for beneficiaries (Li et al., 2012). Moreover, donors look for transparency signals in financial reports that confirm that funds are directed to their intended purpose and are not wasted on administrative or secondary activities. However, donors with different socio-economic characteristics and experience show varying responses to disclosure of financial information. Donors with higher education levels and greater knowledge of humanitarian issues tend to exhibit increased sensitivity to the accuracy and reliability of financial data (Wu & Dai, 2025).

In connection with financial information, non-profit organizations can also increase repeat donations by emphasizing the tax-deductibility of contributions and providing the necessary documentation and proof for fiscal procedures. Both European and U.S. governments offer increasingly generous tax incentives for charitable givings, however, many donors remain unaware of these benefits or underestimate their value. As donations increase in frequency and amounts, tax deductions can significantly improve donation propensity, particularly among middle- and upper-income donors (Saeri et al., 2023).

Donor communication can also involve the request for feedback and opinions on fundraising campaigns and funded projects. Collecting and analyzing donor feedback has proven beneficial because it allows organizations to design more tailored and shared activities for donors in line with their mission (Clavijo, 2023). Furthermore, research (Pittarello & Kogut, 2022) shows that when donors are given the possibility to articulate their views, they become more engaged with the organization and are more likely to donate when asked.

Artificial Intelligence (AI) tools are increasingly being adopted by non-profit organizations, and their use is expected to expand in the coming years. One key application is machine learning, which helps predict how donors develop their relationship with the organization over time. Hesse (2025) has examined peer-donors, i.e., individuals who not only donate but also encourage others to contribute, mainly peers in their personal and professional network. Machine learning has demonstrated to be effective in determining the probability of donors to sponsor the organization to their peers, and it can also be applied to other instances, such as, the probability for repeat donations or membership enrollment.

In addition, AI Large Language Models (LLMs) are increasingly being employed in fundraising with individual donors. Sun and Si (2025) compare LLMs with human agents in fundraising to estimate which communication strategies are more effective in influencing donation intentions and trust in the organization. Their findings reveal that when LLMs

use highly abstract messaging, potential donors perceive the information as less trustworthy than when delivered by human agents. Conversely, more concrete messaging combined with anthropomorphic visual cues increases the level of trust and consequently the donation propensity compared to human agents.

LLMs are also employed to generate social media content and encourage donor engagement. Social media have become important touchpoints for both potential and existing donors, but require a constant and interactive presence that often exceeds the capacity and expertise of non-profit staff. LLMs can address this challenge and offer tailored content for different donor segments, ultimately increasing the donation probability (Cheng & Wang, 2025).

In conclusion, AI models may contribute to address the issue of distributive justice within non-profit organizations. Distributive justice refers to the ethical question of how resources, such as funds and services, are allocated among beneficiaries and stakeholders. AI models can be perceived as more objective and consequently enhance the sense of fairness and justice in donation distribution. Yang et al. (2024) demonstrate that AI models are viewed to deliver greater distribution justice compared with human decisions, hence, improving the relationship between donors and the organization.

Purpose of the paper. This research focuses exclusively on donations from individuals, excluding funds from governments, foundations, and corporations. Within individual donations, only small donors are considered, while large and legacy gifts are omitted. There is no general threshold for defining small donors, as it typically depends on the size and type of the organization. However, given the non-profit organization under investigation and its top-gift percentiles, small donors are defined those who give less than 5,000 euro per year (Kelley et al., 2024).

The research sample includes only repeat donors, that is, individuals that have previously made at least one donation of 50 euro per year or more to the non-profit, regardless of their formal membership in the organization. The study concentrates on direct communication to repeat donors. In general, direct communication can occur either via traditional mail or electronic channels, however, in this sample, traditional mail is excluded, and donors are contacted via email through the address that they provided when making their donation. General communication, such as social media posts and press releases, is not considered in this analysis. Similarly, other incentive mechanisms, such as thank-you gifts and matching offers, are omitted because, as mentioned before, they tend to have limited efficacy or can even be counterproductive for the non-profit's reputation and public image (Xiao & Yue, 2021).

The purpose of this study is to investigate a potentially innovative application of AI within the non-profit sector. For this purpose, a pilot AI Chatbot was specifically designed to interact with repeat donors at their own convenience and terms, and address any question they may have about the projects that they support, the organization's activities, and any other relevant details such as annual financial statements, staff and volunteer data, civic initiatives. Donors receive the Chatbot link via email. Unlike traditional methods, the Chatbot enables donors to customize interactions to their preferences, mitigating the aforementioned common gaps of understanding donors' information needs (Dethier et al., 2024) as well as issues related to communication frequency (Karlan & Wood, 2017).

The Chatbot is evaluated against a donor newsletter sent by email. The newsletter summarizes the actual individual and social impact of projects, their outcomes, and provides detailed and transparent financial information. The previous literature review confirms that these types of clear, concrete, and financially informative messages (Bodem-Schrötgens & Becker, 2020; Levontin et al., 2025; Saeri et al., 2023; Alkire et al., 2025; Agyemang et al., 2019; Li et al., 2012; Wu & Dai, 2025) are the most effective forms of donor direct communication. The comparison between the AI Chatbot and the newsletter is conducted by assessing the level of trust that donors develop toward each communication tool, as well as the frequency and the amount of donations generated.

Methodology. This study employs a between-subjects, cross-sectional survey design to compare donors' trust in two non-profit communication channels: an AI Chatbot and a newsletter. Participants are randomly assigned to one of the two conditions and evaluate only the communication channel to which they are exposed.

Trust is measured using identical constructs across conditions, enabling comparison between groups. The questionnaire also collects socio-demographic variables, which are included to control for individual differences, prior experience with the non-profit organization and the non-profit sector in general, and behavioral intention measures, in particular, willingness to re-donate to the same or different projects. Following the survey, actual donations made by participants are recorded and matched with the donation propensity reported in the questionnaire.

One non-profit organization, which chose to remain anonymous, agreed to cooperate in the experiment allowing a group of its donors to participate in the survey. The non-profit operates in the health sector in developing countries, and primarily recruits donors in the Italian market.

Participants are adult repeat donors recruited from the organization's permissioned email list. To be eligible, participants must be between 18 to 55 years of age. This upper age limit was established to maximize the probability of participant familiarity with digital communication tools, which was self-declared. As mentioned before, the sample is restricted to donors that contribute less than 5,000 euro per year, excluding major donor outliers.

Participants will be randomly assigned to one of two experimental conditions: the Chatbot Group (n = 200) or the Newsletter Group (n = 200). Random assignment ensures that any observed differences can be attributed to the communication medium rather than pre-existing donor characteristics and preferences. However, the socio-demographic characteristics of the sample will be monitored to ensure a balanced distribution across both conditions.

An a priori power analysis for an independent-samples t-test indicated that a total sample of N = 400 (n = 200 per group) provides sufficient power (1-\beta = .80) to detect a small-to-medium effect size (d \approx 0.28) at a significance level of \alpha = .05, two-tailed. This sample size also exceeds the recommended 5:1 or 10:1 participant-to-item ratio for factor-analytic validation of the measurement scales. N=400 represents approximately 9% (4,300) of the entire donor population for the non-profit. To account for potential data exclusions or incomplete responses, oversampling from the initial recruitment pool will be conducted.

The survey instrument is grounded in the Integrative Model of Organizational Trust (Mayer et al., 1995), a well-established framework that conceptualizes trust as a function of perceived trustworthiness. This model has been widely extended to digital contexts (Hoff & Bashir, 2015), in this case, it can be applied to examine trust in human–AI interactions.

Given that this study compares two distinct communication tools, in detail, an interactive conversational AI (Chatbot) and a static informational medium (Newsletter), the theoretical framework integrates constructs related both to the trustworthiness of the information source and the perceived characteristics of the communication medium, including its level of social presence. Accordingly, trust is conceptualized as a multidimensional construct including three core dimensions: perceived trustworthiness, trust in technology, and social presence. Perceived trustworthiness is operationalized using the Ability–Benevolence–Integrity (ABI) model (Mayer et al., 1995). This model assesses trust across organizational, technological, and artificial agents:

- Ability: refers to the perceived competence of the communication channel in providing accurate, relevant, and reliable information.
- Benevolence: looks at the extent to which donors believe that the organization, as represented through the Chatbot or newsletter, acts in their best interests.
- Integrity: reflects perceptions of honesty, transparency, and adherence to ethical principles in the information provided.

To account for the technological nature of the Chatbot relative to the passive structure of the newsletter, the framework incorporates constructs from the Trust in Automation (TiA) literature (Hoff & Bashir, 2015). These constructs express both cognitive and affective components of trust in technological systems, including:

- Predictability: refers to the consistency and reliability of the system's behavior.
- Transparency: is defined as the clarity with which information sources and system processes are communicated.
- Perceived privacy and security risk: is particularly relevant for interactive AI systems that may involve personal data exchange.

The framework includes social presence and anthropomorphism, which draws on the Computers Are Social Actors (CASA) paradigm (Reeves & Nass, 1996). These constructs assess whether human-like interaction cues associated with conversational AI influence donor trust, either positively by encouraging engagement or negatively by prompting skepticism, in comparison with the impersonal and static nature of newsletter-based communication.

In conclusion, propensity to donate is commonly conceptualized as a behavioral intention, reflecting an individual's motivational readiness to engage in donor behavior. In the non-profit literature, donation behavior can be modeled using intention-based frameworks derived from social psychology, particularly the Theory of Planned Behavior (TPB) (Ajzen, 1991). According to TPB, behavioral intentions are the most proximal determinants of actual behavior. Within the charitable giving context, intention to donate has been shown to be a strong and consistent predictor of realized donation behavior (Bekkers & Wiepking, 2011). The propensity of behavior after using the communication tools will be compared with the actual donations that the donors accomplished.

All items employ a 7-point Likert scale to allow sensitivity to moderate effects and be consistent with previous trust measurement methodologies in academic literature. For the AI chatbot, anthropomorphic cues are not shown in the baseline instrument to avoid confounding, but a short neutral screenshot or mock transcript can be included in an experimental extension if desired. Wording is minimal and non-technical to reduce comprehension variance.

The final survey will be administered online via a secure survey platform. Respondents receive a unique link after two weeks from receiving either the AI link or the newsletter. After screening and consent, participants complete the socio-demographics (education, age, gender, income range, donation history, interests in non-profit sector, general use of AI tools), followed by frequency of use for AI and typologies of questions, trust items for each channel, behavioral intention (donor intentions), experience measures (in particular, prior exposure to the organization's newsletter), and completion time flags will be used to identify careless responses. After three months from the survey, the actual donations will be associated with each donor and compared with the anticipated donor intentions.

Results. At the moment of writing, 90 questionnaires (45 Chatbot, 45 newsletter) were conducted and analyzed as part of the initial quantitative phase. This paragraph offers a summary of the preliminary findings before the completion and analysis of all 400 questionnaires.

A strong relationship is observed between donors' demographic characteristics and their attitudes toward AI Chatbot. Younger donors tend to trust AI tools more, while older donors are more skeptical, particularly regarding the variables integrity, perceived privacy, and security. Donors who are more familiar with the non-profit sector show lower perceived benevolence toward the organization when interacting with AI, probably because they are used to traditional newsletters rather than AI-based communication. Familiarity with AI itself is also relevant. Those who use AI frequently are more

open to an AI Chatbot and believe that it can provide detailed and transparent information, whereas donors who rarely use AI trust the Chatbot less and often question its ability to communicate effectively.

When interacting with the AI tool, donors mostly inquire about the progress of the projects they previously funded and about potential new projects to support. They also ask the AI for advice on which additional project to choose, especially when the tool presents multiple options and they want to know which one the AI considers most relevant. A notable behavioral difference emerges in the type of information donors seek. AI users rarely check financial data, while donors who rely on newsletters review financial information significantly more often. Donors using the AI tool seldom ask for sources, and the majority appears unaware of the risk of potential AI hallucinations. Nonetheless, this lack of checking does not seem to affect their level of trust in the non-profit organization.

Regarding donation behavior, there is no overall difference in donation propensity between AI users and newsletter recipients. However, among AI users, those with high AI usage tend to donate more frequently and in larger amounts, while those with low AI usage tend to donate less. Newsletter recipients, in contrast, display a more uniform donation pattern.

Finally, we observe a strong correspondence, around 85%, between donors' stated intention to donate and their actual donation behavior, with no notable differences between AI users and those who only receive newsletters.

Research limitations. The central limitation of this research is the unpredictability surrounding the future development of AI and the ways users will eventually engage with it. Given that the current AI systems are at the early stages of their technological maturation, their full capabilities remain unexplored, so that long-term outcomes and user behaviors are difficult to predict. Also, the still-evolving regulatory framework governing AI Chatbots means that clear rules have to be created. Hence, it remains uncertain whether stringent regulations will be introduced and, if so, how these interventions may influence users' overall trust in these systems.

Another important limitation concerns the sample. All participants in this study are Italian speakers and the non-profit organization involved operates exclusively in the Italian fundraising market. As a result, the findings cannot be transferred to other national cultural settings. National cultural norms influence how individuals relate to technology and how they interpret information, and they can also shape expectations regarding non-profit transparency and accountability. Moreover, this study focused on a single cause, while other relevant causes were excluded, where donor behavioral patterns and motivations can change completely across different non-profit sectors. Some non-profit organizations, particularly those with adversarial and controversial missions, may attract donor profiles with distinct attitudes and personality traits that were not included in this research.

In conclusion, the methodological limitations, which are typical of a between-subjects, cross-sectional survey design, apply to this research as well. The modest number of respondents in the preliminary quantitative analysis also restricts the generalizability of the research results.

Managerial implications. This study shows that the AI Chatbot is associated with higher levels of trust and can positively influence the donation propensity of certain donor segments. Therefore, non-profit fundraisers should examine adopting these Chatbots to strengthen their relationships with their supporters. However, they should carefully weigh the increased donation flows that Chatbots may generate with the costs of implementing and managing them. While expenses are certain and immediate, potential increases in donations are uncertain and projected in the long-term.

As AI becomes more widespread and commonly used by the general public, wider segments of donors will likely expect AI-based interactions. Hence, non-profit organizations should not only take into consideration current user demand, but also the anticipated future expectations. At the same time, because technology evolves rapidly and often unpredictably, today's platforms may change radically, and the costs of implementation may drop over time. Still, implementing AI now offers non-profits the possibility of positioning themselves as innovative and interactive in the donors' minds, while developing valuable expertise in AI communication touchpoints.

Fundraisers are advised to adopt a Chatbot that can also engage with potential first-time donors, as their queries can be similar and the associated costs can be allocated more efficiently. As the organization ventures into AI, it would be probably better to include first-time donors, although, academic research is yet to prove the Chatbot efficacy for this group.

Finally, non-profit organizations should ensure that their Chatbots are carefully trained by a team of experts to mitigate the risks of hallucinations and false and misleading responses that affect AI and can harm the organization's reputation and donor relationship. During the implementation phase, the Chatbot should be constantly tested and monitored to avoid persistent inaccuracies.

Originality of the paper. This study offers an innovative contribution to the non-profit and fundraising literature by being one of the first empirical analyses to investigate donor trust and donation behavior in response to an AI-based conversational tool against a traditional newsletter, within a real non-profit setting. Previous studies have explored the role of AI in donor communication, focusing mainly on comparison between AI and human interaction, social media content creation, machine-learning donor prediction, or distributive justice. No published work has assessed how repeat donors perceive and respond to an interactive AI Chatbot specifically designed to answer questions about ongoing projects, organizational transparency, and financial information. By concentrating on repeat small donors, this study

addresses an understudied group that is the financial cornerstone for many non-profits but whose information needs are often poorly understood.

The research also advances the literature by integrating the Integrative Model of Organizational Trust, Trust in Automation frameworks, and social presence theory to develop a multidimensional measurement of trust for non-profit communication tools. This theoretical integration is original in its application to donor–AI interactions, a context where perceptions of benevolence, integrity, and ability overlap with privacy risks and information reliability.

In addition, the comparison between the Chatbot and the newsletter examines not only self-reported trust and donation intentions but also actual donation behavior, which is a methodological improvement over previous research that relies exclusively on intentions. Behavioral data improves the external validity and managerial relevance of the findings.

Finally, this research introduces a innovative application of AI as a on-demand information tool, addressing persistent issues in donor communication such as diversity in information needs and tolerance for communication frequency. By granting donors autonomy in the interaction and examining its behavioral consequences, this study opens a new path for understanding how AI can reshape relational fundraising practices.

User Resistance to AI in Healthcare: A Systematic Review

NICOLAS MALTAURO, MICHELA C. MASON, ANDREA MORETTI

Abstract. *Artificial intelligence is becoming part of everyday healthcare, but many users are still reluctant to rely on it. Adoption depends not only on technical performance, but also on how key stakeholders, especially physicians and patients, respond to these systems. Existing studies have examined the issue from several disciplinary angles, including information systems, marketing, healthcare, and medical research, yet the evidence remains scattered and difficult to integrate. To address this gap, the paper systematically reviews 137 articles. Drawing on Innovation Resistance Theory and the sociotechnical perspective, it develops a framework that explains the main drivers of resistance, the conditions that can reduce it, and the ways it manifests before and after use. The review brings coherence to a fragmented body of knowledge and shows that resistance is not only a question of acceptance, but also one of trust, professional roles, workflow, and service design. It therefore offers a clearer basis for future research and practical guidance for managers introducing AI into everyday care settings.*
Keywords: *artificial intelligence; healthcare; user resistance; systematic literature review; healthcare management; AI*

Framing of the research. Global health systems face growing structural and economic pressure. Aging populations, the rising incidence of chronic disease, increasing demand for care, and persistent inequalities continue to strain capacity (Karaflou and Goulis, 2025; Rad, 2025). At the same time, many organizations operate with staffing shortages, limited resources, and fragmented information systems (Lal et al., 2021). These pressures affect not only costs and efficiency, but also the quality, accessibility, and continuity of care.

Artificial intelligence (AI) has emerged as one of the most visible responses to these challenges. Unlike more conventional information systems, AI can perform tasks that are partly cognitive in nature. It can learn from data, adapt its outputs over time, and, in some applications, operate with a degree of autonomy that changes how decisions are produced and evaluated. For this reason, AI is widely presented as a strategic tool for improving quality, reducing costs, and extending access to care (Chong et al., 2022). Yet its implementation remains difficult. A major obstacle is user resistance (Liang and Xue, 2022).

Although resistance to artificial intelligence in healthcare (AIH) is receiving growing attention, research is in its infancy and the knowledge base remains fragmented. Studies have emerged across information systems (Park et al., 2022), marketing (Yun et al., 2021), healthcare delivery (van Bussel et al., 2022), and medicine (Richardson et al., 2021), but these streams have rarely been integrated (see Table 1 for reference on the number of relevant articles by journal). Medical research often focuses on the attitudes and behavioral intentions of physicians and patients, offering limited examination of AI functionalities and their consequences on user resistance (Khanijahani et al., 2022). By contrast, information systems and business research provides richer accounts of resistance mechanisms, but often overlooks the clinical context in which these systems are introduced. This fragmentation creates a clear need for synthesis. A systematic review can connect findings that remain dispersed, identify the main drivers of resistance, clarify the conditions that reduce it, and distinguish between different forms of resistance across stakeholder groups and stages of adoption. It is also useful for management research. After all, reluctance toward AI is not only a behavioral response, but also a signal of deeper tensions in implementation, governance, accountability, and professional legitimacy. Understanding these tensions is essential if organizations are to introduce AI in ways that are both effective and trusted.

Purpose of the paper. This paper aims to develop an integrated understanding of resistance to artificial intelligence in healthcare and to clarify its implications for management research and practice.

Although resistance to AI in healthcare has attracted growing attention, the literature remains fragmented across information systems, marketing, healthcare, and medical research. As a result, existing studies provide useful but disconnected insights into why resistance emerges, how it can be reduced, and how it differs across users and stages of adoption. This gap is important for management because resistance affects not only acceptance, but also implementation, workflow integration, professional authority, accountability, and the design of AI-enabled services. To address this gap, the paper examines three questions. First, what factors generate resistance among healthcare providers and healthcare recipients? Second, what interventions reduce resistance and support more constructive human–AI relations in care settings? Third, how does resistance appear across stages of adoption and across different stakeholder groups?

Methodology. To identify and synthesize the literature, this study conducts a systematic review of 137 articles on resistance to artificial intelligence in healthcare. The review follows PRISMA guidelines (Page et al., 2021), which are widely used in information systems and management research (Lee et al., 2023), and combines database searching with forward and backward searches to strengthen rigor and coverage (Webster and Watson, 2002).

The search was conducted in the Web of Science Core Collection, including the Science Citation Index Expanded (SCIE) and the Social Sciences Citation Index (SSCI). The search strategy drew on keywords used in earlier reviews on related topics (Lee et al., 2023; Yang et al., 2024), which made it possible to capture studies from business, economics, marketing, management, information systems, medical informatics, psychology, computer science, and behavioral science.

The review covers studies published between 2014 and 2024, a period in which AI expanded rapidly and became more visible in healthcare research and practice (Yang et al., 2024). Three exclusion criteria were applied. First, purely technical studies were excluded when they focused on model development, optimization, or system performance without examining human attitudes or behaviors toward AI. Second, articles without full-text access, as well as commentaries, responses, perspectives, and book chapters, were excluded because they were not suitable for systematic analysis. Third, studies were excluded when the technology under study did not contain an explicit AI component. The final sample includes 137 studies.

To analyze this literature, the study adopts the input-process-output (IPO) model (Mathieu et al., 2008). Within this framework, the input dimension captures the antecedents of resistance among healthcare providers and healthcare recipients. These antecedents are classified through Innovation Resistance Theory, which distinguishes between adopter-related, situation-related, and innovation-related factors (Talke and Heidenreich, 2014). The process dimension focuses on the mechanisms that mitigate or reduce resistance. To organize these mechanisms, the study adopts a sociotechnical perspective, which views systems as combinations of technology, humans, and tasks (Goodhue and Thompson, 1995). Building on later work on hybrid intelligence, the study also treats human–AI collaboration as a distinct dimension (Hemmer et al., 2021). The output dimension captures the behavioral manifestations of resistance and distinguishes between pre-adoption reactions, which arise before direct interaction with AI, and post-adoption reactions, which appear after use. This analytical structure makes it possible to examine resistance to AI in healthcare consistently across a diverse body of studies. It also strengthens the management relevance of the review by showing not only why resistance emerges, but also how it can be addressed and how it shapes adoption over time.

Results. Resistance to artificial intelligence in healthcare is shaped by three broad sets of antecedents: adopter-specific, situation-specific, and innovation-specific factors (see Annex 1 for a synthetic mapping of these findings).

Among healthcare providers, adopter-specific antecedents include greater inertia, lower affinity with technology, lower self-efficacy, and stronger anxiety about technological change. Some studies also link resistance to age and professional experience (Pedro et al., 2023). Situation-specific antecedents arise when AI disrupts established routines, enters demanding hospital settings, or is introduced without sufficient organizational support (Zheng et al., 2021). The strongest sources of resistance, however, concern the technology itself. Providers react negatively when systems are opaque, difficult to integrate into workflows, or of uncertain usefulness. Concerns also increase when AI is associated with privacy risks, legal liability, threats to professional autonomy, or fears of replacement (Kotsis et al., 2023). These reactions are reinforced by psychological factors, especially low initial trust, limited prior experience, and attachment (Howe et al., 2024).

Among healthcare recipients, the pattern is similar in structure but different in content. Adopter-specific antecedents include low digital literacy, low self-efficacy, and high technological anxiety. Several studies also report effects for age, gender, and income (Fritsch et al., 2022). Situation-specific antecedents become stronger in high anxiety settings, in family monitoring and intimate care, where trust and human sensitivity are particularly important (Park et al., 2022; van Bussel et al., 2022). Again, the most prominent obstacles are innovation-specific. Recipients are more hesitant when diagnostic processes are opaque, interfaces are difficult to use, expected benefits are weak, or costs are high. Concerns also rise when privacy feels threatened, bias is feared, or the system is seen as reducing patient choice and control (Cadario et al., 2021; Zhang and Zhao, 2024). Psychological factors intensify these reactions when patients prefer human physicians, or see AI as impersonal and unable to recognize individual uniqueness (Longoni et al., 2019; Riedl et al., 2024).

The review also shows that resistance can be reduced, but only through interventions that address both the technology and the human system around it (see Annex 2 for a synthetic mapping of these findings). For healthcare providers, resistance declines when AI provides clear explanations, transparent limits, and supporting information that helps clinicians interpret outputs and understand where the system may fail (Reis et al., 2020; Diprose et al., 2020). It also falls when AI is integrated into workflows, framed as a supporting tool, and introduced through participatory design and protected learning time (Blanes-Selva et al., 2023). For healthcare recipients, the range of effective interventions is broader and more sensitive to design choices. Acceptance improves when AI uses accessible interfaces, calibrated anthropomorphic cues, and personalized communication. At the same time, overly technical explanations and excessive humanness can increase discomfort or privacy concerns (Shi et al., 2024). Trust also increases when AI shows strong performance, a credible track record, and a clear role in care (Howe et al., 2024). Most importantly, patient resistance declines when AI remains visibly embedded in human oversight (Esmaeilzadeh et al., 2021).
Finally, resistance varies across stages of adoption. Among providers, pre-adoption reactions appear mainly as opposition to implementation, concern that AI may weaken task performance, and reluctance to incorporate it into clinical judgment (Reis et al., 2020). After adoption, these reactions become more visible in practice. Clinicians may disregard AI recommendations, refuse to collaborate with AI assistants, express negative views, or simply use the systems less than expected (Jussupow et al., 2021). Among recipients, pre-adoption reactions are expressed mainly as a preference for human physicians, reluctance to use AI for diagnosis or monitoring, dislike of robotic assistance, low acceptance across care tasks, and lower willingness to pay for AI-based services (Longoni et al., 2019; van Bussel et al., 2022). After use, resistance appears as negative evaluations, lower continuance intention, disappointment, and non-compliance with AI-generated advice or recommendations (Riedl et al., 2024).

Research limitations. Despite its theoretical and practical contributions, this study is subject to several limitations that pave the way for future research. First, the scope of our data collection was restricted to WoS Core Collection, which may introduce a degree of selection bias. Relevant studies indexed exclusively in other databases or those that did not meet our inclusion criteria may have been omitted. Second, the field is still developing and does not yet rely on a stable vocabulary. As a result, some relevant studies may have been missed even with a broad search strategy. Third, to ensure the methodological rigor and reliability of our findings, this review prioritized peer-reviewed journal articles. We explicitly excluded conference proceedings and gray literature, including book chapters, working papers, and pre-prints. Although this strategy supports the quality of the relevant literature, the most recent, albeit unverified, emerging research may have been excluded.

Managerial implications. Healthcare managers should prioritize psychological support over technical deployment. Physician resistance is often rooted in perceived threats to professional autonomy rather than technical incompetence. A possible solution could be to position AI as a tool that handles routine analytical tasks, thus demonstrating that the technology supports, rather than replaces, the clinician's role. Furthermore, organizations must establish psychological safety. They should transition from punitive performance monitoring to supportive environments.

For AI developers and vendors, the "black box" nature of machine learning models remains an antecedent of resistance. Developers should focus on targeted explainability tailored to the specific stakeholder. Physicians require global interpretability (understanding the model's general logic) to validate clinical safety, whereas patients require local interpretability (understanding why a specific decision was made for them) to perceive fairness. Additionally, developers must exercise caution regarding anthropomorphism. While conversational agents can improve engagement, hyper-realistic avatars may exacerbate patient resistance due to feelings of eeriness. We suggest a design philosophy of "functional aesthetics" that delineates the AI agent as a tool rather than a synthetic human, thereby reducing cognitive dissonance in clinical settings.

A significant driver of physician resistance is the knowledge gap regarding AI capabilities. Educational institutions should update medical curricula to include AI literacy as a core competency. Simultaneously, policymakers must address the ambiguity concerning legal accountability that currently paralyzes adoption. It is imperative to establish clear liability frameworks that define the shared responsibility between the clinician, the healthcare organization, and the AI developer.

Originality of the paper. This paper contributes by updating and refining the emerging literature on resistance to AI in healthcare through an integrated dual-stakeholder perspective. Building on prior review work, it consolidates antecedents, interventions, and manifestations within a single framework. More specifically, it classifies antecedents through Innovation Resistance Theory, organizes mitigation mechanisms through the sociotechnical lens, and distinguishes manifestations across providers and recipients as well as pre-adoption and post-adoption stages. In doing so, it offers a more coherent basis for theory development and a more precise account of how resistance to healthcare AI differs from resistance to earlier forms of healthcare technology.

Track:
Entrepreneurship

Commencing Countdown, Engines On: Rethinking the Lifecycle of Entrepreneurial Ecosystems

ALBERTO ONETTI[1], ALESSIA PISONI[2], SERENA VALENTE[3], GIORGIO DI FIORE[4]

Abstract. *Entrepreneurial Ecosystems are increasingly recognized as key drivers of productive entrepreneurship and regional economic development. While the literature proposes several lifecycle models describing the emergence and evolution of ecosystems, these frameworks remain only partially supported by empirical evidence. The purpose of this study is to investigate how Entrepreneurial Ecosystems evolve across lifecycle stages over time. Drawing on a proprietary longitudinal dataset covering 80 national ecosystems between 2013 and 2024, we adopt an output-oriented perspective and measure ecosystem dynamics through scaleup creation, interpreted as an observable manifestation of productive entrepreneurship. To capture the dynamic nature of ecosystem evolution, we combine scaleup intensity with two additional indicators, namely growth velocity and acceleration, and identify lifecycle configurations using clustering analysis. We interpret the resulting phases through the metaphor of a rocket launch, and we label them Ignition, Liftoff, Orbit, Reentry and Docking, to underline the sequential dynamics of ecosystem development. Preliminary findings suggest that ecosystems do not follow strictly linear trajectories: phases of slowdown often represent temporary deceleration rather than structural decline. By conceptualizing ecosystem evolution as a dynamic and probabilistic process, this study contributes to the emerging literature on Entrepreneurial Ecosystem lifecycles and offers new insights for policymakers seeking to monitor and support ecosystem development over time.*
Keywords: *Entrepreneurial Ecosystems; Ecosystem Lifecycle; Startup; Scaleup*

Framing of the research. Entrepreneurship is a key driver of economic and social value, especially when entrepreneurial activity results in innovation. Innovation is heavily concentrated in specific global hubs that continue growing due to the presence of specialized networks of new ventures, technology, easier access to capital, and rich pools of talent. The Silicon Valley, for instance, is an example of a productive business ecosystem where the tradition of these networks has led to the pursuit of sustained entrepreneurship over time. Regions that have similar characteristics and innovation outputs (e.g., Singapore, New York, London) have become important "innovation hubs". They attract the attention of new ventures and multinational corporations and investments from venture capital funds and governments, leading to a self-reinforcing "virtuous cycle" that consolidates their leading position and attractiveness. Relatedly, a recent industry report highlights that 50% of the Fortune 500 Companies maintain a presence in Silicon Valley (Mind the Bridge, 2024). These geographical areas are concentrated, dynamic, and continue to grow, attracting the attention of policymakers and researchers interested in how to support, drive, and even replicate elsewhere these ecosystems. From a policy perspective, these ecosystems are critical because they allow governments to move beyond fragmented interventions and instead foster a systemic environment where innovation and growth can thrive (OECD, 2025). Relatedly, Entrepreneurial Ecosystems (EEs) are increasingly getting attention in research, practice and policy as national and local governments promote their countries or cities to constitute active ecosystems while managers of incubators and accelerators consider themselves as managers of ecosystems (Audretsch et al., 2019). Broadly, EEs are defined as multifaced, territorially embedded structures that enable the creation and growth of new ventures thanks to the interaction of institutional, financial, social and knowledge components (Audretsch et al., 2019). They became so important that now they constitute a consolidated research field with its own research agenda (Wurth et al., 2022).

The literature on EEs builds on research traditions related to clusters, innovation systems and urban economics. While these traditions differ in their assumptions about how the economy functions, they converge on the idea that firm-level competitive advantage is influenced by factors lying outside organizational boundaries but embedded in the regional context (Spigel & Harrison, 2018; Wurth et al., 2022). What sets EEs apart from other territorial approaches is their focus on productive entrepreneurship, which is supported and realized by the interdependencies between the above-mentioned components. EEs are in fact conceptualized both as entities that emerge and evolve in specific local contexts and as a conceptual lens that researchers can use to understand and explain how local, regional, or national economies enable or constrain entrepreneurial activity (Wurth et al., 2022).

Scholars interested in the processes of ecosystem emergence and evolution study how entrepreneurial activity is supported by the surrounding ecosystem. Autio et al. (2018), for example, propose a structural model where the combination of digital affordances (decoupling, disintermediation, and generativity) and spatial affordances creates a unique environment that facilitates the discovery and pursuit of entrepreneurial opportunities. They argue that, in contrast with traditional clusters, EEs support the cultivation of knowledge for business model innovation and provide the structure

to support new ventures through the stages of stand-up, startup, and scale-up. Similar frameworks have been proposed in the attempt to map the temporal evolution of EEs, which vary in terms of stages and drivers of change. Mack & Mayer (2016) propose a four-stage model (birth, growth, sustainment and decline) identifying each stage based on the balance between firm entries and exits and shifts in the orientation of regional policy and finance. Cantner et al. (2021) introduce a five-stage model including birth, growth, maturity, decline, and re-emergence, which describes the system's oscillation between a startup-focused "entrepreneurial ecosystem" and a corporate-focused "business ecosystem". Other notable taxonomies include Kapturkiewicz (2022) three phases (emergent, developmental, and growth) anchored in institutional work and "flagship" successes like unicorn or big exits, and Spigel & Harrison (2018) process-based view that classifies systems as nascent, strengthening, or resilient (or, alternatively, weakened) based on the flow and recycling of entrepreneurial resources. Finally, frameworks inspired by ecology and complex adaptive systems, such as the one proposed by Auerswald & Dani (2017), suggest adaptive cycles characterized by the capacity to reorganize and reconfigure regional assets rather than following a linear path. This latter perspective reflects the recent calls in EE research concerning the use of Complex Systems (CAS) theory lens to the study of EEs. Roundy et al. (2018) explain that an EE is "a self-organized, adaptive, and geographically bounded community of complex agents operating at multiple, aggregated levels, whose non-linear interactions result in the patterns of activities through which new ventures form and dissolve over time" (p. 5). EEs thus follow discontinuous trajectories, are subject to path dependence and are characterized by non-linearity (Wurth et al., 2022; Brown et al., 2023; Ceci et al., 2026).

Based on this, we ask: How do EEs evolve across lifecycle stages over time?

Purpose of the paper. Our research question addresses the critical debate regarding the evolutionary dynamics of EEs. EE vitality has become a central issue for regional economic development as it allows researchers and policymakers to compare the performance of EEs across countries (OECD, 2025). However, the current scientific understanding we have about EEs emergence, growth and decline is still fragmented (Cantner et al., 2021). Our research question reflects the need to test, empirically, whether the lifecycle trajectories of EEs predicted by existing theory follow linear trajectories.

To guide our research inquiry, we introduce the metaphor of the rocket launch. We chose to use this metaphor for its explicatory impact, as we believe it responds to the conceptual resonance criterion that metaphors should have when used for theory formulation and testing (Biscaro et al., 2025; Cornelissen and Kafouros, 2008). To illustrate the lifecycle of EEs, we adopt the metaphor of a rocket launch, which captures the sequential nature of the ecosystem evolution. The first phase, Ignition, refers to the moment when the rocket's engines are activated while the vehicle remains on the launch pad. In our framework, this stage corresponds to the emergence of an EE, when initial actors, resources, and relationships begin to form but the system has not yet generated significant momentum. The second phase, Liftoff, occurs when thrust exceeds the rocket's weight and the vehicle leaves the launch pad, beginning its ascent through the atmosphere. This stage represents an ecosystem that is consolidating and gaining momentum. Much like in a rocket launch, this is a particularly critical phase as reaching orbit directly from the launch pad would violate the laws of physics, and similarly ecosystems require a gradual process of accumulation before reaching maturity. The third phase, Orbit, is reached when the rocket attains orbital velocity and enters a stable orbit around Earth. We associate this stage with the first moment of stability in the ecosystem, when its output is sustained productive entrepreneurship. The last two phases are alternatives. Reentry describes the moment when a spacecraft slows down and reenters the Earth's atmosphere, which we associate with a slowdown in ecosystem output, reflected in declining levels of productive entrepreneurship. Alternatively, the phase may be interpreted as Docking, the moment when a spacecraft successfully attaches to a space station, representing the peak of productive entrepreneurship, when the ecosystem reaches a high level of coordination and integration. We illustrate our metaphorical framework in Figure 1.

Figure 1. Evolutionary Framework of the EE Lifecycle

Methodology.

Data and Sample. The study leverages privileged access to the Mind the Bridge (MTB)[5] proprietary database, which provides data on the annual creation of scaleups across countries. The dataset includes both the number of newly identified scaleups and the cumulative number of scaleups operating in each country and year. These data are combined with macroeconomic indicators retrieved from the World Bank World Development Indicators, including GDP, GDP per capita, and population. The MTB database focuses on scaleups operating in technology and digital sectors, which are typically characterized by strong scaling dynamics and high growth potential (Piaskowska et al., 2021; Reuber et al., 2021; Tippmann et al., 2023). Our analysis therefore captures the evolution of technology-oriented entrepreneurial ecosystems, where the scaling of innovative ventures represents a central ecosystem outcome. The dataset covers the annual creation of scaleups across national EEs between 2013 and 2024. The initial dataset includes observations for a large set of countries. To ensure meaningful comparison across ecosystems, countries with excessive zero activity were excluded. Specifically, countries with more than eight years of zero scaleup creation during the observation period were removed from the sample, as these cases provide insufficient variation to identify ecosystem dynamics. In addition, micro-states with populations below 500,000 inhabitants were excluded to avoid distortions arising from very small denominators when computing per-capita indicators. The final balanced panel consists of 80 countries, observed annually from 2013 to 2024, resulting in 960 country-year observations. The list of countries included in the analysis is reported in Table 1.

Productive entrepreneurship and the role of scaleups. EEs are commonly defined as sets of interdependent actors and factors that collectively enable productive entrepreneurship within a territory (Stam and van de Ven, 2021). Much of the empirical literature on EEs has focused on measuring the presence of ecosystem components, such as access to finance, institutions, talent, or support organizations. Even if these approaches provide insights into the structure and characteristics of ecosystems, they do not necessarily capture whether these structures actually translate into observable entrepreneurial outcomes. In this study, we adopt an output-oriented perspective and focus on scaleup[6] creation as an observable manifestation of productive entrepreneurship. Scaleups represent ventures that have successfully moved beyond the early startup stage and entered a phase of sustained growth, making them an important outcome of ecosystem dynamics. The importance of scaling processes has been underlined in several conceptual models of EEs. For instance, Autio et al. (2018) describe ecosystem development as enabling ventures to progress through phases of stand-up, startup, and scaleup, where the latter stage reflects the successful scaling of validated business models. In this perspective, the emergence of scaleups can be interpreted as an observable signal that ecosystem conditions enable entrepreneurial ventures to grow and expand.

Variable construction. To enable comparison across countries of different sizes, scaleup activity is normalized by population. Scaleup intensity is defined as the number of newly created scaleups per million inhabitants. This indicator captures the capacity of the EE to generate high-growth ventures. Yet, EEs are dynamic systems whose evolution cannot be fully captured by static measures alone. Studies drawing on complex adaptive systems perspectives point out that ecosystem trajectories are characterized by non-linear dynamics, path dependence, and temporal fluctuations (Brown et al., 2023; Roundy et al., 2018). To capture these dynamics, we complement scaleup intensity with two additional indicators. First, we compute the growth rate of scaleup creation (growth velocity), which captures the direction and speed of change in ecosystem output. Because scaleup formation can be episodic and subject to short-term volatility, growth rates are smoothed using a centred three-year moving average. Second, we compute acceleration, defined as the year-on-year change in the smoothed growth rate. This measure captures whether the momentum of scaleup formation is strengthening or weakening over time. Scaleup intensity, growth velocity, and acceleration provide a dynamic representation of ecosystem output, capturing both the level of productive entrepreneurial activity and the direction of its evolution. In particular, acceleration allows us to detect situations in which ecosystem growth is slowing down even if scaleup activity remains relatively high. Given the lack of systematic data on venture exits at the ecosystem level, ecosystem decline is therefore operationalized as a slowdown in the dynamic of scaleup creation.

Results. We identify five distinct configurations of ecosystem dynamics based on scaleup intensity, growth velocity, and acceleration. Table 2 reports the average values of these indicators for each phase and shows that the clusters are empirically well differentiated. The Ignition phase describes ecosystems characterized by very low scaleup intensity (0.244) but strong positive growth velocity (0.989) and high acceleration (0.871). This configuration corresponds to ecosystems where scaleup activity is still limited but the dynamics of entrepreneurial output growth are strengthening rapidly. The Liftoff phase combines higher scaleup intensity (0.892) with the highest growth velocity observed across all

[5] *Mind the Bridge is a global organization that provides innovation advisory services for corporates and startups. In 2014, Mind the Bridge was selected by the European Commission to lead the Startup Europe Partnership (SEP). Established in January 2014 at the World Economic Forum in Davos, SEP is a Startup Europe initiative dedicated to support the growth and sustainability of European startups able to compete and raise funds internationally. Based on its proprietary database, Mind the Bridge research unit regularly produces reports with the goal of sharing insights and data about startup/scaleup ecosystems in order to give relevant parties a macro overview of the current landscape (https://mindthebridge.com/research/).*

[6] *Although the definition of scaleups remains debated in the literature, it is acknowledged the role they play in introducing technologies to the market (Coutu, 2014). In line with Onetti (2014), Startup Europe Partnership (2015) and Autio (2016), we operationalize scaleups as ventures that have attracted at least USD 1 million in venture capital funding.*

phases (1.061) and the second highest acceleration (0.050). This configuration reflects ecosystems experiencing rapid upward expansion following the initial ignition stage. The Orbit phase corresponds to ecosystems with moderate scaleup intensity (2.163), positive but more moderate growth velocity (0.258), and limited acceleration (0.040). In the rocket metaphor, this phase captures ecosystems that have reached a relatively stable configuration characterized by sustained scaleup activity. The Reentry phase, by contrast, reflects ecosystems experiencing a slowdown in their growth dynamics. It is characterized by moderate scaleup intensity (1.534), near-zero growth velocity (-0.005), and strongly negative acceleration (-0.467), indicating a significant loss of momentum in scaleup creation. Finally, the Docking phase captures a small group of ecosystems with exceptionally high scaleup intensity (22.799), combined with moderate growth velocity (0.216) and slightly negative acceleration (-0.108).

