This literature generally concentrates on the family-productivity nexus without considering the potential moderating effect of the economic cycle. Thus, the question remains as to whether the advent of an external crisis alters the balance between economic and non-economic goals, and whether this effect is contingent on a firm's position in the productivity distribution.

More generally, the literature examining family versus non-family ownership during systemic crises presents a nuanced and context-dependent picture of resilience, productivity, and financial performance. While family ownership has long been associated with distinctive governance features, such as concentrated ownership, long-term orientation, and socioemotional wealth considerations, the extent to which these characteristics enhance or hinder performance during economic downturns remains debated.

A comprehensive meta-analysis by Hansen, Block, and Neuenkirch (2020) provides the broadest cross-country evidence on this issue. Analyzing 155 primary studies across 35 countries, they find that family firms in developed markets exhibit a statistically significant but economically negligible outperformance relative to nonfamily firms in general. The work of Hansen et al. (2020) shows that, although family firms may perform slightly better on average, their relative advantage diminishes during downturns; they also identify substantial regional heterogeneity, with procyclical effects in Anglo-American countries and emerging markets, but no strong crisis sensitivity in Continental Europe.

The Hansen et al. (2020) review synthesizes conflicting crisis-era findings. During the Asian financial crisis, studies such as Baek et al. (2004) and Lemmon and Lins (2003) report that concentrated family control and separation of control from cash-flow rights amplified performance declines. Similarly, Lins, Volpin, and Wagner (2013) show that family-controlled firms reduced investments more aggressively during the global financial crisis and underperformed in stock returns. In contrast, other European studies (e.g., van Essen et al., 2015; Minichilli, Brogi, and Calabrò, 2016) find that family firms exhibited stronger profitability during crisis periods. Thus, the meta-analytic conclusion is that family ownership does not universally confer crisis resilience; its effect depends on institutional and governance context.

More recent evidence from the Covid-19 pandemic provides additional insights. Amore, Pelucco, and Quarato (2022), focusing on Italian listed firms, find that family firms outperformed nonfamily firms in both stock market performance and operating profitability during the pandemic. This outperformance was stronger in firms without large minority investors and in firms with multiple family shareholders, suggesting that cohesive and concentrated family control enhanced crisis responsiveness. Mechanism analyses reveal that family firms experienced smaller revenue declines and more efficient labor utilization. The authors frame these results against competing theoretical expectations: on one hand, long-term orientation and stakeholder relationships may enhance resilience; on the other hand, entrenchment and labor rigidity may reduce adaptability. Thus, in the Italian context, the resilience channel appears to dominate.

Similarly, Jarchow, Kaserer, and Keppler (2023) document significant outperformance of German family firms during the 2008–2010 crisis period in terms of return on assets, and to a lesser extent, Tobin's. Notably, this crisis resilience becomes stronger as family equity ownership increases. The authors identify leverage reduction during the crisis as a key channel, while also showing that this financial conservatism did not come at the expense of long-term investment or employment. These findings stand in contrast to the international evidence of Lins et al. (2013), who attribute crisis underperformance to investment cuts. The German evidence suggests that prior financial conservatism and lower leverage may have created buffers that enhanced resilience rather than constrained growth.

Complementing firm-level financial analyses, Valentino, Diaz Matajira, and Szymanska (2025) examine crisis responses across 2,344 family firms around the world during Covid-19. Their results indicate that crisis outcomes depend not only on family involvement but also on leadership configuration. Specifically, directive leadership reduces revenue and employment losses, whereas high family involvement without directive leadership exacerbates negative outcomes. These findings underscore that familiness alone does not guarantee resilience; governance structure and crisis leadership style moderate performance outcomes.