Figure 2 presents the cross-sectional distribution of ecosystem phases in 2024. The figure confirms the predominance of intermediate and slowing configurations. Orbit accounts for 45% of ecosystems, while Reentry represents 46.25%. Only two ecosystems appear in the Docking phase (Luxembourg and Singapore), while Ignition is observed only in Bahrain and Slovakia, and Liftoff only in Morocco, Mexico, and Uganda.

Figure 3 reports the distribution of lifecycle phases across years between 2013 and 2024. The results reveal substantial variation in the composition of phases over time. The Orbit phase remains the dominant configuration throughout most of the observation period, consistently representing around half of all ecosystems. Yet, its prevalence declines sharply in the later years of the sample, particularly in 2023, when it falls to 27.5% of observations before partially recovering in 2024. At the same time, the Reentry phase becomes increasingly prominent in the later years of the dataset. In 2023, Reentry accounted for more than 60% of ecosystems, and it remains highly prevalent in 2024 (46.25%). This pattern suggests that many ecosystems experienced a slowdown in scaleup creation dynamics during the most recent years of the observation period. Early-stage phases show greater volatility. Ignition increases sharply in 2020 (22.5%), indicating a temporary rise in ecosystems characterized by rapid changes in scaleup activity. Liftoff also fluctuates over time, peaking in 2021 (18.85%) before declining again in the most recent years. Finally, the Docking phase remains rare throughout the sample, although its share temporarily increases in 2021 and 2022 before declining again thereafter.

Table 1. Cluster characteristics by ecosystem phase

	Mean	SD	N
Ignition			
Scaleup intensity (per million inhabitants)	.244	.467	64
Growth velocity (3-year moving average)	.989	.424	64

Figure 3. Distribution of EE lifecycle phases over time

Source: Authors' own elaboration

To examine whether ecosystems follow predictable trajectories over time, Table 3 reports the transition matrix between lifecycle phases from year t-1 to year t. The results reveal a combination of persistence and movement across phases. Persistence is strongest for ecosystems in Orbit and Docking. Ecosystems already in Orbit remain in the same phase in 63.12% of cases, while ecosystems in Docking remain there in 71.43% of observations. These results suggest that both intermediate-stable and highly developed ecosystem configurations tend to be relatively persistent over time. By contrast, early-stage phases exhibit substantially greater instability. Ecosystems in Ignition, most frequently transition to Liftoff (48.39%), but also move to Orbit (27.42%) or directly to Reentry (24.19%). Similarly, ecosystems in Liftoff show high transition rates, with 44.14% remaining in the same phase and 43.24% moving to Reentry. These patterns indicate that rapid growth does not necessarily translate into sustained consolidation. The transition matrix also shows that Reentry does not represent a terminal phase. Although 24.17% of ecosystems remain in Reentry, a majority (62.09%) move back to Orbit in the following year. This suggests that slowdown in scaleup creation is often temporary and not irreversible. Thus, the transition patterns do not support a strictly deterministic lifecycle sequence: ecosystems show a mixture of persistence, reversibility, and occasional discontinuous shifts, consistent with the view of EEs as adaptive and evolving systems.

These dynamic patterns are further illustrated in Figure 4, which presents the temporal trajectories of ecosystem phases for a set of selected countries. The trajectories highlight the heterogeneity of ecosystem dynamics. Highly developed ecosystems such as Israel, Singapore, and Luxembourg exhibit persistent Docking configurations, reflecting extremely high scaleup intensity. Mature ecosystems such as the US, the United Kingdom, and Germany remain predominantly in the Orbit phase, with occasional temporary slowdowns. By contrast, emerging ecosystems such as Mexico and Morocco follow more volatile trajectories, moving across early-stage phases before reaching more stable configurations.

Table 2. Year-to-year transition matrix of EE phases (in %)

	Phase (t)					
Phase (t-1)	Ignition	Liftoff	Orbit	Reentry	Docking	Total

Source: Authors' own elaboration

Research limitations. The study has several limitations. First, research is still ongoing and the analysis represents an initial attempt to identify large-scale dynamic patterns in the evolution of EEs using scaleups as a proxy for productive entrepreneurship. Yet, entrepreneurial ecosystems are complex adaptive systems shaped by multiple structural and institutional factors - including capital, infrastructures, entrepreneurial culture, networks, etc. (Stam and van de Ven, 2021) - which are not directly captured by the indicators so far used in the study. Third, the clustering approach identifies empirical patterns in ecosystem dynamics but does not establish causal mechanisms driving transitions between phases. As the research is still in progress, next steps include extending the analysis in several ways. First, we plan to examine the determinants of phase transitions by estimating panel models linking movements between lifecycle stages to macroeconomic conditions. Second, we will conduct robustness analyses of the clustering procedure, testing alternative specifications and clustering algorithms to assess the stability of the identified lifecycle configurations. Third, future research will investigate whether ecosystem lifecycle phases are associated with broader economic outcomes, such as innovation performance and the intensity of venture capital activity.

Managerial implications. Our framework reveals how entrepreneurial ecosystems transition across different phases of their lifecycle. Measuring ecosystem evolution through specific outputs such as the generation of scaleups can help ecosystem actors monitor the system's momentum over time, identifying phases of acceleration or slowdown. Our preliminary results also suggest that the phases initially framed as "reentry", may in fact represent periods of moderate slowdown rather than genuine ecosystem decline. This finding highlights that temporary reductions in productive entrepreneurship do not necessarily imply structural deterioration of the ecosystem. These insights also connect to important policy implications. In particular, they suggest the value of considering not only the level of ecosystem performance, but also the velocity and direction of its trajectory. Positioning ecosystems within lifecycle stages may therefore help policymakers design more targeted interventions and identify early signals of potential slowdown. Moreover, policymakers could focus not only on fostering ecosystem growth but also on facilitating transitions between lifecycle stages, which appear to represent critical moments in the evolutionary process of entrepreneurial ecosystems.

Originality of the paper. The study contributes to the EE literature in three main ways. First, we adopt an output-oriented perspective on EEs by focusing on scaleup creation as an observable manifestation of productive entrepreneurship. While much of the existing literature measures the presence of ecosystem components, this study instead examines the entrepreneurial outcomes generated by the ecosystem. Second, the paper introduces a dynamic empirical framework to analyze ecosystem evolution over time. By combining scaleup intensity, growth velocity, and acceleration, the study captures not only the level of ecosystem activity but also the direction and momentum of its evolution. This approach allows us to move beyond static comparisons across regions, and instead identify distinct configurations of ecosystem dynamics. Third, we provide empirical evidence on the lifecycle dynamics of EEs. While several conceptual models propose that ecosystems evolve through different stages, empirical tests of these lifecycle trajectories remain limited. Leveraging the MTB proprietary longitudinal database covering 80 countries over more than a decade, the study identifies lifecycle configurations and examines transitions between phases over time. The results show that ecosystem evolution does not follow a linear path. Instead, ecosystems exhibit a combination of persistence, reversibility, and discontinuous transitions across stages, consistent with perspectives that conceptualize EEs as complex adaptive systems.

Cultural Embeddedness and Entrepreneurial Risk Perception in Peripheral Regions

FORSTER AMPADU[1], BICE DELLA PIANA[2]

Abstract. *Entrepreneurship is vital for economic growth, especially in emerging economies where small and informal businesses are key sources of income and jobs. Previous studies have largely focused on structural barriers such as limited access to finance, poor infrastructure, and regulatory issues, but have paid less attention to how socio-cultural factors influence entrepreneurial decisions, particularly in peripheral areas. This research examines how cultural embeddedness affects risk perception among rural entrepreneurs in Ghana. Using embeddedness theory and entrepreneurship perspectives that consider context, the study examines how kinship ties, community norms, and informal institutions shape entrepreneurs' views and risk management.*

The research employs an emic, qualitative approach to understand entrepreneurs' experiences within their socio-cultural setting. A multiple-case study was conducted, with data gathered from semi-structured interviews of ten entrepreneurs across various sectors in Ghana's Gomoa East District. Thematic analysis revealed common patterns in how entrepreneurs perceive and handle risk in socially embedded environments.

Initial results show that social bonds and community structures significantly shape risk perception. Social networks serve as risk buffers by offering informal financial help, labour, and market information, which lessens financial uncertainty. Conversely, strong community ties increase reputational risk from potential business failures. Family duties and kinship obligations also influence risk-taking, often leading to more cautious choices. Additionally, informal institutions and local authorities help legitimise businesses and mediate economic exchanges.

This study advances entrepreneurship research by emphasising the social construction of risk perception in peripheral contexts. It also provides useful insights for policymakers designing entrepreneurship support that aligns with culturally embedded ecosystems in developing economies.

Keywords: E*mbeddedness; Risk perception; Entrepreneurship; Peripheral regions; Ghana; Social networks*

Framing of the research. Entrepreneurship is vital for economic growth, innovation and job creation worldwide (Stam and Van de Ven, 2021). In developing nations, where formal jobs are scarce and economies rely heavily on small and medium enterprises (SMEs), entrepreneurship often serves as a key means for creating livelihoods and reducing poverty (Acs, Desai, and Hessels, 2008; Naudé, 2010). Recent research continues to highlight its role in promoting inclusive growth and resilience in emerging markets (Acs et al., 2014). In sub-Saharan Africa, many entrepreneurial efforts occur in the informal sector (Musara and Nieuwenhuizen, 2020; Danquah, Schotte, and Sen, 2019; Sutter, Bruton, and Chen, 2019).

In Ghana, entrepreneurship is a key pillar of the national economy. The country consistently ranks high in early-stage entrepreneurial activity according to the Global Entrepreneurship Monitor (Singer, Amorós, and Moska, 2015). More recent assessments also recognise Ghana as one of Africa's most entrepreneurial economies, with a significant portion of economic activity driven by SMEs and microenterprises (Quartey et al., 2017; Agyapong and Attram, 2019). However, many of these entrepreneurial efforts take place within small, informal businesses embedded in local community networks and informal institutions (Abor and Quartey, 2010; Amankwah-Amoah, Boso, and Antwi-Agyei, 2018).

Despite high entrepreneurial activity, many Ghanaian enterprises remain small and face barriers such as limited capital, poor infrastructure, institutional issues, and market volatility (Abor and Biekpe, 2006; Mohammed and Bunyaminu, 2021, 2023). Research shows financial limits, complex regulations, skill gaps, and macroeconomic instability hinder SME growth. Access to credit remains a major obstacle, as SMEs often cannot meet collateral requirements or navigate financial systems, thereby restricting expansion and innovation (Agyapong, Mmieh, and Mordi, 2018).

Although the literature has extensively examined structural factors, there has been less focus on how social and cultural environments influence entrepreneurial decision-making, especially regarding risk perceptions. Risk perception is widely acknowledged as a crucial factor in entrepreneurial behaviour (Martínez, Crespo and Fernández-Laviada, 2017; Yin and Wu, 2023). Entrepreneurs frequently operate in uncertain conditions, and their decisions to pursue opportunities often hinge on how they interpret and manage potential risks (Shane and Venkataraman, 2000; Rauch and Frese, 2007). Recent studies increasingly emphasise the importance of perceived risks and barriers in shaping entrepreneurial intentions and sustainability, particularly in emerging economies with high institutional uncertainty (Hoogendoorn, Zwan, and Thurik, 2019).

[1] 3CLab-Cross Cultural Competence Learning & Education, Department of Management & Innovation Systems (DISA-MIS), University of Salerno
[2] 3CLab-Cross Cultural Competence Learning & Education, Department of Management & Innovation Systems (DISA-MIS), University of Salerno

Historically, entrepreneurship research viewed risk perception primarily as an individual cognitive process shaped by personality traits, experience, and knowledge (Baron, 2004). More recent scholarship, however, indicates that risk perception is also socially constructed, influenced by cultural, institutional, and relational contexts (Gimenez-Jimenez et al.,2022; Welter, 2011; Welter and Gartner, 2016). Cultural norms, social expectations, and institutional environments all impact how individuals interpret uncertainty and assess entrepreneurial opportunities (Gimenez-Jimenez et al., 2022).

The embeddedness theory offers a key framework for understanding how social ties affect economic actions (Granovetter, 1985). It suggests that economic behaviour is rooted in social networks that influence access to resources, information, and opportunities (Granovetter, 1985). In entrepreneurial settings, this view indicates that entrepreneurs' risk perceptions are shaped not just by market factors but also by social expectations, community norms, and institutional contexts (Dammicco and Diaz-Zagarra, 2025). Recent studies on entrepreneurial networks show that relational and structural embeddedness greatly impact entrepreneurial actions and firm success by shaping access to information, advice, and support from family, friends, and professional contacts (Korsgaard et al., 2022).

This is particularly important in peripheral regions, typically situated outside major economic hubs and often lacking extensive infrastructure, industrial development, and formal institutional support (Rodríguez-Pose and Hardy, 2015; Fritsch and Wyrwich, 2017; De Rosa, Bartoli, and Pia, 2019). Despite these challenges, peripheral areas frequently demonstrate strong social cohesion, dense community networks, and locally embedded governance, all of which can significantly impact economic and entrepreneurial initiatives.

In rural Ghana, entrepreneurship typically occurs within social frameworks influenced by kinship, traditional leadership, and informal economies (Sutter, Bruton and Chen, 2019; Dzisi, 2008). These cultural factors shape entrepreneurs' perceptions and management of risks associated with the initiation and growth of businesses. For example, community support networks can alleviate financial risks through informal loans, shared labour, or advice. However, strong community ties may also heighten reputational risks if ventures fail, as social consequences in close-knit communities can be significant.

Despite the significance of these socio-cultural factors, research on how cultural embeddedness affects entrepreneurial risk perception in peripheral regions of developing economies remains limited. Most studies concentrate on urban entrepreneurial ecosystems or formal institutions, leaving rural and peripheral entrepreneurial environments less understood. Nonetheless, recent research on entrepreneurship in emerging economies highlights the need to understand how local social structures, community relationships, and institutional contexts influence entrepreneurial cognition and behaviour.

Purpose of the paper. This study seeks to address the identified gap by examining how cultural embeddedness shapes entrepreneurial risk perception in Ghana's peripheral regions. By integrating perspectives from embeddedness theory, institutional theory, and entrepreneurship research, the study aims to provide new insights into the social and cultural mechanisms that shape risk perceptions in rural entrepreneurship. The study thus seeks to answer the question "How do kinship networks, community norms, and traditional institutions both mitigate and amplify entrepreneurial risk perception in rural Ghana?"

To answer this question, the study pursues five primary objectives:

Specifically, the study aims to:

i. To identify the socio-cultural factors shaping entrepreneurial risk perception in peripheral regions
ii. To examine the role of social networks in shaping entrepreneurial risk perception
iii. To explore how kinship obligations and family responsibilities influence entrepreneurial risk-taking behaviour
iv. To analyse the influence of informal institutions on entrepreneurial risk perception
v. To assess how culturally embedded support systems influence entrepreneurial resilience

By addressing these objectives, the study seeks to contribute to the literature on contextualised entrepreneurship and provide insights into the socio-cultural foundations of entrepreneurial ecosystems in developing economies.

Methodology. This study employs an emic qualitative approach (Galperin et al., 2022) to understand how social embeddedness influences entrepreneurial risk perception in Ghana's peripheral regions. The emic perspective captures entrepreneurs' lived experiences within their socio-cultural environment, crucial for analysing behaviour shaped by local norms, community ties, and informal institutions. Originating from Pike's distinction between emic and etic perspectives (Pike, 1967), this method emphasises culturally specific interpretations from local actors. In entrepreneurship, this distinction is vital because behaviour depends on diverse social and cultural contexts.

Researchers in Entrepreneurship Studies emphasise the need for contextualised approaches to study entrepreneurial processes in diverse institutional settings (Welter, 2011; Welter et al., 2017; Autio et al., 2018). Peripheral regions feature complex socio-economic environments where entrepreneurial activity is rooted in community networks, kinship ties, and informal governance. An emic approach effectively explores how entrepreneurs in these areas interpret uncertainty and assess risks. By focusing on entrepreneurs' perspectives, the study shows how social relationships influence decision-making. Context-aware methods are recommended for studying complex social phenomena in entrepreneurship (Halkias et al., 2022).

Case Selection: The study uses a multiple-case study design to explore complex social processes in real-world settings (Yin, 2018). Case studies are common in entrepreneurship research because they enable in-depth exploration while accounting for context (Eisenhardt, 1989; Gehman et al., 2018). Following Eisenhardt's (1989) advice, purposive sampling was used to identify cases relevant to the research. Participants were chosen for their active roles in entrepreneurship in Ghana's peripheral regions and their engagement with local communities, where social ties impact business. Ten local entrepreneurs from Gomoa East District in Ghana were purposively selected based on accessibility and relevance.

Including firms from diverse sectors enhances the study's analytical richness and enables comparisons across entrepreneurial contexts while still focusing on common patterns of socially embedded entrepreneurial behaviour. A summary of the cases used for the research is presented in Table 1.

Table 1: Profile of cases

Case	Line of business	Number of employees	Number of employees
P1	Photography	None	Male
P2	Clothing designing	One	Female
P3	Food vending	None (works with her kids)	Female
P4	Carpentry	Two	Male
P5	Farming	None (works with family)	Male
P6	Metal fabrication	Three	Male
P7	Chemist	None	Female
P8	Poultry	Five	Female
P9	Clothing designing and tailoring	One	Male
P10	Car accessories replacement	None (works with his son)	Male

Data Sources: To develop a comprehensive understanding of socially embedded entrepreneurial risk perception, the study draws on multiple data sources. A multiple-case study strategy enables the identification of both cross-case patterns and context-specific variations, thereby strengthening theory development (Chetty et al., 2014). Primary data were collected through semi-structured interviews, a widely used method in qualitative entrepreneurship research that enables participants to share detailed insights into their experiences and decision-making processes (Kvale and Brinkmann, 2009).

Ten key entrepreneurs participated, providing firsthand knowledge of the risks associated with their activities. Interviews, conducted virtually over three months, were in three stages to enable reflection and depth. The first stage involved 45 semi-structured interviews on uncertainty, decision-making, and the influence of social networks on risk. During the second phase, preliminary insights were shared for validation to ensure credibility. Currently, a final follow-up allows participants to comment on emerging findings and add context.

This iterative data collection process allowed the researchers to refine emerging themes throughout the study and improve the analytical robustness of the research (Locke, Feldman, and Golden-Biddle, 2020). All interviews were recorded with participants' consent and subsequently transcribed for analysis**.**

Data Analysis: Interview transcripts were systematically coded to identify recurring patterns and themes (Braun and Clarke, 2006). The analysis focused on identifying themes related to financial risk perception, reputational risk, social obligations and family responsibilities, informal institutional influences, and community-based support systems. Thematic analysis enabled the researchers to examine how entrepreneurs interpret and negotiate different forms of risk within their socio-cultural environments.

Preliminary Results.

The analysis shows that entrepreneurial risk perception in Ghana's peripheral regions is heavily influenced by social structures. Rather than being purely a financial or market concern, risk is viewed through the lens of social ties, community expectations, and informal institutions. Five key themes emerged: social networks as risk buffers; reputational risk and social visibility; kinship obligations; informal institutions and traditional authorities; and collective resilience. These themes highlight the complex nature of risk perception in peripheral entrepreneurial ecosystems.

Social Networks as Risk-Buffering Mechanisms

A key discovery is how social networks help lessen the perceived financial risks of entrepreneurship. Entrepreneurs often point out that support from family, community ties, and local networks acts as a safety net, fostering business experimentation. Participants mentioned that informal financial methods, such as family loans or community savings groups, play a crucial role in reducing uncertainty during the initial phases of business. These networks frequently replace formal financial institutions, which can be hard to access or viewed as complex in peripheral regions.

One entrepreneur explained:

> "When you start a business here, you are not completely alone. Your brothers, cousins, and friends can help you if things become difficult. That support reduces the fear of starting." (P1, Male, 2026)

Participant 4, who runs a carpentry business, reiterated this by stating that:

> "Even when money is not enough, people you know can give you goods on credit because they trust you." (P4, Male, 2026).

These findings align with the theory of Embeddedness, introduced by Mark Granovetter, which suggests that economic actions are embedded within networks of social relationships that shape access to resources and opportunities (Granovetter, 1985; Stam, 2015). In peripheral regions, where formal financial institutions may be limited, these social networks serve as informal entrepreneurial ecosystems, enabling individuals to pursue business opportunities despite financial constraints.

Reputational Risk and Social Visibility in Close-Knit Communities

While social networks reduce financial risk, they also increase reputational risk associated with entrepreneurial failure. In tightly knit communities, business activities are highly visible, and entrepreneurs often operate within social environments where reputation plays a significant role in determining social status and trust.

Several participants noted that the potential for reputational damage influences their willingness to take risks or pursue innovative ventures.

One entrepreneur who operates a vegetable and animal husbandry farm explained that:

> "In the village, everyone knows your business. If you fail, people will talk about it, and that can affect how they see you." (P5, Male, 2026)

Another participant who operates a metal fabrication shop remarked:

> "You must be careful before starting something new because if it fails, the community may say you made a bad decision." (P6, Male, 2026)

These views emphasise the social aspects of entrepreneurial risk. Failure is seen not just as a financial setback but also as a risk to one's social reputation and standing within the community. Research in entrepreneurship increasingly acknowledges the role of social context in how risk is perceived. Findings indicate that individuals within tight social networks may face greater reputational pressures that affect their entrepreneurial choices (Aldrich and Zimmer, 1986; Welter, 2011).

In peripheral communities where social ties are particularly strong, reputational considerations may therefore act as both a constraint and a guiding mechanism for entrepreneurial behaviour.

Kinship Obligations and Risk Moderation

Another key finding from the data concerns how kinship obligations affect entrepreneurs' perceptions of risk. In numerous peripheral Ghanaian communities, entrepreneurs are often expected to provide financial support to their extended family members. These duties influence their business choices, leading them to favour stability and steady income over risky ventures.

An entrepreneur who operates the only chemist shop in her village explained that:

> "I have many people depending on me. If I take a big risk and the business fails, it will affect the whole family." (P7, Female, 2026)

Participant 3 highlighted this sentiment by reiterating that:

> "Sometimes you want to expand, but you must think about your responsibilities at home first." (P3, Female, 2026)

These findings imply that social responsibilities within kinship systems often temper entrepreneurial risk-taking. Researchers have extensively acknowledged how family structures influence entrepreneurial actions. Studies show that family obligations can affect resource distribution and strategic choices in small enterprises (Steier, 2007). In developing economies, extended family systems frequently serve as informal welfare networks, offering social security in environments with limited formal social protection. Although they provide support, these systems can also restrict entrepreneurial risk-taking by promoting more cautious decision-making.

Informal Institutions and Traditional Authority as Risk Regulators

The findings also emphasise how informal institutions and traditional authority influence entrepreneurial risk perception. In many Ghanaian peripheral regions, chiefs and elders are key figures in overseeing economic activities, settling disputes, and endorsing new ventures. Entrepreneurs frequently seek endorsement or backing from local leaders when starting businesses or exploring new markets.

One participant explained:

> "I started sewing school uniforms for kids in my village and realised the local leaders noticed that I was charging very little to have uniforms sewn for the kids in the town. I realised after a while, almost every parent was bringing their business to me, not knowing the elders had spoken to the schools in the town about my pricing. So, trust me, if the chief supports your business, people will trust you more, and they will be willing to buy from you." (P9, Male, 2026)

Another entrepreneur noted:

> "There is always going to be disagreements in business, but when there is a dispute with customers or suppliers, community elders can help resolve it." (P2, Female, 2026)

These findings show how traditional governance systems act as informal regulatory mechanisms that lower uncertainty and support economic transactions. Institutional theory, especially Douglass North's work, highlights that

economic behaviour is influenced not just by formal rules but also by informal norms and governance structures (North, 1990). When formal institutions are weak or difficult to access, informal institutions often serve as crucial mechanisms for managing economic interactions.

Traditional authorities can reduce perceived institutional risks associated with entrepreneurship by establishing legitimacy, facilitating conflict resolution, and building community trust.

Collective Resilience and Community-Based Coping Mechanisms

The final finding concerns how collective resilience influences entrepreneurs' responses to risk and uncertainty. In peripheral regions, entrepreneurs frequently depend on community-based coping strategies during economic hardships. These strategies can involve cooperative labour arrangements, informal financial aid, shared market information, and collaborative problem-solving.

Such practices enable entrepreneurs to adapt to uncertain economic environments and maintain business continuity. Participant 10 explained:

> "If someone in the community faces difficulties, others will help. That is how we survive." (P10, Male, 2026)

An entrepreneur operating a poultry farm echoed this by explaining that:

> "We share information about suppliers and markets so that everyone can improve their business." (P8, Female, 2026)

These findings underscore the significance of collective resilience in peripheral entrepreneurial ecosystems. Research indicates that collaboration and knowledge sharing within local networks can boost resilience and innovation among small businesses (Stam, 2015). Likewise, studies on informal economies reveal that community-based cooperation often is essential for helping entrepreneurs manage uncertain economic conditions (Williams and Nadin, 2010).

In peripheral regions, these culturally embedded practices contribute to the sustainability of entrepreneurial activities despite structural challenges such as limited infrastructure and financial constraints (Stam, 2015; Stam and Van de Ven, 2021).

The study indicates that in Ghana's peripheral regions, entrepreneurs' perceptions of risk are shaped by a complex interplay of social ties, cultural standards, and institutional influences. Social networks reduce financial uncertainty by providing informal support, while concerns about reputation and family duties can influence risk-taking behaviours. Additionally, informal institutions and traditional authorities impact decision-making by overseeing economic exchanges and granting legitimacy. These factors demonstrate that risk perception isn't solely an individual matter but is rooted in the social and cultural settings in which entrepreneurs operate.

Research limitations. The research is limited in scope, as we used only businesses in the Gomoa East District, which is in the southern part of Ghana; therefore, generalisation may be questioned, as the culture and life in peripheral areas of southern Ghana may differ from those of Northern Ghana and other countries. The result of this research will thus serve as a foundation for future research, starting with a comparison with peripheral entrepreneurs in the Northern part of Ghana, to help explore similarities and differences in how cultural embeddedness impacts risk perceptions amongst entrepreneurs from the two blocs.

Managerial implications. This study offers vital insights into strengthening entrepreneurial ecosystems in Ghana's peripheral regions, highlighting that risk perception is deeply embedded in social relationships and informal institutions. Therefore, effective policies should go beyond Western-centric approaches that focus on formal regulatory reforms and instead recognise the socio-cultural context of local economic activities (Welter, 2011). Since informal norms influence how rural entrepreneurs assess risk and mobilise resources (North, 1990), interventions should support, not override, existing community structures.

Social capital is vital for resilience, as entrepreneurs rely on family and community networks to overcome challenges and access resources (Granovetter, 1985). Support organisations should leverage these networks via trade groups and peer mentorship aligned with local trust. Policies must suit peripheral markets, where SMEs often lack formal credit (Abor and Biekpe, 2006; Abor and Quartey, 2010). Incorporating informal systems, such as rotating savings, and hybrid models that connect microfinance with community groups can enhance stability and flexibility (Beck and Demirgüç-Kunt, 2006).

Involving traditional leaders, such as chiefs and elders, is crucial, as they serve as informal regulators, provide social legitimacy, and mediate disputes. Their involvement in designing incubation or infrastructure projects can boost community support. Management should consider the "dual effects" of social embeddedness: kinship ties support entrepreneurs but may also reinforce conservative, socially driven business practices, risking reputational damage. Improving managerial skills and financial literacy helps entrepreneurs balance social responsibilities and business growth (Agyapong and Attram, 2019).

Originality of the paper. This research advances entrepreneurship by exploring how cultural embeddedness in Ghana's peripheral regions affects entrepreneurial risk perception. While previous studies have examined individual traits and cognitive biases (Simon, Houghton, and Aquino, 2000; Baron, 2004), less attention has been paid to the socio-cultural contexts that shape responses to uncertainty. Granovetter's (1985) concept of embeddedness shows that risk perception is socially constructed through networks, norms, and informal institutions, not just personal cognition. The study adds to

the literature by focusing on underrepresented peripheral environments, particularly in rural sub-Saharan Africa, and reveals how norms, kinship, and community influence perceptions of financial, social, and reputational risks.

It enhances understanding of entrepreneurial risk by showing how social embeddedness has dual effects: strong networks can lower financial risks through support and resources, but may increase reputational risks if failures threaten social standing. This adds complexity beyond traditional views that see social capital mainly as a facilitator of entrepreneurship (Wigren-Kristoferson, et al., 2022). The research also suggests policy insights for better supporting culturally embedded entrepreneurial ecosystems in developing countries. Linking cultural embeddedness to risk perception offers a new framework for understanding entrepreneurial behaviour in peripheral regions.

Cultural heritage management in peripheral areas: the challenge of resource degradation

ROBERTA BOCCONCELLI[1], FRANCESCO MUTIGNANI[2], ALESSANDRO PAGANO[3]

Abstract. *This paper investigates resource development processes in contexts of cultural heritage (CH) degradation, with a particular focus on peripheral areas. Cultural heritage has increasingly become a strategic asset within the cultural and creative industries, contributing to economic development. At the same time, CH is characterized by significant vulnerabilities. While existing literature has extensively addressed CH protection and valorisation, limited attention has been paid to the dynamic processes through which CH evolves as a resource, especially in situations of degradation. To address this gap, the paper explores how resources are developed and combined in contexts where cultural heritage is deteriorating. The study focuses on the case of Castelnuovo, an abandoned 11th-century fortified hamlet located between the Marche and Emilia-Romagna regions in Italy. The analysis adopts the Resource Interaction Approach (RIA), which conceptualizes resources as products, process facilities, organisational units, and business relationships. Findings reveal a cumulative dynamic of resource deficiencies affecting all resource types—physical deterioration of the heritage asset, ineffective legal instruments, missing key actors and fragile or dormant relationships—resulting in a self-reinforcing cycle of decline. The study highlights the importance of analysing CH as a dynamic resource bundle in complex and fragile contexts.*
Keywords: *Cultural Heritage; Resource Degradation; Entrepreneurship; Peripheral Areas*

Framing of the research. Cultural heritage (CH) represents a pillar of the cultural and creative industry, which has been recognised as an engine of economic development (Huggins & Thompson, 2015). The main phenomena supporting this increasing role and impact of CH are the shift from manufacturing to service-led economic development (Bifulco & Russo Spena, 2017), the emergence of culture-led strategies promoting cultural tourism (Folgado-Fernández & Hernández-Rojas, 2025), urban regeneration, and the improving confidence and civic pride in local communities (Pendlebury & Porfyriou, 2017). In this evolving setting, CH is perceived as a «precious resource for the community, rather than a financial burden on the local economy» (Cirillo, 2017: 149)

According to the Faro Convention, CH is defined as "a group of resources inherited from the past which people identify, independently of ownership, as a reflection and expression of their constantly evolving values, beliefs, knowledge and traditions. It includes all aspects of the environment resulting from the interaction between people and places through time" (Faro Convention, art.2, letter a). CH has a few distinctive features. It is a resource closely embedded in a specific location (UNESCO, 2013). Moreover, it is a fragile resource: natural or climate factors could affect the aesthetics and the robustness of tangible remains (Barriga Delgado et al., 2023), and, also, political turmoil and armed conflict could substantially harm CH in an unexpected manner (Schipper, 2022). It might have been left abandoned for a long time by private or public ownership, thus leading to a degradation over time (Meneghin et al., 2023; Barelles-Vicente et al., 2025). Restoration efforts might have been neglected or could have been limited due to fragmentation of activities or lack of adequate funding and technical capabilities. Lack of resources could affect the ability of institutions and local communities to start restoration and renovation projects (Barelles-Vicente et al., 2025). On the contrary, CH could be put in danger when it is excessively exploited as a resource, as in the case of overtourism, having a negative impact on the sustainability of CH initiatives (Folgado-Fernández & Hernández-Rojas, 2025).

CH management (CHM) has thus become a key theme both in the institutional and academic contexts. With regard to the former, over the years a key role has been played by UNESCO, in the light of its mission to protect and valorise CH in all its forms (UNESCO, 2013), which have changed over time, including various dimensions, as tangible, intangible (Vecco, 2010) and digital heritage (Lian & Xie, 2024). Also, the academic debate on CH has grown over the years and has involved a wide array of disciplines, ranging from humanities to economics and business and to the technical and digital ones (Duval et al., 2019). In terms of CHM activities, two main aspects have been discussed in more depth, in line with UNESCO's priorities: the protection of CH, with the goal of maintaining the features and attributes, and thus its value over time, also using advanced technologies (Colace et al., 2025); the valorisation of CH, in terms of its ability in generating cultural and economic value through specific projects and initiatives having direct and indirect effects on the local context (Cerquetti, 2017; Barelles-Vicente et al., 2025). A key aspect is the value dimension related to the use of CH, perceived as a resource or a potential resource. CH might be characterized by different approaches in terms of resource management, such as restoration, reuse, revitalization, integration with new structures (Dalla Torre et al., 2020; Barelles-Vicente et al., 2025). In these studies it is widely recognized that the policy-planning and the management dimensions are often strongly linked and interdependent, in the light of many "public" dimensions of CH and of the

[1] Associate Professor in Management – University of Urbino, roberta.bocconcelli@uniurb.it
[2] Post-Doctoral Research Fellow – University of Pavia, francesco.mutignani@unipv.it
[3] Associate Professor in Management – University of Urbino, alessandro.pagano@uniurb.it

complexity of CHM initiatives, requiring capabilities, institutional support (Imperiale et al., 2025) and also "shared meaning" among different stakeholders, as argued by Barelles-Vicente (et al., 2025).

Thus far, CHM has been analysed in the literature with reference to different theoretical approaches. A recognized, even though fragmented, stream of research is concerned with the institutional and business context, placing emphasis on analysis of clustering processes and local communities' evolution, including those emerging in peripheral areas (Malisiova &Kostopoulou, 2024). CH is a key component of tangible reality in terms of space and time (Lazzeretti, 2024). Within this perspective meta-organizations could build a "strategic set", where local actors - with different nature/logic, resources, organization - are increasingly involved (Cicellin et al., 2017). Another consolidated area of research is linked to the service ecosystem approach, as it is applied to the CH sector (Holleland et al., 2017). The main focus is on the provision of cultural services, in the light of the protection/valorisation strategies, already discussed above, highlighting the interplay of institutions, technologies and actors, leading to specific socio-material practices (Russo Spena et al., 2017). However, existing conceptual frameworks do not discuss and provide analytical conceptualization of resource development in CHM, which could help in a better understanding of the transition from "ruin to resource", quoting the study by Barelles-Vicente (et al., 2025).

Notwithstanding the growing academic attention towards CHM in terms of protection/conservation and valorisation, it could be argued that the "resource" dimension has been largely neglected in its dynamic trajectories related to resource change and resource combinations processes. Various studies within the service ecosystem approach (Bifulco & Russo-Spena, 2017) highlight the role of resources in CHM and in the networked context where the main actors operate. However, with some insightful exceptions (Bareless-Vicente et al., 2025), existing research does not explore in more depth CH as a resource itself, its evolution - degradation, and restoration - and its combination processes with other contextual resources, including those detained by business firms and cultural organizations. This gap is particularly relevant in the analysis of "peripheral settings", where CH degradation processes are more likely and contextual resources are scarce or are based on fragile networks (Meneghin et al., 2023).

Purpose of the paper. This paper aims to undertake explorative research over resource development processes in the context of CH degradation. Therefore, it addresses this research question: how are resources developed and combined in the context of CH degradation in peripheral areas?

To pursue this research objective, an illustrative case study - Castelnuovo hamlet in the Marche Region and the unsuccessful attempts to renovate e valorise this historical site - is discussed according to the Resource Interaction Approach (RIA; Baraldi et al., 2012), which proposes a taxonomy of resources - product, process facilities, organisational units and business relationships (Baraldi et al., 2012). The RIA emphasizes resource interaction processes, which could be distributed over multiple firms, organisations and business networks (Landqvist & Lind, 2019), as shown with regard to inter-organisational projects (Silvestri et al., 2022), where actors might pursue different goals while using or combining shared resources (Lind, 2015) and could engage in conflictual interaction (Vaaland & Håkansson, 2003). A notable example is represented by public-private initiatives (Mattson & Anderson, 2019; Carloni, 2022), whose complexity is caused by the different logics behind the behaviour of partnering actors and by the specific nature of resources, which might show place-related features (Håkansson et al., 2006; Mutignani, 2025), as they are embedded in the local socio-cultural context. Resource-related processes could also be influenced by the existence of specific regulatory frameworks and contractual norms, which might rule over the access and use of specific resources (Mouzas & Ford, 2012), and by complex contexts requiring renewal, such as fragmented business networks (Ingemansson Havenvid et al., 2016) and peripheral areas (Mutignani, 2025). Recent conceptual developments concern the handling of resource deficiencies in terms of scarcity, quality and availability, thus highlighting the "change dimension" in resources (Tunisini et al., 2023).

The expected contribution of this research is twofold. Under an empirical perspective, this paper aims to provide a more fine-grained analysis of resource development and evolution in CH management, to address the gap highlighted above. In this vein, this research and its future development could provide insightful managerial implications for setting up appropriate organisational and networking mechanisms in complex CH contexts, where there is lack of resources - financial, technical, organisational - and difficulties in establishing, cultivating and restoring local relationships and networks, which often represent a weak "heritage" linked to the difficult evolution of CH. Under a conceptual perspective, CH is a context where the analysis of resource evolution - also in terms of degradation, decay (Karadag & Poppo, 2023) - in its networked and contextual settings can be examined more in depth, leading to new conceptual insights, widening the relevance of RIA as an analytical framework for complex business and organisational settings.

Methodology. This paper presents a preliminary analysis of a case-study in the CH sector: the castle of Castelnuovo, a small 11th-century fortified rural hamlet located on a ridge on the border between the Marche and Emilia Romagna regions. The research adopts an exploratory case study design (Yin, 2018), suited to the complex, multi-actor, and longitudinal nature of the phenomenon under investigation. The exploratory orientation reflects the preliminary and theory-building nature of the analysis: at this stage the paper focuses on a single illustrative case, but in the development of the research we aim at adding further exemplary cases to better answer the RQ also with respect to the resource development and combination processes, allowing for a richer understanding of how resources are developed and combined across different CH settings.

The case has been purposefully selected within the CH sector on the basis of three main criteria. First, the nature of the resources involved: the case combines tangible architectural heritage, fragile institutional relationships, and scarce

financial and organisational resources, making it a suitable setting for analysing the dynamic interplay of resource types within the RIA framework. Second, the long and well-documented process of resource degradation: spanning over two decades, the case offers a rich and traceable trajectory of resource change and decline, allowing for a retrospective analysis of the mechanisms driving CH degradation. Third, its typicality as a peripheral case: Castelnuovo exemplifies conditions commonly found in inner and marginal areas of Italy, where depopulation, limited financial capacity of local administrations, and the absence of strong private actors create a context of structural vulnerability for CH valorisation efforts. In this sense, it can be considered a "typical case" (Seawright & Gerring, 2008) of CH management in peripheral areas, likely to share structural features with analogous situations across the Italian territory and comparable European contexts.

Data collection was conducted through a combination of primary and secondary sources, following a multi-source approach consistent with case study methodology (Eisenhardt, 1989; Yin, 2018). Primary data were gathered through two semi-structured in-depth interviews, each lasting approximately one hour: the former Mayor of the Municipality of Auditore, who followed the case in its final phase, and an administrative lawyer, consulted due to his deep knowledge of public-private partnerships and his own engagement with the community of Auditore. Primary sources also include the complete documentation accessible relating to the case: municipal resolutions (delibere), minutes of council and administrative meetings (verbali), and urban planning documents (including the Detailed Plan approved in 2006). These allow for a direct reconstruction of the decisions taken and their official motivations. Secondary data consist of press releases, local and regional press coverage, books (Allegretti & Lombardi, 1995) and previous academic works (Mutignani, 2021; Traversari, 2007), which enabled triangulation of the primary accounts and reconstruction of phases of the process for which direct documentation was limited.

The analysis was conducted retrospectively, drawing on both interview transcripts and documentary sources to reconstruct the longitudinal trajectory of the case. The RIA framework and the 4Rs taxonomy - product, process facilities, organisational units, and business relationships (Baraldi et al., 2012) provided the conceptual lens for interpreting the data. The analytical process involved an iterative movement between the empirical material and the theoretical framework, consistent with an abductive research logic (Dubois & Gadde, 2002), aimed at both applying existing concepts to a new domain and generating new insights on resource degradation processes in CH settings. Given the exploratory and preliminary nature of this research, the findings presented in this paper should be interpreted as the basis for further theoretical development and empirical investigation, to be enriched through the inclusion of additional cases in the next stages of the research.

Results. Castelnuovo is a small 11th-century fortified rural hamlet located on a ridge on the border between the Marche and Emilia Romagna regions. Following the total emigration caused by the transformation of the Italian economy from agricultural to industrial after the Second World War, the hamlet is now completely abandoned and in ruins. In the attempt to preserve the structural heritage of the hamlet and its castle, in the year 2000, the former municipal administration signed a partnership with a private company - eborgo Srl - to restore and transform the village, establishing a purpose-driven urban transformation joint venture company (Società di Trasformazione Urbana - STU) named "Castelnuovo S.p.A." with the plan to be completed by 2010. However, despite two extensions granted until 2014, the new company never fulfilled its agreed obligations by carrying out the planned urbanisation and restoration works. When the municipal administration requested the company's liquidation, the private actor involved in the partnership attempted to appeal through legal ways, but suffered a decisive defeat in the administrative court. In addition to the dissolution of the joint venture, this proceeding led to the definitive abandonment of the restoration project, and the castle of Castelnuovo, after 25 years of abandonment, now lies in complete ruin.

According to RIA, the Castelnuovo hamlet could be qualified as the "product", conceived as a "bundle of resources" (Huemer & Wang, 2021), with some specific features: it is a combination of various tangible and intangible components. It is not a finished product, rather an intermediate product suffering from deterioration over time in its basic physical attributes and lacking complementary resources necessary to generate value according to the specific uses.

In the Castelnuovo hamlet case-study, there are many different organisational units involved, in the various phases: the Municipality, specifically the Mayors in charge and the Technical Office; the company eborgo Srl; the joint company Castelnuovo S.p.A., the Superintendency of Cultural Heritage, the Marche Region, and the hamlet inhabitants/community. There are also shadow "organisational units", as the supposed foreign investors. All these organisational units have a different nature - public, business, civil society (Imperiale et al., 2024), including, as in the case of Castelnuovo S.p.A, a hybrid nature (public/private).

In terms of process facilities, we might consider the procedural and legal frameworks at the basis of Castelnuovo S.p.A as an intangible process facility, in other words as a legal tool, laying the foundation for launching innovative projects aiming to start restoration and then valorisation of the Castelnuovo hamlet, in other words "leveraging" resources for product development (Mouzas & Ford, 2012). However, these legal "facilities" have not been activated and their effects have been left on paper.

The various organisational units are linked through various business relationships. However, the networked context shows some specific features. First, most of the relationships have mainly a formal dimension, are characterized by limited interaction processes and in some cases they are actually "sleeping" relationships, whose reactivation is difficult and complex. Some business relationships are "shadowed", as organisational units do not have a clear knowledge and

understanding of their existence and features. This "relational" uncertainty over time shapes expectations and slows the overall process of restoration and valorisation, making alignment among parties very difficult (Lind, 2015).

Lastly, the evolution of the Castelnuovo case is shaped by the lack of financial resources, both on the public and private sides. From this perspective, the failure of the STU represents not only an administrative and financial failure, but also a missed opportunity to maintain the link between the local community and a heritage that, with the expropriations, has been definitively detached from private ownership.

In terms of handling of resources, this case is characterised by the simultaneous negative impact of resource scarcity, quality and availability (Tunisini et al., 2023). Many of the resources in play show a progressive "change dimension" in one or more of the three resource elements, unfolding over a long timeframe. In this scenario appears clear that resource interaction itself has been largely neglected by the actors involved. This lack of awareness had relevant consequences, as it prevented actors from recognising the cumulative nature of the resource deficiencies and from considering alternative resource combinations or network reconfigurations in a timely manner.

In relation to the product - the Castelnuovo hamlet as a bundle of tangible and intangible resources - the most visible dimension is that of quality. The physical conditions of the buildings, the fortified walls, the church, and the surrounding land have progressively deteriorated over more than two decades of abandonment. What was already a fragile resource at the outset has undergone a continuous process of quality degradation to the point where the restoration effort required today far exceeds what was originally planned. This quality decline is not merely physical: the symbolic and community value attached to the hamlet has also eroded as the gap between the resource and any plausible use has widened over time. Crucially, a more careful analysis of the product's resource interfaces at an early stage could have prompted a selective approach - identifying which physical elements were still recoverable and worth combining with other resources - rather than treating the hamlet as an undifferentiated whole. A selection of key physical resources might have opened more realistic paths of resource recombination.

Concerning facilities - primarily the legal and regulatory instruments underpinning the STU - the deficiencies concern both quality and availability. In terms of quality, the STU instrument proved to be a rigid and poorly designed framework: it lacked feasibility requirements, left risk distribution undefined, and provided no effective enforcement mechanisms. Its structural rigidity made it unable to advance the project, and no attempt was made to compensate for these shortcomings through alternative procedural arrangements. In terms of availability, the instruments activated during the project - i.e., the Detailed Plan, the expropriation procedures, the administrative acts - became progressively unavailable as resources: the Detailed Plan lapsed after ten years without works being carried out, and any future restoration would require entirely new planning instruments, further delaying any recovery of the resource base.

In relation to organisational units, the deficiencies are primarily those of scarcity and availability. Scarcity is evident in the lack of managerial, technical, and financial competencies across all actors involved: the municipality lacked the capacity to monitor and enforce obligations effectively; eborgo S.r.l. lacked financial solidity and operational capability; and no competent third-party investor was ever identified. Availability is equally problematic: several organisational units that should have been active participants - the Superintendency of Cultural Heritage, the Marche Region, potential investors - were either absent, belatedly involved, or present only as "shadow" actors whose engagement never materialised. The neglect of resource interaction meant that the possible contribution of these actors to the resource base was never systematically explored, and no attempt was made to reconfigure the organisational network to compensate for the deficiencies that were accumulating.

Concerning relationships, all three deficiencies are simultaneously at play. Scarcity is visible in the thinness of the relational fabric, with no alternative pathways for resource access. Quality degraded progressively as trust eroded, obligations went unmet, and the relationship between the municipality and eborgo shifted from a collaborative partnership to an adversarial legal confrontation. Availability is perhaps the most structurally significant deficiency: many of the relationships that should have been activated - with investors, with the Superintendency, with the regional administration - were either never formed, formed too late, or remained dormant and difficult to reactivate. Moreover, the relationship with the local community has been definitively "broken", especially due to the expropriation. In Tunisini's (et al., 2023) terms, these are not short-term, single deficiencies but rather structural resource deficiencies, having an impact over the medium-to-long term and requiring a radical reconfiguration of the network that never occurred.

All this depicts a scenario of compounding resource degradation and fragile networks in the context of resource interaction over the years. What makes the Castelnuovo case analytically distinctive is the simultaneity and cumulative nature of the three deficiencies across almost all four resource types, in a self-reinforcing dynamic of decline.

Research limitations. This research is in-progress and is subject to an important limitation: it is based on a single case study. Although Castelnuovo was purposefully selected as a typical instance of CH management failure in peripheral areas - likely sharing structural features with analogous situations across Italy and comparable European contexts - the findings remain inherently illustrative and exploratory. Single-case research is well-suited to theory-building, but does not allow for systematic comparison across contexts, actors, or resource configurations. The mechanisms identified here - compounding deficiencies, dormant relationships, absence of resource interface analysis - may characterize differently other CH settings.

Managerial implications. The Castelnuovo case has also relevant implications for CH management: treating heritage sites as undifferentiated wholes - rather than as complex bundles of resources with different natures, conditions, and

trajectories - prevents actors from identifying what is still recoverable, which combinations remain viable, and where intervention is most urgent. Looking at resources in terms of their scarcity, quality, and availability is therefore not merely an analytical refinement, but a necessary precondition for any credible restoration or valorisation effort in complex CH settings.

Originality of the paper. The original contribution of this research is twofold. From an empirical perspective, this paper provides a contribution to the analysis of CHM and resource development in peripheral areas. Notably, the Castelnuovo case-study provides key insights over public-private interaction for new entrepreneurial initiatives and resource development in connection with CH. From a conceptual perspective, CH has proven a revealing domain for examining resource evolution - specifically in terms of degradation along the dimensions of scarcity, quality and availability - in networked settings, thus providing new insights into the growing stream of research on resources in business firms and in entrepreneurial settings.

Narrating Venture Failure: Configurations of entrepreneurial failure narratives across cultural contexts

LUCIA BARRA[1], MICHELE COSTAGLIOLA DI FIORE[2], ADELE PARMENTOLA[3], ROBERTA PALOMBA[4]

Abstract. *When entrepreneurs experience venture failure, they are often expected to publicly account for what went wrong and explain the causes of the outcome. These explanations are rarely neutral descriptions of events. They are narrative constructions through which founders attribute responsibility, interpret adverse outcomes, and attempt to preserve their legitimacy as entrepreneurial actors. In entrepreneurial contexts where reputation and credibility are critical resources, how failure is narrated may shape how founders are evaluated by investors, collaborators, and other stakeholders. Moreover, because expectations regarding credibility and leadership vary across cultural contexts, the ways in which entrepreneurs publicly narrate failure may differ accordingly. Drawing on qualitative content analysis of 24 post-mortem statements published by startup founders on online platforms, this study examines how entrepreneurs from different cultural contexts narrate venture failure and identifies recurring narrative configurations through which founders attribute responsibility and reconstruct legitimacy after failure. The analysis focuses on two analytical dimensions: responsibility attribution (internal vs external), which captures how entrepreneurs explain the causes of venture failure, and legitimacy reconstruction (individual vs collective or systemic), which reflects how founders attempt to reaffirm credibility and professional identity after failure. The findings identify four narrative configurations through which entrepreneurs account for venture failure: Learning-from-Failure, Collective Learning, Analytical Justification, and Visionary Persistence narratives. These configurations represent distinct ways of framing failure and managing its reputational implications across different entrepreneurial contexts. By examining how these narrative patterns appear across cultural contexts, the study highlights the role of culture in shaping how entrepreneurs publicly interpret and communicate failure. Overall, the paper contributes to research on entrepreneurial failure and impression management by developing a typology of failure narratives and illustrating how founders use narrative practices to negotiate responsibility, legitimacy, and identity after venture failure.*

Keywords*: Entrepreneurial failure; Failure narratives; Impression Management; Narrative configurations; Cross-cultural contexts.*

Framing of the research. Entrepreneurial failure represents a critical moment in the entrepreneurial process, not only because it marks the end of a venture, but also because it generates significant identity, reputational, and legitimacy challenges for founders (Czakon et al., 2024; Klimas et al., 2021). Prior research shows that venture failure can destabilize the self-conceptions entrepreneurs construct around their role as venture creators, calling into question their competence, credibility, and future prospects in the entrepreneurial context (Shepherd, 2003; Shepherd & Haynie, 2011;Costa et al., 2023). Because entrepreneurial identities are often deeply intertwined with the ventures themselves, the venture collapse may also undermine founders' social standing and professional legitimacy, exposing them to negative evaluations and reputational stigma (Cardon et al., 2011; Simmons et al., 2014; Byrne & Shepherd, 2015). As a result, entrepreneurial failure is not only an economic outcome but also a socially consequential event that requires interpretation and explanation. When outcomes deviate from expectations of competence, leadership, and venture creation, entrepreneurs may face pressure to explain what happened and justify their role in the outcome. Classical sociological theory suggests that, in such circumstances, individuals produce accounts, defined as discursive explanations that attribute causes to events and frame responsibility in ways that protect valued aspects of the self (Scott & Lyman, 1968). In entrepreneurial settings, these accounts typically take the form of narratives through which founders interpret the causes of venture collapse and position themselves vis-à-vis relevant audiences within the entrepreneurial ecosystem. Therefore, narratives play a central role in shaping how organizational events are interpreted and evaluated. Organization and entrepreneurship research highlights that they constitute key mechanisms through which actors make sense of events, justify outcomes, and shape stakeholders' understanding of organizational experiences (Lounsbury & Glynn, 2001; Martens, Jennings, & Jennings, 2007). These dynamics become particularly salient in the context of venture failure, where entrepreneurs frequently construct retrospective narratives that explain the causes of collapse and articulate lessons derived from the experience (Mantere et al., 2013). Such narratives function both as explanations of past events and as interpretive frameworks that render failure socially intelligible, while also helping entrepreneurs manage the reputational consequences of venture collapse. In this sense, failure accounts are closely connected to processes of impression management, defined as strategic efforts individuals use to influence how others perceive and evaluate them (Goffman, 1959; Schlenker, 1980; Leary & Kowalski, 1990). In cases of venture collapse, these narratives frequently involve

[4] University of Naples "Parthenope", e-mail:roberta.palomba001@studenti.uniparthenope.it

processes of responsibility attribution, through which entrepreneurs explain whether the collapse resulted from internal decisions or external circumstances. Failure may thus be framed either as the outcome of entrepreneurial mistakes or as the consequence of misfortune beyond the founder's control (Cardon et al., 2011), while explanations of venture collapse may distribute responsibility across individual, organizational, and contextual factors (Mantere et al., 2013). At the same time, such narratives address the legitimacy challenges generated by venture collapse. Because failure may undermine the entrepreneur's perceived appropriateness within socially constructed systems of norms and expectations (Suchman, 1995; Richey et al., 2025), founders often reinterpret failure to protect their credibility and reaffirm their identity as legitimate entrepreneurial actors (Navis & Glynn, 2011).

Purpose of the paper. Despite the growing body of research on entrepreneurial failure narratives and impression management, these literatures have largely evolved in parallel. Studies on entrepreneurial failure have examined how founders interpret and communicate venture collapse through retrospective narratives that explain what went wrong and what can be learned from the experience (Vaara, 2002; Kibler et al., 2017; Dobusch et al., 2022). At the same time, research on impression management highlights how actors strategically construct accounts in order to shape how they are perceived and evaluated by relevant audiences (Goffman, 1959; Leary & Kowalski, 1990). However, the intersection between these two perspectives remains underexplored. In particular, existing research has paid limited attention to the broader cultural contexts in which entrepreneurial failure narratives are produced and interpreted. While failure accounts are often treated as individual sensemaking practices or impression management strategies, institutional and cultural theory suggests that practices of justification, responsibility attribution, and self-presentation are embedded within socially structured systems of meaning that shape how actors interpret events and respond to adverse outcomes (Scott, 1995; Thornton, Ocasio, & Lounsbury, 2012). Therefore, cultural frameworks influence not only how failure is interpreted but also how entrepreneurs are expected to publicly account for it. Building on this perspective, this study explores how entrepreneurial failure narratives may vary across cultural contexts and how founders draw on different narrative strategies when accounting for venture collapse. Specifically, we conceptualize entrepreneurial failure narratives as culturally embedded accounts through which founders attribute responsibility for venture collapse and attempt to reconstruct legitimacy after failure. Accordingly, the study aims to address the following research question: How do entrepreneurs narrate venture failure across different cultural contexts?
To address this question, the study analyzes founders' post-mortem statements published on online platforms where entrepreneurs publicly reflect on the collapse of their ventures. By examining how founders frame failure experiences through different narrative strategies and interpretive forms, the analysis explores how cultural contexts shape the ways entrepreneurs attribute responsibility and reconstruct legitimacy in accounts of venture failure. By integrating insights from impression management theory, entrepreneurial failure research, and cultural perspectives on organizational communication, this study contributes to a deeper understanding of how entrepreneurs publicly account for venture collapse. More broadly, this study highlights how narratives of failure constitute culturally embedded practices through which founders negotiate responsibility, legitimacy, and identity within entrepreneurial ecosystems.

Methodology. This study adopts a qualitative research design to examine how entrepreneurs narrate venture failure and how these narratives reflect different ways of attributing responsibility and reconstructing legitimacy after venture collapse. In particular, the study focuses on founders' post-mortem statements, a form of public narrative in which entrepreneurs retrospectively explain the causes of startup failure and reflect on the entrepreneurial experience.

Post-mortem statements represent a particularly suitable empirical context for this study because they constitute public accounts addressed to entrepreneurial audiences, including investors, founders, and members of the startup ecosystem. As such, they provide rich insights into how entrepreneurs interpret failure and strategically communicate it to preserve credibility and professional identity.

Data collection. The empirical material consists of a dataset of entrepreneurial failure narratives collected from two widely used online platforms within the startup ecosystem: Failory and Medium. These platforms host numerous postmortem accounts written by startup founders who publicly recount the reasons behind their ventures' collapse. Such narratives represent a valuable source of qualitative data because they provide first-person accounts of failure written by entrepreneurs themselves and addressed to a broad audience within entrepreneurial communities. The data collection process followed a systematic multi-step procedure. First, postmortem narratives were identified through targeted searches on the selected platforms using keywords commonly associated with entrepreneurial failure narratives, such as "startup failure," "startup postmortem," "why our startup failed," and "lessons from failure." This initial search generated a broad pool of potential cases.

In a second step, the retrieved narratives were screened according to specific inclusion criteria. Only texts written directly by founders or co-founders describing the failure of their own startup were included in the dataset. Articles written by journalists, investors, consultants, or other external observers were excluded in order to maintain a consistent focus on entrepreneurs' self-narratives. In addition, the narratives had to contain a substantive reflection on the causes of failure and provide sufficient detail regarding the entrepreneurial experience. Very short texts or articles that merely mentioned failure without discussing it in depth were excluded from the sample. After applying these criteria, the final dataset consisted of 24 postmortem narratives describing the failures of startups across different national contexts. For each case, additional contextual information was collected to support subsequent analysis. This information included the startup's

name, industry sector, year of founding and closure (when available), the founder's nationality, and the country in which the venture operated. These details allowed the cases to be organized by the national context of the entrepreneurs and enabled cross-cultural comparisons. Specifically, to explore how narratives of failure may vary across broader cultural environments, the cases were subsequently organized into cultural clusters based on the classification proposed by the GLOBE Project (House et al., 2004). This framework groups countries into broader cultural clusters that share similar societal values and institutional characteristics. The dataset included cases associated with the following clusters: Anglo-American, Nordic, Germanic, Latin European, Latin American, Confucian Asian, and South Asian contexts. In the present study, cultural clusters are primarily used as an analytical lens to organize the empirical material and explore how entrepreneurial failure narratives appear across different contexts. The analysis, therefore, focuses on identifying recurring narrative configurations across cultural environments rather than establishing systematic cross-cultural differences.

Data analysis. The study employs qualitative content analysis to examine how entrepreneurs construct and communicate narratives of venture failure. Content analysis is particularly suitable for this research because it allows systematic interpretation of textual data to identify recurring themes, meanings, and communicative patterns within qualitative material (Krippendorff, 2018). The analysis followed a multi-step coding process. First, all postmortem narratives were carefully read several times to become familiar with the data and identify preliminary thematic patterns. During this initial phase, the texts were examined holistically to capture how entrepreneurs described the causes of venture collapse, the roles of the different actors involved, and the emotional and interpretative framing of the failure experience. In the second step, the analysis was guided by two analytical dimensions derived from the theoretical framework: responsibility attribution (Mantere et al., 2013) and legitimacy reconstruction (Richey et al., 2025). First, narratives were coded according to how founders explained the causes of venture failure. Failure accounts were classified depending on whether responsibility was primarily attributed to internal causes, such as strategic mistakes, managerial decisions, or flawed assumptions, or to external causes, such as market conditions, institutional constraints, or broader environmental dynamics. Second, the analysis examined how founders attempted to reconstruct legitimacy after failure. This dimension was operationalized by analyzing impression management strategies embedded in the narratives as suggested by Kibler et al. (2017). In particular, demonstrative and assertive strategies, typically associated with self-focused narratives emphasizing learning, competence, and leadership, were interpreted as mechanisms for reconstructing individual legitimacy. Conversely, defensive and other-focused strategies, which emphasize contextual constraints, structural conditions, or the collective role of the team, were interpreted as mechanisms for reconstructing collective or systemic legitimacy. Finally, the analysis examined how the two analytical dimensions, responsibility attribution and legitimacy reconstruction, interacted across the narratives. By comparing how different combinations of these two dimensions appear across the dataset, the analysis generated a typology of narrative patterns through which entrepreneurs account for venture collapse.

Results. Consistent with prior research that conceptualizes entrepreneurial failure as a socially interpreted event rather than merely an economic outcome (Cardon et al., 2011; Byrne & Shepherd, 2015; Johnson et al., 2022), the analysis shows that founders employ different narrative strategies when accounting for the collapse of their ventures. While all narratives acknowledge failure, they differ in the extent to which responsibility is attributed to internal decisions or external conditions, and in how founders reposition their professional identity after the venture's collapse. These variations reflect broader cultural expectations regarding leadership, accountability, and emotional expression. When examined through the two analytical dimensions of attribution of responsibility and legitimacy reconstruction, the narratives reveal four recurring configurations through which entrepreneurs interpret and communicate venture failure. These configurations represent distinct ways in which founders frame the causes of failure and position themselves within the entrepreneurial experience.

The first configuration, which we label the “Learning-from-Failure Narrative”, emerges when entrepreneurs attribute failure primarily to internal causes while reconstructing legitimacy at the individual level. In these narratives, founders openly acknowledge strategic mistakes or flawed assumptions but frame the experience as a valuable opportunity for learning and entrepreneurial development. Failure is therefore reinterpreted as a necessary step in the entrepreneurial journey and as evidence of reflexivity and resilience. As one founder admitted, “We did lots of things wrong,” while another stated, “I failed. I made mistakes.” In these accounts, self-criticism does not undermine legitimacy. Rather, it becomes a resource for signaling reflexivity, accountability, and entrepreneurial learning. This narrative pattern appears particularly recurrent in Anglo-American contexts, where publicly reflecting on errors and lessons learned is often interpreted as a marker of credibility, transparency, and entrepreneurial maturity rather than as a threat to professional legitimacy.

A second configuration, which we define as the “Collective Learning Narrative”, emerges when responsibility for failure is interpreted mainly as internal, yet legitimacy is reconstructed through a collective framing of the entrepreneurial experience. Rather than emphasizing individual accountability, founders highlight the team, collaboration, and shared experimentation. In these narratives, failure is often described as the outcome of a collective learning process rather than an individual shortcoming. The narrative focus shifts from personal responsibility to the broader experience of teamwork, collaboration, and joint exploration. For instance, one founder emphasized the collective dimension of the experience by stating, “My gratitude goes to the team who believed in the project until the very end,” while another entrepreneur noted,

"Our team gave everything to try to keep it alive." In such cases, legitimacy is reconstructed collectively through expressions of gratitude, shared commitment, and recognition of the broader community involved in the entrepreneurial journey. This narrative orientation appears in several cases in Nordic contexts, where cultural norms emphasize cooperation, social cohesion, and collective responsibility, shaping how entrepreneurial experiences, including failure, are publicly interpreted and communicated.

A third configuration emerges when founders attribute failure primarily to external or structural factors and reconstruct legitimacy through analytical explanations of contextual constraints. We refer to this configuration as the "Analytical Justification Narrative". In these narratives, entrepreneurs emphasize market dynamics, institutional barriers, or structural limitations that shaped the venture's trajectory. Rather than focusing primarily on personal reflection, founders provide detailed diagnoses of what went wrong. For example, one entrepreneur explained that "Each order generated a loss, pickup and delivery costs were too high," while another noted that "The LTV simply couldn't justify the rising acquisition costs". By framing failure as the outcome of complex external conditions, entrepreneurs maintain their credibility as competent decision-makers while situating it within broader systemic dynamics. Legitimacy is therefore preserved through the demonstration of professional expertise and rational assessment of the venture's collapse. This narrative pattern appears most frequently in Germanic contexts and, to a lesser extent, in Confucian Asian environments, where cultural norms place strong emphasis on analytical reasoning, procedural clarity, and structured explanations of organizational outcomes.

Finally, the fourth configuration, which we label the "Visionary Persistence Narrative", emerges when entrepreneurs attribute failure primarily to external conditions while simultaneously reaffirming their individual entrepreneurial identity and vision. In these narratives, founders frame the venture's failure as the result of contextual constraints while emphasizing their leadership, determination, and long-term entrepreneurial ambitions. Entrepreneurs often reinterpret the outcome not as a definitive failure but as a transitional moment within a broader entrepreneurial trajectory. For instance, one founder stated, "We are more confident today than ever," while another declared, "This is not a failure, this is evolution." Such statements reposition the founder as a persistent visionary whose entrepreneurial capabilities remain intact despite the venture's closure. Failure is therefore presented as a temporary setback rather than a definitive indicator of incompetence. This narrative pattern is particularly evident in Latin American and South Asian contexts, where entrepreneurial storytelling often combines contextual explanations with strong reaffirmations of leadership, ambition, and future entrepreneurial potential.

Research limitations. Although this study advances the understanding of entrepreneurial failure narratives across cultural contexts, it presents several limitations. In particular, the dataset is based on a limited number of publicly available post-mortem statements retrieved from platforms such as Failory and Medium. While these materials provide rich qualitative insights into how founders interpret and communicate failure, they consist primarily of self-reported accounts and publicly curated stories. As such, they capture how entrepreneurs publicly frame failure rather than the full range of internal organizational processes that may have contributed to venture collapse. Therefore, they may not fully capture the internal organizational dynamics behind startup failure or the perspectives of other stakeholders involved in the venture. Moreover, the selection of countries within each cultural cluster was partly constrained by the availability of documented startup failures, meaning that not all clusters identified in cross-cultural frameworks could be equally represented in the dataset. As a consequence, the cultural comparisons presented in this study should be interpreted as exploratory patterns rather than as systematic cross-cultural differences. In addition, the sample is largely composed of technology and digital startups, sectors characterized by high levels of experimentation and a strong culture of publicly narrating entrepreneurial failure. This sectoral concentration may limit the transferability of the findings to other industries. Future research could therefore examine whether similar narrative configurations emerge in more traditional industries or in entrepreneurial contexts where failure is less publicly discussed. Finally, the study relies on an interpretive qualitative framework grounded in narrative categories and impression management strategies. Although this approach enables an in-depth understanding of discursive patterns, interpreting narratives inevitably involves a degree of subjectivity. To strengthen the robustness of these insights, future studies could combine narrative analysis with additional methodological approaches, such as in-depth interviews with founders or mixed method designs that integrate qualitative and quantitative evidence.

Managerial implications. This study offers entrepreneurs, investors, and startup actors practical insights into how entrepreneurial failure can be communicated and managed across different cultural contexts. For entrepreneurs, the findings suggest that there is no universally valid narrative model for communicating entrepreneurial failure, as the legitimacy of different narrative strategies is shaped by the cultural and institutional context in which founders operate. Strategies such as openly admitting personal responsibility or framing failure as a learning experience may be well received in some entrepreneurial settings, particularly in Anglo-American environments, but may be less appropriate in contexts where leadership authority, collective harmony, or reputational stability are more strongly emphasized. This implies that communicating failure is not merely a personal storytelling exercise, but a strategic act of reputation management embedded within culturally specific expectations. Therefore, entrepreneurs operating in international or multicultural environments should carefully consider the cultural expectations surrounding responsibility, vulnerability, and leadership legitimacy when communicating the end of a venture. Being attentive to these expectations may help founders preserve credibility within entrepreneurial ecosystems and maintain access to future opportunities despite venture collapse. For investors, accelerators, and startup support organizations, the results highlight the strategic role of

post-failure communication in shaping founders' reputations and future opportunities. The way founders narrate the closure of a venture can influence how they are perceived by investors, employees, and future collaborators. Encouraging transparent reflection on failure can be valuable for learning within entrepreneurial settings, but communication practices should remain sensitive to cultural differences in how responsibility, authority, and emotional exposure are publicly negotiated. Tailoring communication guidelines and mentorship practices to different cultural environments may therefore improve the effectiveness of failure-learning initiatives.

Originality of the paper. This study advances impression management and entrepreneurship research by introducing a cross-cultural perspective into the analysis of entrepreneurial failure narratives. While prior studies have examined how entrepreneurs strategically frame venture collapse (Kibler et al., 2017; Dobusch et al., 2022; Castelló et al., 2023), they have largely treated impression management strategies as relatively context-independent communicative practices. By comparing founders' postmortem narratives across multiple cultural clusters, this study shows that the narrative strategies entrepreneurs use to attribute responsibility, express emotions, and reconstruct legitimacy are embedded within broader cultural environments. In doing so, the paper extends impression management theory in the entrepreneurship domain by demonstrating that the communication of entrepreneurial failure is shaped by culturally specific expectations regarding leadership, accountability, and reputation management. More broadly, the findings suggest that failure narratives function as discursive mechanisms through which entrepreneurs reinterpret adverse events, protect professional credibility, and renegotiate their entrepreneurial identity after venture collapse. As a result, it contributes to the growing literature on entrepreneurial failure by highlighting the role of narrative practices in legitimacy reconstruction within entrepreneurial ecosystems. Overall, the study provides an exploratory cross-cultural examination of impression management in entrepreneurial failure narratives, illustrating how the communication of failure varies across cultural environments and how these variations reflect broader cultural expectations surrounding legitimacy, responsibility, and leadership.

New actors in entrepreneurial networks: the emerging role of venture builders

CHIARA LUISA CANTÙ, LALA HU, MIRKO OLIVIERI

Abstract. *Entrepreneurial networks support the creation and growth of new ventures by enabling access to resources, knowledge, and strategic relationships. While prior research has mainly focused on actors such as science parks, incubators, and accelerators, the role of venture builders as emerging actors in entrepreneurial networks remains underexplored. This study investigates how venture builders interact with entrepreneurial networks and how network ties influence their business model development. By adopting a qualitative approach, the research is based on a case study of an Italian venture builder. Data were collected through semi-structured interviews and secondary sources. The findings show that venture builders act as new actors that integrate venture creation, strategic consultancy, and resource orchestration, reconfiguring network relationships and supporting the development of new ventures.*
Keywords*: entrepreneurial networks; network ties; network relationships; venture builder*

Framing of the research

Entrepreneurial network

Entrepreneurial ecosystems are complex and interconnected environments that support innovation, collaboration, and economic development by providing entrepreneurs with key resources such as access to funding, mentorship, and a cultural context that encourages experimentation and risk-taking (Tula et al., 2024). The entrepreneurial ecosystem has been considered as the regional aggregate of economic, political, cultural, and social factors that support the establishment and growth of innovative enterprises by encouraging early entrepreneurs and other actors to start their own businesses, raise funding, and take high-level risks. This ecosystem includes cultural factors (supportive culture, entrepreneurial history), social factors (employees' ability, financial capital, and human networks), physical factors (universities, infrastructure, and markets) and so on. In other words, an entrepreneurial ecosystem is a conceptual model designed to stimulate economic growth by supporting entrepreneurship and the development of innovative small firms, while emphasizing the broader business environment in which entrepreneurs and startups operate as individual actors (Kumari et al., 2025).

In a wider perspective, Entrepreneurial Network (EN) provides social capital that increases a new venture's likelihood of success (Smith and Lohrke, 2008). The high network density supports collaboration between large companies and local startups, sustaining access to relevant resources (Ancona et al., 2023). Particularly, EN provides SMEs with easy access to resources in the external environment (Pulka et al., 2021; Das and Goswami, 2019). In the EN, a key role for entrepreneurial innovation has been undertaken by science and technology parks, incubators and accelerators, and more recently by venture builders. Science and technology parks create an environment that promotes technology transfer and innovation (Hansson et al. 2005), mainly related to the development of new ventures based on physical space. Science and technology parks have been considered urban innovation projects that provide the local infrastructure for an intensified cooperation between companies and scientific institutions (Mieg, 2012). The minimum infrastructure of science and technology parks is made up by a compound with private companies and one or more university institutes, a business incubation center, a centralized park management, an urban structure with a minimum of centralized facilities (Mieg, 2012). Particularly, science park characteristics can facilitate the advantages of cluster dynamics, affecting science park performance (Yang and Lee, 2021), firm performance (Clemente-Ciscar et al., 2025) and universities' innovation (Iqbal et al., 2026). In this regard, the function of Science Parks has been focused on collaboration with different internal and external organizations to improve the innovation development process. The increasing focus on more intangible and high-value services also outlined a new incubating business model (Grimaldi and Grandi, 2005). The value provided by incubators to new firms includes access to networks as part of their value proposition (Hansen et al., 2000). Such incubators are often located inside the science parks that support the innovation process for tenants and other actors involved in R&D projects. Incubation is considered as a model of start-up facilitation (Bruneel et al., 2012). As stated by Hackett and Dilts (2004, p.71), most researchers agree that incubators-incubation represents a systematic method of providing business assistance to firms in the early-stages of their development. This assistance is provided with the aim of increasing firm survival (Bollingtoft, 2012), promoting innovation and entrepreneurship (Aerts, Matthyssens, and Vandenbempt 2007). From this perspective, an incubator is an innovative system designed to provide technology and management supports to assist entrepreneurs in the development of new ventures (Colombo and Delmastro, 2002), through three mechanisms identified in buffering, bridging and curating (Amezcua et al., 2020). The buffering mechanism is founded on resources provided to tenants in a protected environment. The bridging mechanism relates to connections of tenants with the external environment, while the curating mechanism is a particular form of bridging as a start-up could be best paired with a specific resource. In this regard, the increasing density of community can improve the opportunities for mutualism and learning among incubators (Hou et al., 2020).

In general, innovation hubs support entrepreneurial ideas, leading to business startups, or work together to develop innovative ideas that benefit the organizations in the hub (Pfotenhauer et al., 2022). Science parks and business incubators are property-based organizations with identifiable administrative centers focused on the mission of business acceleration through knowledge agglomeration and resource sharing (Phana, Siegel, and Wright, 2005). Policy actors see them as a tool to initiate or revive innovativeness in regions and universities as a way to commercialize research results (Aaboen, 2009). An incubator can achieve service differentiation and enhanced customer (tenant) value (Vanderstraeten and Matthyssens, 2012). Three different types of incubators have been identified: for profit, non-profit, university-based incubators (Peters et al., 2004). The differences between incubator models relate to the purpose of the incubator and the nature of relationships it manages.
Over the years, accelerators have been considered as new incubators with specific peculiarities (Clarysse et al., 2015) and thus central intermediary (Clayton et al., 2018; Goswhami et al., 2023) within the EN. Accelerators sustain startups in the identification of funding opportunities to strengthen their financial capabilities (Paoloni and Modaffari, 2022) and offer strong infrastructural backing to innovative ventures (Fuad et al., 2024). Accelerators are classified by considering the supporters (e.g., corporate accelerators versus university accelerators) and the sector of reference (e.g., social accelerators, ecosystem builders) (Mansoori et al., 2019). In some cases, innovation hubs are compared to accelerators, as they focus on nurturing early-stage startups and helping de-risk innovative ventures (Ayamga et al., 2026).
Recent literature on ENs highlights that the increasing complexity and dynamism of markets have favored the emergence of new categories of actors and a consequent decline of traditional forms of corporate entrepreneurship, in favor of more distributed and hybrid support organizations. For example, corporate service providers are gaining relevance in ENs, offering specialized resources, mentorship, and market access (Ferrigno et al., 2025). This evolution in the ENs reflects the central role of flexibility, external collaboration, and support programs, which are becoming critical in favoring startup growth (Amjad, 2025). These new actors play a fundamental role in promoting networking opportunities, facilitating connections among startups, investors, and established firms, and enhancing knowledge exchange and resource mobilization within the ENs (Pardo-del-Val et al., 2025).
In this context, venture builders (VB) are emerging for their ability to start from scratch, providing not only financial support but also technological, human and strategic resources (Hassel et al., 2025). A VB is a start-up factory, an organization that systematically creates new businesses based on market trend analysis to identify and meet potential and latent demand (Baumann et al., 2018). VBs create a portfolio of high-quality, low-risk start-ups. The structured and methodical approach enables businesses to grow more quickly and reach the market in a short time frame. The VB business model is founded on an in-depth analysis of the market and its emerging trends to identify entrepreneurial opportunities. Unlike the traditional approach, which starts with the idea of a single founder, VBs use an analytical and systematic approach to create start-ups with a higher scalability.

Actor's business model: a relational perspective
The literature on business planning mainly focused on both antecedents to business planning (Brinckmann et al., 2019) and its outcomes (Brinckmann et al., 2010). A key element of business plan is the description of business model that includes concepts relating to the firm's value offering, economic model, customer interface and relationships, partner network and roles, internal infrastructure/ connected activities and target markets (Morris et al., 2005). In addition, the business model has been considered as a representation of strategic choices for creating and capturing value within a value network. Business model describes "the structure, content, and governance of transactions between the focal firm and its exchange partners and represents a conceptualization of the pattern of transactional links between the firm and its exchange partners" (Zott and Amit, 2007, p. 181). The business model involves the "configurations of interrelated capabilities, governing the content, process and management of the interaction and exchange in dyadic value co-creation" (Nenonen and Storbacka, 2010, p 9).
According to Zott et al. (2011), systems-level thinking in business models is required as dynamic activities are performed by the firm and by third parties, such as partners, suppliers, and customers. Multiple stakeholders interact and co-operate to face challenges (Zott & Amit, 2009). In this regard, business models are founded on new forms of collaboration for value creation that require a whole-system approach (Ng et al, 2013).
As stated by Ford and Mouzas, networking relates to the way business relationships are framed. Focusing on a structural perspective, business models depict how an organization creates, delivers, and captures value. Considering firm activities (Pinazo-Dallenbach et al. 2016), business models refer to how firms develop their business, based on the value proposition, value creation, and value capture (Clauss et al. 2019).
Business models, founded on Industrial Network, recognize that firms are embedded in a network (Freytag and Clarke 2012). In this regard, "an open-business model examines the creation of value between stakeholders, rather than simply considering the value created within the boundaries of a single firm" (Coombes and Nicholson, 2013, p. 658).

Purpose of the paper. In the ENs, new actors have been identified in the role of venture builders (VBs), i.e., new entrepreneurial players that systematically produce, develop, and market startups (Hassel et al., 2025). For example, in 2023, Italian VBs received funding of € 41,022 million to focus primarily on managerial support, product and service design and development, marketing and sales strategies, and initial capital for starting the company (Social Innovation Monitor, 2025).

Even if the literature on ENs from the perspective of resource dependency theory has received increasing attention, the consequences of entrepreneurial networks have been considered vague (Abu-Rumman et al., 2021). In this context, the aim of the research is to investigate the key role undertaken by VBs and the reconfiguration of the EN. Particularly, the VB is a new type of actor that operates as a venture factory (Baumann et al., 2018; Hassel et al., 2025). This study tries to address the following research questions: What is the role of VBs in the EN? What is the role of network ties in the configuration of their business model?

Methodology. Due to the exploratory nature of the research, we adopted a qualitative research design based on a single case study (Siggelkow, 2007), which enables an in-depth and contextualized understanding of complex phenomena (Yin, 2009). This methodological approach is particularly appropriate when investigating emerging organizational models and processes which are still underexplored in the literature, such as venture builders and the evolution of their business models. A single case study allows researchers to capture insights and analyze the relationships and mechanisms of the phenomenon under investigation. Specifically, our data collection relies on both primary and secondary sources to ensure a comprehensive and triangulated understanding of the case (Yin, 2009).
Company A was selected as the focal case for this study as it represents a relevant example of a VB operating within a dynamic EN. The organization provides a suitable context to investigate how venture builders structure their activities, interact with partners in the EN, and evolve their business models over time. Moreover, the accessibility of key informants and the availability of internal documentation make Company A an appropriate case for conducting our qualitative investigation. The case selection was guided by the following selection criteria: representativeness of the phenomenon, relevance within the EN, accessibility to key informants, and availability of rich and longitudinal data sources.
The data collection process is currently ongoing. The case has been elaborated on the basis of semi-structured interviews conducted from 2020 to 2026 with the founder of venture incubators. Over these years, the entrepreneurial context has been analyzed also through interviews with innovation experts.
The semi-structured interview followed a protocol developed based on the academic literature on VBs and ENs. The interview protocol includes questions on the founder's professional background, the role of business relationships in the establishment of the VB, the most relevant actors within its EN, and the main challenges encountered during its development. In addition to the interview, we collected secondary data from multiple sources, such as the official corporate website, social media platforms, articles from specialized magazines, and available documents (e.g., Social Innovation Monitor, 2025), in order to improve robustness (Natow, 2020; Jack and Raturi, 2006). These data, together with the interview transcript, were analyzed by the researchers using coding procedures.

Results.
Key partners in business model development
Company A is a venture building company founded in 2021. Company A manages digital startups and SMEs from their inception, bringing them to market with rapid and effective execution. As a venture builder, Company A offers its expertise in the development of new digital business models created by entrepreneurs or professionals with specific know-how. In the initial phase, Company A operated as a vertical innovation consulting center, connecting the needs of firms with European-level scouting: the goal was to bring tangible benefits to businesses by offering targeted solutions and support in the dialogue between companies and startups.
In 2022 Company A and a venture capital company listed on the Italian Stock Exchange that invests in early-stage digital startups have signed a partnership agreement to launch joint innovation programmes aimed at large companies. The collaboration aimed to expand the joint open innovation offering to large companies through the creation of tailor-made programs using the Corporate Venture Building approach: the identification, creation, development and market launch of new "on-demand" businesses, based on specific innovation needs. The relationship with this venture capital company supported the transformation of Company A's Venture Building model aimed at SMEs and large companies defined as "originators", promoters of the initiative. Company A, thanks to its expertise in the operational execution of digital business models, supports the originator throughout the entire development process, from inception to scaleup.
In this initial phase of Company A's development, several actors played a key role. In this regard, the founder of Company A highlighted the importance of a crowdfunding lending platform that allows small and medium-sized businesses to quickly access financing through a fully digital process:
"Among our project's first partners was a crowdfunding lending platform, which helped us validate our model. From there, after this first case, we began to scale."
Company A's business model involves a team and a three-year contract with companies, with an annual fee that increases based on the company's performance. The team is made up of managers with significant experience in the digital sector, who constantly study solutions that can improve customers' businesses, understand needs, and offer customized solutions. Company A handles tax and financial matters, as well as internal processes for digital start-ups and SMEs. In this regard, Company A develops solutions for companies belonging to various sectors that are activating the process of digital transformation. The company acts as a temporary team partner, working with the client to improve operational efficiency and promote growth.
In 2025, a qualified investment holding company and innovation platform dedicated to innovative start-ups and SMEs, has acquired Company A. The innovative approach of Company A has been strengthening by expanding the offering to new customer categories, including corporate companies, thanks to the integration of the expertise and network of the

investment holding platform. Company A continues to operate with its own brand by offering venture building services. The evolution of Company A has led to a clear distinction between strategy/technology and legal areas. The legal division oversees consulting services, while the strategy/technology division focuses on the development of new business models and the implementation of digital transformation projects.

Key activities in business model development

Three key activities have been identified as characterizing the business model of Company A: validation, creation, and execution. With reference to validation activity, Company A identifies the business idea and implements the methodologies and processes to validate its feasibility and market competitiveness. Company A analyzes the market, problem relevance, economic viability, and investor appeal to determine whether a project has a solid foundation to be built. In this regard, the founder of Company A stated:

"When it comes to validation, our company has expertise it can share with clients to improve their business model. [...] For example, we intervene during generational transitions in SMEs. We analyze skills, the market, and technologies and produce a feasibility study in which we provide a series of our insights. If they match the client's goals, they effectively become a key business driver."

The main output delivered by Company A is the market analysis, the MVP analysis, planning and valuation, and investor strategy. In terms of market analysis, quantitative and qualitative analysis of the target market is developed to identify and assess key trends, market size, and the competitive landscape. As regards MVP analysis, mixed methods (surveys, interviews, landing pages) are adopted for preliminary business model and MVP definition, along with problem-solution fit validation. The planning and valuation stage is founded on the development of a short- and mid-term financial plan to assess the project's economic feasibility, funding needs, and company pre-money valuation. The investor strategy relates to the preparation of the investor deck and definition of the fundraising strategy.

Following the creation activity, Company A experts co-found the startup and support technical, legal, and operational aspects related to incorporation, launch preparation, and go-live. Company A experts move forward only after the capital increase has been approved and subscribed, ensuring real commitment and project sustainability. The output delivered is the venture foundation, the operations setup, the team, and partners setup. In terms of venture foundation, the incorporation of the newco is considered together with the management of technical and legal aspects, and the execution of the funding round. The operations setup involves the setup of tools for monitoring business performance, communication systems, document sharing, and administration. The team setup and the team and partners setup involve the definition of the organizational structure, the search and selection of the professional roles needed by the startup, together with the training of the internal team and the identification of partners relevant to industrial or commercial business development.