Overall, the prior literature suggests that family ownership does not exert a uniform effect on performance, but rather that its impact varies with macroeconomic conditions, institutional context, and governance structure, with evidence of modest outperformance in stable periods and heterogeneous effects in crises. In particular, studies documenting procyclical patterns (Hansen et al., 2020) and crisis underperformance in certain settings (e.g., Lins et al., 2013) imply that family control may weaken when firms face heightened vulnerability, especially if risk aversion and resource extraction dominate strategic responses. Conversely, evidence of crisis resilience in coordinated market economies such as Germany and Italy (Jarchow et al., 2023; Amore et al., 2022) indicates that under specific structural conditions—such as strong ownership concentration or financial conservatism—family firms can leverage control rights to stabilize performance and preserve productivity. These contrasting findings align with the property rights perspective (Aguilera et al., 2024; Schulze and Zellweger, 2021), which emphasizes that the benefits and hazards of family control—relating to the use, appropriation, and transfer of resources—depend on contextual incentives and constraints.

Purpose of the paper. *This paper focuses on family and non-family ownership as an internal driver of productivity and its role in explaining between-firm differences in performance during periods of systemic crisis or, conversely, stability. Specifically, we address two research questions: to what extent do differences in firm ownership explain the differentials in firm productivity during periods of stability? How do family firms perform, in terms of productivity and with respect to non-family firms, during an economic crisis?*

Building on the above framing, our hypotheses propose that both macroeconomic conditions (critical versus non-critical times) and the firm's productivity position condition whether family ownership mitigates or exacerbates vulnerability.

We formulate four testable hypotheses. First, we predict that in non-critical times and for low levels of productivity, family firms outperform non-family firms (H1a). The rationale is that at low level of productivity, i.e. when the firm appears as more vulnerable, family leaders are prompted to prioritize preventing economic imbalance. Second, in non-critical times and for high level of productivity, family firms are expected to underperform non-family firms (H1b), as family leaders might perceive the business as secure and shift toward rent extraction.

Regarding the crisis, we hypothesize that in critical times and at the low level of productivity, family firms underperform non-family firms (H2a). The rationale is that in critical times, already vulnerable family firms are more likely to prioritize short-term private benefits over long-term firm growth. Conversely, in critical times and at the high level of productivity, family firms are expected to outperform non-family firms (H2b), since high-performing family firms are expected to respond to crises with proactive, long-term-oriented strategies.

These predictions are informed by the property rights perspective (Aguilera et al., 2024; Schulze and Zellweger, 2021), which emphasizes how the exercise of control rights by family owners and the associated hazards of use, appropriation, and transfer of firm resources shape the production process and productivity outcomes. We extend this

logic by arguing that macroeconomic conditions and the firm's competitive position may amplify or attenuate these hazards.

The purpose of this study is therefore to empirically test these four hypotheses using TFP as a comprehensive performance measure, applying unconditional quantile regression to capture the heterogeneous effects of family ownership across the entire productivity distribution, and explicitly incorporating the crisis as a moderating variable.

Methodology. *We adopt a two-stage empirical strategy. In the first stage, we estimate a Cobb-Douglas production function to derive firm-level TFP. We employ the Levinsohn and Petrin (2003) semiparametric estimator, which addresses the simultaneity bias arising from the correlation between input choices and the unobserved, time-varying productivity component. This approach uses intermediate inputs as a proxy for the unobserved productivity and is widely regarded as producing consistent and unbiased estimates of the production function parameters.*

In the second stage, we use the estimated TFP values as the dependent variable in an unconditional quantile regression model (Firpo, Fortin, and Lemieux, 2009). This allows us to estimate the effect of family ownership on TFP at different points of the unconditional productivity distribution, a feature that is essential for testing our hypotheses, which posit heterogeneous effects across the distribution. The empirical model includes as key explanatory variables a FAMILY dummy (equal to 1 if the firm is family-owned or family managed), a CRISIS dummy (equal to 1 for the year 2020), and their interaction term FAMILY × CRISIS. The FAMILY coefficient captures the family-nonfamily productivity differential during stable periods, thereby testing H1a and H1b. The interaction term captures the moderating effect of the crisis on this relationship, allowing us to test H2a and H2b. We adopt different definitions of family to build alternative measure of the variable FAMILY, according to the percentage of voting rights in the family's hands and the family members' involvement in the firm management.