With reference to the execution activity, after laying out the foundations, Company A takes a proactive role in managerial decisions, with the goal of achieving metrics and market traction. According to the key informant, this is most challenging activity for a VB:

"Execution is the most challenging part of our process, but not internally for us, as we simply need to be ready to manage the metrics. The challenge of this phase is making the client, who may not have digital experience, understand that they need to completely overhaul their business model. This often creates friction and slowdowns in the process."

The areas of intervention relate to operations, finance, strategy, and marketing. The operations are identified in the operational coordination of the team and monitoring business performance. Finance relates to the financial management of the newco, including planning, management control, accounting oversight, performance monitoring, and reporting. With reference to strategy, business development and strategy supervision, including the definition of growth objectives and management of investor relations. Furthermore, marketing and digital strategy are combined with digital advertising, content creation, social media marketing, UX/UI design, and web development. In addition, legal management includes supervision of legal matters, risk management, and advisory on regulatory compliance and corporate governance.

Furthermore, the execution phase can evolve in two operational directions, depending on the maturity of the team and the needs of the project, venture building complete service or CXO as a service. In the first case, venture building complete service, Company A continues to operate as the internal team, guiding the startup through go-to-market, growth, and day-to-day management. This is the continuation for businesses that started with Company A from 0 to 1 and need full-team support.

In the second case, CXO as a service, Company A develops activities to strengthen specific functions to accelerate the growth of structured teams. Particularly, CFO As a Service is an innovative service that allows companies to access the expertise of a Chief Financial Officer without having to hire a full-time employee. It is designed to support businesses in strategic consulting and operational finance management. The CIO as a Service aims to strategically coordinate technological changes, identify new opportunities, and models to promote business innovation. The 'COO as a Service' service supports companies in operational management, business strategy and process improvement. The 'CLO as a Service' service offers companies strategic legal support to manage compliance, legal risks and constantly evolving regulations.

Research limitations. This work in progress study presents some limitations related to its exploratory nature and the adoption of a single case study, which may limit the generalizability of the findings to other contexts. The analysis focuses

on one VB operating within a specific EN. Furthermore, as the research is still in progress, the data collection process is ongoing, and additional interviews and evidence will be required to further refine and validate the emerging insights.

Managerial implications. In terms of managerial implications, this study highlights that the VB requires new competences and capabilities more oriented to the analysis of the business landscape and the configuration of strategic thinking. Network competence and network ability are also required.
In addition, VBs outline the relevance of a relational perspective in the configuration of a business model and access to resources in the early stage of new ventures (Bally et al., 2025). As VBs serve as central nodes connecting entrepreneurs, investors, mentors, service providers, and corporations, managers should focus on building and maintaining strong relational capital across stakeholders. VBs have become increasingly influential actors within entrepreneurial networks as they combine venture creation, resource integration, and ecosystem coordination. For managers, this means shifting from traditional startup support toward a more systemic, portfolio-based, and network-centric approach. Organizations that effectively leverage VBs can enhance innovation outcomes, reduce entrepreneurial risk, and strengthen long-term ecosystem competitiveness.
While VBs provide several advantages to startups, some power dynamics and governance challenges emerge. Because venture builders often hold significant equity and operational control, tensions may arise with founders, therefore transparent governance models are essential.

Originality of the paper. The preliminary results of this study highlight that VBs can rely on institutional investors such as venture capital funds, family offices, banks, and even public funds. These channels provide the resources needed to launch and support the start-ups created that benefit from a structured ecosystem, provider of financial, strategic, and operational resources. The development path of startups is strongly influenced by the approach and priorities of the venture builder (Baumann et al., 2018). Our findings contribute to the literature by highlighting how VBs orchestrate multiple funding channels simultaneously and expanding the current understandings of resource mobilization in ENs.
According to our findings, the VB combines the peculiarities of incubators and accelerators, considering the support provided at startup foundation, early stage, and growth. As a new actor, VB presents peculiarities different from other actors belonging to the EN. The VB identifies entrepreneurial opportunities, launches the startup, and provides equity. This new actor is also characterized by consultancy services provided to startups and other firms.
As highlighted by findings, the business model of the VB has been transformed over the years through networking that ensures fertile ground for the development of entrepreneurial ideas. At the beginning, the attention of VB was focused on startups while later the attention moved to new ventures and corporations as well, based on the competences provided by key business partners. This evolution reveals a dynamic and adaptive business model, offering novel empirical evidence on how VBs continuously reconfigure their value proposition in response to ecosystem changes.
Focusing on the entrepreneurial process, the first key activity is the identification of new business opportunities through market analysis and evaluation of current trends. Once a promising opportunity has been identified, the next step is market validation, which involves testing the idea in the field and verifying that it meets market needs. The venture builder then proceeds to build the team needed to develop the idea. Professionals with specialized skills are selected, and teams are formed to work together to transform the idea into a concrete product or service. The choice of startup team members, including the CEO of the company, is crucial to ensure the necessary skills. In parallel, the venture builder also raises the necessary funding to support the startup in its early stages. This process recognizes the VB as a key player of EN characterized by a strategic role. VB support new venture launch and development through traditional entrepreneurial services (tutorship, mentorship, networking) and additional strategic consultancy services related to the identification of latent needs and the configuration of a strategy for the launch of the company and its solution. Our study extends prior research by detailing VB activities, highlighting how these actors actively shape venture creation processes. Furthermore, VBs support the launch and growth stages of new ventures as well as the new business development (corporate VBs).
Over the years, the attention of VB has moved to strategic consultancy services provided to SMEs in order to improve their growth strategies. The changes in business model, that supported the growth of the VB, have been enabled by interconnected business relationships that facilitated the sharing of resources, mainly competences, to provide innovative consultancy services. Relationships activated with other actors have supported Company A in the development of CXO services. In a rapidly evolving context, Company A supports start-ups, SMEs and large companies in digitization and the development of innovation culture. In addition, startups, SMEs and large companies can benefit from high-level part-time operational leadership to optimize operations, implement lean strategies, and manage organizational change. Moreover, Company A assists companies in implementing effective legal policies and creating governance processes that promote sustainable growth. In this regard, VBs are associated with activities characterized by a stronger focus on the later stages of business consolidation.
The VB business model requires the integration between the internal and external perspective of value creation sustaining its mission. In pursuing its mission, Company A aims to consolidate the startup ecosystem by introducing validated solutions. Another key objective is to support entrepreneurial skills with a view to growing innovative new businesses. In this regard, business partners support the direction of VB development, also considering the focus on new ventures and corporations. Changes in EN take place in a continuum structured by actor bonds, resource ties and activity links (Chou and Zolkiewski, 2012; Ford and Håkansson, 2006), considering different actors of the EN. In conclusion, this study

provides original insights into the evolving role of VBs as integrators of ecosystem resources, contributing to the understanding of value co-creation dynamics within ENs.

Non-financial support by reward-based crowdfunding backers: An exploratory study

BARBARA DEL BOSCO[1], SALVATORE TORRISI[2 3]

Abstract. *The paper investigates the decisions to provide additional non-financial support to reward-based crowdfunding campaigns by backers who have pledged financial support. In particular, the study analyzes two forms of non-financial support: (a) word-of-mouth (WOM) and (b) active contribution or suggestions for the development of the product/service object of the funded project or suggestions for the dissemination of the project (project development support). Building on the literature on reward-based crowdfunding, we account for various factors associated with non-financial contribution, such as the backers' motivations (e.g., interest in the product and social or environmental impact), their psycho-cognitive profile (trust and altruism) and pre-existing relations with project creators. The search for information about the project or its creators outside the platform is another potentially important factor, revealing that the decision to contribute is based on a significant level of backers' sophistication and cognitive effort. The empirical analysis drawn on data collected through an online survey of 211 backers contributing to Ideaginger, an Italian reward-based crowdfunding platform. Logit estimates highlight the importance of motivational, relational and psychological correlates of backers' non-financial contribution.*
Keywords: *reward-based crowdfunding; WOM; non-financial support; backers' motivations and psychological traits*

Framing of the research. Crowdfunding is an alternative source of financing for innovation that has received increasing attention from management scholars and business practitioners (Chemla & Tinn, 2020; Mollick, 2014; Stanko & Henard, 2017). Along with funding, crowdfunding is used to test new business ideas in the market, learn about consumers' preferences, and engage in user-based innovations (Belleflamme et al., 2014). Unlike other crowdfunding models, e.g., equity-based, lending and donation models, reward-based crowdfunding offers mainly three types of rewards to supporters: pre-orders of products, services (e.g., writing software code) and recognition (e.g., the backer's name on the company website and in-product acknowledgment). In reward-based crowdfunding, often, users are key players driven by different motivations than traditional financiers and respond to various values such as "what is in it for me" and "what is in it for others" (Nielsen & Binder, 2021).

Beyond financial support, backers may provide non-monetary contributions. Backers may act as "ambassadors" who contribute through word of mouth (Bi et al., 2017; Thies et al., 2016), promoting a campaign by sharing it with their contacts on social networks or leaving positive comments online (opinion-based social interaction). Even if the impact of word of mouth is weaker than the public availability of the number of backers (action-based social interaction), it is more persistent over time (Thies et al., 2016).

Moreover, crowdfunders may provide product- and market-related insights, which represent a form of crowdsourcing. Involvement of customer investors, in particular, increases funding success, as customers influence product development and reduce agency costs for prospective customers (e.g., Cornelius & Gokpinar, 2020).

Despite the variety of studies addressing different dimensions of reward-based crowdfunding, there is still a limited understanding of the mechanisms underlying the behavior of participants, such as the process through which funders' motivations and psychological profile affect how they search for (and select) projects to support and the type of (monetary and non-monetary) support they provide. Earlier studies have found that non-monetary and pro-social motives are important among reward-based crowdfunders (Boudreau et al., 2021; Jiang et al., 2021; Li & Wang, 2019; Zhang & Chen, 2019). However, other works have reported that campaigns' performance improves when offering tangible resources - goods and services - rather than symbolic resources - love or status, which could appear at odds with pro-social motivations and reveal utilitarian motivations (e.g., James et al., 2021). The importance of utilitarian motives is indicated by the positive impact of reward-based rhetoric, such as, for example, "this is an opportunity for backers to obtain access to an exciting product with the best features" (Tajvarpour & Pujari, 2022: 128). The literature has also found that pre-existing relations with the campaign positively affect the contribution and that backers with pre-existing relations with the fundraiser make higher contributions (Shneor et al., 2023). Funders' willingness to contribute also depends on their perception and beliefs about the expected impact of their support on the project outcome. The motivation to support a

[3] **Acknowledgements.** This project has been carried out within the MUSA – Multilayered Urban Sustainability Action – project, funded by the European Union – NextGenerationEU, under the National Recovery and Resilience Plan (NRRP) Mission 4 Component 2 Investment Line 1.5: Strengthening of research structures and creation of R&D "innovation ecosystems", set up of "territorial leaders in R&D". Filippo Rizzato has provided valuable support in designing the survey, constructing the dataset, and preliminary data elaboration.

crowdfunding project increases as the project funding approaches its target goal and significantly decreases after the target goal is reached (Kuppuswamy & Bayus, 2017). Moreover, funders possessing greater ability and motivation to make careful evaluations scrutinize issue-relevant information, e.g., entrepreneurs' education. Instead, inexperienced, first-time funders are mostly influenced by cues as calls for commitment based on group identity (Allison et al., 2017). Heuristic cues have proven to affect crowdfunding performance, suggesting that unsophisticated crowdfunding investors use psychological shortcuts to make decisions rather than engaging in extensive reasoning and algorithmic processing (Zhu et al., 2023).

The crowdfunders' motivations and psychological characteristics, such as trust and altruism, have received limited attention in the reward-based literature. This is an important gap, since accounting for these factors exogenous to participation may help understand the crowdfunders' willingness to engage and contribute to project co-creation and campaign success. Motivations and psychological traits may affect funders' search for projects to support and the selection process, which in turn could affect their commitment.

Purpose of the paper. The paper aims to investigate factors related to backers' decisions to provide additional non-financial support to the campaigns they have pledged to. In particular, the study analyzes two forms of non-financial support: word-of-mouth (WOM) and active support or suggestions for the development of the product/service that is the objective of the funded project or for the dissemination of the project (project development support). Both forms of support may be relevant for the success of a project. On the one hand, spreading information on the project favors the success of an "all-or-nothing" crowdfunding campaign and the consequent project start, and on the other hand, active support and suggestions for the project's development offered by backers may help improve it, providing the campaign's creators with benefits that are typical of crowdsourcing experiences.

Given the exploratory, preliminary nature of the study, we investigate the potential relevance of two categories of factors: backers' individual characteristics and the relationship between backers and campaigns.

Methodology. Data were collected in the first half of 2025 through an online questionnaire administered to individuals who supported a campaign on the Ideaginger platform from 2021 onwards. Ideaginger (www.ideaginger.it) is an Italian "all-or-nothing" reward-based crowdfunding platform established in 2013. Since its launch, this platform has hosted nearly 2,000 crowdfunding campaigns, with a success rate of 96%, raising over 21.8 million euros from more than 281,500 backers (Ideaginger, 2026). The invitation to complete the questionnaire was sent to around 60,000 backers. Some questionnaires could not be delivered because the associated email accounts had been deactivated, and others may no longer have been in use. We received 1,017 responses, corresponding to a response rate of approximately 1.7%. Of these, only 271 were considered valid questionnaires suitable for the analysis. Due to the presence of missing data, our final sample is made up of 211 backers.

We conducted logistic regression analyses to test the relationships between the backer's individual characteristics and his/her relationship with the campaign, on the one hand, and the decision to offer non-financial support (in addition to funding), on the other. We tested three models using three different dependent dummy variables: "WOM", which equals 1 if the respondent has provided non-financial support by spreading information about the project, and 0 otherwise; "Project development support" which equals 1 if the respondent has actively contributed to the product/service creation or has offered suggestions concerning the project, and 0 otherwise; and "Non-financial support", which is equal to 1 if the backer declared to provide at least one of the two previous forms of support.

Regarding independent variables, we operationalized backers' individual characteristics using psychological trait measures. In particular, we focus on two psychological traits related to interpersonal relationships – altruism and trust – which we measured using scales validated in previous studies. We drew from the 7-point scale 10 items IPIP-derived metrics to measure "Altruism" (Goldberg, 1999), and tracked the tendency to trust others ("Trust") with a single-item 11-point scale (Zmerli & Newton, 2008).

The other category of factors examined concerns the backer-campaign relationship (with regard to the last campaign supported by the backer), since the decision to offer non-financial support may be affected by the backer's relationship with the creator and the path and decision-making process that have led to financing the campaign. We thus included in the analysis the dummy variable "Pre-existing relationship", which equals 1 if the backer knew the project creator before offering support. Concerning the process that has led to the decision to pledge to the campaign, we included the dummy variable "Other information sources" as a proxy of the depth of information gathering; the variable equals 1 if the respondent has collected information from sources external to the platform before deciding to support a project, and 0 otherwise. Concerning the motivations underlying the decision to support the project, backers were asked to indicate the factors they evaluated when selecting the project they backed; the dummy variable "Interest in product/service" indicates whether respondents reported being interested in the product or service the project aimed to create. Given that pro-social motivations may determine different behaviors while deciding whether and how to help the campaign creators, we introduced a dummy variable that measures backers' orientation towards pro-social projects ("Interest in pro-social projects"), which equals 1 if the respondent flagged "social", "environment" and/or "social inclusion" among the categories of crowdfunding projects they are more interested in.

We included a set of control variables regarding both backers' characteristics and their relationship with the campaign. Concerning the backers, we controlled for their previous experience with crowdfunding, measured by the overall number of campaigns supported by the respondent on Ideaginger or other platforms ("N. projects backed"). We also included

some variables to control for potential effects of socio-demographic traits of backers: gender (operationalized through the dummy variable "Gender: male"), "Age", "Education" (measured using a scale from 1, corresponding to lower high school, to 5 for PhD), "Income" (operationalized through a scale comprising 4 discrete income brackets), geographic area (represented with dummy variables "Emilia Romagna", that is the region in which is located the platform owner, "North-East", for the other north-eastern Italian regions, "North-West", using "Centre-South" as the baseline), and occupation (represented with dummy variables "Entrepreneur or self-employed" and "Student", using other types of occupation as the baseline).

Concerning the relationship between the backer and the last campaign supported by the backer, we first included two variables related to the financial support offered and concerning, respectively, the amount of the backer's contribution ("Pledged amount") and the choice made between receiving a reward and providing a donation without reward (dummy variable "Reward"). Given the potential influence of the process that has led to the decision to pledge to the campaign, we also introduced the variable "Project known", which is a dummy that equals 1 if the backer has known about the project outside the crowdfunding platform, and 0 if the backer learned about the campaign by navigating the crowdfunding platform. Finally, we asked backers to assign a score indicating to what extent the creator, the project characteristics, and the rewards, respectively, influenced their decision to support the campaign; we included in the analysis the variables "Project % weight" and "Rewards % weight" which measure the percentage weight attributed to the project characteristics and to the promised rewards respectively (the weight assigned to the creator characteristics is the baseline).

Results. Tab. 1 and 2 report, respectively, descriptive statistics and the correlation matrix (including jointly the three dependent variables). Correlation coefficients suggest that collinearity is not a major concern.

Tab. 3 reports the results of the logistic regression analyses conducted using as dependent variables, respectively, the dummy variable concerning the overall "Non-financial support" (Models 1 and 2), and the two dummy variables concerning the two different kinds of non-financial support studied, "WOM" (Models 3 and 4) and "Project development support" (Models 5 and 6). Models 1, 3, and 5 include only control variables as predictors, while Models 2, 4, and 6 also include the independent variables of interest.

We find that the likelihood of providing non-financial support, in terms of both WOM and project development support, is higher in the case of backers who knew the creator before the crowdfunding campaign, testifying to the relevance of personal relationships in shaping backers' behaviors that go beyond financial support.

We also find an association between non-financial support and crowdfunders' psychological characteristics, which points to their importance in shaping this kind of supportive behavior. More specifically, altruism is positively and significantly related to the likelihood of offering non-financial support in general (Model 2), as well as the two specific forms of support analyzed - the spreading of information about the project (Model 4) and help and suggestions for the development of the product/service and the crowdfunding campaign (Model 6). The coefficient for the variable trust, instead, is negative and significant in the model concerning overall non-financial support (Model 2), and in the model with WOM as the dependent variable (Model 4), while it is not significant in the model explaining support for project development (Model 6). While the positive coefficients on altruism are expected, the negative coefficients on trust could be surprising. Why are crowdfunders with a high level of trust less willing to support a project they have financed through word of mouth? A possible explanation is that funders with a high level of trust are more confident that project creators will be able to autonomously reach the target or that other backers will provide non-financial support, thus making their support less compelling.

Another variable that turns out to be positively related to non-financial support in general and to WOM in particular is the dummy "other information sources", which traces whether the backer has searched for information about the project outside the platform before deciding to finance it. This variable, instead, is not a significant predictor of project development support. This result seems to suggest that those who have pledged money to a project after collecting information from multiple sources outside the crowdfunding platform have adopted an informed and rational decision-making approach, and are also more motivated to support the project by spreading information about it.

We also find that respondents more interested in the product or service the project aims to create are more likely to offer non-financial support. Models 2, 4, and 6, indeed, show that the variable "Interest in product/service" is positively and significantly associated with the three dependent variables. A possible interpretation of this result is that a backer motivated by a utilitarian interest in the development of the product or service has an incentive to provide additional forms of support to increase the probability of campaign success. On the contrary, the backers' pro-social orientation, proxied

by the variable "Interest in pro-social projects", turns out to be non-significant.

Research limitations. The study has some limitations pointing to opportunities for future research. It investigates the behavior of backers of crowdfunding campaigns hosted on the Ideaginger platform. This platform operates in Italy, focuses on reward-based campaigns with an "all-or-nothing" model, and is characterized by a very high success rate. Although financial contribution and crowdfunding success are not the object of this study, future research could extend the analysis to other platforms to investigate the relationship between non-financial contributions and the success of crowdfunding campaigns. Generalizing the analysis to other platforms would also allow understanding whether and how the specificities of the local context and the platform hosting reward-based crowdfunding are related to different behaviors regarding non-financial support.

Moreover, this study investigates the relevance of individual traits and the relationship between backers and campaign creators, but it does not account for campaign characteristics. Further research is needed to investigate how backers' non-financial support is affected by campaign characteristics, such as its social impact, size, location, and narrative rhetoric.

Managerial implications. The analysis of non-financial contributions to reward-based crowdfunding campaigns yields interesting insights into the motivations and psychological traits of funders, whose knowledge is useful to both project creators and crowdfunding platform owners. Our findings show that pre-existing relationships with project creators increase the likelihood that the funder spreads information on the project (word of mouth) and provides suggestions to improve the project's quality. This highlights the importance of actions that project creators should take to leverage their professional or personal network and engage supporters in co-creation, i.e., allowing them to contribute by sharing ideas, making comments on updates of the project, responding to other crowdfunders' comments, or testing early prototypes. Co-creation affects psychological ownership, a mental state in which crowdfunders have the feeling of ownership and influence over the decisions concerning the organization and directions of the project (Zheng et al., 2018), which favors crowdfunders' commitment to the project and eventually benefits the outcome of the project (Gerber & Hui, 2013; Xu et al., 2016). Moreover, crowdfunders' non-financial contribution - especially suggestions to improve the project - is driven by their interest in the product/services associated with the campaigns. Instead, word of mouth is positively associated with the search for information on the projects or their creators outside the platform hosting the crowdfunding campaign. The two findings underscore the importance of utilitarian motivations as a driver of non-nancial contributions and indicate that funders provide such contributions based on data and reasoning rather than heuristics. The implications for project creators are clear and highlight the value of investing in communication strategies targeting sophisticated users who can be reached through information channels beyond the crowdfunding platform. By the same token, the association between non-financial support and crowdfunders' psychological characteristics points to the importance of altruism and trust that should be accounted for in drafting a campaign communication strategy.

**** p<0.01, ** p<0.05, * p<0.1*

Originality of the paper. While the crowdfunding literature primarily focuses on individual decisions to support a campaign and the characteristics of projects that may affect these decisions, backers' non-financial support to a campaign remains much less explored (e.g., Cornelius & Gokpinar, 2020; Thies et al., 2016). This paper contributes to the latter stream of research by providing a novel contribution on the following grounds. First, studying a sample of individuals who have supported a reward-based crowdfunding campaign allows us to identify the factors that differentiate backers who limit their support to financial resources from those who also try to favor the campaign's success by spreading information about the project or providing suggestions or aid for project development. In doing so, the paper highlights the importance of motivational factors (e.g., interest in the product or service promoted by a campaign) and relational factors (e.g., pre-existing relationships with project creators). Second, this paper analyzes the roles of psychological traits, which have also received limited attention in previous crowdfunding studies. To the best of our knowledge, only a few studies on reward-based crowdfunding have addressed the effect of campaigns' rhetoric (e.g., heuristic cues and calls for commitment using a group identity) on backers' action (e.g., Allison et al. 2017; Zhu et al., 2023). We contribute to this stream of research by directly examining backers' psychological characteristics (trust and altruism) and search for information about the project or project creators outside the platform, leading to non-financial support. In doing so, the study aims to enhance our understanding of the process that leads from the backers' awareness of the campaign to their pre- and post-donation behaviors, and how these behaviors are interrelated.

Processi di legittimazione e di differenziazione competitiva nei mercati nascenti: una rassegna della letteratura

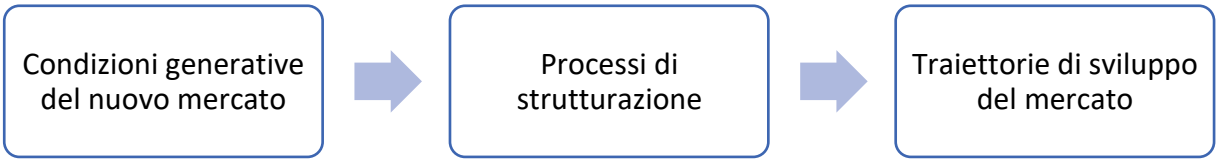
MARTINA CASTRONOVO, ANNA MINÀ, PASQUALE MASSIMO PICONE

Abstract. *La nascita di nuovi mercati è un tema che ha suscitato crescente interesse negli studi di management e imprenditorialità. Tuttavia, la letteratura ha finora trattato in modo relativamente separato i processi di legittimazione e le dinamiche di differenziazione competitiva tra le imprese nei suddetti mercati. Il presente lavoro ha l'obiettivo di sviluppare una sintesi teorico-integrativa della letteratura. In primo luogo, il paper presenta una mappa della letteratura sui processi di legittimazione del mercato. In secondo luogo, lo studio analizza i processi di differenziazione competitiva nei mercati nascenti e presenta una seconda mappa della letteratura. Da una lettura parallela delle due mappe, proponiamo un framework integrativo che indica gli elementi determinanti nella dinamica evolutiva potenziale dei mercati nascenti, nonché il ruolo della legittimità e delle dinamiche competitive di differenziazione. In particolare, facendo leva sul framework, noi proponiamo che il raggiungimento di una soglia di legittimità collettiva possa riconfigurare la natura della competizione nei mercati nascenti, fungendo da possibile punto di inflessione tra logiche di costruzione della categoria e logiche di differenziazione competitiva. Questo cambiamento può riconfigurare — piuttosto che dissolverla — la tensione tra il mantenimento dell'appartenenza categoriale e la differenziazione necessaria a garantire il vantaggio competitivo, offrendo una possibile base strutturata per comprendere l'evoluzione dei mercati nascenti.*
Keywords: *mercati nascenti; legittimazione; processi competitivi; creazione di mercati.*

Inquadramento della ricerca. I mercati nascenti rappresentano un contesto competitivo in fase di formazione in cui le imprese devono ancora stabilire le condizioni per la propria sopravvivenza e il conseguimento di un vantaggio competitivo (Rindova et al., 2010; Santos & Eisenhardt, 2009; Guerra et al., 2025). Da un lato, tali mercati presentano elevate potenzialità di sviluppo e nuove opportunità per le imprese, come è avvenuto a valle della commercializzazione di Internet (Santos & Eisenhardt, 2009; Rindova et al., 2010) e/o per le tecnologie fotovoltaiche solari (Guerra et al., 2025). Dall'altro lato, la genesi di un mercato nascente è caratterizzata da condizioni di instabilità ed incertezza. L'incertezza sia tecnologica sia della domanda, derivante, ad esempio, dalla definizione del prodotto e dei bisogni dei consumatori, aumenta le sfide strategiche che le imprese sono chiamate ad affrontare (Santos & Eisenhardt, 2009; Guerra et al., 2025).

A partire dal crescente interesse per comprendere la genesi e l'affermazione dei mercati nascenti, la letteratura ha prodotto numerosi studi sul tema (Agarwal et al., 2025). Molti hanno messo in luce il modo in cui i mercati nascenti si affermano, trovano legittimità e accettazione sociale attraverso narrazioni, standard e argomentazioni prospettiche (Navis & Glynn, 2010; Kennedy, 2008; Harmon et al., 2023). Altri studi hanno concluso che le imprese fanno fronte all'incertezza attraverso la sperimentazione (Guerra et al., 2025) e che gli attori del mercato costruiscono collettivamente infrastrutture che consentono l'apprendimento collettivo (Casasnovas & Ferraro, 2022). Ulteriori contributi hanno indagato come le imprese definiscano i confini del mercato attraverso la formazione dell'identità e le dinamiche di potere inter-impresa (Santos & Eisenhardt, 2009; Ozcan & Santos, 2015), come le azioni competitive possano operare in modo diverso nei mercati nascenti (Rindova et al., 2010), e i meccanismi sottesi alla frammentazione in diversi mercati, ciascuno con determinate caratteristiche e ambito di operatività (Casasnovas & Ferraro, 2022). Nonostante questi contributi abbiano permesso, nel complesso, di accrescere la conoscenza esistente sul tema, essi focalizzano l'attenzione su aspetti specifici, restituendo una visione inevitabilmente frammentata dei mercati nascenti. Nello specifico, il rapporto tra questi due processi (legittimazione vs. differenziazione) è stato ancora limitatamente analizzato in modo integrato e dinamico, lasciando aperta la questione di come essi si influenzino reciprocamente nel tempo. La letteratura esistente non fornisce ancora una cornice integrata capace di valorizzare tali diversi focus e di chiarire come essi entrino in gioco nel favorire l'evoluzione e lo sviluppo dei mercati nascenti. Or dunque, gli studi non consentono di mettere a fuoco l'interazione tra legittimità e processi di differenziazione competitiva in siffatte configurazioni di mercato.

Obiettivo del paper. L'obiettivo del paper è quello di sviluppare un framework concettuale che metta in relazione i processi di costruzione del mercato e le dinamiche di differenziazione competitiva, evidenziando il ruolo della legittimità collettiva come elemento di riconfigurazione delle logiche competitive. In particolare, proponiamo che, al crescere della legittimità collettiva e della comprensibilità della categoria da parte dei pubblici di riferimento, le imprese possano progressivamente spostare il focus da attività di costruzione del mercato verso strategie di differenziazione intra-categoriale. A tal fine, si intende restituire una visione complessiva degli studi fin qui pubblicati sui mercati nascenti, attraverso due mappe della letteratura e, infine, pervenire a un unico framework processuale che integra la ricerca della legittimità e le dinamiche competitive. Il framework suggerisce che la legittimità collettiva opera come punto di inflessione che trasforma, piuttosto che dissolvere, la tensione tra legittimità e posizionamento competitivo fino al raggiungimento di livelli sufficienti di legittimità. Al crescere del riconoscimento sociale, le imprese operanti in quel mercato tendono a modificare la loro azione competitiva, affiancando progressivamente la costruzione cooperativa con



strategie di differenziazione, sebbene l'appartenenza categoriale continui a conferire legittimità, generando una tensione strategica riconfigurata tra la conformità alle norme della categoria e la differenziazione necessaria per garantire il vantaggio competitivo. In nuce, il lavoro intende riorganizzare la letteratura esistente e frammentata in un framework integrato capace di identificare gli elementi che plasmano l'evoluzione dei mercati nascenti. All'uopo, tale studio rappresenta una sintesi strutturata sui mercati nascenti che possa fungere da riferimento per gli studiosi che si approcciano al tema, ma anche per i manager e gli imprenditori, affinché comprendano quali dinamiche supportino l'evoluzione di tali mercati nel tempo e riescano a cogliere elementi utili a una gestione efficace di tali dinamiche, ma anche con un intento precipuo di chiarificazione teorica e applicativa.

Metodologia. Al fine di predisporre un framework integrato della letteratura sui mercati nascenti (Torraco, 2005; Palmatier et al., 2018), si seguono le indicazioni offerte da Tranfield et al. (2003) per l'identificazione e la selezione degli articoli. La revisione dei contributi sui mercati nascenti consente di consolidare conoscenze frammentate e di costruire basi solide che possono condurre, in prospettiva, a nuove teorizzazioni (Torraco, 2005). Tale approccio appare particolarmente adatto allo studio dei mercati nascenti, poiché si tratta di un ambito caratterizzato da prospettive teoriche ed evidenze empiriche eterogenee e disperse, da cui discende la necessità di predisporre un framework integrato capace di delineare un quadro generale che, mappando i diversi aspetti studiati fin qui, consenta di orientare verso prospettive di ricerca futura (Palmatier et al., 2018). Considerato lo scopo dello studio e il panorama frammentato della ricerca sui mercati nascenti, a gennaio 2026 ci si è avvalsi del database Scopus, ampiamente adottato per le review della letteratura negli studi di management e imprenditorialità (Bartoloni & Ancillai, 2024). Questa scelta muove da due principali considerazioni: in primo luogo, Scopus fornisce una copertura completa delle riviste di fascia alta e, dunque, di alto impatto; in secondo luogo, esso presenta una robusta capacità di selezione e filtraggio dei documenti che supporta procedure di ricerca articolate e replicabili. In via preliminare, sono state condotte ricerche tese a identificare la terminologia più appropriata per cogliere i fenomeni legati ai mercati nascenti, dalle quali è emerso che il termine 'nascent market*' coglieva solo una parte, peraltro limitata, della letteratura sul tema. Questa prima indicazione riflette il fatto che gli studi centrali sui mercati nascenti adottano diverse terminologie — incluse anche descrizioni orientate al processo della formazione del mercato ('market* formation', 'build market*') e formulazioni a livello settoriale ('nascent industry') — facendo riferimento allo stesso concetto **o a** declinazioni simili. È stata sviluppata una stringa di ricerca booleana completa: "nascent market*" OR "nascent industry" OR "market* formation" OR "build market*" OR "nascent W/2 market*". L'operatore di prossimità 'W/2' (within 2 words) ha permesso di includere anche espressioni modificate (ad es. 'nascent drone market') e di preservare la coerenza semantica. Al fine di affinare l'analisi, migliorarne la rilevanza per gli studi manageriali e garantirne la replicabilità (Hüttinger et al., 2012), si è scelto di applicare filtri specifici per aree disciplinari, tipologia di documento e lingua, includendo tutti gli articoli e le review in inglese pubblicati nelle aree di Business, Management and Accounting. Conformemente all'obiettivo di privilegiare la rilevanza concettuale dei contributi, si segue il lavoro di Adams et al. (2016) nel non applicare soglie di impact factor per la selezione delle riviste, preferendo garantire una maggiore e più ampia copertura e mantenere il rigore scientifico attraverso l'esclusivo ricorso a pubblicazioni peer-reviewed indicizzate su Scopus. Si tratta di una scelta che tiene in considerazione la novità del dominio di ricerca sui mercati nascenti. La ricerca così condotta ha prodotto 251 risultati, coprendo il periodo dal 1981 al 2026, con una crescita significativa delle pubblicazioni a partire dal 2015. Sono stati inclusi i lavori che: (1) affrontavano esplicitamente il tema dei mercati nascenti, inclusi aspetti quali l'emergere, la formazione e/o lo sviluppo; (2) fornivano contributi teorici o empirici sulle condizioni generative, sui processi o sulle conseguenze dell'evoluzione dei mercati nascenti. Sono stati, ad esempio, esclusi i lavori che affrontavano il tema dei mercati maturi e solo tangenzialmente il tema dei mercati nascenti per poi focalizzarsi sui mercati maturi.

I contributi che rispettano i criteri di inclusione/esclusione sopra definiti sono stati letti ed esaminati seguendo un processo di codifica ancora in fieri iterativo e induttivo: le principali intuizioni sono state estratte mediante codifica aperta, progressivamente raffinate in categorie tematiche attraverso il confronto costante tra articoli. Laddove più contributi affrontavano fenomeni correlati, questi venivano poi sintetizzati al fine di identificare convergenze e lacune teoriche, fornendo la base delle due mappe processuali sviluppate nelle sezioni seguenti sulla costruzione del mercato e sulla legittimazione, indi integrate in un unico framework. Tale integrazione risulta necessaria onde restituire una visione sistematica del fenomeno.

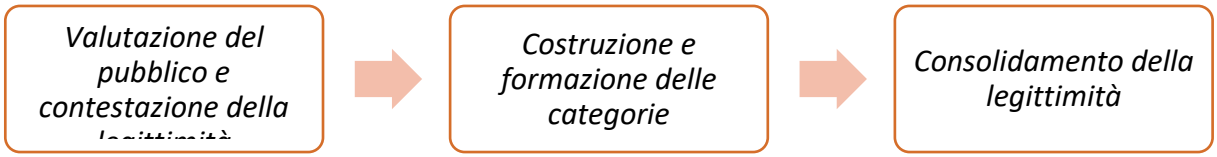
Risultati. Dall'analisi della letteratura si sviluppano due diverse mappe della letteratura. La prima mappa (Figura 1) è stata sviluppata codificando induttivamente le condizioni generative, i processi di strutturazione e le traiettorie di sviluppo del mercato con un focus sulla prospettiva competitiva.

Figura 1: Mappa della letteratura sulla costruzione dei mercati: una prospettiva competitiva

Condizioni generative del nuovo mercato. I mercati nascenti emergono in condizioni generative che simultaneamente o separatamente abilitano la costruzione del mercato. Tali condizioni generative comprendono tutti quei fattori che concorrono a formare il processo di creazione di un mercato nascente, vale a dire: la generatività tecnologica, le incertezze della domanda e quelle tecnologiche, l'ambiguità e l'hype imprenditoriale.

La generatività tecnologica riguarda l'insieme di tutte le condizioni dirompenti e le profonde trasformazioni capaci di innescare un cambiamento radicale dell'intero paradigma settoriale (Anderson & Tushman, 1990; Christensen, 2003, in Golicic & Sebastiao, 2011). A partire da questa innovazione tecnologica, che costituisce la condizione generativa primaria (Guerra et al., 2025; Santos & Eisenhardt, 2009), si innescano successive evoluzioni tecnologiche che aprono la strada ad applicazioni destinate a differenti segmenti di clientela, e che danno origine a una pluralità di mercati nascenti. Questi ultimi si manifestano in sequenza temporale, con strutture settoriali ancora non definite e definizioni di prodotto poco chiare. Tale condizione costringe le imprese a gestire una duplice traiettoria evolutiva, sia tecnologica sia della domanda, dal momento che l'obiettivo finale non è chiaro (Wang & Seidle, 2020).

L'incertezza di mercato e tecnologica rappresentano entrambe fattori cruciali per le imprese che operano in contesti in cui gli standard tecnologici non sono ancora definiti, le caratteristiche della domanda — in termini di bisogni e aspettative — sono poco chiare e le soglie minime di performance, unitamente al ritmo e alla direzione tecnologica, rimangono imprevedibili (Guerra et al., 2025; Wang & Seidle, 2020; Hilkamo et al., 2021).



L'ambiguità, intesa quale assenza di strutture di significato condiviso che definiscano che cosa sia il mercato, chi vi appartenga e cosa costituisca una partecipazione legittima (Santos & Eisenhardt, 2009; Rindova et al., 2010), si distingue concettualmente dall'incertezza, che attiene all'incapacità di assegnare probabilità ai risultati futuri.

Infine, l'hype imprenditoriale opera come meccanismo di sensegiving orientato al futuro, capace di generare crescente attenzione e supporto da parte degli stakeholder nonostante l'incertezza prevalente, risultando particolarmente critico nel superare la liability of newness dei nuovi venture (Logue & Grimes, 2022), sostenendo la mobilitazione iniziale delle risorse.

I processi di strutturazione. Tali processi si riferiscono alle attività attraverso cui gli attori del mercato riducono progressivamente l'indeterminatezza che caratterizza i mercati nascenti — sia cognitiva, riguardante cos'è il mercato e come funziona, sia relazionale, riguardante chi sono gli attori rilevanti e come si coordinano: due meccanismi interconnessi che trasformano i mercati nascenti da una condizione di ambiguità iniziale verso realtà sempre più strutturate. Tra i processi di strutturazione, la costruzione della conoscenza e la sperimentazione consentono alle imprese di navigare l'incertezza attraverso la verifica sistematica delle varianti di prodotto, l'esplorazione dei casi d'uso e lo sviluppo di asset complementari (Guerra et al., 2025; Wang & Seidle, 2020). Le imprese osservano i concorrenti attraverso il vicarious learning e si impegnano direttamente con i clienti attraverso accordi di beta testing per perfezionare l'offerta. Simultaneamente, lo scaffolding culturale e materiale (ovvero la costruzione di framework regolatori, organizzazioni intermediarie e strumenti di mercato condivisi) trasforma i mercati nascenti da possibilità concettuali in sistemi di scambio funzionanti (Casasnovas & Ferraro, 2022), allorché tali elementi raggiungono una sufficiente stabilizzazione. Un secondo elemento, altrettanto critico, è rappresentato dalla struttura relazionale e di rete. Gli imprenditori impiegano strategie di alleanza per gestire le minacce competitive provenienti da imprese dominanti nei mercati adiacenti, cooptando i potenziali concorrenti attraverso accordi di revenue-sharing, investimenti azionari e antileader positioning (Santos & Eisenhardt, 2009). I modelli di business in rete guidano il modo in cui gruppi di imprese creano valore collettivamente, mentre il multimarket contact plasma il modo in cui le imprese sviluppano e contestano i frame tecnologici (Bankel & Govik, 2024; Hsu & Cohen, 2022).

Le traiettorie dei mercati nascenti. Infine, le traiettorie che i mercati nascenti seguono nel tempo possono consolidarsi in un mercato stabile quando le aspettative dei clienti sulle funzionalità del prodotto diventano chiare e si sviluppano i asset complementari (ovvero le risorse e infrastrutture di supporto, come canali distributivi, standard tecnici e partnership commerciali, necessarie alla commercializzazione su larga scala; Guerra et al., 2025). In alternativa, il mercato può non riuscire ad emergere: quando gli attori chiave provenienti da settori diversi non raggiungono un accordo sull'architettura del nuovo mercato (ovvero su chi controlla il cliente finale, quali standard tecnici adottare e come distribuire il valore tra gli attori) si innesca un ciclo di rinvio degli investimenti che impedisce la commercializzazione su larga scala (Ozcan & Santos, 2015; Guerra et al., 2025). Sennonché, si parla anche di speciazione del mercato quando un mercato nascente inizialmente unificato si divide in mercati autonomi con identità, pratiche e infrastrutture distinte (Casasnovas & Ferraro, 2022). Questo processo emerge in presenza di due specifiche condizioni strutturali: field overlap, che si verifica quando il mercato nascente emerge a seguito dell'intersezione di più campi preesistenti, ciascuno con logiche distinte che spingono il mercato in direzioni diverse; e il material anchoring, che si verifica quando le strutture materiali sviluppate nelle prime fasi del mercato — ovvero le pratiche condivise, le organizzazioni intermediarie e i quadri regolatori a supporto dell'attività di mercato — attraggono risorse significative e consolidano una posizione di riferimento nel campo. Ciò rende difficile l'affermazione di modelli alternativi, favorendo la coesistenza di mercati separati piuttosto che la convergenza verso un unico disegno (Casasnovas & Ferraro, 2022). La speciazione si attiva quando gli attori coinvolti nel processo di costruzione del mercato, valutando i risultati concreti delle pratiche e delle infrastrutture sviluppate collettivamente, concludono che queste non stanno risolvendo i problemi che li avevano motivati a parteciparvi e, in presenza di sottogruppi con obiettivi sufficientemente divergenti, il mercato tende a frammentarsi in entità distinte

(Casasnovas & Ferraro, 2022). Infine, la struttura del settore e le dinamiche competitive possono emergere dall'interazione tra le strategie deliberate delle imprese dominanti (Bradley & Kolev, 2023) e le risposte adattive delle altre imprese, che osservano il comportamento dei concorrenti per ridurre l'incertezza strategica (Wang & Seidle, 2020), delineate e, per tal ragione, d'uopo considerate in chiave sistemica.
La seconda mappa della letteratura, rappresentata in Figura 2, organizza la ricerca esistente sulla legittimazione nei mercati nascenti in tre fasi che riflettono una progressione temporale: i mercati affrontano inizialmente la contestazione del pubblico su ciò che è legittimo; successivamente, gli attori costruiscono attivamente un'identità collettiva condivisa e definiscono i confini della categoria (ovvero i criteri che stabiliscono chi ne fa parte e secondo quali pratiche); infine, la legittimità si consolida, sebbene non senza generare trade-off intrinseci tra la crescita del mercato e la coerenza dell'identità, dacché tali dinamiche evolvono congiuntamente.

La valutazione del pubblico e la contestazione della legittimità. La legittimazione delle nuove categorie di mercato include processi in cui le imprese produttrici si impegnano nel sensegiving attraverso etichette, frame e narrazioni affinché le nuove identità diventino intelligibili, comprensibili e attraenti, mentre i pubblici si impegnano nel sensemaking per valutare le rivendicazioni organizzative (Lounsbury & Glynn, 2001; Navis & Glynn, 2010, in Lee et al., 2017). La legittimità può essere raggiunta attraverso tre percorsi: (1) legittimazione retrospettiva: la credibilità si costruisce gradualmente man mano che i prodotti dimostrano la propria utilità attraverso prove accumulate, ma rimane largamente inaccessibile ai primi entranti, data l'assenza di un track record storico; (2) legittimazione associativa: la credibilità proviene da domini legittimi adiacenti; e (3) legittimazione prospettica: la credibilità emerge attraverso narrazioni orientate al futuro, collegando nuove offerte a esiti futuri desiderabili prima che emergano prove materiali (Harmon et al., 2023). Quest'ultimo percorso rappresenta la via più critica per i mercati nascenti, chiaramente caratterizzati da elevata incertezza. Inoltre, i mercati nascenti sperimentano anche la contestazione della legittimità, poiché vari attori avanzano rivendicazioni in competizione relative ai confini della categoria e alle pratiche appropriate, onde tale dinamica si intensifica quando più pubblici presentano aspettative contraddittorie (Lee et al., 2017).

Costruzione e formazione delle categorie. Gli imprenditori ricorrono proattivamente a meccanismi per costruire e consolidare la propria identità di mercato (adottando template familiari ma sufficientemente distanti, diffondendo storie vivide e segnalando la leadership) dimostrandosi così più propensi a diventare referenti cognitivi nei mercati che rivendicano, raggiungendo il dominio cognitivo attraverso un processo di sensegiving (Santos & Eisenhardt, 2009). A livello collettivo, i produttori si impegnano in comportamenti di legittimazione per demarcare i confini categoriali attorno all'identità condivisa, utilizzando storie, comunicati stampa e codici per stabilire identità prototipiche (Lee et al., 2017), all'uopo rafforzando la riconoscibilità della categoria. Emerge una tensione centrale: i pionieri che impongono un rigido isomorfismo identitario tra i membri possono garantire la coerenza della categoria di mercato, ma al costo di una crescita limitata e della marginalità, donde deriva un equilibrio instabile tra coerenza e sviluppo (Lee et al., 2017).

Il consolidamento della legittimità. Il consolidamento della legittimità è critico e richiede che i mercati nascenti evolvano da contesti di elevata ambiguità verso forme più stabili e socialmente accettate. Dopo che una soglia di legittimità è stata raggiunta, gli attori del mercato si concentrano sul differenziare le proprie organizzazioni e sul ritagliarsi una nicchia vitale, confrontandosi con altri produttori per raggiungere posizioni competitive stabili (Navis & Glynn, 2010). Il processo di legittimazione si completa quando le comprensioni derivanti dalle fasi precedenti diventano compiute (Harmon et al., 2023). Tuttavia, la legittimità rappresenta una lama a doppio taglio: mentre una più ampia accettazione sociale può favorire la crescita della categoria, i comportamenti di ricerca della legittimità generano tensioni tra i nuovi pubblici e l'identità collettiva dei membri originali, potenzialmente separando la categoria dal suo ethos fondante (Lee et al., 2017), per l'appunto alterandone i confini simbolici. Inoltre, il consolidamento della legittimità non è irreversibile — la perdita della legittimità pubblica può innescare la perdita del supporto delle politiche e il declino del mercato (Chung & Kaynak, 2025), indi evidenziando la natura dinamica e contingente di tale processo.
Mentre la prima mappa relativa alla costruzione del mercato da una prospettiva competitiva (figura 1) suggerisce come le imprese sviluppino progressivamente conoscenze, relazioni e strutture settoriali in condizioni di elevata incertezza, la seconda mappa (figura 2) è incentrata sul ruolo della legittimazione e illustra come la legittimità collettiva venga costruita, contestata e consolidata nel tempo. L'integrazione tra la prima e la seconda mappa in un unico framework rivela una dinamica temporale critica: la legittimazione non precede semplicemente la costruzione del mercato come prerequisito, ma co-evolve con essa in modo ricorsivo, e la sua accumulazione genera un cambiamento qualitativo nella natura delle sfide che le imprese devono affrontare. In particolare, man mano che la legittimità collettiva si avvicina e supera un punto di inflessione (Navis & Glynn, 2010; Ozcan & Santos, 2015), il problema strategico centrale si trasforma: la priorità si sposta dalla costruzione cooperativa della categoria, in cui le imprese beneficiano della legittimazione collettiva del

mercato, alla differenziazione competitiva, in cui devono ritagliarsi posizioni distinte all'interno di uno spazio di mercato ormai riconosciuto. Tale tensione riguarda il modo in cui le imprese si conformano alle norme categoriali emergenti, preservando al contempo la distintività organizzativa (Lee et al., 2017). Dopo il punto di inflessione, la tensione si inverte: le imprese non si interrogano più su come costruire collettivamente la legittimità della categoria, bensì su come mantenere l'appartenenza categoriale, che continua a conferire legittimità, differenziandosi al tempo stesso in misura sufficiente a garantire un vantaggio competitivo, di poi ricalibrando le proprie strategie. Pertanto, tale dinamica evidenzia il carattere evolutivo e non lineare del rapporto tra legittimità e competizione nei mercati nascenti

Limitazioni della ricerca. Il presente studio presenta alcune limitazioni. In primo luogo, il framework processuale sviluppato si fonda su una sintesi concettuale della letteratura esistente e non sono stati ancora sottoposti a corroborazione empirica: in particolare, la proposta teorica relativa alla riconfigurazione della tensione tra appartenenza categoriale e differenziazione competitiva nella fase post-inflection point costituisce un contributo originale che necessita di ulteriore scrutinio empirico. In secondo luogo, l'analisi della letteratura è ancora in fieri e necessita di un double check di tutti gli autori. Sebbene questa pratica possa ridurre i potenziali bias interpretativi degli autori, essi non sono completamente eliminabili, risultando peraltro intrinseci a ogni processo di sintesi teorica e, nondimeno, meritevoli di attenta considerazione.

Implicazioni manageriali. Il framework integrativo proposto offre ai manager e agli imprenditori che operano in contesti di mercato nascente uno strumento per riconoscere connessioni tra variabili che, osservate separatamente, risulterebbero difficilmente interpretabili. Le condizioni generative identificate non rappresentano solamente degli elementi che caratterizzano il mercato nascente, ma costituiscono leve strategiche attraverso cui si gioca la rivalità inter-impresa prima ancora che il mercato prenda forma e si consolidi. Comprendere queste condizioni consente al manager di identificare in quale fase del processo evolutivo si trova il proprio contesto competitivo e, di conseguenza, su quali meccanismi sia più opportuno agire, all'uopo orientando le decisioni strategiche.

Un'implicazione centrale emerge dalla struttura tripartita della mappa in figura 1: nei mercati nascenti, la rivalità competitiva non si esercita primariamente sul prodotto o sul servizio, ma sui meccanismi di costruzione del mercato stesso. Le attività di strutturazione della conoscenza, di sperimentazione, di costruzione delle relazioni inter-impresa e di scaffolding istituzionale rappresentano elementi che caratterizzano la strategia competitiva. Il manager che riconosce questo punto può riorientare le proprie priorità: investire nella costruzione della categoria, nella definizione dei confini del mercato e nella cooptazione di attori chiave non è un costo, ma la forma primaria di posizionamento competitivo nella fase nascente, donde deriva un vantaggio anticipato.

Infine, il framework aiuta il manager a comprendere quale tipo di player voglia essere. Le traiettorie di sviluppo di un mercato nascente (consolidamento, speciazione, fallimento del mercato) non sono determinate esclusivamente dalla tecnologia o dalla domanda, ma dalla capacità degli attori di costruire framework cognitivi condivisi, di allineare scaffolding materiale e culturale, e di navigare i trade-off tra ricerca di legittimità, coerenza dell'identità e posizionamento competitivo. Questa lettura apre una prospettiva strategica concreta: il manager di un mercato nascente non è solo un competitor in un'arena già definita, ma un co-costruttore dell'arena stessa. Riconoscere questo ruolo - e agire di conseguenza - rappresenta la principale implicazione pratica che il framework consente di derivare, al fine di guidare l'azione strategica.

Originalità del paper. Il contributo originale di questo studio risiede in due piani complementari. Sul piano della sintesi, le due mappe organizzano in modo coerente i principali filoni della letteratura sui mercati nascenti in una struttura tripartita, con un contenuto sostantivo che emerge interamente dalla nostra analisi della letteratura sui mercati nascenti. Sul piano del contributo teorico, tuttavia, la giustapposizione tra i due framework supporta una nuova concettualizzazione della legittimità collettiva come punto di inflessione che riconfigura — piuttosto che eliminarla — la tensione tra appartenenza categoriale e differenziazione competitiva. Questa riconfigurazione dei trade-off è invisibile quando i due framework processuali vengono letti separatamente ed emerge solo dalla loro integrazione, costituendo il contributo teorico primario di questa revisione.

Quantifying Ethics: The E3S Model for Student Entrepreneurship Education

MARIACARMELA PASSARELLI[1], ALESSANDRA SCROCCARO[2], GIUSEPPE BONGIORNO[3]

Abstract. *In an era defined by climate change, social inequality, and shifting institutional trust, higher education systems must evolve beyond traditional knowledge transfer to cultivate responsible, value-driven individuals. Entrepreneurship education, specifically Student Entrepreneurship Educational Programs (SEEPs), represents a critical frontier for this transformation. SEEPs are uniquely positioned to foster "relational ethics" and "social learning" by combining practical business experience with social value creation. However, a significant gap remains: how do we measure the ethical impact of these programs? Traditional metrics—such as revenue, scalability, or business plan robustness—fail to capture the internalization of ethical principles. This work-in-progress paper addresses the central research question: Is it possible to propose a dynamic tool for measuring ethics in SEEPs that incorporates individual, team, and ecosystem levels? To answer this, we conducted a non-systematic literature review considering the General Ethics Scales, the Managers' Ethics Scales, and the Entrepreneurs' Ethics Scales. Starting from that, we propose the Ethical Entrepreneurial Education Scorecard (E3S). The study adopts an exploratory sequential design in the context of the ENACTUS program as the ideal pilot for validating the E3S. For educators, it provides a roadmap for ethics-focused pedagogy. For universities, it offers a tool to align global sustainability standards and demonstrate social impact to stakeholders. For policymakers, the model suggests new standards for national quality assurance that reward the creation of conscientious global citizens rather than just the number of startups launched.*
Keywords: *Entrepreneurship Education; Ethics Measurement; SEEPs; E3S Scorecard; Social Impact; ENACTUS*

Framing of the research. Amidst an intensifying global crisis from ecological instability to the fracture of institutional trust, the mandate for higher education has shifted from mere knowledge dissemination toward the cultivation of "value-driven" agency (Malone, 2015; Ul Hassan et al., 2025). This pedagogical evolution is most critical within entrepreneurship education, which is increasingly tasked with developing individuals capable of navigating systemic complexity with ethical resolve (Passarelli & Bongiorno, 2025). Rather than prioritizing the output of profit-centric graduates, institutions are now required to foster competencies that catalyze inclusive and sustainable societal transitions (Redman & Wiek, 2021).

Student Entrepreneurship Educational Programs (SEEPs) represent a transformative nexus where experiential learning converges with social value creation (Duval-Couetil, 2013; Kassean et al., 2015). These programs serve as incubators for a new cohort of "ethical entrepreneurs" change agents who internalize relational ethics and care through collective social learning (Dacin et al., 2010; Elmes et al., 2012). Because SEEPs function across micro, meso, and macro scales, they provide a unique longitudinal laboratory for examining ethics as both an individual virtue and a systemic practice.

Consequently, this conceptual paper investigates a pivotal research question: Is it possible to design a dynamic assessment tool for SEEPs that integrates individual, team, and ecosystem-level ethical dimensions? To address this, we propose a multidimensional, context-sensitive framework that challenges the hegemony of traditional metrics.

While existing literature offers various quantitative instruments to evaluate moral judgment and ethical reasoning (Pathak & Muralidharan, 2020), these often overlook the "lived" and contingent nature of morality. Quantitative methods provide essential standardization but frequently reduce the density of ethical decision-making to static variables, risking the omission of cultural nuance and the distortion of results through social desirability bias (Islam, 2022). Furthermore, ethical maturation is an inherently fluid process, shaped by emotional triggers, interpersonal friction, and iterative reflection—elements that remain largely invisible to survey-based scales.

We therefore argue for a hybrid methodological approach that synthesizes the objective rigor of quantitative data with the descriptive depth of qualitative inquiry (Heyler et al., 2016; Casali & Perano, 2021). Ethics within the entrepreneurial journey cannot be audited via a simplified checklist; it must be mapped as a developmental trajectory deeply embedded in emotional, relational, and institutional contexts. By framing ethics as a multifaceted construct, the proposed model seeks to capture the authentic moral evolution of students as they navigate the complexities of the modern entrepreneurial landscape.

Traditional entrepreneurship indicators—primarily revenue growth, market scalability, and the technical robustness of business plans—insufficiently capture the transformative participant experiences and the substantive social value generated by educational programs (Saebi et al., 2019). While specialized instruments like the primary school "sense of belonging to ethical values" scale (Yardimciel & Kılıç, 2023) and the Ethical Leadership Scale (Sen & Gocen, 2021) have been validated, a significant research gap persists regarding the application of these values across diverse educational and

organizational landscapes. To authentically evaluate the impact of ethics-centric entrepreneurial pedagogy, next-generation assessment tools must account for the longitudinal evolution of personal values, the deep internalization of moral principles, and the development of systems-thinking competencies (Douglas et al., 2001; Vázquez-Parra et al., 2022; Passarelli et al., 2025).

To contextualize the current state of measurement within SEEPs, a non-systematic literature review was undertaken (Aria and Cuccurullo, 2017). This approach was particularly suitable for the aims of the present study. Specifically, it enabled the development of a broad and up-to-date overview of ethics measurement scales within the fields of management and entrepreneurship, while avoiding the limitations associated with the rigid inclusion and exclusion criteria that typically characterize systematic reviews. Such flexibility is especially valuable in an emerging and conceptually heterogeneous area of research, as it allows the incorporation of recent and relevant contributions that may not be captured through more restrictive review procedures. In addition, this approach facilitates the exploration of diverse theoretical perspectives and methodological traditions, thereby supporting a more comprehensive and nuanced understanding of the phenomenon under investigation. The review was conducted in Web of Science (WoS) and initially using a very basic query, which generated a first set of 3653 academic contributions. However, the preliminary screening of the literature revealed the presence of heterogeneous streams of research, thus indicating the need to broaden the scope of the inquiry. More specifically, it became evident that the analysis should not be limited to the entrepreneurial domain alone, but should also encompass the managerial sphere and, more broadly, the ethical dimensions associated with the principal actors operating within firms. Accordingly, the initial search terms were subsequently combined with additional keywords such as "management," "manager," and "entrepreneur" to identify a broader, more coherent, and analytically relevant body of literature ((TS =(ethic* AND (scale* OR instrument* OR measure* OR measurement*) AND (business OR management OR firm* OR organization* OR entrepreneur*))).

Thus, the analysis of the papers allows us to select some specific papers that allowed us to identify three distinct typologies of ethics scales (see Table 1):

- General Ethics Scales: Universal instruments addressing ethical evaluation without actor-specific constraints.
- Managers' Ethics Scales: Frameworks designed to quantify ethicality and moral reasoning within managerial roles.
- Entrepreneurs' Ethics Scales: Specialized research developing metrics for entrepreneurial virtues and social orientation.

Table 1. The three major typologies of Ethics Scales in the literature

General Ethics Scale					
Title	***Authors***	***Year***	***Journal***	***Scale Description***	***Conceptual Aspect***
Some Initial Steps toward Improving the Measurement of Ethical Evaluations of Marketing Activities	*R. Eric Reidenbach & Donald P. Robin*	*1988*	*Journal of Business Ethics, Volume 7, pages 871–879*	*"Multidimensional Ethics Scale" (MES), composed of 5 factors summarizing 29 items: (1) Justice scale – 3 items; (2) Relativist scale – 5 items; (3) Egoism scale – 7 items; (4) Utilitarian scale – 9 items; (5) Deontological scale – 5 items.*	*Using the framework of Pluralistic Moral Philosophy, it rejects the use of a single global philosophy, suggesting that individuals use a combination of morals. It evaluates decisions through deontology, utilitarianism, relativism, egoism, and justice.*
A Multidimensional Scale for Measuring Business Ethics: A Purification and Refinement	*Randall S. Hansen*	*1992*	*Journal of Business Ethics, Volume 11, pages 523–534*	*Scale composed of 4 factors totaling 16 items: (1) Broad ethical judgment – 8 items; (2) Deontological judgment – 2 items; (3) Social contract judgment – 2 items; (4) Teleological judgment (includes elements of egoism and utilitarianism) – 4 items.*	*Through Multidimensional Scale Refinement, it refines the measurement of ethics by including a specific dimension of social contract, assessing whether an action violates unwritten promises or commitments to society.*
Judging the morality of business practices: The influence of personal moral philosophies	*Donelson R. Forsyth*	*1992*	*Journal of Business Ethics, Volume 11, pages 461–470*	*(1) Idealism scale – measures concern for others' well-being. Example: 'One should never intentionally harm another person, even to a small degree.' (2) Relativism scale – assesses rejection of universal moral principles in favor of context-based ethics. Example: 'What is ethical varies from one situation to another.'*	*Through a Taxonomy of Ethical Ideologies, it classifies personal moral philosophies on two dimensions: Idealism (concern for the well-being of others) and Relativism (skepticism toward universal rules).*

The perceived role of ethics and social responsibility: A scale development	*Anusorn Singhapakdi, Scott J. Vitell, Kumar C. Rallapalli, Kenneth L. Kraft*	*1996*	*Journal of Business Ethics, Volume 15, pages 1131–1140*	*PRESOR Scale, with 3 factors comprising 13 items: (1) 'Social Responsibility and Profitability' – 4 items including 'If company survival is at stake, ethics and social responsibility should be ignored'; (2) 'Long-term gains' – 6 items; (3) 'Short-term gains' – 3 items including 'If shareholders are unhappy, nothing else matters.'*	*Based on the Determinants of Organizational Effectiveness, he proposes that the perception of the importance of ethics (PRESOR) is a critical determinant in recognizing ethical issues and guiding decision-making toward social responsibility.*
Proposal for a Measurement Scale of the Ethical Climate in Business: A Study in the Area of B-to-B Selling	*Laure Lavorata*	*2007*	*Recherche et Applications en Marketing (English Edition), Vol. 22(1), pages 1–23*	*Ethical climate measurement scale with 14 items across 4 dimensions: (1) Business ethics procedures – 5 items; (2) Peer behavior – 3 items; (3) Sales practices – 3 items; (4) Compensation plan – 3 items.*	*Using Ethical Climate for Salesforce, adapt the concept of ethical climate to the B2B sector, highlighting how pressure to perform and compensation plans influence perceptions of moral standards.*
Measuring Corporate Social Responsibility: A Scale Development Study	*Duygu Turker*	*2008*	*Journal of Business Ethics, Volume 85, pages 411–427 (2009)*	*CSR scale includes 4 factors summarizing 17 items: (1) CSR toward social and non-social stakeholders – society, environment, future generations, NGOs; (2) CSR toward employees – e.g., 'Management decisions are generally fair'; (3) CSR toward customers – e.g., 'Our company respects consumer rights beyond legal requirements'; (4) CSR toward government – e.g., 'Our company complies with legal regulations in full and timely manner.'*	*Using Stakeholder Theory, it defines CSR as corporate behavior that aims to positively influence various stakeholders, going beyond mere economic interests.*
The Corporate Ethical Virtues Scale: Factorial Invariance Across Organizational Samples	*Maiju Kangas, Taru Feldt, Mari Huhtala & Johanna Rantanen*	*2013*	*Journal of Business Ethics, Volume 124, pages 161–171 (2014)*	*Corporate Ethical Virtues Scale (CEV), includes 8 dimensions (58 items): (1) Clarity – 'The organization clarifies how to obtain necessary authorizations'; (2) Supervisor congruence – 'My supervisor sets a good example in ethical behavior'; (3) Senior management congruence – 'Senior leaders reflect shared norms and values'; (4) Feasibility – 'I don't have enough time to act responsibly'; (5) Supportability – 'There is mutual trust in my work environment'; (6) Transparency – 'If a colleague does something wrong, my manager will find out'; (7) Discussability – 'There is room to discuss unethical behavior in my workplace'; (8) Sanctionability – 'Ethical conduct is rewarded in my workplace'.*	*Using Aristotelian Virtues in Organizations, identify eight "corporate virtues" that act as organizational traits to stimulate ethical conduct among members.*
Ethics scale for management					
Title	***Authors***	***Year***	***Journal***	***Scale Description***	***Conceptual Aspect***
Toward the development of a multidimensional scale for improving evaluations of business ethics	*R. Eric Reidenbach & Donald P. Robin*	*1990*	*Journal of Business Ethics, Volume 9, pages 639–653*	*The scale consists of 3 dimensions: (1) Broad moral equity dimension (4 items: Right/wrong, Fair/unfair, acceptable/unacceptable for my family, Morally/not morally right); (2) Relativistic dimension (2 items: Traditionally acceptable/unacceptable, Culturally acceptable/unacceptable); (3) Contractual dimension (2 items: Violates/does not violate an implicit promise, Violates/does not violate an unwritten contract).*	*Seeking to refine the Multidimensional Ethics Scale, Distilla distills ethical judgment into three fundamental dimensions: moral equity (justice), relativism (cultural norms), and contractualism (mutual obligations).*
An investigation of the moral reasoning of managers	*Dawn R. Elm & Mary Lippitt Nichols*	*1993*	*Journal of Business Ethics, Volume 12, pages 817–833*	*Uses 3 scales: (1) Defining Issues Test (DIT) – assesses moral reasoning level based on Kohlberg's theory, evaluating post-conventional moral thinking; (2) Ethical Climate Questionnaire (ECQ) – 26 items across 3 dimensions: Egoistic, Utilitarian, Principle-based climates; (3)*	*Using the Interactionist Perspective, they argue that moral reasoning (Kohlberg's stages) is a function of the interaction between individual attributes (self-monitoring) and*

				Snyder's Self-Monitoring Scale – measures personal orientation to internal vs. external behavioral standards.	*situational attributes (perceived ethical climate).*
The Perceived Role of Ethics and Social Responsibility: An Alternative Scale Structure	*John M. Etheredge*	*1999*	*Journal of Business Ethics, Volume 18, pages 51–64*	*Uses Singhapakdi's PRESOR Scale, with 2 primary factors: (1) Importance of ethics and social responsibility (5 items, e.g., 'Moral values are irrelevant to business'); (2) Subordination of ethics and social responsibility (4 items, e.g., 'Shareholders' primary interest is maximum return').*	*Through the Cultural Theory of Perception, examine how cultural differences (e.g., Hong Kong vs. the US) influence the structure of ethical perception. Distinguish between the intrinsic importance of ethics and its subordination to profitability or survival objectives.*
A Multidimensional Ethics Scale for Indian Managers' Moral Decision Making	*Seema Gupta*	*2010*	*JBO - Electronic Journal of Business Ethics and Organization Studies, Vol. 15 (1)*	*Adapted from Reidenbach & Robin's MES (1988). Factor analysis revealed: Scenario 1: four factors – Moral equity, Egoism, Utilitarianism, Contractualism; Scenario 2: three factors – Moral equity, Egoism, Utilitarianism. Confirms the relevance of justice, contractualism, relativism, utilitarianism, and egoism in managerial ethical decision-making.*	*It analyzes how managers integrate five moral philosophies: justice, deontology (contractualism), relativism, utilitarianism, and egoism. A central aspect is the identification of a distinct construct of egoism that emerges as a critical factor in the Indian context.*
Cultural values and management ethics: A 10-nation study	*Terence Jackson*	*2001*	*Human Relations, Vol. 54(10), pages 1267–1302*	*Scale includes 3 categories of ethical relationships in management: (1) External stakeholders – 2 items (e.g., 'Giving gifts/favors for preferential treatment'); (2) Organizational loyalty – 6 items (e.g., 'Disclosure of confidential information'); (3) Group loyalty – 2 items (e.g., 'Taking credit for others' work').*	*Use Hofstede's dimensions (individualism-collectivism and uncertainty) to explain different attitudes toward the "gray areas" of day-to-day management, emphasizing the value of socio-cultural aspects.*
A Scale to Assess Ethical Leadership of Indian Private and Public Sector Managers	*Rooplekha Khuntia & Damodar Suar*	*2004*	*Journal of Business Ethics, Volume 49, pages 13–26 (2004)*	*Ethical Leadership Scale (ELI), 22 items across 2 main dimensions: (1) Empowerment – 12 items on leaders enhancing subordinates' self-efficacy through inclusion and support; (2) Motive and Character – 10 items on altruism, integrity, openness to criticism, and consistency between words and actions.*	*It integrates the altruistic motivation of the leader with their strategies of influence. It defines ethical leadership through the empowerment of subordinates and the moral character of the leader in a context of transformational leadership.*
Ethics scale for entrepreneurship					
Title	***Authors***	***Year***	***Journal***	***Scale Description***	***Conceptual Aspect***
The Ethical Context of Entrepreneurship: Proposing and Testing a Developmental Framework	*Michael H. Morris, Minet Schindehutte, John Walton & Jeffrey Allen*	*2002*	*Journal of Business Ethics, Volume 40, pages 331–361*	*The measurement scale used by the authors is based on a combination of: (1) Locus of control: perception of control over outcomes, measured using a modified version of Rotter's scale (6 items); (2) Achievement motivation: level of drive to achieve success, measured using a subscale from the Entrepreneurial Attitude Orientation (EAO) scale; (3) Tolerance of ambiguity: ability to manage uncertainty, measured using Budner's scale (16 items); (4) Machiavellianism: tendency to manipulate others to achieve goals, measured using the Mach IV scale; (5) Composite scales: Sophistication scale (7 items), Scenarios scale (ethical situations), and Satisfaction scale (ethical program satisfaction).*	*Within the Ethical Development Framework, they analyze how the ethical climate evolves throughout the life cycle of the company. They distinguish between explicit structures (formal, compliance with rules) and implicit structures (informal, based on integrity and core culture).*
The Development of a Virtue Ethics Scale	*Kevin J. Shanahan & Michael R. Hyman*	*2003*	*Journal of Business Ethics, Volume 42, pages 197–208*	*Virtue Ethics Scale (VES) includes 6 factors: (1) Empathy – awareness and sensitivity to others' needs; (2) Protestant Work Ethic – individualism, responsibility, and belief in equal opportunity; (3) Piety – moral emotions like shame and guilt; (4) Respect – openness to dissenting views; (5) Reliability – trustworthiness; (6)*	*Based on the belief that ethics reside in the character of the individual, drawing on Aristotelian Virtue Ethics, it identifies specific traits such as empathy (caring for others), reliability, and incorruptibility*

				Incorruptibility – honor, honesty, and integrity, key traits for leaders.	*as preferred traits in the business world.*
Ethical leadership: A social learning perspective for construct development and testing	*Michael E. Brown, Linda K. Treviño & David A. Harrison*	*2004*	*Organizational Behavior and Human Decision Processes, Volume 97, Issue 2, July 2005, Pages 117–134*	*Ethics Leadership Scale includes 10 items such as: (1) listening to employees, (2) disciplining unethical behavior, (3) living ethically, (4) caring for employee interests, (5) fairness, (6) trust, (7) discussing ethics, (8) modeling ethical conduct, (9) emphasizing ethical processes as well as results, and (10) asking 'what is the right thing to do?'*	*Using the framework of Social Learning Theory, he proposes that ethical leadership depends on the perception of the leader as an attractive and legitimate role model. He focuses on moral management through the communication of values and the reinforcement of ethical behavior.*
The Impact of Moral Intensity and Desire for Control on Scaling Decisions in Social Entrepreneurship	*Brett R. Smith, Geoffrey M. Kistruck & Benedetto Cannatelli*	*2014*	*Journal of Business Ethics, Volume 133, pages 677–689 (2016)*	*Multidimensional scale based on moral intensity, including: (1) Magnitude of consequences; (2) Social consensus; (3) Probability of effect; (4) Temporal immediacy; (5) Proximity; (6) Concentration of effect.*	*Using Moral Intensity Theory, examine how the perception of a problem's intensity (magnitude of consequences, social consensus, proximity) influences decisions to increase social impact.*
Individual social entrepreneurship orientation: towards the development of a measurement scale	*Mir Shahid Satar & Saqib Natasha*	*2019*	*Asia Pacific Journal of Innovation and Entrepreneurship, Vol. 13, Issue 1, pages 49–72*	*Individual Social Entrepreneurship Orientation Scale (ISEO) includes 4 dimensions: (1) Social passion – e.g., 'I explicitly focus on creating social value'; (2) Innovativeness – 4 items; (3) Proactiveness – 3 items, e.g., 'I plan projects in advance'; (4) Risk-taking – 3 items.*	*Based on Individual Social Entrepreneurial Orientation Adapts classic entrepreneurial orientation (innovation, risk, proactivity) to the social context. Introduces Social Passion as an individual drive to alleviate the suffering of others.*
Organizational social entrepreneurship: scale development and validation	*Merie Kannampuzha & Kai Hockerts*	*2019*	*Social Enterprise Journal, Vol. 15, Issue 3, pages 290–319*	*Organizational Social Entrepreneurship Scale (OSE) includes: (1) Social change intent: 'social mission' (2 items), 'change enacted' (4 items); (2) Commercial activities: 'earned income' (4 items), 'paid employees' (2 items); (3) Inclusive governance: 'democratic decision-making' (4 items), 'stakeholder participation' (4 items), 'social impact' (3 items).*	*Processes based on social entrepreneurship and conceived as a set of practices and behaviors rather than a legal form. It includes three formative pillars: intention for social change, commercial activity, and inclusive governance.*
Societal Ethics and Social Entrepreneurship: A Cross-Cultural Comparison	*Saurav Pathak & Etayankara Muralidharan*	*2020*	*Cross-Cultural Research, Vol. 54(2–3), pages 180–208*	*The study positions ethics as a factor influencing the likelihood of individuals engaging in social entrepreneurship at the national level. Includes: (1) Normative ethical context – behavioral ethics index based on WVS; (2) Cognitive context – importance attributed to altruism (WVS); (3) Normative public-sector ethics – derived from WEF, measures integrity, corruption, and favoritism.*	*Using an institutional theory approach, he links ethics to three institutional pillars: normative (behavioral ethics), cognitive (altruism/unselfishness), and regulatory (public sector ethics).*

Purpose of the paper. While SEEPs are uniquely positioned to foster this transformation, existing evaluation metrics remain stuck in a "profit-first" paradigm, focusing on revenue or scalability. This paper addresses a critical gap: the lack of a dynamic, multi-level tool to measure ethical development within SEEPs. We propose the Ethical Entrepreneurial Education Scorecard (E3S) to answer the question: How can we measure ethics as a developmental journey involving individuals, teams, and the broader ecosystem? The preliminary literature review underscores a critical fragmentation in existing evaluative instruments; while various scales address ethics in entrepreneurship, there remains a distinct lack of an integrated metric capable of simultaneously capturing the micro (individual), meso (team), and macro (ecosystem) perspectives. To bridge this gap, this research develops a holistic measurement tool aimed at capturing the multi-layered nature of ethical development in SEEPs.

Methodology. The study utilizes an exploratory sequential mixed-methods design, structured in two distinct phases. The initial qualitative phase employs semi-structured interviews and focus groups to generate, refine, and contextualize potential scale items, ensuring the tool reflects the "lived" ethical experiences of participants. These qualitative insights

will inform the construction of a structured instrument to be deployed in the subsequent quantitative phase, where a broad-scale survey will be conducted to establish psychometric reliability and construct validity.

The purposive sample for this study comprises students and project teams from Enactus, a global non-profit organization operating across universities worldwide. Enactus provides an unparalleled research laboratory: it engages diverse cohorts of students in the execution of real-world, socially impactful ventures. This context offers the necessary environmental complexity to observe and measure how ethical constructs—such as social responsibility, relational care, and sustainability orientation—are operationalized in practice.

Data analysis will proceed through a rigorous statistical workflow. An Exploratory Factor Analysis (EFA) will be performed to uncover the underlying dimensional structure of the newly developed scale and verify its alignment with the proposed three-level framework. Furthermore, Cronbach's alpha coefficients will be calculated to ensure high levels of internal consistency and instrument reliability. By synthesizing qualitative depth with quantitative rigor, this methodology aims to provide a validated, context-sensitive scorecard for the future of ethical entrepreneurial education.

Results. To address the multifaceted nature of ethical maturation in SEEPs, the Ethical Entrepreneurial Education Scorecard (E3S) offers a granular, three-tiered assessment framework. By synthesizing individual, team, and ecosystemic dimensions, the model provides a holistic lens through which to evaluate ethics not as a static state, but as a dynamic competence (see Table 2).

At the individual level, the framework moves beyond traditional psychometric snapshots to capture the "lived" ethical orientation of the student. By utilizing longitudinal, pre- and post-program assessments, educators can map how students mobilize ethical reasoning and creative problem-solving during real-world project delivery. This longitudinal tracking provides visibility into the evolution of emotional intelligence and leadership maturity, offering a deeper understanding of the student's moral trajectory.

At the team level, the analytical focus shifts toward the dynamics of "relational ethics" and collective agency. Recognizing that entrepreneurial decisions are rarely solitary, the E3S makes explicit the processes of negotiation, contestation, and shared accountability. This dimension evaluates the qualitative aspects of interpersonal communication and the degree to which ethical standards are co-constructed and maintained within the peer group.

The ecosystem level expands the evaluative scope to the institutional and innovation landscape. This tier is bifurcated into the University domain—incorporating global benchmarks such as HEInnovate, STARS, and THE Impact Rankings—and the Entrepreneurial domain. The latter enables an audit of how external stakeholders (mentors, funders, and partners) either facilitate or obstruct ethical practice and sustainable innovation.

Furthermore, the E3S integrates cross-dimensional quantitative metrics via adapted Multidimensional Ethics Scales (MES). This ensures structural coherence, capturing universal value orientations such as justice and care-based reasoning across all levels of the scorecard. Designed for contextual flexibility, the E3S allows program coordinators to recalibrate assessment strategies based on specific cultural settings and resource availability.

Table 2. The E3S (Ethical Entrepreneurial Education Scorecard)

Dimensions/Pillars	***Sub-Dimensions***	***Indicators & Tools***	***Type***
1. Ethical Orientation	*a) Real-Life Ethical Decision-Making*	*Vignettes/scenario-based assessment*	
		360-degree ethical feedback (peers, mentors, stakeholders)	
		Stakeholders' interviews	*Qualitative*
	b) Hypothetical Scenario Ethics	*Moral Reasoning Scale (e.g., DIT2)*	*Quantitative*
2. Ethical Entrepreneurial Mindset	*a) Empathy, Adaptability, Resilience*	*Ethical Entrepreneurial Mindset Profile (EMP)*	
		Design thinking challenge feedback	
		Peer/team evaluation reports	*Mixed*
	b) Impact and Sustainability Orientation	*Social impact pitch simulation*	
		Theory of Change articulation	
		Resource mobilization analysis	*Qualitative*
3. Ethical Personal Development	*a) Emotional & Leadership Maturity*	*Emotional Intelligence Survey (e.g., TEIQue, MSCEIT)*	
		Leadership reflection log	*Mixed*
	b) Civic and Professional Engagement	*Longitudinal survey (1-3 years post-program)*	
		Community engagement logbook	
		Capstone interviews	*Mixed*
4. Cross-Dimensional Quantitative Ethics Measures	*a) Ethical Value Orientation*	*Adapted Multidimensional Ethics Scales*	*Quantitative*

	b) Integrity in Practice	*Ethical Climate/Organizational Fit Score* *Compliance/adherence during project implementation*	*Mixed*
5. Ethics in the SEEP	*a) Ethical contents* *b) Educator's ethical orientation*	*Syllabus assessment* *Educators' interviews*	*Qualitative* *Qualitative*

Research limitations. While the E3S model provides a robust conceptual framework for assessing ethics in SEEPs, several limitations remain that invite further empirical exploration and validation. Primarily, as a newly proposed assessment tool, its cross-cultural applicability and institutional scalability require rigorous testing across diverse global settings.

A significant limitation lies in the implementation requirements of the E3S, which necessitate deep engagement from educators, coordinators, and policy-makers. The transition from theory to practice requires faculty training in ethics-centered experiential pedagogy and a systemic shift in university reward structures, moving beyond academic excellence to incentivize sustainable innovation. This underscores that the integration of ethics is not merely a matter of metrics, but a fundamental cultural shift in the definition of 21st-century education.

Future research should specifically address Impact Realization to capture the tangible and intangible effects of student-led projects on beneficiary communities. Integrating methodologies such as Social Return on Investment (SROI) and environmental impact assessments will be essential to fully quantify the "value" created. Additionally, longitudinal studies are needed to evaluate Lifelong Transformation, tracking the enduring influence of SEEPs on alumni career trajectories, social commitments, and leadership behaviors.

By employing alumni tracking and qualitative storytelling, future scholars can move beyond the "subtlety" of personal transformation to provide empirical evidence of education as a force for ethical and sustainable societal change. Ultimately, validating the E3S through case studies like ENACTUS will help refine the metrics needed to reflect the complex, long-term nature of human and social development.

Managerial implications. From a managerial perspective, the paper suggests that universities and program managers should rethink the way they design, manage, and evaluate entrepreneurial education. In this perspective, the value of the program does not depend solely on the number of startups generated, but on the ability to train "conscious entrepreneurs" who are thoughtful and capable of producing sustainable and ethically valid impact. The E3S offers a tool for integrating qualitative and quantitative dimensions, orienting teaching, mentoring, and incentive systems toward outcomes of social impact and sustainability. Therefore, the design, implementation, and reporting of programs cannot focus solely on economic KPIs but require indicators capable of capturing moral learning processes, ethical deliberation skills, and responsibility toward stakeholders. In particular, it is not enough to consider the results of the team's work, but also the quality of interactions, transparency in decision-making, inclusiveness of deliberative processes, the ability to deal with dissent, and the effective distribution of responsibilities. Meanwhile, with regard to policy and administrative mechanisms, incentive systems could be created not only for the ability to generate numerically significant business projects, but also for the effective creation of pathways that produce social impact. Only in this way will it be possible to make the definitive transition from ethics treated rhetorically to the driving force behind entrepreneurial education programs.

Originality of the paper. The paper was written to fill a gap in the measurement of ethics as a dynamic process in the context of SEEPs, seeking to overcome or integrate traditional indicators linked to business planning. In fact, E3S is a multidimensional tool that, through three levels, seeks to understand how students develop responsibility, social awareness, and a focus on sustainability throughout their educational journey. Therefore, on the one hand, it seeks to integrate the concept of success in SEEPs with 'value-based' elements. On the other hand, it provides a managerial basis for aligning existing or developing programs with standards linked to a vision of entrepreneurship as a responsible and socially oriented practice.

Rethinking Mixed Embeddedness in Incubation Programmes for Migrant Women Entrepreneurs

GIULIO PALMAS[1]

Abstract. *Questo studio riconcettualizza programmi di incubazione come mediatori strutturali di livello meso all'interno del framework della Mixed Embeddedness (ME), esaminando come il posizionamento istituzionale dell'incubatore, e non soltanto i servizi offerti, influenzi la capacità delle imprenditrici migranti (MWE) di convertire le proprie risorse in accesso al mercato mainstream in Italia. Attraverso uno studio qualitativo comparativo basato su 20 interviste semi-strutturate con MWE che hanno partecipato a due modelli di incubazione strutturalmente differenti (un programma fisico a governance pubblica e un programma digitale a governance privata), lo studio mostra che i due modelli producono forme qualitativamente diverse di embeddedness. Il programma istituzionalmente radicato opera come equalizzatore di risorse, abilitando la traduzione istituzionale, la navigazione burocratica e l'accesso ai finanziamenti pubblici. Il programma digitale deterritorializzato funziona come amplificatore di risorse i cui esiti dipendono dalle dotazioni preesistenti e dalla maturità imprenditoriale delle partecipanti. Le MWE dimostrano un'agency generativa, convertendo l'identità migrante e le barriere burocratiche in posizionamento competitivo, ma tale conversione è condizionata dall'embeddedness istituzionale dell'incubatore. Lo studio estende la teoria ME mostrando che gli incubatori sono mediatori strutturalmente situati la cui embeddedness determina se il supporto equalizza o amplifica le diseguaglianze preesistenti.*

Inquadramento della ricerca. I servizi di supporto all'imprenditorialità (BSS) sono considerati uno strumento per favorire l'integrazione economica dei migranti, tuttavia la loro efficacia rimane controversa e fortemente situata (Marchand e Dijkhuizen, 2018; Bruton et al., 2023). Per le imprenditrici migranti (MWE), i vincoli intersezionali di genere, status migratorio e isolamento dalle reti professionali possono rendere il supporto ricevuto inefficace o addirittura controproducente, confinandole in attività marginali anziché facilitare l'accesso al mercato mainstream, inteso come lo spazio economico in cui gli scambi avvengono su base impersonale e contrattuale e in cui l'impresa serve una clientela generalista in diretta concorrenza con gli operatori nativi (Jones et al., 2014; Zubair e Brzozowski, 2018).