We control for firm size, investment intensity, geographical location (Italian North-West, North-East, Centre, South) and industry at two-digit level. To address selection bias, a concern frequently highlighted in family business research (Zhang, Fang, and Chrisman, 2022), we follow the two-step Heckman (1979) procedure. We estimate a probit model for the probability of being a family firm and derive an inverse Mills ratio (IMR), which is included as an additional regressor in the quantile regression.

The empirical analysis is based on a dataset of 250 listed Italian firms observed continuously from 2015 to 2024, yielding 2,500 firm-year observations. As a robustness check, we run the same analysis on 205 non-listed Italian firms observed from 2001 to 2011 (a period of time including the 2007-2009 financial crisis), of which approximately 58% correspond to family firms and 42% to non-family firms. The economic data are drawn from the AIDA Bureau Van Dijk database, while the governance and ownership data are retrieved from NRG metrics. All monetary variables are deflated to 2024 (2010 for the non-listed sample used in the robustness check) values using appropriate industry-level deflators.

Results. *During non-crisis periods, family firms are expected to adopt strategies that preserve long-term value, allowing them to maintain or even enhance performance relative to non-family firms, particularly among firms located at the lower tail of the productivity distribution. In this range, family firms may be motivated to strive more than their non-family counterparts due to their embedded long-term stance. Conversely, at higher levels of productivity during non-crisis periods, family firms may engage more in the extraction of private benefits of control, which can result in a relative performance lag compared to non-family firms.*

During crisis periods, adverse conditions are likely to push family firms—especially those operating at low levels of productivity—toward short-term and opportunistic decisions, limiting their ability to sustain performance and potentially widening the gap with non-family firms. In contrast, highly productive family firms during crises are expected to adopt stronger defensive strategies to preserve their productivity and safeguard long-term objectives, thereby enabling them to outperform non-family firms.

Research limitations. *While our study provides robust evidence on the heterogeneous impact of family ownership on productivity across the distribution and over the economic cycle, several limitations must be acknowledged. First, our analysis is limited to Italian firms, which constrains the generalizability of the findings to other institutional contexts. Italy's concentrated ownership structure, its specific legal framework, and its deep spatial disparities in productivity may not be fully representative of other European or global settings. The cross-country evidence in Aguilera et al. (2024) suggests that the family-productivity gap varies across national contexts, with larger differences in Germany and Italy and smaller differences in the United Kingdom. Future research could extend the quantile regression approach to multi-country samples to assess whether the distributional patterns we identify hold across diverse institutional environments.*

Secondly, although we sampled to whole population of Italian listed firms to address potential selection bias (and controlled for it through methodological refinements), the sample size (250 firms and 2,500 observations) is relatively small compared to the large-scale datasets used in other studies.

Finally, we do not observe specific characteristics of family members, such as their educational profiles or managerial competence, which Aguilera et al. (2024) identify as potentially important determinants of productivity outcomes.

Managerial implications. *The findings of this study potentially carry important implications for family firm leaders, corporate governance practitioners, and policymakers. The fact that family firms may underperform non-family peers at*

the high productivity level in stable times, and at the low level of the productivity distribution during crises, underscores the need for robust governance structures that can counterbalance agency-driven behaviours emerging under both prosperity and adversity. Family leaders should be particularly vigilant about the risk of shifting toward rent extraction and self-serving behaviour, since this shift progressively erodes the competitive position relative to non-family peers especially as the firm's performance improves in stable times.