Questa tensione è particolarmente rilevante nel contesto italiano, dove l'imprenditoria femminile migrante ha registrato una crescita del 37,8% negli ultimi anni, con 164.509 imprese guidate da donne straniere (Centro Studi e Ricerche IDOS, 2025). Tuttavia, la crescita quantitativa non è accompagnata da condizioni paritarie di accesso: il 75,6% delle imprenditrici migranti ricorre esclusivamente all'autofinanziamento e il 71% non intrattiene alcun rapporto con le associazioni di categoria italiane (Fondazione Leone Moressa, 2024). Inoltre,il quadro istituzionale rimane fondato su logiche di controllo piuttosto che di integrazione (Sciortino e Vittoria, 2023). Le MWE si trovano così in una condizione di disallineamento strutturale che riflette una più ampia liability of foreignness (Zaheer, 1995; García-Cabrera et al., 2020): la mancata valorizzazione dei titoli produce una svalutazione professionale di genere (Bijedić e Piper, 2018), l'accesso al credito è ostacolato dall'assenza di garanzie reali (Desiderio, 2014; Chreim et al., 2018), e l'opacità normativa trasforma l'informazione in un processo difficile da interpretare (Jones et al., 2014; Qin, 2023). Le reti sociali, infine, pur offrendo supporto pratico ed emotivo, possono confinare l'attività in nicchie autoreferenziali (Azmat e Fujimoto, 2016; Ram et al., 2017).

La ricerca sui BSS per migranti ha identificato diverse barriere di accesso e ha evidenziato i limiti di approcci standardizzati che ignorano l'autonomia dei partecipanti (Qin, 2023; Polychronopoulos e Nguyen-Duc, 2024). Due aspetti restano tuttavia da approfondire: come il posizionamento strutturale dell'incubatore nell'ecosistema locale condizioni la capacità di convertire le risorse in accesso al mercato (Knox et al., 2025), e come i meccanismi relazionali interni influenzino specificamente l'embeddedness delle MWE, intesa come la loro capacità di radicarsi nel tessuto economico del paese ospitante superando l'isolamento etnico (Jürgens et al., 2022; Bergman e McMullen, 2022).

Obiettivo del contributo. Attraverso la lente della Mixed Embeddedness (Kloosterman et al., 1999; Kloosterman, 2010), che considera l'interazione tra risorse individuali (micro), struttura delle opportunità (meso) e vincoli istituzionali (macro) come elementi determinanti del comportamento imprenditoriale, questo studio riconceptualizza gli incubatori come mediatori strutturali di livello meso la cui efficacia dipende dal loro radicamento istituzionale nella struttura locale delle opportunità. Estendendo lo studio di Meister e Mauer (2019), sosteniamo che è l'embeddedness istituzionale dell'incubatore stesso, e non soltanto le risorse erogate, a determinare se il supporto si traduce in accesso effettivo al mercato. Tale mediazione si realizza attraverso la traduzione istituzionale, intesa come la conversione concreta dei

[1] Università degli studi di Cagliari, e-mail: giulio.palmas@unica.it

progetti imprenditoriali in strumenti leggibili dalle istituzioni e dai canali di finanziamento del paese ospitante, il brokeraggio verso gli stakeholder dell'ecosistema, e i meccanismi di legittimazione (Barrios et al., 2025; Suchman, 1995).

Lo studio affronta due domande di ricerca: (1) In che modo i programmi di incubazione influenzano la conversione delle risorse delle MWE in accesso istituzionale e supporto relazionale? (2) In che modo modelli di incubazione strutturalmente diversi influenzano l'embeddedness delle MWE nel mercato mainstream? Per rispondere a tali domande è stato condotto uno studio multi-caso qualitativo (Eisenhardt, 1989; Yin, 2018) su un campione di 20 MWE che hanno partecipato a due programmi di incubazione strutturalmente diversi nel contesto italiano. Lo studio si concentra sulle voci delle imprenditrici, analizzando le loro narrazioni per ricostruire come negozino i vincoli e percepiscano l'efficacia del supporto ricevuto (Adeeko e Treanor, 2022; Lassalle e Shaw, 2021).

Lo studio offre tre contributi principali. In primo luogo, estende la teoria ME (Kloosterman et al., 1999; Kloosterman, 2010) introducendo l'embeddedness istituzionale dell'incubatore come variabile di mediazione meso, mostrando che gli incubatori radicati operano come equalizzatori di risorse, quelli deterritorializzati come amplificatori. In secondo luogo, riconceptualizza l'agency delle MWE come generativa: non intesa come mera reazione ai vincoli strutturali, ma come capacità di convertire l'esperienza migrante in un vantaggio competitivo (Knox et al., 2025). In terzo luogo, mette in discussione la misurazione dell'efficacia dell'incubazione attraverso la sola sopravvivenza economica (Bergman e McMullen, 2022), rispondendo alle sollecitazioni per una lettura intersezionale della ME (Romero e Valdez, 2016; Ram et al., 2017).

Metodologia. La ricerca adotta un disegno qualitativo esplorativo basato su casi di studio multipli (Eisenhardt, 1989; Yin, 2018), particolarmente adatto a catturare gli effetti intersezionali che caratterizzano l'esperienza di imprenditrici situate all'intersezione di molteplici strutture di svantaggio difficili da identificare attraverso indagini quantitative (Lassalle e Shaw, 2021). Il disegno multi-caso consente di esaminare pattern di somiglianza e differenza tra gli incubatori analizzati, identificando quali meccanismi di supporto producono esiti simili o diversi a seconda del modello adottato (Yin, 2018).

Sono stati selezionati due programmi di incubazione in Italia mediante un campionamento ragionato (Patton, 1990; 2014) come casi emblematici di approcci strutturalmente distinti in termini di governance, modalità di erogazione e approccio al supporto. Il Programma A è un incubatore fisico a governance pubblica promosso congiuntamente dal Ministero e dalla Camera di Commercio, che offre un percorso di 2-3 mesi con formazione prevalentemente in presenza, sviluppato in fasi progressive che includono orientamento, formazione tecnico-pratica, supporto alla stesura del business plan, assistenza all'avvio dell'impresa e monitoraggio iniziale. Il Programma B è un incubatore digitale a governance privata gestito da un'organizzazione non profit internazionale, che offre un percorso di cinque mesi interamente online, con mentoring individuale settimanale e workshop di gruppo, finalizzato alla realizzazione di un business plan, un pitch deck e un open day pubblico.

Il campione finale è composto da 20 MWE (16 dal Programma A e 4 dal Programma B) provenienti da 16 diversi paesi d'origine, per lo più in possesso di laurea e con precedente esperienza professionale, operanti in settori che spaziano dalla biotecnologia alla gastronomia, dalla mediazione culturale all'ingegneria. Il reclutamento è stato mediato dai responsabili dei programmi, che hanno agito come gatekeeper fidati per questa popolazione difficile da raggiungere (Harima et al., 2020; Meister e Mauer, 2019). I dati sono stati raccolti tramite 20 interviste semi-strutturate condotte online tra maggio e novembre 2025, della durata di 30-40 minuti ciascuna, strutturate attorno a quattro aree tematiche: percorso migratorio e motivazioni alla partecipazione, sfide imprenditoriali e reti di supporto preesistenti, esperienza durante il percorso, esiti post-programma (Kallio et al., 2016). Le interviste sono state condotte in italiano o in inglese secondo la preferenza di ciascuna partecipante, trascritte verbatim e verificate da ricercatori bilingui attraverso un confronto riga per riga con la registrazione audio (Khatib et al., 2024). Fonti secondarie costituite da report ufficiali degli incubatori, interviste ai partecipanti condotte dagli stessi programmi e partecipazione diretta a eventi pubblici di presentazione dei risultati sono state utilizzate per triangolare i dati (Yin, 2018; Jack e Raturi, 2006). L'analisi è stata condotta mediante Analisi Tematica Riflessiva con approccio deduttivo-induttivo ibrido (Braun e Clarke, 2006; 2019), supportata dal software NVivo 15, con due codificatori indipendenti, sessioni di peer debriefing e procedure di member-checking per garantire il rigore analitico e la corrispondenza dei risultati con l'esperienza vissuta dalle partecipanti (Creswell e Miller, 2000).

Risultati. I due modelli di incubazione producono forme qualitativamente diverse di embeddedness. Il Programma A, istituzionalmente radicato nella struttura locale delle opportunità attraverso la Camera di Commercio, opera come equalizzatore di risorse: converte attivamente i business plan in strumenti leggibili dalle istituzioni e dai canali di finanziamento pubblico, fornisce navigazione burocratica e offre un sostituto relazionale alle reti familiari e comunitarie assenti (Kloosterman, 2010; Suchman, 1995). Le partecipanti descrivono i propri tutor in termini affettivi e parentali, rivelando una funzione sostitutiva che va ben oltre il supporto imprenditoriale standard e che risponde a un bisogno specifico della condizione migrante, ovvero l'assenza di reti primarie di riferimento nel paese ospitante (Azmat e Fujimoto, 2016). Il Programma A consente alle MWE di trasformare la propria identità migrante e le stesse barriere burocratiche in posizionamento competitivo, sfruttando l'ibridità culturale e il doppio radicamento come vantaggio di mercato nell'accesso a segmenti di clientela che le imprenditrici native non riescono a raggiungere (Sandoz et al., 2022; García-Cabrera et al., 2020).

Tuttavia, anche il Programma A incontra un limite strutturale nel sistema creditizio privato, dove i requisiti di garanzia reale prevalgono sulla valutazione meritocratica e dove genere, origine geografica e status migratorio si intersecano per rafforzare la diffidenza istituzionale (Desiderio, 2014; Chreim et al., 2018). La liability of foreignness (Zaheer, 1995) non è ridotta dall'accumulo di qualifiche, ma dipende dall'inserimento nel sistema amministrativo del paese ospitante: è proprio su questo squilibrio che l'incubatore istituzionalmente radicato interviene con maggiore efficacia.

Il Programma B produce contributi significativi alla strutturazione cognitiva dei progetti imprenditoriali ma, in assenza di mediazione con il sistema amministrativo locale, funziona come amplificatore di risorse: i suoi esiti dipendono dalle dotazioni preesistenti e dalla maturità imprenditoriale delle partecipanti (Qin, 2023). Chi aveva già avviato un'attività riesce a trasformare gli strumenti formativi in connessioni locali; chi era in fase di pre-avvio tende a restare in una fase intermedia. L'isolamento dalla comunità di pari e la variabilità del mentoring amplificano tali effetti (Jürgens et al., 2022; Bergman e McMullen, 2022). Emerge infine una barriera specifica al contesto italiano: la chiusura relazionale delle reti produttive familiari, superabile solo attraverso la mediazione istituzionale locale (González et al., 2025).

Limitazioni della ricerca. I risultati devono essere interpretati entro condizioni specifiche. Il contesto normativo italiano, caratterizzato da elevata complessità burocratica e politiche di integrazione degli immigrati ancora limitate (Sciortino e Vittoria, 2023; Centro Studi e Ricerche IDOS, 2025), può amplificare l'importanza della traduzione istituzionale e rendere più visibili le limitazioni dei modelli deterritorializzati rispetto ad altri contesti nazionali. Il disegno qualitativo e la selezione di due casi, pur garantendo una profondità analitica difficilmente raggiungibile con altri approcci (Marshall e Rossman, 2014), suggeriscono cautela nella generalizzazione dei risultati a contesti istituzionali e culturali diversi.

Il reclutamento mediato da gatekeeper, pur essendo la prassi standard per popolazioni difficili da raggiungere (Harima et al., 2020; Adeeko e Treanor, 2022), potrebbe aver introdotto un bias di selezione, favorendo le partecipanti con esperienze più strutturate o con relazioni più consolidate con i responsabili dei programmi. Il disegno cross-sezionale coglie l'embeddedness in un unico momento temporale, escludendo l'osservazione delle dinamiche evolutive nel corso del tempo e la possibilità di verificare se gli effetti dell'incubazione si intensifichino, si attenuino o si trasformino a distanza di anni dalla partecipazione al programma.

Le ricerche future potrebbero adottare disegni longitudinali per osservare se l'embeddedness acquisita durante l'incubazione si consolidi nel tempo. Studi comparativi con incubatori digitali a diverso grado di connessione locale aiuterebbero a distinguere gli effetti del formato da quelli dell'embeddedness istituzionale. L'adozione di metodi misti permetterebbe di validare i risultati su scala più ampia (Parry et al., 2021), mentre studi cross-country potrebbero chiarire come diversi framework normativi influenzino le opportunità e i vincoli delle MWE.

Implicazioni manageriali. Gli interventi orientati all'inclusione economica dovrebbero incorporare funzioni di traduzione istituzionale e brokeraggio verso gli attori territoriali, anziché limitarsi a moduli formativi (Meister e Mauer, 2019; Qin, 2023). Un supporto efficace per le MWE richiede una mediazione attiva tra la singola imprenditrice e l'ecosistema istituzionale locale, inclusi le Camere di Commercio, i canali di finanziamento pubblico e le reti professionali, e non soltanto la fornitura di formazione imprenditoriale di carattere generale. Gli incubatori che aspirano a produrre una reale integrazione economica dovrebbero pertanto valutare il proprio posizionamento istituzionale come una variabile strategica, e non soltanto come un contesto dato (Serpente et al., 2025).

Il vincolo creditizio basato sulle garanzie reali costituisce una barriera strutturale che le MWE non possono superare mediante il solo sforzo individuale (Desiderio, 2014; Chreim et al., 2018). Strumenti ponte come programmi di microcredito, fondi di garanzia e partnership pubblico-private sono necessari per abilitare l'accesso al sistema finanziario formale, interrompendo il circolo vizioso che spinge le imprenditrici verso l'autofinanziamento (Romero e Valdez, 2016; Ram et al., 2017).

Originalità del contributo. Questo studio contribuisce alla teoria ME (Kloosterman et al., 1999; Kloosterman, 2010) introducendo l'embeddedness istituzionale dell'incubatore come variabile finora inesplorata a livello meso. Sebbene la letteratura esistente abbia mostrato che l'incubazione rafforza l'embeddedness dei migranti attraverso l'espansione del capitale sociale e lo scambio di conoscenze (Meister e Mauer, 2019) e che le dinamiche relazionali interne abilitino connessioni all'ecosistema locale (Jürgens et al., 2022), l'analisi comparativa evidenzia che tale rafforzamento non è automatico ma dipende dalla posizione strutturale dell'incubatore all'interno della struttura locale delle opportunità. Gli incubatori istituzionalmente radicati operano come equalizzatori di risorse, riducendo la dipendenza dal capitale preesistente pur con un limite strutturale nel credito privato (Desiderio, 2014; Chreim et al., 2018); quelli deterritorializzati operano come amplificatori, con esiti dipendenti dalle dotazioni iniziali e dalla maturità dell'attività. Questa distinzione non era stata teorizzata in precedenza nella letteratura ME e risponde alle osservazioni di Serpente et al. (2025), che evidenziano come strutture prive di embeddedness rischino di operare come sistemi paralleli che non producono reale integrazione.

Lo studio avanza la concettualizzazione dell'agency delle MWE da reattiva a generativa. La letteratura ha spesso raffigurato le imprenditrici migranti come vittime passive delle ingiustizie strutturali o come mere estensioni di strategie familiari (Villares-Varela e Essers, 2019), lasciando i meccanismi concreti di tale agency sottosviluppati (Knox et al., 2025; David e Terstriep, 2025). I meccanismi documentati in questo studio vanno oltre la tendenza a trattare l'agency come mera disponibilità di risorse (Cunha et al., 2024) e dimostrano che tali leve diventano operative soltanto quando

vengono stabilite connessioni efficaci con il mercato mainstream (Lassalle e Shaw, 2021; Adeeko e Treanor, 2022), rispondendo alle sollecitazioni per una lettura intersezionale della ME (Romero e Valdez, 2016; Ram et al., 2017).

Infine, lo studio mette in discussione l'assunzione che gli effetti dell'incubazione siano misurabili esclusivamente attraverso la sopravvivenza economica (Bergman e McMullen, 2022). Mostrando che la legittimazione identitaria perdura oltre la cessazione dell'attività e che la funzione sostitutiva delle reti familiari risponde a bisogni specifici della condizione migrante femminile, il lavoro offre la prima evidenza empirica dal contesto italiano di come genere e embeddedness familiare plasmino i percorsi di legittimazione in modi irriducibili alle sole dimensioni economiche (Sandoz et al., 2022; García-Cabrera et al., 2020).

Signaling Theory in Venture Capital Stage Financing Research: A Review and Research Agenda

LUIGIA CALELLA, PIETRO TARAGONI

Abstract. *Information asymmetry represents a fundamental challenge in venture capital markets, where investors must evaluate ventures with little to no established performance history. The Signaling Theory offers a lens to analyze how ventures communicate unobservable qualities to potential investors. While existing literature has extensively examined signaling dynamics in early-stage financing, comparatively little attention has been devoted to how signals evolve across the different stages of venture capital financing. This paper addresses this overlooked area through a narrative literature review, that maps signals and their relevance as ventures progress through subsequent stages. The findings suggest that signals should be understood as dynamic mechanisms, whose relevance evolves, rather than as static indicators of venture quality.*
Keywords: *Signaling Theory; Venture Capital; Stage Financing; Entrepreneurial Finance; Narrative Literature Review; Information Asymmetry.*

Framing of the research. In markets where information is scarce, the ability to send and receive signals might be considered privileged, as signals can become an asset to competitive advantage and investment opportunities. Therefore, the possibility to differentiate good investment from "lemons", known as bad investments (Akerlof, 1970), is crucial for investors, who could reduce the risk of investing in the wrong venture (Connelly et al., 2011). Building on the information asymmetry proposed by Akerlof (1970), Spence (1973, 2002) developed the "Signaling Theory", as a mechanism in which an informed party can transmit information to an uninformed party. In his seminal work, the employer (receiver) can't perfectly assess the job applicant (signaler) qualities, thus the signaler provides the information that is not observable, in this way remarkable employees can stand out with, for example, signaling a higher educational level (Spence, 1973). It is precisely from this tension between what is known and what, instead, remains hidden, that the necessity to decipher, interpret, and trust the information, or signals, of others becomes an inescapable condition of market participation. Over the years this theory had a great impact on the entrepreneurial landscape (Bergemann & Hege, 1998; Connelly et al., 2011; Kleinert et al., 2022), demonstrating how ventures use signals to convey unobservable information to investors, in order to obtain financing for their projects (Busenitz et al., 2005).

This paper turns its attention to venture capital investments, a context particularly fruitful for Signaling Theory, since new ventures at early stages are characterized by high uncertainty because of a lack of track record and, thus, verifiable data (e.g. Plummer et al., 2016). Under these conditions, venture capitalists face information asymmetry when deciding whether to invest in a new venture or not (Busenitz et al., 2005), this problem arises especially in the beginning, when investors need to assess the venture's performance, at the early stage, where the most uncertainty resides (Gompers, 1995; Gompers & Lerner, 2001). Gompers (1995) identifies the stages of capital infusions as one of the control mechanisms that the venture capital can draw upon to monitor the project, while retaining the option to discontinue the investment, if it underperforms. Monitoring and control are central for the venture capitalist, which does not play a passive role, but is instead an active actor in the firm's life (Gompers, 1995), hence every staging round serves as a learning process for the venture capitalist (Chan et al., 1990), and for the entrepreneur, that can benefit from the non-monetary value of the investors' contribution: expertise, mentorship and guidance (Perry, 1988).

Consequently, because of uncertainties, both parties are exposed to moral hazard, and contracts are structured to share this risk across different stages (Bergemann & Hege, 1998). Both internal and external uncertainty shape the design of the financial contract between the venture capitalist and the entrepreneur: the first is proved to be an important factor for incentives and control mechanism; the second is meant to align the contractual risk to the exogenous environmental risk (Kaplan & Stromberg, 2004). Whereas in the short-term period the investor needs to recover the costs at each stage, given the absence of any binding commitment, long-term contracts can enhance risk distribution by granting the investor a greater return in the early stages (Bergemann & Hege, 1998).

However, several studies (e.g. Reuer & Ragozzino, 2012; Hallen & Pahnke, 2016; Liu & Tian, 2022) identify, apart from the most known dyad – venture-venture capitalist – other non-conventional signalers and receivers. For instance, the relationship venture-venture, venture capitalist-venture, and market-venture capitalist, constitute other relevant interactions that highlight that almost all the economic agents involved in the marketplace can take part in the signaling process, either as signalers or receivers.

It is precisely in this context of informational imbalances that signaling is frequently applied in the study of entrepreneurial finance, due to its ability to address information asymmetries between parties with different levels of knowledge, because of its "accessible" character it has been often adopted in various research fields (Bafera & Kleinert, 2022).

Purpose of the paper. Despite the growing body of literature on signaling theory, few gaps remain unresolved.

Past research has analyzed several signals, predominantly concentrated in the early stage, between the entrepreneur and the investor, such as crowdfunding success (Ahlers, 2015); affiliation with venture development organizations (VDOs) (Renault, 2012); founder's expertise (Reuber & Fischer, 1994); third-party affiliations (Plummer et al., 2016); marketing innovation (Sapienza & Amason, 1993); dividend payment (Asquith & Mullins, 1986); amongst the most cited. Yet also third parties can send signals, as an endorsement for the new venture, putting their reputation on the line (Pollock et al., 2010). Signalers and receivers have multiple connections – for example, the most extensively studied connection in the literature, as widely acknowledged, is between new ventures at the early stage and venture capitalists, but signals could also be sent from ventures to ventures, in relation to competitive market signaling (Heil & Robertson, 1991); venture capitalists can act as signalers to ventures (Hallen & Pahnke, 2016). Additionally, the role of the market could have prominence in signaling toward venture capitalists (Liu & Tian, 2022) and toward ventures' investments (Soh et al., 2004). This evidence highlights how signaling operates across a broader ecosystem of actors, and across multiple research fields, beyond the entrepreneur-venture capitalist relationship alone.

While past research has improved our understanding on how signals impact venture capital stage financing shedding light on a variety of signals and actors, this literature remains largely anchored to the early stage of the financing process, where information asymmetry is most acute and the need for truthful signals is greatest (Gompers, 1995; Busenitz et al., 2005). Specifically, little attention has been paid to how signaling can manifest itself across the different stages of the financing process, and to understanding whether the same signal carries more prominence in an early stage or a subsequent one, thus providing different degrees of significance in a multi-stage process (Ko & Mckelvie, 2018). Hence, extant research leaves critical research questions unresolved: first, in what ways do the intrinsic properties of signals contribute to building the relationship between signalers and receivers, and how do they change in relation to the different financing stages? Second, how does the interpretation of signals change in relation to the different relationships between economic agents? Third, how does the relevance of signals evolve throughout the financing stages?

This paper aims to contribute to literature by reviewing existing theoretical and empirical contributions on Signaling Theory applied to venture capital stage financing. Rather than advancing a novel empirical test, the purpose of this work is to study how signaling mechanisms affect venture capitalists' decision making across the different financing phases, while identifying underexplored connection between signals and financing stages, and lay the ground for future contribution in this field.

Methodology. This paper adopts a narrative literature review methodology, an approach often used in management and entrepreneurship research, suited to the purpose of synthesizing and evaluating existing theoretical contributions (Baumeister & Leary, 1997). Unlike systematic reviews, which prioritize exhaustiveness and protocol, narrative review allows for a more flexible engagement (Tranfield et al., 2003).

The review process began with the identification of foundational works in Signaling Theory, starting from the most prominent contributions, such as Spence (1973) and Akerlof (1970), whose frameworks on signaling and information asymmetry constitute the backbone of this field. From this origin, the research was extended to include subsequent theoretical developments and empirical applications in the entrepreneurial finance domain. The primary databases consulted were SCOPUS and Web of Science databases which collectively provided a broad coverage of peer-reviewed journals. The search was conducted using a combination of keywords including: "signaling theory", "signals", "venture capital", "stage financing", "information asymmetry", "entrepreneurial finance", "startup signals", "investor decision-making", and "early-stage funding", as well as combinations of these keywords to capture intersections between relevant streams.

The selection of papers followed a criterion of theoretical and contextual relevance rather than a predefined numerical threshold. The articles included contributed meaningfully to the understanding of signaling mechanisms, with a particular focus on venture capital relationships. Priority was given to contributions published in high-quality peer reviewed journals, including the Journal of Finance, Academy of Management Journal, the Journal of Business Venturing, and Entrepreneurship Theory and Practice, among others. Seminal works were included regardless of their publication date, given their foundational role in shaping the field, while more recent contributions were selected to reflect the current state of the debate. The papers were included (see Tab. 1) if they met the following criteria: if they applied signaling theory to entrepreneurial finance or venture capital and if they addressed dimensions of signaling theory, for example, the actors, signal characteristics and financing stages. An initial database included 81 results, after the screening, 37 papers were excluded; the exclusion was based on the type of journal they were published on, publication date and contribution prominence.

The review was further guided by three key review papers on signaling theory: Connelly et al. (2011), who established the theory's core constructs across management research; Colombo (2020), who mapped signal use specifically in new venture financing; and Bafera and Kleinert (2022), whose systematic review of signaling in entrepreneurship research provided a direct reference point.

The paper is organized around three areas: the characteristics of signals and properties, the different relationships between signalers and receivers, and the role of financing stages where signals dynamics evolve. This organization allows the research to move from the general concept of signals to their role in the financing stages, and to how the relationship between entrepreneurs and venture capitalists evolves as successive funding rounds unfold.

Results. The following analysis unfolds along three interconnected dimensions: the characteristics and properties of signals, the relationships between signalers and receivers, and the evolution of signaling dynamics across the financing stages. The first examines how signals are defined and evaluated for credibility; the second maps the actors involved, moving beyond the conventional venture-venture capitalist dyad; the third investigates how the relevance of signals shifts across financing stages.

Signals can be divided in different categories, regarding the characteristics: clarity, consistency, aggressiveness (Heil & Robertson, 1991), message, intentionality (Bafera & Kleinert, 2022) and costs (Connelly et al., 2011). These properties determine if a signal shows credibility for investment decisions, and their relative importance in the financing stage.

A signal is clear when the receiver can read it rapidly and accurately, because of the certain nature; instead, a noisy signal is an ambiguous announcement used to lure receivers to disclose potential responses (Heil & Robertson, 1991), in stock markets they can also create differences in signal quality between large and small firms, with the former, being more informed, leading the latter's returns (Chan, 1993). According to Gomulya and Mishina (2017), noisy signals can be distinguished depending on their source: signal's own nature and signaler's conduct, when the latter it's called into question, investors try to rely toward signals that are harder to manipulate, it appears to matter particularly in early-stage ventures, where the absence of observable track records makes it is difficult to establish signal clarity.

The consistency of a signal refers to the degree to which a current signal aligns with its past behavior (Heil & Robertson, 1991), indeed prior success achieved by the founder on a crowdfunding platform represents a salient signal to prospective investors, as it conveys both credibility and experiential knowledge (Courtney et al., 2017), therefore it is a property that gains relevance over time, a venture's consistency accumulates overtime, thus investors can analyze it.

A signal is likely to be interpreted as aggressive if it could damage the receiver, or if it seems disproportionate relative to industry norms (Heil & Robertson, 1991). In this case, for example, the receiver is another company, that needs to interpret the competitor's signals in order to formulate or adjust its competitive response. In contrast, it is more difficult to find aggressive signals in a venture-venture capitalist relationship, since the former has the necessity to demonstrate quality to the latter to attract investments.

The degree to which signals are sent purposefully is known as signal intentionality, but they are not always intended as calculated moves, sometimes the signals reach the market without an explicit intent (Bafera & Kleinert, 2022), if the venture capitalist decides to withdraw from an investment, this action could send an unintentional signal about the venture's quality to possible new investors, even though the decision was based on personal priorities (Shafi et al., 2020; Bafera & Kleinert, 2022), this dimension regards the later stages, when a relationship between the venture and venture capitalist was already established.

The idea of costs refers to the fact that certain signalers are better able to bear the related expenses than others (Connelly et al., 2011). An example is endorsement, which functions as a credible signal, that derives from the endorser's reputational exposure to potential harm, as they incur in losses, if the venture fails to perform well (Gomulya et al., 2019).

The message of a signal refers to the object of the information that signal communicates to receivers (Bafera & Kleinert, 2022). In discussing the message of signals, Bafera and Kleinert draw on Bruton et al. (2009, p. 911), citing that "signals are not universal in the issues they address", a distinction could be observed in conflicts between adverse selection and moral hazard conflicts, the first is more acute in early stages and requires the signals confirming the firm's information

credibility, whilst the second requires the signals demonstrating that the firm is precisely monitored, which becomes more important in later stages, because there is the need to monitor how funding was allocated (Bruton et al., 2009).

A signaler might be encouraged to consider false signaling, if they lack the reliability of the signal, but, in the meantime, they feel that the advantages of signaling surpass the expenses of creating it; however, those who incur in false signals are exposed to penalty costs (Connelly et al., 2011). Entrepreneurs and venture capitalists might have different interests, thus low-performing ventures could communicate deceptive signals, because of this problem, the receiver has the necessity to rely on "universal signals" (Colombo, 2020, p. 253), which give reliable proof of the message (Colombo, 2020). However, this does not contradict the idea of Bruton et al. (2009) that note that "signals are not universal in the issues they address", because it does not preclude the existence of "universal signals", which don't refer to a signal's ability to address all information, but to its capacity do provide verifiable proof to the receiver.

Therefore, trust becomes a crucial element in economic relationships, particularly when it may be undermined by opportunistic behavior and strategic ambiguity; citing Rousseau et al. (1998, p. 395), trust can be defined as "a psychological state comprising the intention to accept vulnerability to the actions of another party based upon the expectation that the other will perform a particular action that is important to you" (Six et al., 2010, pp. 289-290). In the economic field the argument of trust could have managerial implications, because economic agents need to rely on other parties to achieve their individual objectives (Mayer et al., 1995).

In venture capital operations, where there are informational asymmetries and diverging interest, trust can't be fully guaranteed, hence stage financing acts as a "leash", by limiting managerial discretion and reduce the investor's exposure to value destroying decisions (Gompers, 1995). Stage financing, therefore, serves a mechanism to address the misalignment of interests between the entrepreneur and the venture capitalist; entrepreneurs might be driven by personal motivations to continue a project, even if it is poorly performing, these motivations bear little attention to financial returns investors expect, thus creating a risk with knowingly channeling resources toward projects that only serve their ambition (Gompers, 1995).

A trustworthy indicator of a project-specific uncertainty is the stage of development at the time of financing, which gradually declines as the venture grows, Li (2008) distinguishes three general stages based on the Venture Economics classifications: at the Seed/Startup stage, both the funding needed and the possibility of success remain uncertain, in this stage investors rely on the founder's educational path and expertise; at the Early stage, commercial viability starts to emerge, whilst uncertainty remains, thus for the venture having the backing of an endorser amplifies the chances of subsequent investments (Ko & Mckelvie, 2018); at the Expansion/Late stage, established products and predictable revenues enable the venture capitalist to assess costs and returns with less uncertainty (Li, 2008). A growing trend is the "spray-and-spray" (Ewens et al., 2018, p. 423), where venture capitalists, rather than concentrating capital and oversight a selected number of ventures, distribute little amounts across multiple early-stage companies and, eventually, abandon them (Ewens et al., 2018).

Across these stages, venture capitalists consistently occupy the role of the receivers, and it is their ability to interpret signals that ultimately determines the outcome of the relationship: whether they will commit to funding the venture or not. It is therefore important to take into account their main characteristics as receivers according to Bafera and Kleinert (2022): ability, the degree to which they are able to detect and comprehend signals, based on their individual experiences; identity, the degree to which the receiver shares similarities with the signalers, for example a venture capitalist might prefer to invest in companies geographically closer (Tian, 2011); objectives, the degree to which receiver institutional logic affect how they perceive signals; irrationality, which refers to the influence of cognitive biases on investors.

However, shifting the focus from the signal and its properties to the signaling relationships requires acknowledging the actors involved to understand how their role evolves beyond the know venture-venture capitalist relationship, because venture capitalists are not the only receivers in the entrepreneurial finance field, signals can also flow from ventures to other ventures, from the venture capitalist to ventures and from the market to the venture capitalists.

In M&A transactions involving newly public firms, for instance, where acquirers face information asymmetry when evaluating a target's quality, and therefore rely on signals such as a venture capitalist backing or the reputation of the underwriting investment bank (Reuer & Ragozzino, 2012). Signals between ventures can also include competitive marketing signals, including announcements of new goods, price reductions or market entry, which could be genuine or deceptive (Heil & & Robertson, 1991).

Hallen and Pahnke (2016) considered a reverse relationship, with the venture capitalist acting as signaler and the venture as a receiver, the latter will need to evaluate potential investors' quality, the evaluation is found to be shaped by their embeddedness in networks, motivation in the evaluation process, and the target firm's prominence, this last one plays a great role, because entrepreneurs are often biased, thus, despite being well-connected, they remain vulnerable. This reverse relationship demonstrates that the quality of the investor is itself an object of uncertainty, thus both parties send and receive signals.

Macroeconomic factors also function as important signals for venture capitalists' investments, providing informational input for the receiver, for instance, the capital flowing into venture funds acts as a market signal for the venture capitalist: when capital is abundant, investors are more willing to experiment with risky early-stage ventures; when it is scarce, they retreat toward safer and more mature investments (Paik & Woo, 2014). From a real option perspective, when market conditions are volatile, venture capitalists tend to postpone financing decisions, as preserving the option to act later holds more value than committing capital under uncertainty (Li, 2008). Furthermore, Liu and Tian (2022) show that venture capitalists actively extract information from public market to guide their investment decisions, and that the quality of the

information influences how they structure their involvement with portfolio companies, when stock prices reflect future business prospects, investors rely less on tight monitoring through the financing stages as the market itself provides reliable signals.

Throughout the various phases of venture creation and funding, signaling methods are dynamic rather than constant, with a temporal approach, it is possible to contend that various signals can provide varied degrees of significance overtime (Ko & Mckelvie, 2018). Paik and Woo (2014) highlight that ventures in intermediate and later stages face a different signaling challenge compared to their early-stage counterparts: rather than needing to signal credibility, they must demonstrate that their project justifies other capital allocations. Intermediate-stage ventures offer neither the low-cost appeal of early-stage ventures nor the proximity to exit that characterizes later-stage investment, thus venture capitalists need evidence that the venture is not consuming viable resources (Paik & Woo, 2014).

Ko and Mckelvie (2018) show that signals do not carry the same weight throughout the entire financing process, but rather shift in relevance as the venture progresses to next rounds, in the early-stage human capital signals play an important role, because venture capitalists rely on the founder's education and managerial capabilities, however after the initial phase, past experience becomes less decisive, whereas education continues to matter, especially if it is accompanied by the endorsement of prominent investors, whose backing signals quality.

Venture capitalists primarily engage in financing firms during their earliest stages of development, when ventures typically lack an established track record that investors can rely upon (Ewens et al., 2018). At this stage, investment decisions are therefore often shaped by the interpretation of signals conveyed by entrepreneurs and their ventures. However, once this initial phase has been overcome, namely, when a venture begins to accumulate observable performance indicators and the relationship between the entrepreneur and the investors becomes more established, venture capitalist may rely less on interpreting and trusting such signals (Sapienza & Amason, 1993). In principle, the interaction between the two parties should evolve toward a relationship characterized by greater mutual knowledge and trust. Accordingly, in later stages they will likely employ well-established channels to interact as the business develops and its issues become more clearly delineated (Sapienza & Amason, 1993).

Nevertheless, as discussed above, broader market dynamics continue to play a significant role in shaping venture capitalists' investment decisions. Moreover, it can't be assumed that entrepreneurs will always communicate transparently. In some cases, they might strategically deploy misleading or exaggerated signals in an attempt to influence investors' perceptions (Trester, 1998). Given that venture capitalists typically lack full visibility into how the funds they provide are ultimately deployed within the venture, they may once again face conditions of uncertainty.

For this reason, it would be particularly valuable to examine how signaling mechanisms evolve across subsequent funding rounds and to investigate how venture capitalists adjust their investment decisions in response to these evolving signals.

Research limitations. It is important to acknowledge the inherent limitations of this review methodology. The absence of a formal screening protocol means that the review cannot claim exhaustiveness, and the possibility of omitting relevant contributions cannot be entirely ruled out. Additionally, the paper does not empirically test the arguments it advances; the considerations emerged remain theoretical and would benefit from validation.

Managerial implications. Although primarily theoretical, this review might lead to practical relevance. For entrepreneurs, it suggests the importance of adapting their signaling strategy as the venture matures, since signals effectiveness in attracting early-stage investment may carry less weight in later stages (Ko & Mckelvie, 2018), it was seen that human capital signals carry an important weight in the first phase, furthermore, entrepreneurs must cultivate relationships with prominent endorsers to enhance prior human qualities and then rely on observable metrics to communicate efficiency and trust. For venture capitalists, the review sheds light on the value of remaining attentive to how informational environment shifts across stages, as ventures can manipulate signals to their advantage, therefore investors should privilege signals that are costly to fake; venture capitalists could also be biased by the VC syndicate they belong to (Gomulya et al., 2019), which could lead to herd behavior (Gompers et al., 2008). For future contributions, it would be useful to investigate which signal influences investor's investment decisions, since a venture capitalist normally invests in multiple rounds.

Finally, more broadly, the findings suggest that monitoring mechanisms might benefit from being sensitive to the evolving signaling context at each stage of the financing relationship, stage financing contracts might be structured to explicitly account for signal evolution by incorporating the different milestones that the venture should achieve in the various financing rounds, particularly with the aim of mitigating moral hazard concerns.

Originality of the paper. This review contributes to the literature by offering a stage-sensitive lens on signaling in the venture capital financing field. While prior contributions (Connelly et al., 2011; Colombo, 2020; Bafera & Kleinert, 2022) have extensively examined signals, signalers and receivers, the importance of signals throughout financing stages has received comparatively little attention. This paper attempts to organize existing knowledge around the evolution of signaling dynamics throughout the financing lifecycle, and to offer a starting point for future empirical research.

Student Micro-Entrepreneurship and the role of technologies: preliminary findings from 4 African Public Universities

FORSTER AMPADU[1], SARA CARBONE[2], VERA AMPADU[3]

Abstract. *The rapid growth of financial technology (fintech) has greatly transformed access to finance in developing countries, especially in Sub-Saharan Africa, where mobile money plays a key role in digital financial inclusion. Although previous research has mainly examined households, informal traders, and macro-financial indicators, there has been little qualitative focus on student entrepreneurs in universities. This study investigates how mobile money assists student entrepreneurship in Ghana and influences their venture strategies, liquidity management, and risk mitigation efforts.*
Utilising the Technology Acceptance Model (TAM), Financial Inclusion Theory, and Effectuation Theory, this study employs an exploratory qualitative approach. Seventeen student entrepreneurs from Ghanaian public universities completed open-ended questionnaires. Thematic analysis indicates that mobile money serves as more than just a payment method; it is a vital entrepreneurial infrastructure. It promotes liquidity flow, enables immediate supplier payments, boosts customer trust with instant confirmations, reduces dependence on formal banking, supports low-cost risk testing through prepayment options, and aids market growth by integrating with social media commerce.
Despite challenges such as transaction fees, fraud risks, and network instability, participants view these as manageable trade-offs given the operational benefits. The findings expand TAM to micro-entrepreneurial environments, demonstrate how digital finance facilitates financial inclusion at the venture level, and show how mobile money aids effective decision-making under uncertainty. This paper adds to entrepreneurship research by showing how digital financial tools influence venture resilience and growth in resource-limited settings.
Keywords*: Mobile Money; Student Entrepreneurship; Fintech; Financial Inclusion; Ghana; Effectuation*

Framing of the research. The rapid diffusion of financial technology (fintech) has significantly transformed global financial transactions by offering digital alternatives to traditional banking systems (Gomber et al., 2018). In many developing economies, fintech innovations have played a crucial role in expanding financial access for populations that were previously excluded from formal financial systems (Aker and Mbiti, 2010). These technologies reduce barriers such as high transaction costs, limited banking infrastructure, and geographical constraints that often prevent individuals from accessing financial services (Demirgüç-Kunt et al., 2018).

Among fintech innovations, mobile money has emerged as one of the most transformative financial tools. Mobile money refers to electronic financial services accessed via mobile phones, allowing users to send, receive, and store funds without relying on conventional banking institutions (Jack and Suri, 2011). By eliminating the need for physical bank branches and extensive documentation, mobile money has enabled millions of previously unbanked individuals to participate in formal financial systems.

Sub-Saharan Africa has emerged as the global leader in mobile money adoption, mainly due to high mobile phone penetration and limited traditional banking infrastructure. Kenya's M-Pesa exemplifies how mobile money can improve household resilience and enable more stable consumption (Jack and Suri, 2014; Suri and Jack, 2016). In addition to peer-to-peer transfers, these platforms are now supporting savings, microcredit, and merchant transactions, which help foster small businesses and microenterprise growth.

Ghana is a notable example in the development of mobile money in Sub-Saharan Africa. Since 2009, mobile money, locally called "MoMo" has transformed from basic peer-to-peer transfers to a full-fledged digital financial ecosystem. The sector has seen swift increases in transaction numbers and account openings, reflecting its significant role in the country's economy (GSMA, 2024; GSMA, 2025).

Government and regulatory support have further boosted this growth. Policies by the Bank of Ghana, such as interoperability frameworks linking mobile wallets with bank accounts, have improved the functionality and accessibility of mobile money services (Bank of Ghana, 2019; 2024). Consequently, Ghana has become one of the leading mobile money markets in Sub-Saharan Africa.

Existing research highlights how mobile money promotes financial inclusion and helps small businesses thrive (Osei-Assibey, 2015; Odei-Appiah, Wiredu, and Adjei, 2022). However, most studies focus on rural households, informal traders, or low-income groups. Less attention is paid to digitally literate users, like university students, a rapidly growing segment of mobile money users.

As fintech expands, student entrepreneurship is becoming more prominent in higher education worldwide. Universities promote entrepreneurial endeavours among students to address youth unemployment and stimulate innovation (Musariwa and Tinonetsana, 2023). Student entrepreneurship involves business activities that students start and manage during their studies (Morris, Kuratko, and Cornwall, 2013).

In Ghana, entrepreneurship education programs and institutional initiatives have fostered the growth of student-led ventures (Gyamfi, 2014; Larbi and Gyedu, 2021). Many universities have created incubation centres and entrepreneurship hubs to support student innovators and encourage self-employment among graduates (Nyadu-Addo and Mensah, 2018). As a result, Ghanaian students more frequently run micro-enterprises in fields like online retail, digital marketing, fashion, and creative services (Owusu, Yankson, and Osei, 2016; Arko *et al.,* 2024).

Despite this growth, student entrepreneurs face structural challenges similar to those of other microenterprises, including limited access to start-up capital, difficulty obtaining formal credit, and dependence on informal funding such as personal savings or family support (Abor and Biekpe, 2006; Galloway and Brown, 2002). Although social media platforms like Facebook and WhatsApp have lowered entry barriers with affordable marketing options (Ainin et al., 2015; Boateng and Okoe, 2015), the financial infrastructure supporting these student ventures, especially mobile money, remains relatively underexplored.

While quantitative research has explored patterns of mobile money adoption and usage (Blay and Caesar, 2022; Takyi, Sorkpor and Asante, 2025), there remains a lack of qualitative studies examining how different user groups strategically utilise these technologies in routine business activities. Notably, the experiences of student entrepreneurs who use mobile money in their enterprises have been largely overlooked in scholarly discussions.

Considering Ghana's youthful population, widespread mobile phone use, and a growing digital financial sector, university students form a distinct, tech-savvy demographic whose entrepreneurial efforts increasingly rely on digital payment platforms. Analysing how student entrepreneurs incorporate mobile money into their businesses can offer important insights into the links between fintech, financial inclusion, and youth entrepreneurship.

This study draws on three complementary theoretical perspectives to understand how student entrepreneurs utilise mobile money in their business activities. Initially, the Technology Acceptance Model (TAM) (Davis, 1989) describes how people decide to adopt new technologies through two main factors: perceived usefulness and perceived ease of use. TAM has been extensively used in research on mobile payment adoption (Zhou, 2011). Second, Financial Inclusion Theory highlights the crucial role of access to affordable and suitable financial services in promoting economic participation and growth (Demirgüç-Kunt *et al.,* 2018). Mobile money platforms help overcome geographic, institutional, and procedural obstacles that typically hinder access to financial services. Third, Effectuation Theory (Sarasvathy, 2001) proposes that entrepreneurs tend to rely on readily available resources and means rather than on forecasting, especially in uncertain settings. Digital financial tools, such as mobile money, serve as strategic resources, enabling entrepreneurs to test business ideas and manage financial risks at low cost.

Together, these theoretical perspectives provide a comprehensive framework for examining how student entrepreneurs adopt and strategically deploy mobile money within their business operations.

The paper thus seeks to answer the question, "*How does mobile money shape the strategic and operational practices of student entrepreneurs in Ghana?"*

Purpose of the paper. In answering the research question, the paper seeks to:

i. Examine how student entrepreneurs perceive the usefulness and ease of use of mobile money.
ii. Explore how mobile money influences liquidity management and resource circulation.
iii. Analyse how digital payments enable risk mitigation and effectual decision-making.
iv. Identify constraints associated with mobile money adoption in student-led ventures.

The study advances entrepreneurship research in three ways. First, it broadens TAM into micro-venture contexts, redefining perceived usefulness in terms of performance-oriented entrepreneurship. Second, it enhances understanding of financial inclusion by examining how digital finance becomes part of everyday venture routines. Third, it shows how fintech can operationalise effectuation principles in uncertain conditions. Instead of viewing mobile money as merely a supplementary payment tool, the paper positions it as an integral part of entrepreneurial infrastructure that shapes the exploitation of opportunities, experimentation, and resilience.

Methodology. This study adopts an exploratory qualitative research design (Creswell and Poth, 2018) to capture in-depth insights into student entrepreneurial practices. At this time, 17 student entrepreneurs have been purposively selected from Ghanaian tertiary institutions. Participants operated micro-enterprises in fashion retail, food vending, cosmetics sales, digital marketing, online reselling, and baking. All participants actively used mobile money for business transactions.

The selection was based on currently enrolled students who are engaged in an entrepreneurial activity on or off campus. The use of open-ended questionnaires was deemed appropriate and convenient for obtaining responses from student entrepreneurs, given constraints on access to them (Neergaard and Ulhøi, 2007). The instrument included questions on frequency and purpose of mobile money use, perceived benefits and challenges, cash-flow management practices, and risk mitigation strategies. The open-ended nature of the questions allowed participants to articulate experiences in their own words.

Data were analysed using thematic analysis, following Braun and Clarke's (2006) approach, which combines deductive and inductive approaches. The deductive codes were derived from TAM, financial inclusion theory and effectuation

theory. The inductive codes emerged from participant narratives. TO enhance credibility, patterns were cross-validated across responses and themes were refined.
To protect respondents' anonymity, each participant was assigned an abbreviated identifier (P1–P17). These codes were used in all quotations reported in the study, and any identifying information was removed. Participation was voluntary, and responses were used solely for academic research purposes.
Analysis focused on identifying how mobile money shaped operational efficiency, strategic risk management and institutional position vis-à-vis formal banking. Findings were interpreted in relation to established literature on entrepreneurship and fintech to strengthen the theoretical contribution.

Results. The findings show that mobile money has a complex role in student entrepreneurship. It is not just a payment tool but also serves as an entrepreneurial infrastructure integrated into daily business activities. Six key themes emerged: ease of use and perceived usefulness; faster liquidity access; decreased reliance on banking; managing uncertainty via prepayments; market growth; and operational limitations.

1. Perceived Ease of Use and Entrepreneurial Usefulness

Aligned with the TAM (Davis, 1989), participants highlighted ease of use and usefulness as key factors for adoption. However, unlike typical consumer-focused TAM research, usefulness was specifically described using entrepreneurial language.
Participant 1 noted:

> *"Mobile money is straightforward. Even if you are busy with lectures, you can send and receive payments quickly without going to the bank."*

Similarly, Participant 4 explained:

> *"I don't need to leave campus to handle payments. Everything is on my phone."*

Ease of use was associated with improved time efficiency and greater operational flexibility, which are especially important for those balancing roles as students and entrepreneurs. This supports Zhou (2011), who suggests that perceived convenience encourages ongoing use and, in this context, contributes to venture sustainability.
Usefulness was repeatedly framed in terms of performance outcomes. Participant 7, who operates a cosmetology business, stated:

> *"Customers trust you more when you have mobile money because they can pay instantly."*

This indicates that usefulness is partly based on reputation. Instant transaction confirmation serves as a trust signal, aligning with Oliveira et al. (2016), who claim that perceived usefulness increases when users link technology to economic benefits. In this case, economic benefits include greater legitimacy and more seamless customer relationships.

2. Liquidity Acceleration and Cash-Flow Management

A dominant theme was liquidity management. Participants highlighted how mobile money accelerates working capital rotation, which is crucial for micro-ventures operating with minimal financial buffers. Participant 3 stated:

> *"When customers pay through Momo, I can quickly pay my supplier. It keeps the business moving."*

Participant 8 also added:

> *"There is no need to wait for bank clearance. I receive money and use it immediately."*

Liquidity acceleration shortens transaction delays and reduces cash-flow bottlenecks, aligning with findings from Jack and Suri (2014) and Riley (2018) that mobile money enhances financial resilience through quick transfers. In student entrepreneurship, this means faster reinvestment and lower operational downtime. Additionally, having instant access to funds decreases dependence on informal credit. Participant 10 noted:

> *"Before, I sometimes had to borrow a little money to restock. Now, when customers pay instantly, I don't face that problem."*

This suggests that mobile money indirectly lessens reliance on short-term borrowing, aligning with Beck et al. (2018)'s argument that digital payment systems decrease transaction frictions in developing economies.

3. Financial Inclusion and Reduced Dependence on Formal Banking

Mobile money has become a replacement for formal banking systems. While most users had bank accounts, they used them little for business purposes. Participant 5 explained:

> *"I have a bank account, but I hardly use it for my business. Mobile money is faster and more flexible."*

Participant 12 reiterated this sentiment by stating that:

> *"As a student, you don't always have the time for banking procedures. Mobile money works anytime."*

Participant 14 emphasised accessibility:

> *"There's always an agent nearby if you need to withdraw or deposit. It makes business easier."*

These findings align with the existing literature on financial inclusion (Demirgüç-Kunt et al., 2018; Osei-Assibey, 2015), which emphasises accessibility as a key component. Nonetheless, this study broadens the perspective by demonstrating that inclusion goes beyond mere access; it also involves seamless integration into venture operations.
Therefore, mobile money functions as a quasi-bank embedded within entrepreneurial routines. It reduces bureaucratic obstacles associated with formal institutions, aligning with Evans and Pirchio (2014), who argue that mobile money

thrives in regions with scarce or complex formal banking infrastructure.

4. Managing Uncertainty Through Prepayment Strategies

Participants explained how they use mobile money strategically to handle demand uncertainty and inventory risks. Prepayment systems became a key means of reducing these risks. Participant 11, an owner of a baking business, explained:

"Customers pay before I bake. That way I don't waste ingredients."

Similarly, Participant 6, involved in fashion retail, explained:

"I only order items after customers confirm payment. It reduces losses."

These strategies adhere to the "affordable loss" principle central to Effectuation Theory (Sarasvathy, 2001). Instead of predicting demand, students reduce risk by collecting payments upfront. Fisher (2012) asserts that effectual reasoning is prevalent in uncertain and resource-limited situations. Mobile money supports effectuation by reducing transaction barriers and securing commitments before resources are allocated.

Therefore, digital payment systems do more than facilitate transactions; they influence entrepreneurial thinking. Mobile money acts as a tool for iterative experimentation, aligning with Nambisan's (2017) view that digital technologies boost entrepreneurial improvisation.

5. Market Expansion and Hybrid Digital Business Models

The study showed that integrating with social media platforms enabled entrepreneurs to expand their geographic reach beyond campus boundaries, as explained by Participant 9:

"I have customers outside the university. They pay through mobile money, and I send the product through a delivery service."

This sentiment was similarly shared by Participant 13, who added:

"Most of my orders come from Instagram. Customers send payment through momo and I arrange delivery."

From these Mobile money complements social media marketing (Ainin et al., 2015; Boateng and Okoe, 2015), enabling hybrid digital commerce models. In remote transactions, payment confirmations were used to reduce barriers. This demonstrates how fintech integrates into broader digital entrepreneurship ecosystems, reinforcing the argument of Gomber et al. (2018) that fintech reshapes value-creation processes across sectors.

6. Constraints: Fees, Fraud and Network Instability

Despite strong benefits, participants reported operational challenges. These challenges ranged from transaction and other fees, which can impact the profit margins of student businesses, since these businesses are currently operating at a micro scale. This sentiment was shared by Participants 2 and 16. Participant 2 argued that:

"The charges can reduce your profit, especially when transactions are small."

Participant 16 also expressed negative sentiments about network connectivity, noting that it sometimes affects business operations. She stated:

"Sometimes the network delays confirmation, and customers think you haven't received payment."

Fraud risks, particularly fake alerts, were also mentioned. These findings align with Kelly and Palaniappan (2023), who highlight perceived risk and cost as moderators of continued mobile money usage.

However, participants largely framed these issues as manageable trade-offs. As Participant 1 concluded:

"Even with the challenges, I prefer mobile money. It makes business smoother."

This cost-benefit framing suggests that perceived usefulness outweighs perceived risk, reinforcing TAM's predictive relevance in entrepreneurial contexts.

Discussion. This research validates the Technology Acceptance Model (TAM), showing that perceived ease of use and usefulness drive the ongoing adoption of mobile money by student entrepreneurs in Ghana. Participants described the technology as intuitive, accessible, and efficient, supporting Davis's (1989) view that user perceptions are key to technology acceptance. While TAM typically targets individual consumers, this study broadens its scope to include entrepreneurs, in which technology serves as a vital business facilitator. In this setting, mobile money's usefulness goes beyond convenience, aiding liquidity management, speeding up supplier payments, and enabling real-time transaction tracking. This aligns with Zhou's (2011) conclusion that usefulness is closely tied to performance enhancement. Additionally, Oliveira et al. (2016) highlight that perceived usefulness strongly predicts long-term usage when users perceive clear economic benefits, such as better working capital management.

Recent adaptations of TAM in sub-Saharan Africa, particularly by Kelly and Palaniappan (2023), indicate that perceived risk and cost significantly influence perceived usefulness. Despite transaction fees and fraud risks, mobile money's operational advantages usually outweigh these issues. From a financial inclusion perspective, this research shows how mobile money overcomes traditional banking barriers such as collateral requirements and formal income verification. As shown by Jack and Suri (2011) in Kenya and supported by Osei-Assibey (2015) in Ghana, mobile money greatly reduces access barriers to financial services. Acting as a "quasi-bank account," these platforms exemplify a broader move towards digital-first financial systems that may complement or replace conventional banks (GSMA, 2025). This shift is crucial for entrepreneurs with limited capital who face geographic and bureaucratic challenges.

Beyond just technical approval, effectuation theory (Sarasvathy, 2001) details how entrepreneurs leverage mobile money to handle uncertainty. By using the platform to secure prepayments and test new offerings, students follow the "affordable

loss" principle, reducing financial risks. This transforms mobile money from a simple transaction tool into a strategic decision-making aid. Fisher (2012) emphasises that such approaches are essential in resource-limited environments. Ultimately, the incorporation of fintech into student ventures results from a synergy of technological utility, structural accessibility, and behavioural risk management.

Research limitations. The study is exploratory and limited to 17 participants, constraining generalisability. Data are self-reported and context-specific to Ghana. Future research could adopt mixed-methods, longitudinal, or cross-country approaches.

Managerial implications. This study's findings offer several managerial insights for universities, fintech providers, policymakers, and student entrepreneurs. It shows that mobile money serves not just as a payment tool but also as an integrated entrepreneurial infrastructure, emphasising how digital financial technologies can enhance youth entrepreneurial ecosystems in emerging economies.

Universities and entrepreneurship support organisations should incorporate digital financial tools into entrepreneurship curricula and incubation programs. Data show that student entrepreneurs frequently rely on mobile money platforms such as Mpesa and MTN Momo to manage transactions, liquidity, and payments to suppliers. Therefore, entrepreneurship training should cover digital financial management, fintech adoption, and the integration of online commerce. Research on entrepreneurial education highlights that experiential learning and the use of practical resources significantly enhance venture success and entrepreneurial skills (Morris, Kuratko and Cornwall, 2013). Additionally, as entrepreneurial ecosystems become increasingly digital, universities need to prepare students to operate effectively within digitally mediated business environments (Nambisan, 2017). Incorporating fintech literacy into entrepreneurship curricula can therefore strengthen students' ability to manage financial flows and leverage digital infrastructures in their ventures.

Second, fintech providers should recognise university students as a rising segment of micro-entrepreneurs and develop services tailored to their operational needs. The data indicates that student ventures often depend on frequent, low-value transactions and need quick access to liquidity. Therefore, fintech companies could introduce specialised features, such as micro-business wallets, simplified transaction dashboards, and integrated sales-tracking tools. Digital financial platforms add value by minimising transaction friction, enhancing transparency, and enabling resource flow within small firms (Beck *et al.,* 2018; Gomber *et al.,* 2018). Additionally, research on digital platforms shows that ecosystem-focused fintech services can significantly boost the scalability of small ventures by linking payment systems to broader digital networks (Parker, Van Alstyne and Choudary, 2016). By creating solutions tailored for micro-entrepreneurs, fintech providers can boost platform adoption and foster youth business growth.

Third, policymakers and regulators should recognise mobile money as a vital tool for fostering youth entrepreneurship and financial inclusion. Data indicate that many student entrepreneurs prefer mobile money over traditional banking because it is more accessible, faster, and offers greater operational flexibility. Establishing regulatory frameworks that promote interoperability between banks and mobile money services, such as initiatives by the Bank of Ghana, can significantly enhance financial access and efficiency. Research on financial inclusion emphasises that accessible financial services are essential for empowering entrepreneurship and encouraging economic participation among underserved groups (Demirgüç-Kunt et al., 2018; Aker and Mbiti, 2010). Furthermore, studies of mobile money ecosystems show that digital financial services can stimulate local economies by lowering transaction costs and strengthening financial resilience (Jack and Suri, 2014; Suri and Jack, 2016). Thus, policies that support digital payment infrastructure can bolster entrepreneurial ecosystems and reduce barriers for young entrepreneurs with limited financial resources.

Fourth, the findings indicate that student entrepreneurs can enhance their financial management by using mobile money to make effective decisions. Many participants reported employing prepayment strategies to mitigate uncertainty and prevent inventory losses. This behaviour aligns with the "affordable loss" principle in Effectuation Theory, which suggests that entrepreneurs facing uncertainty should focus on minimising potential losses rather than relying solely on predictive planning (Sarasvathy, 2001). Digital payment systems support this by allowing entrepreneurs to secure customer commitments before allocating resources. Research shows that effectual logic is especially prevalent among resource-limited entrepreneurs working in uncertain settings (Fisher, 2012). Mobile money fosters experimentation and iterative opportunity development, helping student entrepreneurs test products, validate demand, and grow gradually with limited risk.

Finally, managers of digital business ecosystems should acknowledge the increasing integration of social media platforms and mobile payment systems in emerging entrepreneurial models. Many entrepreneurs use platforms like Instagram, WhatsApp, and Facebook, along with mobile money, to enable online orders, remote payments, and delivery-based commerce. This hybrid digital commerce approach illustrates broader changes in entrepreneurial ecosystems, where digital technologies foster new opportunities and market access (Nambisan, 2017). Existing research confirms that social media significantly extends small businesses' marketing reach, especially when paired with accessible digital payment systems (Ainin *et al.,* 2015; Boateng and Okoe, 2015). Promoting the integration of digital marketing, logistics, and payment systems can therefore help student entrepreneurs expand their market access beyond campus.

Overall, the managerial implication of this research is that mobile money should be viewed as a foundational component of contemporary entrepreneurial ecosystems rather than merely a financial service. When effectively integrated into entrepreneurship education, fintech platform design, and public policy frameworks, digital financial technologies can

accelerate venture experimentation, enhance financial inclusion, and strengthen the operational capabilities of youth-led enterprises.

Originality of the paper. This paper conceptualises mobile money as entrepreneurial infrastructure embedded within student venture ecosystems. By integrating TAM, Financial Inclusion Theory, and Effectuation Theory, it bridges fintech and entrepreneurship scholarship and contributes context-sensitive insight into youth-led micro-enterprises in emerging markets.

The Evolving Role of University in the development of Entrepreneurial Ecosystems: a multi-stage framework

ROSANGELA FEOLA[1], CHIARA CRUDELE[2], RICKY CELENTA[3], ROBERTO PARENTE[4]

Abstract. *This short paper examines how an entrepreneurial university catalyzes the emergence of an entrepreneurial ecosystem in a peripheral and institutionally thin context by orchestrating social capital. The study focuses on SEIUNISA, a university-led platform launched by the University of Salerno to promote student entrepreneurship and activate multi-stakeholder engagement. Adopting a qualitative single-case design, the paper draws on interviews, participant observation, and documentary evidence. Findings identify a four-stage process through which the university acts as an anchor organization: building an internal community, activating boundary-spanning ties, converting external connections into embedded collaborations, and enabling more autonomous bottom-up ecosystem dynamics. The paper shows that university-led ecosystem emergence depends on the sequential development of bonding and bridging social capital and on their transformation through structural, cognitive, and relational mechanisms. The study contributes to entrepreneurial ecosystem and entrepreneurial university research by offering a process model of university-led ecosystem leadership in peripheral contexts, highlighting bridging-to-bonding conversion as a key mechanism, and showing that autonomous ecosystem development is path-dependent on prior orchestration. Managerially, the findings stress the importance of dedicated platform capabilities, recurring co-creation arenas, and long-term institutional commitment.*

Keywords: *entrepreneurial universities; entrepreneurial ecosystems; social capital; anchor organizations; peripheral regions; case study*

Framing of the research. In recent years, the entrepreneurial ecosystem (EE) perspective has become a central lens for understanding how entrepreneurship is enabled within specific territories (Audretsch & Belitski, 2017; Theodoraki, 2020; Wurth et al., 2022). EEs are commonly described as configurations of interdependent actors, institutions, and contextual conditions that jointly support productive entrepreneurship within a given territory (Stam & Spigel, 2016; Spigel, 2017). While this literature has significantly improved our understanding of the key components of ecosystems, much of it still adopts a structural and relatively static view, focusing on the presence or absence of enabling factors rather than on the processes through which ecosystems actually emerge and evolve over time (Brown & Mason, 2017; Stam & van de Ven, 2021).

A growing stream of research has started to challenge this limitation by emphasizing that EEs are not pre-existing systems waiting to be activated, but socially constructed, path-dependent, and institutionally embedded processes (Audretsch et al., 2021; Wurth et al., 2022; Ritala et al., 2021). From this perspective, ecosystems are shaped through continuous interaction among heterogeneous actors, legitimacy-building efforts, institutional work, and the gradual alignment of resources and expectations (Mack & Mayer, 2016; Ritala et al., 2021). This processual view is particularly relevant in nascent or fragile contexts, where entrepreneurial density is low, support infrastructures are weak, and coordination mechanisms are underdeveloped (Spigel & Harrison, 2018; Donaldson et al., 2025). In such settings, the emergence of EEs depends less on optimizing an already existing system and more on creating the conditions that enable collective entrepreneurial action in the first place ((Sotarauta & Pulkkinen, 2011).

Within this debate, universities have increasingly been recognized as strategic actors in ecosystem development (Audretsch & Link, 2017; Lira & Guerrero, 2025). Entrepreneurial university (EU) research has shown that universities are no longer confined to their traditional missions of teaching and research, but are progressively expected to contribute to regional innovation, venture creation, and wider socio-economic development (Hayter, 2016; Klofsten et al., 2019; Rådberg & Löfsten, 2024). However, although prior studies have documented the importance of entrepreneurship education, technology transfer, incubators, and partnerships, fewer contributions have explained how universities actively foster the emergence of an EE, especially in contexts where intermediary organizations are scarce and local coordination is weak (Foss & Gibson, 2015; Kwong et al., 2022; Maritz et al., 2024). In other words, the literature acknowledges that universities matter, but still provides limited understanding of the mechanisms through which they build communities, connect internal and external actors, and sustain ecosystem evolution and consolidation beyond isolated initiatives.

This issue becomes even more significant in peripheral and institutionally thin regions. In these contexts, resource constraints, fragmented networks, lower levels of trust, and weak support structures can hinder the development of opportunity-driven entrepreneurship and reduce the capacity of local actors to coordinate around shared innovation agendas (Xu & Dobson, 2019; Ghio et al., 2019). Under such conditions, the role of a legitimate and relatively stable

actor becomes crucial. Recent studies suggest that universities may perform this function as anchor organizations, namely actors capable of providing continuity, legitimacy, brokerage, and strategic direction to emerging ecosystems (Benneworth & Cunha, 2015; Breznitz & Feldman, 2012; Spigel & Harrison, 2018). Yet the anchoring role of universities should not be interpreted merely in infrastructural or organizational terms. Rather, it is fundamentally relational: it depends on the capacity to foster repeated interaction, shared narratives, trust-based collaboration, and durable linkages across multiple categories of stakeholders (Lamine et al., 2015; Roundy et al., 2018).

This is why social capital offers a particularly useful lens for framing university-led ecosystem emergence. In the formative stages of an ecosystem, when formal institutions and market connections are still fragile, the development of social capital becomes a key mechanism through which actors gain access to information, legitimacy, mentoring, and collaborative opportunities (Spigel, 2017; Spigel & Harrison, 2018; Davidsson & Honig, 2003). Social capital is not only about network density or the existence of ties; it also concerns the presence of shared meanings, reciprocal expectations, and trust that make coordination sustainable over time (Bourdieu, 1986; Nahapiet & Ghoshal, 1998). For this reason, distinguishing between bonding and bridging social capital is especially valuable. Bonding ties help create internal cohesion, a shared identity, and an initial entrepreneurial community, while bridging ties connect that community to external stakeholders such as firms, investors, incubators, and public organizations (Claridge, 2018; Liao & Welsch, 2005; Burt, 2000). However, ecosystem emergence and consolidation ultimately depend on more than the coexistence of these ties: it requires mechanisms through which external connections are progressively transformed into embedded and durable collaborations (Harima & Harima, 2025; Inkpen & Tsang, 2005).

Against this background, the present study frames university-led ecosystem emergence as a staged and relational process. The paper conceptualizes EU as an anchor organization that intentionally orchestrates the formation and transformation of social capital over time (Harima & Harima, 2025; Spigel & Harrison, 2018). This framing is particularly suitable for understanding how ecosystems can be built "from scratch" in peripheral regions, where the challenge is not only to connect actors, but also to create the relational foundations that allow an entrepreneurial ecosystem to take shape and progressively become more self-sustaining.

Purpose of the paper. The purpose of this paper is twofold. First, it aims to explain how an EU can catalyze the emergence of an EE in a peripheral and institutionally thin context. Second, the study investigates how university-led action can intentionally support the creation, expansion, and consolidation of relationships among heterogeneous actors in ways that progressively enable ecosystem development beyond emergence. To address these aims, the study adopts a social capital perspective. This lens is particularly suitable because it allows entrepreneurial ecosystem emergence to be interpreted as a relational and staged process, rather than as the mere presence of favorable actors or conditions. In particular, the paper draws on the distinction between bonding and bridging social capital, and on the idea that ecosystem development depends on mechanisms through which these ties are progressively transformed into more embedded and durable forms of collaboration. On this basis, the paper investigates how a university-led platform builds and transforms bonding, bridging, and conversion social capital during the emergence of an entrepreneurial ecosystem in an institutionally thin region. At the same time, it examines the conditions under which university-led orchestration can foster a transition from coordinated, top-down ecosystem building to more autonomous, bottom-up ecosystem dynamics. Overall, the paper seeks to offer a process-based understanding of university-led ecosystem emergence by clarifying the relational mechanisms through which entrepreneurial universities move from internal community formation to broader and more self-sustaining ecosystem dynamics.

Methodology. The study adopts a qualitative single-case study design (Yin, 2018; Eisenhardt, 1989) that is particularly appropriate for investigating complex, context-dependent, and processual phenomena such as ecosystem orchestration, community formation, and cross-boundary collaboration. The inquiry follows an abductive logic, iterating between empirical material and theory in order to refine the interpretation of bonding, bridging, and conversion dynamics rather than testing predefined hypotheses. The research aimed to investigate the role of the entrepreneurial university across different stages of entrepreneurial ecosystem development, follows a two-step approach. In the first step, the study focused on the emergence phase of the ecosystem. In the second phase (currently under development), the study explores the university's role in the consolidation of the ecosystem.

The empirical setting is SEIUNISA (Student Entrepreneurship and Innovation @UNISA), a university-led initiative developed at the University of Salerno in Southern Italy. The case was selected purposively because it offered a suitable context for observing ecosystem emergence in a peripheral and institutionally thin environment, and because the initiative was explicitly designed to activate student entrepreneurship through interaction with a broader set of external stakeholders. As such, the case provides a useful opportunity to examine how a university-led platform can operate as an anchor for ecosystem development.

Data were collected through the triangulation of multiple qualitative sources between 2022 and 2024. First, the study relied on extended participant observation across a broad range of SEIUNISA activities, including workshops, mentoring sessions, team-building moments, project meetings, training activities, community events, and international study tours. This longitudinal immersion made it possible to observe how relationships evolved over time across both formal and informal settings. Second, six semi-structured interviews were conducted with key actors involved in the initiative, including the program coordinator, tutors, students, startup founders, and external stakeholders. The interviews explored participants' perceptions of the initiative's evolution, with particular attention to trust formation, collaboration patterns,

and interactions across organizational and institutional boundaries. Third, documentary sources were collected to support triangulation and temporal reconstruction, including internal reports, communication materials, calls, slide decks, web content, media coverage, and other program-related documents.

A second wave of follow-up data collection started in 2025 and is still ongoing. This phase involves interviews with entrepreneurs and founders of university startups connected to the SEIUNISA program, with the aim of understanding the needs and challenges that emerge in the later stage of ecosystem development and exploring how the EU can support them during this phase.

All interviews were recorded and transcribed, and observational and documentary materials were systematically archived through a case study protocol.

Data analysis was conducted through iterative rounds of qualitative coding and interpretive comparison. In the first stage, descriptive coding was used to identify relevant actors, activities, and interaction contexts. In the second stage, the analysis focused on relational mechanisms associated with the structural, cognitive, and relational dimensions of social capital, such as trust building, knowledge sharing, collective identity formation, and stakeholder engagement. In the final stage, these mechanisms were interpreted through the bonding–bridging–conversion framework in order to reconstruct the process through which the university-led platform supported ecosystem emergence over time. Triangulation across interviews, observations, and documents, together with analytical memos and ongoing comparison among sources, strengthened the credibility and internal consistency of the findings. All participants provided informed consent and data were anonymized.

Results. The analysis shows that SEIUNISA supported entrepreneurial ecosystem emergence through four cumulative, interconnected, and partially overlapping stages of social capital creation. Across these stages, the university acted not merely as a provider of entrepreneurship support, but as an anchor organization that intentionally built an internal community, connected it to external stakeholders, consolidated selected ties into embedded collaboration, and progressively enabled more autonomous ecosystem dynamics. In this sense, ecosystem emergence in a peripheral context depended on the sequential development of bonding and bridging social capital across cognitive, structural, and relational dimensions.

Stage 1: Building an internal community. The first stage focused on creating an internal entrepreneurial core of students, researchers, laboratories, and university staff around a shared entrepreneurial mindset. SEIUNISA primarily fostered bonding social capital through cognitive and relational mechanisms, especially via the Innovators program, which selected 50 students from 17 departments and positioned them as both trainees and peer diffusers of entrepreneurial culture within the university. This internal consolidation was reinforced through branding, identity-building, communication channels, and enabling infrastructures such as laboratories, research centers, and co-working spaces. Together, these mechanisms strengthened trust, belonging, and collective identification, while also increasing the initiative's credibility toward external stakeholders.

Stage 2: Connecting external stakeholders. Once an internal core had been established, SEIUNISA expanded outward and activated bridging social capital by connecting the community with regional and international actors, including incubators, investors, public agencies, entrepreneurs, innovation networks, and academic partners. This stage was mainly structural and cognitive, as the platform broadened its relational reach through mentoring, inspirational talks, one-to-one meetings, and international exposure activities. Internationalization played a particularly important role through study tours, visiting professors, and participation in international networks. These activities did more than simply add contacts: they enhanced the legitimacy of both the platform and its participants and transformed the university's institutional standing into actionable opportunities and boundary-spanning ties.

Stage 3: Integrating and converting ties. The third stage marked a shift from network expansion to tie consolidation. The evidence suggests that simple connectivity was not sufficient to sustain ecosystem emergence; what mattered was the platform's ability to convert selected external ties into more embedded, trust-based, and durable collaborations. SEIUNISA pursued this through repeated interaction, co-creation formats, and mechanisms that institutionalized collaboration around projects and ventures. Meet-up events, team-building activities, the collection of external calls for ideas, and the A.L.I. program (providing pre-incubation and seed support for student-founded startups), all contributed to connecting internal and external actors through concrete collaboration and validation processes. In this phase, internal bonding ties were projected outward, while external bridging ties were progressively internalized into the ecosystem's relational core. As a result, external stakeholders ceased to be occasional contacts and became recurring collaborators embedded in shared practices and mutual expectations.

Stage 4: Advancing toward autonomous ecosystem dynamics. In the fourth stage, ecosystem dynamics became increasingly self-reinforcing and less directly dependent on university coordination. While earlier phases were shaped by visible top-down orchestration, this phase was marked by bottom-up initiatives from students, startups, and external organizations. Local banks, public agencies, corporations, and other actors proactively engaged with initiatives generated by the SEIUNISA community, while student-founded ventures independently expanded their networks within and beyond

the university. The cases of Startup A and Startup B illustrate this transition, showing how the relational infrastructure built in earlier stages generated path-dependent effects: once trust, legitimacy, and collaboration routines had been established, actors increasingly mobilized resources and formed partnerships without direct orchestration by the university. Autonomy therefore emerged not as an alternative to leadership, but as the outcome of earlier sequenced orchestration.

With specific reference to the second step of the research project, preliminary follow-up evidence suggests that the transition toward ecosystem consolidation, does not imply a complete withdrawal of the EU. Rather, once startups begin to emerge from the ecosystem and move toward market-facing development, a new set of needs becomes visible, requiring a different and more selective form of university support. In this post-emergence phase, the role of the university appears to shift from broad ecosystem orchestration to venture-oriented anchoring, especially for startups that still depend on external validation, access to specialized competences, and legitimacy in front of key stakeholders such as incubators, corporate partners, and investors. More specifically, the follow-up interviews indicate two recurrent areas in which university role remains relevant. First, startups continue to require active support in the early development of their ventures, particularly in product, technology, and market validation. Even when entrepreneurial teams have already gained a degree of autonomy, they often still rely on university laboratories, expert networks, mentors, and applied research competences to refine prototypes, test assumptions, and strengthen the technical and commercial credibility of their projects. In this sense, some of the validation mechanisms already observed in Stage 3 do not disappear after ecosystem emergence, but continue to matter in a more targeted way as startups move from relational embedding to venture consolidation. Second, the university continues to play an important reputational and legitimating role. As startups approach investors and external markets, affiliation with the university can function as a signal of quality, seriousness, and selection, reducing uncertainty for external evaluators. This suggests that, in the consolidation phase, the university's contribution is not limited to providing knowledge or infrastructure, but also includes symbolic and reputational intermediation that supports startups in crossing the threshold from ecosystem emergence to broader market recognition.

Overall, the results indicate that SEIUNISA fostered ecosystem emergence through a multi-staged process in which internal cohesion, external brokerage, relational conversion, and autonomous advancement built on one another over time. At the same time, preliminary follow-up evidence suggests that the end of the emergence phase does not eliminate the role of the entrepreneurial university, but redefines it: as the ecosystem enters a consolidation phase, university support becomes more selective and venture-oriented, especially in relation to validation activities and reputational endorsement toward external stakeholders. The case therefore shows that in institutionally thin contexts, university-led ecosystem building depends not only on the capacity to intentionally generate and transform social capital during emergence, but also on the ability to sustain post-emergence venture development through targeted forms of technical, relational, and legitimacy support.

Research limitations. This study presents some limitations that should be acknowledged. First, the findings are based on a single qualitative case study and are therefore context-specific. SEIUNISA operates in a peripheral and institutionally thin region of Southern Italy, characterized by particular institutional, economic, and cultural conditions. As a result, the transferability of the findings to other university settings, regions, or more mature entrepreneurial ecosystems should be considered with caution. Second, although the study benefits from longitudinal immersion and rich triangulation across interviews, observation, and documentary sources, it mainly captures the early stages of ecosystem emergence. The analysis therefore offers limited evidence on the long-term stability of the relational dynamics observed, especially regarding whether the transition toward more autonomous ecosystem development can be sustained over time. Third, the qualitative design privileges processual depth over empirical breadth. While this approach is appropriate for reconstructing mechanisms of bonding, bridging, and conversion social capital, it does not allow systematic comparison across different institutional environments or program configurations. Future studies could strengthen external validity by adopting comparative multi-case designs and longer-term longitudinal approaches.

Implications. This study advances research on EE, social capital, and EU. First, it develops a process-based account of university-led ecosystem emergence by illustrating how the bonding–bridging–conversion logic unfolds across a four-stage orchestration sequence. In doing so, the paper extends recent work on ecosystem leadership by specifying the enabling conditions and action mechanisms through which a university-led platform builds internal cohesion, activates boundary-spanning ties, converts them into embedded collaboration, and gradually enables more autonomous ecosystem dynamics. The findings also suggest that these stages are sequenced yet partially overlapping, and that ecosystem momentum depends on continuity across stages rather than on a linear progression from one phase to the next (Harima and Harima, 2025; Spigel and Harrison, 2018; Wurth et al., 2022). Second, the study advances social capital theorization in entrepreneurial ecosystem research by clarifying the dynamic interplay between social capital forms and dimensions during ecosystem emergence. The findings show that bridging ties and structural brokerage, while necessary, are not sufficient to generate durable ecosystem development unless they are supported by cognitive alignment, repeated interaction, and trust-based collaboration. In particular, the paper identifies bridging-to-bonding conversion as a pivotal mechanism through which external connections become embedded partnerships. This helps explain how ecosystems move from a loose network of contacts to a collaborative community capable of sustained collective action (Nahapiet & Ghoshal, 1998; Inkpen & Tsang, 2005). Third, the paper refines EU theory by conceptualizing the university not simply as a provider of entrepreneurial support, but as an anchor organization whose orchestration capabilities accumulate path-

dependently over time. The case shows that bottom-up initiatives and decentralized ecosystem dynamics do not emerge spontaneously, but become feasible only after earlier orchestration has created legitimacy, trust, and collaborative norms. The study therefore contributes to a more relational and evolutionary understanding of the EU, particularly in peripheral and institutionally thin contexts where ecosystem emergence depends on the presence of a stable and legitimate coordinating actor (Benneworth and Cunha, 2015; Breznitz and Feldman, 2012; Rådberg and Löfsten, 2024). Fourth, the preliminary follow-up evidence extends this contribution by suggesting that once startups begin to operate more autonomously in the ecosystem and approach broader market-facing development, the university's function appears to shift from ecosystem orchestration to more selective forms of venture-oriented support, especially in relation to product, technological, and market validation, as well as reputational endorsement toward external stakeholders such as incubators and investors.

The findings generate practical implications for both universities and policymakers. For universities, the results suggest that effective ecosystem building requires a stage-contingent and platform-based approach. In early phases, universities should invest in internal community formation by creating recurring programs, visible identity markers, stable interaction spaces, and shared narratives that cultivate an entrepreneurial culture across students, researchers, and laboratories. Once an internal nucleus is established, universities should deliberately expand toward external engagement by designing mentoring programs, challenge-based initiatives, networking events, and partnership formats that connect internal actors with firms, incubators, investors, public agencies, and innovation networks. The findings also show that universities should move beyond episodic collaborations and invest in conversion mechanisms that stabilize external ties over time. Structured co-creation events, matchmaking tools, and shared validation routines are especially important because they help transform temporary contacts into trust-based and recurrent partnerships. This, however, requires sustained institutional commitment and dedicated professional capacity, including governance roles, staff, and routines that ensure continuity and prevent fragmentation across short-term initiatives. Finally, universities should plan for progressive decentralization by enabling peer-led formats, community champions, and bottom-up initiatives once relational infrastructure and legitimacy are sufficiently established.

For policymakers, the study suggests that ecosystem policy should not be limited to startup-level or project-based support. In institutionally thin contexts, policy should also strengthen the orchestration capacity of legitimate coordinating actors, often universities, by providing multi-year funding, capability-building support, and incentive systems that reward collaboration, engagement, and durable cross-actor outcomes. Policymakers can also facilitate ecosystem maturation by supporting joint forums and shared platforms where universities, industry, government, and civil society interact regularly and co-design priorities. At the same time, policy frameworks should encourage governance arrangements that progressively reduce long-term dependency on the orchestrator as the ecosystem becomes more autonomous and self-reinforcing.

Originality of the paper. The originality of this paper lies in its process-based explanation of how an EU catalyzes the emergence of an entrepreneurial ecosystem in a peripheral and institutionally thin context. Rather than portraying the university as a simple provider of entrepreneurial support, the study conceptualizes it as an anchor organization that intentionally orchestrates the staged development of social capital over time. In particular, the paper advances existing research by proposing a multi-stage process model that shows how internal community building, external stakeholder connection, relational conversion, and autonomous ecosystem advancement unfold through partially overlapping phases. It also highlights bridging-to-bonding conversion as a pivotal mechanism through which external ties become embedded, trust-based, and durable collaborations, thereby clarifying how ecosystems move from fragmented connections to more self-sustaining dynamics. In this way, the study contributes a relational and evolutionary account of university-led ecosystem emergence that is especially relevant for peripheral settings, where ecosystem development depends on deliberate orchestration before more autonomous bottom-up dynamics can emerge (Harima and Harima, 2025; Spigel and Harrison, 2018; Wurth et al., 2022). Moreover, research follow-up insights suggest that advancing toward autonomous ecosystem dynamics should not be interpreted as a condition of full independence from the university, but rather as the beginning of a new phase in which ecosystem autonomy and selective university support coexist. While collective ecosystem dynamics become more decentralized, some ventures still require the university to act as validator, broker, and reputational guarantor. This extension opens an important line of inquiry for the broader research project, namely how the role of the entrepreneurial university evolves from ecosystem emergence to ecosystem consolidation, and how its support mechanisms change as ventures move from community-based development to market-facing growth.

The Hidden Costs of Entrepreneurial Soft Skills: Identity, Behavioural Integrity and Word-Deed Misalignment. Evidence from a ZMET Analysis.

ALESSIO SARTORE[1], PAOLA SIGNORI[2]

Abstract. *Identity economics theorises that misalignment between values and behaviours generates Identity Costs (IC). While this construct has considerable theoretical appeal, its assessment remains critical. Behavioural Integrity (BI) research offers validated word-deed alignment measures but has analysed alignment exclusively from the observer's perspective, leaving the actor's own experience unexplored.*

This study aims to reveal the hidden costs of entrepreneurial soft skills and operationalises Identity Cost (IC) through Behavioural Integrity (BI), reorienting BI from observer perception to actor experience.

The Zaltman Metaphor Elicitation Technique (ZMET), which leverages the metaphorical nature of cognition to access deeper cognitive patterns, was applied in twelve interview sessions. Data coding, run with Atlas.ti, distinguishes Espoused Prescriptions (ESP) and Enacted Behaviours (ENA). Further interpretations rely on Carl Rogers' framework of intrapersonal congruence, where word-deed alignment is assessed as congruent or incongruent.

As a result, two types of entrepreneurial practices emerge: "Congruent" entrepreneurs with aligned patterns and coherence metaphors ("pack", "little fish"); and "Incongruent" entrepreneurs with misaligned patterns and distance metaphors ("drawer", "solitary battle"), showing entrepreneurial hidden costs in the use of soft skills.

Research limitations: Cross-sectional, single-region design requires longitudinal and cross-industry replication.