In light of the property rights perspective, an actionable strategy for family firms is to share a degree of ownership and control with non-family members. For policymakers, results might suggest that policies incentivizing families to adopt governance structures that balance family control with external accountability could generate significant productivity gains. Given that family firms represent the overwhelming majority of Italian companies, even marginal improvements in their productivity could have substantial aggregate effects on national economic growth.

From a practical standpoint, family firms should separate family and business priorities, particularly in good times when the temptation to extract private benefits is strongest, and establish clear governance mechanisms, such as independent boards, professional management, and external shareholders, that maintain discipline and strategic focus throughout the economic cycle.

Originality of the paper. *This study contributes to the longstanding debate on the relative performance of family and non-family firms in several ways. First, it bridges the mixed evidence on family versus non-family firm performance with the macroeconomic context, an intersection that has received limited attention in the literature. While Creemers et al. (2023) demonstrate the distributional heterogeneity of the family-productivity relationship, they do not consider the moderating role of the economic cycle. We extend their framework by investigating how the potential family firms' advantage (possibly observed at the lower tail of the productivity distribution in stable periods) may vanish during crises and argue that crisis support mechanisms can be tailored to account for the heterogeneous vulnerabilities of family firms across different productivity levels.*

Second, the study provides a real-side corroboration to the financial evidence documented by Attig et al. (2016), who find that family firms are more likely to decrease or omit dividends during the global financial crisis. By shifting the lens from financial outcomes to the full distribution of productivity, we expect that the crisis introduces heterogeneity in the property rights-driven behaviours in family firms, producing productivity shortfalls that are not visible in aggregate accounting metrics. This helps reinterpret the apparent resilience of family firms during crises documented by Minichilli et al. (2016): resilience in aggregate financial measures can coexist with productivity underperformance once the firm's position along the productivity spectrum is considered.

Third, methodologically, the application of TFP, rather than to single-factor productivity measures or accounting ratios, represents an advancement. TFP captures the efficiency with which all inputs are combined in the production process and provides a more comprehensive assessment of firm performance. The Levinsohn and Petrin (2003) semiparametric approach ensures that simultaneity bias in production function estimation is rigorously addressed. Furthermore, the suggested empirical model, and the subsequent findings, are compatible with potential changes in ownership structures and governance arrangements, that have been suggested as possible corrective mechanisms. Specifically, our analysis relies on unconditional quantile regression, which does not condition the estimated effects on a predetermined ownership or governance configuration.

Finally, by focusing on the Italian context, a country where family firms are overwhelmingly dominant yet national productivity growth has been stagnant, the study offers policy-relevant evidence on a question of macroeconomic significance: whether the prevalence of family ownership is a structural constraint on productivity, and under what conditions family firms can close the productivity gap with their non-family counterparts.

Sustainability Disclosure Strategies in Family Firms: A Systematic Literature Review

REBECCA QUARANTA, CRISTINA BETTINELLI

Abstract. *Environmental, Social, and Governance (ESG) issues have become central in both research and corporate practice, as firms face growing pressure from investors, regulators, and society to demonstrate accountability for their environmental and social impact. Sustainability reporting and ESG disclosures are key mechanisms for communicating responsible business conduct (Dhaliwal et al., 2010; Plumlee et al., 2010). Family firms offer a particularly insightful context, given their distinctive governance structures and strategic priorities shaped by family ownership and involvement.*

Family-controlled firms often exhibit long-term orientation, strong community ties, and a desire to preserve family reputation and legacy (Campopiano & De Massis, 2015). Socioemotional wealth (SEW) theory suggests that family owners prioritize non-economic goals such as identity, control, and transgenerational continuity alongside financial performance (Gomez-Mejia et al., 2007). These motivations can encourage socially responsible behavior and environmental stewardship yet concerns about privacy and control may limit public disclosure.