Managerial implications: Reflexive practices help entrepreneurs surface word-deed incongruence. Behavioural Integrity offers entrepreneurs a path toward sustainable competitive advantage.

Originality of the paper: The study offers a multidisciplinary exploration of entrepreneurial soft skills' hidden costs, through a novel operationalisation of Identity Costs, shifting the measurement perspective of Behavioural Integrity from external observer to the actor's own experience.

Keywords: *Soft Skills, Entrepreneurship, Identity Cost, Behavioural Integrity, Identity Economics, ZMET, SMEs entrepreneurs.*

Framing of the research. When entrepreneurs publicly espouse values about how they manage people and organisations, yet struggle to act on them, the problem is not simply one of inconsistency. The gap between words and deeds carries a specific theoretical name: Akerlof and Kranton (2000, 2005, 2010) call it Identity Cost (IC), a utility loss that occurs when a person's behaviour violates the prescriptions attached to the social category they belong to. For SME entrepreneurs, these prescriptions go beyond technical excellence (hard skills) and extend into how people are managed.

This gap between what entrepreneurs say and what they do has concrete consequences: psychological distress and eroded sense of authenticity and ultimately, constrained performance (Simons et al., 2015, 2022). Identity Economics, as developed by Akerlof and Kranton (2000, 2005, 2010), provides a robust theoretical foundation for understanding how personal identity shapes economic behaviour. However, translating their economic model into measurable constructs within specific organisational contexts requires methodological innovation to quantify identity costs. A separate line of research, Behavioural Integrity (BI), has followed a different path. Simons (2002) and Simons et al. (2022) built validated scales to measure how followers perceive the consistency between what their leaders say and what they do (Palanski & Yammarino, 2007, 2009). Both BI and Identity Economics deal with the consequences of gaps between words and actions, but so far the two literatures have remained largely disconnected. This is especially problematic in entrepreneurial settings, where the behavioural prescriptions tied to identity are often implicit and constructed individually rather than shared across a professional group (Simons et al., 2022). As such, this study addresses the following research question:"How do soft skills incongruence generate hidden costs that constrain entrepreneurial practice?"

This study adopts three complementary theoretical lenses to address this gap. Behavioural Integrity (BI) provides the observational framework to detect word-deed misalignment, yet has so far measured alignment only from the observer's side (company workers evaluating their leaders). In contrast, the actor's own experience of misalignment remains unexplored. Identity Economics addresses precisely this gap. In Akerlof and Kranton's model, when a person violates the behavioural prescriptions associated with their social category, the result is a utility loss, which the authors describe as "evokes anxiety and discomfort in oneself" (2000, p. 728). The construct is theoretically powerful, but the economic framework stops there: it tells us that the cost exists, not what it looks like psychologically. This is where Rogers (1959) becomes necessary. In his person-centred theory, congruence refers to how close or how far the distance is between a person's self-concept, meaning how they represent themselves to themselves, and their experience, meaning what they do

and feel in practice. When a significant discrepancy exists between these two levels, the person enters a state of incongruence that generates anxiety and reliance on defensive processes. Translated into our framework, the entrepreneur's espoused soft-skill prescriptions (ESP) function as self-concept declarations, while enacted behaviours (ENA) constitute experience. When ESP and ENA align, the entrepreneur is congruent in Rogers' sense of the term. When the two levels diverge, the person enters a state of incongruence, and the discomfort that follows, we argue, is what Akerlof and Kranton (2000) formalise as Identity Cost. Rogers gives us something that Identity Economics alone does not provide: a psychological account of why misalignment is costly for the person who experiences it, not only for those who observe it from the outside. It is this convergence across the three frameworks (BI to detect the gap, Identity Economics to frame it as a cost, Rogers to explain why it hurts) that allows us to study what happens when entrepreneurs live a distance between what they declare and what they practice. Recent management scholarship helps fill this gap: identity processes operate at an intrapersonal level (Bataille & Vough, 2022), and identity threats are subjective experiences appraised by the actor (Petriglieri, 2011), not evaluations made by external observers. So, if IC is intrapersonal in nature, studying it requires a conceptual reorientation of BI, moving from observer perception to actor intrapersonal experience. A methodology can access that internal experience: the Zaltman Metaphor Elicitation Technique (ZMET), a projective interview method that surfaces unconscious cognitive structures through visual metaphor analysis (Utama & Widyarini, 2025; Zaltman & Coulter, 1995; Lakoff & Johnson, 2008), precisely because IC, as a latent construct rooted in self-perception, would remain systematically concealed by conventional interview or survey approaches.

Entrepreneurs of micro-enterprises and SMEs (10–30 employees) provide an appropriate empirical context. In firms of this size, it is difficult to separate the entrepreneur from the enterprise. The founder's personal values and behavioural integrity directly affect how the firm is perceived and how it performs (Cardon et al., 2005). When the entrepreneur says one thing and does another, clients, employees, and the local community notice. The Veneto region, in northeastern Italy, offers a particularly suitable context for this investigation: it hosts one of the highest concentrations of SMEs in Europe, and its artisan tradition emphasises quality, authenticity, and the relationship with the client (Kroezen et al., 2021; Micelli, 2011). Measuring IC in this context, however, is not straightforward. Entrepreneurs may incur identity costs without realising it. The constraints that word-deed misalignment imposes on practice often operate through mechanisms that are implicit and hard to put into words, which is precisely why conventional survey instruments risk missing them. This study contributes to filling this gap by operationalising identity costs and connecting Identity Economics with the BI literature. It also shows that ZMET can surface identity prescriptions that would otherwise remain invisible to other methods.

Purpose of the paper. This study aims to reveal the hidden costs of entrepreneurial soft skills and operationalises Identity Cost (IC) through Behavioural Integrity (BI), reorienting BI from observer perception to actor experience. Akerlof and Kranton (2000, 2005, 2010) introduced personal identity as a key variable in economic behaviour, extending utility models to incorporate social categories and the behavioural prescriptions associated with them. In their framework, identity derives from social categories, such as "entrepreneur," "craftsperson," or "professional", each carrying prescribed behaviours (Davis, 2011). Individuals experience utility gains when actions align with identity-based prescriptions and utility losses when they misalign (Solomon & Mathias, 2020). As Akerlof and Kranton (2000, p. 719) observe, "People may choose their actions to avoid losses in identity". When actions diverge from prescriptions, "there is a loss of utility" (ibid., p. 720) that may exceed material gains from divergent behaviour. This psychological cost operates through the cognitive dissonance arising when behaviour contradicts internalised norms (Tajfel et al., 2001). Entrepreneurial identity presents a compelling application of this framework as entrepreneurs occupy a social category with strong behavioural prescriptions around autonomy and innovation, among others (Mmbaga et al., 2020; Shepherd & Haynie, 2009; Cardon et al., 2005). In the case of SMEs entrepreneurs, identity prescriptions often go beyond technical competence and extend into how people are managed: collaboration, leadership, communication, and participative decision-making. When an entrepreneur declares these values but does not consistently act on them, the result can be psychological tension and a sense of reduced authenticity. Simons et al. (2015, p. 832) define BI as "the perceived pattern of alignment between an actor's words and deeds". What makes BI particularly useful for our purposes is that, unlike IC, it has been operationalised through validated scales. Simons' meta-analysis shows that word-deed alignment is strongly associated with trust, commitment, and performance: when leaders do what they say, followers trust them more and engage more (Simons et al., 2022). BI can serve as a measure of IC. Our conceptual Hidden Costs formula is operationalised as follows:

$P = K - CI$

Where P represents entrepreneurial practice, K represents competency endowment (encompassing hard skills, soft skills and human capital; Teece, 2007), and CI captures identity costs. We present this as a conceptual formula rather than a testable equation: K is held constant across our analysis, while CI varies across entrepreneur profiles. The formula proposes that entrepreneurial practice depends not only on what entrepreneurs can do (K = competencies) but also on IC from behavioural inconsistency. We measure IC as inversely related to BI: entrepreneurs with high word-deed alignment experience lower costs, whereas those with persistent misalignment incur higher costs. Both constructs address the psychological discomfort and performance consequences of gaps between stated values and enacted behaviours. Our ZMET approach is designed to reveal these IC in entrepreneurial contexts where prescriptions may be tacit and individually constructed.

Methodology. This study uses ZMET to assess IC through BI in SME entrepreneurial contexts. We randomly selected twelve entrepreneurs from the membership of Confartigianato Vicenza, a major trade association in the Veneto region. Target firms employ 10–30 workers and are led by founder-owners who participate directly in production and client relations. At this size, the entrepreneur operates at once as leader, producer, and organisational representative — a condition that makes identity-behaviour dynamics observable in their full range. ZMET differs from conventional interviews in that it does not depend on verbal fluency or conscious recall. Instead, participants work with visual images, and the technique draws on the idea that metaphors are not ornamental but constitute a primary structure of thought, one that connects what people can articulate with what they understand only tacitly (Lakoff & Johnson, 2008). Each participant collected 8-12 images that, in their view, symbolised soft skills relevant to their business. The instruction was to choose images on the basis of felt resonance, not analytical fit. Each sessions lasted approximately 50 minutes and took place at each entrepreneur's business places. Conducting the interviews on site had a practical reason: the familiar setting helped participants speak more freely and refer spontaneously to actual workplace situations. All sessions were audio-recorded with informed consent and transcribed verbatim. The interview protocol followed Zaltman's (2003) established procedures while adapting elicitation prompts to the specific context of entrepreneurial BI. Each session began with storytelling, as entrepreneurs described their selected images and their personal significance. The interviewer employed laddering techniques to probe deeper into metaphorical meanings: "What does this image represent for you? Why did you choose this specific image? What would the opposite look like?". These questions made it possible to trace how surface concepts connect to deeper values, and how concrete visual elements point toward abstract identity commitments (Hill & Levenhagen, 1995). Participants were also asked whether any important idea was missing, something they had wanted to represent but could not find an image for. These absent images often turned out to be among the most revealing, precisely because they pointed to tacit dimensions of BI that do not lend themselves to visual expression. Throughout the sessions, the interviewer's role was to elicit meanings, not to interpret them; analysis was deferred to a later phase in order to avoid premature closure. The data corpus consists of twelve transcribed interviews of approximately 35,000 words in total. Field notes complement the transcripts: they record hesitations, emotional reactions, non-verbal cues. Some participants spontaneously placed images side by side during the session and constructed composite visual arrangements that showed how different identity elements related to one another in their experience. Transcript analysis was carried out with Atlas.ti, following thematic analysis principles (Braun & Clarke, 2006) adapted to the specific demands of ZMET data. The coding framework draws on BI research (Simons, 2022) and distinguishes two categories: Espoused Soft-skill Prescriptions (ESP), for instance the values entrepreneurs declared through their metaphors, and Enacted Behaviours (ENA), such as how those same skills surfaced or failed to surface in descriptions of daily management practice. Comparing ESP and ENA revealed the word-deed alignment central to BI. Following Rogers (1959), we adopt the terms Congruent and Incongruent to classify predominant ESP-ENA patterns.

Results. Analysis revealed two profiles based on predominant ESP–ENA patterns: Congruent profile entrepreneurs showing aligned word-deeds, and Incongruent profile entrepreneurs showing misaligned patterns.

Table 1 reveals a recurring pattern across the five soft skills examined: for each competency, some entrepreneurs demonstrate word-deed alignment while others present evident gaps. Note that only soft skills with a minimum of 5 total occurrences across the sample are included. Leadership, for instance, can be enacted coherently, as E4 shows through the "pack leader" metaphor sustained by collaborative behaviours ("we work as a pack, together"); or remain misaligned, as in E9's case, where "inspiring, setting example for others" collapses into "one life alone, it is isolation". The same dynamic emerges for the soft skills: Teamwork, Empathy, Time Management, and Collaboration. What distinguishes Congruent and Incongruent entrepreneurs is not which soft skill the entrepreneur espouses, but whether daily enacted behaviours correspond to espoused values. When words find corroboration in deeds, IC remain contained and competencies translate effectively into practice. When, instead, a persistent incongruence separates what entrepreneurs declare they value from what they actually practice, IC accumulates progressively. Table 1 shows that the congruence/incongruence distinction is detectable at the metaphorical level: congruent cases show semantic continuity between espoused and enacted metaphors, while incongruent cases reveal a structural fracture between the two.

Tab. 1: Soft Skills Espoused-Enacted Analysis

Soft Skill	Interviewee number	Representative Quotes of GAPS	Roger's Congruence
Leadership	E9	ESP: "Leadership means inspiring, setting example for others..." ENA: "...entrepreneurship is one life alone, it is isolation"	Incongruent
	E4	ESP: "I'm the leader of a pack..." ENA: "...we work as pack, together. I'm thin on my own... at my back people said: you go, we deliver"	Congruent
Teamwork	E7	ESP: "Teamwork is a squad pulling together..." (E7) ENA: "...I experienced repeated betrayals"	Incongruent
	E4	ESP: "Teamwork is like being in a pack..." ENA: "...in a pack you have defined roles with individual freedom"	Congruent
Empathy	E7	ESP: "I know I have to be very empathetic..." ENA: "...I put empathy in the drawer"	Incongruent
	E12	ESP: "Empathy is a choice..." ENA: "I chose concentric circles - if you're inside the circle, I've embraced you...	Congruent
Time management	E6	ESP: "Managing time is one the greatest skills..." (E6) ENA: "...time left is zero, it is renouncing"	Incongruent
	E4	ESP: "Time management always represented me..." ENA: "...I used to work unitl 9-10pm, now I stop at 4: 30. I take time for myself".	Congruent
Collaboration	E2	ESP: "Reasoning together" ENA: "Solitary battle against everyone"	Incongruent
	E3	ESP: "You need everyone, so you try to get along with all..." ENA: "... You must find common ground, mediate because truth is in the middle"	Congruent

Source: Authors' own elaboration

Congruent profile entrepreneurs articulated clear soft-skill values and practised them in daily operations. What distinguished them was not perfect execution, but a capacity for self-awareness: when gaps existed, they recognised and named them. The clearest illustration comes from E4, who expressed leadership through the metaphor of being "thin on my own", recognising his dependence on others and actively learning from his son. This humility translated directly into teamwork practices described as a "pack" where each member has defined roles with individual freedom. Rather than framing competitiveness as external aggression, he spoke of it as an internal challenge: "I remove the world around me". His "intraprendenza" (entrepreneurial spirit) emerged through the "little fish" metaphor, lived with authentic emotion in how he navigated market challenges. Throughout his interview, espoused values and daily practices pointed in the same direction. A similar coherence appeared in E5, who valued teamwork without idealising it, accepting disappointments and losses as part of collaboration. He described competitiveness as "being first in class", but practised it as an economic necessity rather than aggression toward competitors. His espoused value of evolution matched concrete actions: transitioning from manual cutting to digital systems, implementing ISO 9001, and maintaining continuous learning. "Courage" was not merely declared but evidenced through taking a substantial personal loan at age 21 and innovating despite market scepticism. E8 articulated "Creativity" as a resource and lived it as "the only space of authentic joy" in daily work. Her observation skills, spontaneously added as a competency during the interview session, were demonstrated through concrete examples of studying competitors and structured companies. Not all alignment came through confident enactment. E10 demonstrated an unusual form of coherence through acknowledged limitations: she valued "Empathy" but openly admitted, "I don't know how to do it." Rather than generating IC, this awareness of the incongruence itself created coherence: an honest recognition that maintained BI. She valued not neglecting family relationships and practised this by maintaining family as "backstage certainty", which supported her work. E11 described "Teamwork" as central,

discovered over time, starting from "doing everything myself", narrating an evolution from isolation to collaboration that he had actually lived. When he spoke of "Delegation", he called it necessary and difficult, and he was actively working on it rather than claiming false competence. Finally, E12 expressed "Vision" as "prospective, sixth sense" and demonstrated it consistently in strategic decisions. "Curiosity" meant "studying, getting my hands in it", determination was described as "constancy, training" and lived coherently in daily practice. Even "Energy", which was abundant ("I have it to sell"), came with honest acknowledgement of needing to "escape" periodically. These entrepreneurs showed minimal IC because their metaphorical articulations of soft-skill values matched enacted behaviours. When misalignment existed, they were recognised and acknowledged, creating what Rogers (1959) would describe as congruence through awareness rather than through perfect execution. It is worth noting that Rogerian congruence does not require flawless alignment; rather, it requires that the person remain open to the discrepancy rather than distort or deny it.

Incongruent profile entrepreneurs showed predominantly misaligned patterns between espoused and enacted soft skills. These artisans articulated soft-skill values but struggled to translate them into consistent behaviours. The metaphors they used frequently conveyed distance or isolation. E1 and E2 illustrate two different manifestations of the same dynamic. E1 valued "Collaboration" as active and reciprocal but practised it passively, with "a need to be protected". She emphasised "Mediation" but consistently avoided conflict, fleeing confrontation and delegating difficult conversations. Though she declared that entrepreneurship implies "Leadership", she felt "not visionary". Her "Quick thinking", presented as a strength, became "isolation and fear": seeing what others did not, created distance rather than connection. E2's pattern was more extreme. He talked about "Collaboration" as "reasoning together", but practised a "solitary battle against everyone" where "I" was the only subject. He valued "Giving support" yet experienced "disappointment and betrayal". Most strikingly, despite his entrepreneurial role, he believed "I'm not capable", confirming an old family judgment. "Risk" was described as normal, but lived as "teetering, fear". E6 showed a pattern where soft-skill values were espoused in principle but experienced as exhausting or absent in practice. She declared "Collaboration" as primary but reduced it to instrumental necessity: "you just need everyone". "Conflict management" was fundamental in principle, but practised with "so much effort" and desire to "escape". "Empathy" was a stated competence, but felt draining: "I shouldn't be the nurse", the "giant ear" creating discomfort rather than connection. "Patience" was a virtue in words, but "exhaustion, resistance to the limit" in practice. E6 called "Collaboration" the most important, yet described it as "absent, not realised". "Teamwork" was something you breathed, but remained idealised, with no mention of conflict. "Energy" was positive in words, but lived as "running without stopping". "Time management", which E6 described as fundamental, was practised with "regret, renunciation, pain", illustrating the distance between declaration and experience. The remaining two cases show particularly vivid metaphorical distance. E7 said "I would be very empathetic" but admitted "I put empathy in the drawer" with "bitterness", a containment metaphor suggesting conscious suppression of a valued skill. Teamwork meant pulling together, but her experience was "repeated betrayals". She claimed, "I'm not inclined to control" while doing everything herself. E9 valued "Welcoming" but practised selective empathy: "inside the circle or outside". "Leadership" meant inspiring others, but she lived "one life alone". She resisted questions about personal limits and showed difficulty acknowledging misalignments. These entrepreneurs experienced IC through recurrent distance between stated soft-skill values and actual behaviours across multiple domains. The distinction between profiles is not perfectly binary: entrepreneurs' behaviours and beliefs may shift over time, and some individuals showed mixed patterns. The key difference is whether alignment or misalignment predominates across the full range of espoused soft skills. Self-awareness also differed between profiles. Congruent profile entrepreneurs openly recognised their limits (E10 admitted she could not do empathy, E11 acknowledged delegation struggles). Incongruent profile entrepreneurs tend to normalise gaps as inevitable or attribute them to external pressures. In Rogerian terms, these entrepreneurs exhibit defensive processes, such as distortion and denial, that protect their self-concept from acknowledging discrepancies between experience and reality.

A second interpretive round, now under way, goes back to the ESP–ENA coding and reads it through the lens of intrapersonal congruence. In practice, this means reorganising the soft skills from Table 1 into four thematic clusters derived inductively from the interviews: Self-Management, Interpersonal, Team & Organisation, and Entrepreneurial. What is emerging is that incongruence concentrates almost entirely in the Interpersonal cluster. The entrepreneurs who show persistent misalignment do so in relational competencies: empathy, conflict management, collaboration. If this pattern holds, it would mean that the hidden costs we are tracking are primarily relational, not technical or managerial, which makes sense given how central interpersonal prescriptions are to craft-based professional identity. These results are preliminary and will be further developed in the extended version of the paper. Overall, the distinction between congruent and incongruent profiles suggests a consistent pattern: identity costs do not stem from the absence of soft skills, but from the extent to which they are enacted consistently in practice.

Discussion. The findings support the proposition that BI can function as a measure of IC. Congruent profile entrepreneurs show minimal ESP-ENA distance. When a gap does appear, they register discomfort and correct course, that is a response pattern consistent with identity threat dynamics. In terms of the Hidden Cost formula, P = K - CI, this means that CI stays low and P remains close to K: competencies translate into practice with relatively little loss.

Incongruent profile entrepreneurs show systematic ESP-ENA misalignment. Their metaphors suggest BI has become peripheral to their operative identity. Drawing on Simons' (2022) findings and subsequent meta-analytic evidence, we suggest that the pathways through which IC constrains P include trust erosion and reduced follower commitment. IC also operates through internal psychological mechanisms. Incongruent entrepreneurs, by contrast, showed little conscious

discomfort as if their self-concepts had adjusted to accommodate the gap. The costs, however, do not disappear simply because the person stops noticing them. Rogers (1959) described exactly this mechanism: when incongruence is denied or distorted, the underlying tension is not resolved but re-routed into rigidity and selective perception. This is what we observed in the incongruent entrepreneurs' metaphors of containment and isolation. The two profiles also differed in the business outcomes they reported. Congruent entrepreneurs pointed to concrete results like media coverage ("articles in Il Sole 24 Ore"), quality certifications (ISO 9001), and team autonomy ("you go, we'll deliver"). Incongruent entrepreneurs described a different reality: stakeholder criticism ("some criticise me"), a sense of fragility ("I seem weaker"), and acknowledged strategic limits ("one cannot be visionary"). These findings have a practical side. The most direct implication concerns self-monitoring. Congruent entrepreneurs already do it: they notice when their behaviour drifts from their stated values, and the discomfort this produces is itself the corrective mechanism. For incongruent entrepreneurs, who lack this internal feedback loop, the equivalent would need to come from outside as structured self-assessment or peer feedback. Trade associations like Confartigianato are well placed to facilitate this: peer-coaching circles that pair entrepreneurs with different alignment profiles, or an annual BI self-assessment built into existing member services, would be low-cost interventions with potentially significant returns.

For entrepreneurship education, the findings suggest that BI matters for entrepreneurial practice. Current programs typically emphasise hard and soft skills development (building K) while neglecting IC, something that, as we suggest, affects how competencies translate into results. Training programs could incorporate reflective exercises, helping entrepreneurs recognise value-behaviour gaps and drawing on approaches from counseling and coaching practice.

Conclusion. This study started from a concrete problem: Identity Economics tells us that violating one's own behavioural prescriptions is costly, but it does not tell us how to detect or measure that cost. We proposed that Behavioural Integrity (the alignment between what a person says and what a person does) can serve as a way of assessing Identity Cost, and we tested this proposition with twelve SMEs entrepreneurs from the Veneto region through ZMET interviews.

What emerged were two distinct profiles. Congruent entrepreneurs showed aligned ESP-ENA patterns, and their metaphors reflected this: shared effort ("pack"), natural challenges ("little fish"), honest self-recognition ("thin on my own"). Incongruent entrepreneurs showed persistent misalignment, and their metaphors carried a different register, one of distance ("drawer"), selective inclusion ("inside/outside circle"), isolation ("solitary battle"). The distinction maps into Rogers' (1959) framework: congruent entrepreneurs remained open to discrepancies between self-concept and experience, while incongruent entrepreneurs relied on defensive processes that masked the gap without resolving it. The interview narratives also pointed to performance differences that are consistent with the Hidden Costs formula: congruent entrepreneurs could name concrete business results; incongruent entrepreneurs described constraints they could not fully explain. Clarifying the theoretical contribution on Behavioural Integrity (BI), prior research has predominantly approached BI as an externally perceived alignment between words and deeds. The present study complements this view by considering how alignment is experienced by the actor, and uses BI to explore identity-related tensions at the intrapersonal level.

The limits of the study are evident. Twelve entrepreneurs, one region, one sector, one point in time. As such, the findings are not intended to be generalised in a statistical sense. Rather, the study adopts an exploratory and theory-oriented approach, aimed at uncovering underlying mechanisms that are difficult to capture through standard methods. Whether these profiles are stable or whether entrepreneurs move between them over the course of their careers is a question we cannot answer with a cross-sectional design. In this respect, the contribution lies in offering an interpretive framework that can be further examined across contexts. Testing the P = K - CI formula against objective performance data would be a necessary next step, as would replication in different industries and geographical contexts. The relationship between gap awareness and IC (why some entrepreneurs see the misalignment and others do not) remains, in our view, the most promising direction for further work.

This study suggests that the most consequential hidden cost for SMEs entrepreneurs may not reside in the soft skills they lack, but in those they espouse yet consistently fail to enact. This is a cost that remains hidden precisely because it disguises itself as competence. If this is the case, then investing in soft skills development alone is not sufficient. What entrepreneurs need is not more competencies, but greater alignment between the ones they declare and the ones they live. Future research could examine how identity costs evolve over time, and whether entrepreneurs move between congruent and incongruent profiles across different stages of their activity. A further step would be to test the proposed relationship between BI and IC using mixed or quantitative designs.BI gives entrepreneurs and those who support them a concrete lens through which to examine how word-deed alignment shapes relationships, daily practice, and professional identity.

The role of entrepreneurship support organizations in creating inclusive entrepreneurial ecosystems for immigrant entrepreneurs: A relational approach

DANIELA BOLZANI[1]

Abstract. *Immigrant entrepreneurs contribute to innovation, job creation, and the diversification of entrepreneurial ecosystems, yet often face barriers to accessing host-country resources, networks, legitimacy, and finance. Entrepreneurial support organizations (ESOs) are commonly presented as mechanisms for addressing these barriers through training, mentoring, networking, and access to resources. This paper reframes ESOs as intermediary organizations that mediate immigrant entrepreneurs' access to entrepreneurial ecosystems by connecting them with relevant actors, supporting capability development, coordinating access to resources, and shaping selection and legitimacy processes. Drawing on qualitative research on ESO models and migrant entrepreneur profiles in Italy, the study examines how organizational orientations and relational practices influence access to networks, knowledge, and institutional support. The findings show that ESOs can both facilitate and constrain inclusion depending on how they structure selection processes, mentoring relationships, and ecosystem connections. The paper contributes to research on entrepreneurial ecosystems and migrant entrepreneurship by showing how ESOs operate as relational intermediaries through which inclusion and exclusion are actively produced, and by highlighting the importance of aligning support models with heterogeneous migrant entrepreneur profiles.*
Keywords: *immigrant entrepreneurship; entrepreneurial ecosystems; entrepreneurship support organizations; inclusion; relational approach*

Framing of the research. Entrepreneurial ecosystems have become a central framework for understanding how new ventures emerge and grow within specific regional contexts. These ecosystems consist of interconnected actors, institutions, and resources—including entrepreneurs, investors, universities, incubators, accelerators, and public agencies—that collectively facilitate the circulation of knowledge, capital, and talent (Stam, 2015; Spigel, 2017; Autio et al., 2018). Rather than functioning as neutral infrastructures, entrepreneurial ecosystems are shaped by relational dynamics that influence how opportunities, resources, and information are distributed among different actors (Spigel, 2017; Theodoraki et al., 2018; Hernandez-Chea et al., 2021). In this sense, ecosystems are constituted by networks of relationships that determine who gains access to key resources and who remains excluded from them (Bolzani et al., 2025).

Within these ecosystems, entrepreneurial support organizations (ESOs)—such as incubators, accelerators, and pre-incubation programs—play a particularly important role. Over the past two decades, governments, universities, and private actors have increasingly invested in these support infrastructures in an effort to stimulate innovation and improve the survival rates of new ventures (Audretsch et al., 2020). Broadly speaking, ESOs provide entrepreneurs with structured forms of assistance—including mentoring, training programs, networking opportunities, workspace, and access to financial resources—to facilitate the creation and development of new ventures (Ratinho et al., 2020). However, recent research suggests that ESOs should not be understood only as service providers, but also as intermediary organizations operating between entrepreneurs and the wider ecosystem (e.g. Goswami et al., 2018; Hernandez-Crea et al., 2021).

The literature on innovation intermediaries provides a useful basis for this conceptualization. Howells (2006) shows that intermediaries perform a broad range of functions in innovation processes, including scanning and processing information, combining knowledge, brokering relationships, gatekeeping access, supporting commercialization, and evaluating outcomes. Applied to entrepreneurial ecosystems, this means that ESOs do not merely deliver predefined services to entrepreneurs; they also mediate relationships among entrepreneurs, mentors, investors, universities, public agencies, and other resource providers. In particular, they mobilize resources, coordinate relationships, and influence collaboration patterns within entrepreneurial ecosystems through practices of connection, development, coordination, and selection (Hernandez-Chea et al., 2021; Goswami et al., 2018).

This intermediary role is closely connected to the relational foundations of entrepreneurial ecosystems. By developing structural, cognitive, and relational forms of social capital, ESOs can create ties that enable access to resources, foster shared goals and language among ecosystem members, and build trust and complementarity across actors. Their effectiveness therefore depends not only on connecting entrepreneurs to networks, but also on coordinating the fit between entrepreneurs, mentors, and ecosystem actors, and on selecting participants and mentors with appropriate knowledge, motivation, and relational orientation. In this sense, ESOs organize relational processes, match entrepreneurs with relevant resources, and structure access to ecosystem opportunities (Theodoraki et al., 2018; Goswami et al., 2018).

[1] Department of Management, Alma Mater Studiorum - University of Bologna, daniela.bolzani@unibo.it

Despite their growing prominence within entrepreneurial ecosystems, the effectiveness and functioning of these organizations remain subjects of ongoing debate. Existing research has primarily examined incubators and accelerators in terms of their service portfolios, performance outcomes, and contribution to venture growth (Bruneel et al., 2012; Hausberg & Korreck, 2020). At the same time, scholars have highlighted that the capacity of these organizations to provide meaningful relational support—such as mentorship, network brokerage, and legitimacy-building—varies significantly across different models and institutional contexts (Assenova, 2020; Bergman & McMullen, 2021; Goswami et al., 2018). Moreover, much of the literature has focused on highly skilled entrepreneurs in developed economies or on disadvantaged entrepreneurs in developing contexts, leaving important questions unanswered about how entrepreneurial support infrastructures operate for different social groups (Assenova, 2020; Anderson et al., 2018; Dutt et al., 2016).

One group for which these dynamics are particularly relevant is migrant entrepreneurs. International migration is having a profound impact on European labor markets and local economies, bringing new resources, capabilities, and entrepreneurial aspirations into cities and regions. Migrant entrepreneurs contribute significantly to job creation, innovation, and the revitalization of local communities (Arrighetti et al., 2014; Raimi & Mahmoud, 2025; OECD/European Union, 2024). However, their entrepreneurial trajectories are often shaped by unequal access to financial resources, market opportunities, professional networks, and institutional support. These disparities are frequently analyzed through the lens of mixed embeddedness, which emphasizes how entrepreneurial outcomes emerge from the interaction between individual resources and the opportunity structures created by markets, regulatory frameworks, and local institutions (Kloosterman et al., 1999; Kloosterman, 2010).

Research on migrant entrepreneurship further shows that migrants are embedded in multiple relational spheres simultaneously. On the one hand, co-ethnic and transnational networks can facilitate entry into entrepreneurship by providing trust-based relationships, information flows, and access to capital (Saxenian, 2002; Elo et al., 2018). On the other hand, reliance on homophilous networks may confine entrepreneurs to saturated niches and limit access to high-value knowledge, investors, and broader market opportunities (Guercini et al., 2017; Sepulveda et al., 2011). Migrant entrepreneurs therefore often face the challenge of navigating between these relational spheres in order to access more resource-rich segments of entrepreneurial ecosystems.

Against this backdrop, ESOs have increasingly been considered important instruments for promoting inclusion within entrepreneurial ecosystems (Serpente et al., 2025). Incubators and accelerators are expected to function not only as providers of physical space or training programs but also as gateways to networks, knowledge, and legitimacy (Rath & Swagerman, 2016; Solano et al., 2019). Yet, when viewed as intermediary organizations, their role appears more complex. ESOs may help migrant entrepreneurs build connections, develop entrepreneurial capabilities, coordinate access to relevant mentors and ecosystem actors, and gain legitimacy within the host-country ecosystem (Serpente et al., 2025). At the same time, they may also operate as gatekeepers, since their selection criteria, business models, and organizational logics influence which entrepreneurs are admitted, which forms of entrepreneurship are valued, and which types of support are made available (Assenova, 2020; Bruneel et al., 2012; Hausberg & Korreck, 2020). This point is particularly important because support systems for migrant entrepreneurship cannot be assumed to be neutral (Bolzani et al., 2025). Access to markets, technologies, and entrepreneurial ecosystems is mediated by institutional arrangements, support practices, and intersectional factors such as legal status, race, gender, and socio-economic background. Institutional intermediaries—including incubators, accelerators, NGOs, and funding agencies—may therefore both enable and constrain migrant entrepreneurship through the ways they design, target, and implement support initiatives. In this sense, ESOs are not simply instruments for inclusion, but organizations through which inclusion and exclusion are actively produced (Bolzani et al., 2025).

This article addresses these gaps by integrating perspectives from migrant entrepreneurship, mixed embeddedness, entrepreneurial ecosystems, and intermediary organization research to conceptualize ESOs as relational intermediaries. Rather than treating ESOs as neutral support providers, the paper argues that these organizations actively shape migrants' embeddedness by mediating access to economic, social, and institutional resources (Bolzani et al., 2025). Through their selection practices, organizational logics, support programs, and everyday interactions with entrepreneurs, ESOs influence which entrepreneurial projects are considered legitimate, which networks entrepreneurs can access, and how migrant entrepreneurs become integrated into—or remain disconnected from—local entrepreneurial ecosystems.

Purpose of the paper. This study explores how ESOs and related support infrastructures mediate the relationship between migrant entrepreneurs and the opportunity structures available in host-country entrepreneurial environments (Rath & Swagerman, 2016; Solano et al., 2019).

More specifically, the paper seeks to address two research questions. First, how do the organizational structures associated with different ESO business and governance models shape opportunities and constraints for immigrant entrepreneurs? Second, what types of interactions are established within ESOs between staff members and immigrant entrepreneurs, and how do these interactions influence entrepreneurs' access to ecosystem resources?

These research questions allow us to account for the heterogeneity present on both sides of the ESO–entrepreneur relationship. On the supply side, ESOs differ significantly in terms of their missions, funding structures, governance arrangements, and operational practices. These organizational characteristics influence how support programs are designed, how participants are selected, and how ESOs engage with diverse entrepreneurial populations (Bruneel et al., 2012; Assenova, 2020; Hausberg & Korreck, 2020). Consequently, different types of ESOs may offer distinct pathways through which entrepreneurs access networks, knowledge, and financial resources.

On the demand side, immigrant entrepreneurs themselves represent a highly heterogeneous group. Their entrepreneurial trajectories are shaped by differences in migration histories, legal status, educational backgrounds, professional experience, and transnational ties (Bolzani, 2024). These factors influence not only the resources available to entrepreneurs but also their ability to navigate the institutional and relational opportunity structures within the host-country ecosystem (Kloosterman et al., 1999; Kloosterman, 2010; Elo et al., 2018). By examining these variations, the study aims to identify the mechanisms through which ESOs can either facilitate or hinder connections between immigrant entrepreneurs and the broader entrepreneurial ecosystem.

To address these objectives, the paper adopts a relational perspective that emphasizes the role of networks, interactions, and institutional contexts in shaping entrepreneurial processes. From this perspective, ESOs are not simply providers of services or infrastructure; rather, they function as relational spaces in which entrepreneurs interact with mentors, peers, investors, and institutional actors, thereby gaining access to knowledge, legitimacy, and strategic connections (Spigel, 2017; Bergman & McMullen, 2021). Understanding these relational dynamics is essential for explaining how entrepreneurial support organizations influence the inclusion—or exclusion—of immigrant entrepreneurs within entrepreneurial ecosystems.

Methodology. In this paper, we draw on the Italian context as a significant site for research. Italy has experienced a rapid increase in international migration over the past two decades, contributing to a more diverse and transnational socio-economic context (UN DESA, 2020; Ambrosini, 2012; Riccio, 2008). Despite migrants often facing labour market disadvantages and precarious employment (Istituto Cattaneo, 2019; Zanfrini, 2020), migrant entrepreneurship has become a consolidated phenomenon, with over 600,000 firms representing about 9.6% of all Italian businesses (Unioncamere, 2018a; Bolzani, 2021). While migrant businesses remain concentrated in traditional sectors, participation in innovative and high-tech activities is gradually increasing (Sepulveda et al., 2011; Kloosterman, 2014; Solano, 2020). To investigate the research question, a qualitative approach was employed. We first produced a list of all the ESOs in the country, based on manual search on the Internet, use of available listings (e.g., Italian government-certified incubators), and referrals from industry/entrepreneurship experts and academics. For each ESO, we carried out desk research to collect information about the year of foundation, governance structure, business model, main goals, services provided, and target groups. We have identified "immigrant-focused" ESOs, who exclusively focus on immigrants; and "generalist" ESOs, who do not declare a specific target group. We then designed a selection grid so that we could invite for interviews those ESOs ensuring heterogeneity across the following dimensions: governance structure (i.e., private vs. public vs. mixed), services provided (i.e., pre-incubation training, incubation, acceleration and seed investing), and target group (i.e., migrant-focused vs. generalist). These ESOs were contacted via email or telephone, to ask participation in a semi-structured interview. We interviewed 24 people working for 20 ESOs. To triangulate these information, we asked the interviewed ESOs to provide us with access to some of their beneficiaries, and we thereby interviewed 11 entrepreneurs.

Results. The findings suggest that ESOs play a significant but complex role in shaping the inclusion of immigrant entrepreneurs within entrepreneurial ecosystems, as they produce differentiated outcomes depending on their organizational orientation and relational practices.

ESOs act as intermediaries that facilitate access to key ecosystem resources such as funding, mentorship, and professional networks. For immigrant entrepreneurs who often lack established local networks, this intermediary role can be particularly valuable. ESOs can introduce entrepreneurs to investors, industry partners, and potential collaborators, thereby reducing barriers to entry within the ecosystem. However, the study also finds that access to ESOs themselves is often uneven. Many organizations rely on selection processes that prioritize certain characteristics such as advanced education, prior entrepreneurial experience, or technological innovation. These criteria tend to favor highly skilled immigrant entrepreneurs who already possess significant human capital. As a result, immigrant entrepreneurs with fewer resources may struggle to gain entry into these programs.

The research also highlights the importance of relational practices within ESOs. Successful organizations often emphasize mentorship, peer learning, and network-building activities that allow entrepreneurs to develop trust-based relationships with mentors and ecosystem actors, allowing immigrant entrepreneurs gain legitimacy and credibility within the ecosystem. In contrast, ESOs that focus primarily on standardized training programs or short-term acceleration models may provide limited opportunities for relationship-building. In such environments, immigrant entrepreneurs may struggle to access informal networks that are essential for securing funding or partnerships.

Another important finding concerns the alignment between ESOs' models and entrepreneur profiles. Socially oriented ESOs tend to adopt more inclusive selection criteria and offer tailored support programs that address the specific challenges faced by immigrant entrepreneurs. These organizations may provide language support, legal guidance, or networking opportunities specifically designed for immigrant founders. Mainstream for-profit ESOs, on the other hand, tend to prioritize ventures with strong growth potential and may provide less targeted support for immigrant entrepreneurs. While these ESOs can offer valuable resources and investor connections, they may inadvertently exclude entrepreneurs who lack the credentials or networks required to meet their selection criteria.

Overall, the findings suggest that inclusion within entrepreneurial ecosystems is not simply determined by the presence of ESOs but by how these organizations structure their relational practices and selection processes.

Research limitations. As with any study, several limitations should be acknowledged. First, the research is based primarily on qualitative data collected in one country and therefore, while the selected context provides valuable insights, the findings may not be fully generalizable to other regions with different institutional environments or immigration patterns. Second, the study focuses primarily on ESOs and does not examine other ecosystem actors such as venture capital firms, universities, or government agencies in depth. These actors also play important roles in shaping entrepreneurial ecosystems and may influence the inclusion of immigrant entrepreneurs in ways not fully captured in this study. Third, the research relies on interview data that reflect participants' perceptions and experiences. While these perspectives provide rich insights into relational dynamics, they may also be influenced by individual biases or subjective interpretations. Future research could build on these limitations by conducting comparative analyses across a wider range of countries and ecosystem contexts. Quantitative studies could also complement qualitative insights by examining patterns of ESO participation and entrepreneurial outcomes among immigrant entrepreneurs.

Managerial implications. The findings of this study have important implications for ESO managers, policy makers, and ecosystem stakeholders seeking to promote inclusive entrepreneurship. For ESO managers, the results highlight the importance of adopting relational practices that actively facilitate network-building and mentorship for immigrant entrepreneurs. Programs that emphasize long-term mentoring relationships, peer learning, and ecosystem integration can significantly enhance immigrant entrepreneurs' ability to access resources and opportunities. ESOs should also consider revising their selection criteria to ensure that they do not inadvertently exclude promising entrepreneurs who may lack traditional indicators of entrepreneurial success, such as formal educational credentials or prior startup experience.

For policy makers, the study suggests that supporting socially oriented or hybrid entrepreneurial support models may be particularly effective in fostering inclusive ecosystems. Public funding programs could encourage ESOs to develop targeted initiatives for immigrant entrepreneurs, including mentorship programs, legal guidance, and networking events.

Finally, ecosystem stakeholders such as investors, universities, and industry partners can contribute to inclusive ecosystems by collaborating with ESOs to expand access to networks and resources for immigrant entrepreneurs.

Originality of the paper. By focusing on the relational dynamics of entrepreneurial support, this study contributes to ongoing debates about inclusiveness within entrepreneurial ecosystems and provides insights into how ESOs can better support immigrant entrepreneurs.

This paper contributes to the literature on entrepreneurial ecosystems and immigrant entrepreneurship by adopting a relational perspective on entrepreneurial support. While previous studies have examined the role of ESOs in supporting startups, relatively little attention has been paid to how relational dynamics within ESOs influence inclusion for immigrant entrepreneurs.

By highlighting the interaction between support models and entrepreneur profiles, the study provides a more nuanced understanding of how ESOs shape access to entrepreneurial ecosystems. The findings suggest that inclusion is not simply a matter of providing services but depends on the relational practices through which entrepreneurs connect to networks, resources, and institutions. This relational perspective offers new insights into how ESOs can function as key intermediaries within entrepreneurial ecosystems and how their organizational practices can either promote or constrain inclusion.