Empirical evidence on CSR and ESG disclosure in family firms is mixed. Some studies show stronger environmental performance and sustainability commitment compared with non-family firms (Battisti et al., 2023; Berrone et al., 2010), while others find reduced disclosure due to discretion and reluctance to expose internal practices (Arduino et al., 2024; Biswas et al., 2018; Venturelli et al., 2021). This paradox highlights the complexity of ESG communication in family-controlled organizations.

This embryonal study systematically reviews 93 peer-reviewed articles to address: What do we currently know about CSR and ESG disclosure strategies in family firms, and what factors shape these practices? Our thematic analysis identifies six key research streams and our initial findings reveal that disclosure strategies reflect interactions between family motivations, governance structures, and institutional environments. We find that governance features often mediate the link between family ownership and sustainability communication (Arayssi et al., 2019; Ghaleb et al., 2024; Ghinizzini et al., 2025).

Key gaps remain: most studies focus on publicly listed firms and formal reports, overlooking private firms and informal channels, and few examine the alignment between disclosure and actual ESG performance. Addressing these gaps advances understanding of how family firms balance socioemotional wealth, governance, and stakeholder expectations in sustainability communication, providing insights for both research and practice amid evolving regulatory frameworks such as the European Corporate Sustainability Reporting Directive.

Keywords: *family firms; CSR disclosure; ESG reporting; nonfinancial reporting; socioemotional wealth*

Framing of the research. The increasing importance of environmental, social, and governance (ESG) issues has profoundly transformed the contemporary business landscape. Firms are facing growing expectations from investors, regulators, and civil society to demonstrate responsible behavior and to communicate transparently about their social and environmental impact (Dhaliwal et al., 2010). Consequently, sustainability reporting and nonfinancial disclosure have become key instruments through which organizations signal accountability and commitment to responsible business practices.

Within this broader context, family firms represent a particularly relevant organizational form for studying sustainability engagement and communication. Family businesses account for a significant proportion of firms worldwide and play a central role in many national economies. Compared to non-family firms, family-controlled organizations often exhibit distinctive governance structures, characterized by concentrated ownership, strong family involvement in management, and long-term strategic orientation (Campopiano & De Massis, 2015).

Previous literature reviews have focused on highlighting and explaining why family firms tend to me more adept and involved in social issues compared to non-family firms, long-term orientation, stewardship values and reputational concerns all lead to increased interest in social issues (Van Gils et al., 2014). Brunelli et al., (2024) consider how family businesses with strong family involvement can drive nonfinancial reporting and further study various factors influencing the relationship, including individual, relational, business and contextual factors moderate this relationship. There is a great deal of heterogeneity in results due to the different interactions of the aforementioned factors. Generally scholars find that agency theory leads to lower disclosure levels as type one agency problem and information asymmetries are lower by the very nature of being a family firm. On the other hand, SEW perspective suggests that family firms seeking to gain long term benefits and reputational strength will engage in greater and higher quality financial disclosures (Häußler & Ulrich, 2024). In his perspective article, Caccialanza (2024), calls for greater attention to be placed both the "how" and the "why" family firms disclose CSR/ESG information, providing important insight into the implicit transparency-control trade-off that family firms face. This trade-off shapes strategic choices and actions, therefore a more nuanced, qualitative understanding is fundamental to explain the deep heterogeneity that characterizes this field of study. A recent review

considers corporate governance characteristics specifically, finding that in general board independence, female directors, institutional investors, some CEO specificities and sustainability committees are all tied to great ESG outcomes, with family ownership sometimes weaking this relationship due to concerns about privacy and control (Buchetti et al., 2025). Notwithstanding these important reviews, there remains a large gap in the literature firstly in the conceptualization of sustainability disclosures and how to measure them, secondly there is very little attention placed on the generational differences in reporting practices and how these delicate moments shape future strategic choices. Lastly, as of yet, there is insufficient research focusing on the owning family's values, TMT (top management team) characteristics and firm lifecycle phase.

Our review seeks to systematize current research into thematic groups, firstly to provide a concise representation of what has been studied so far and what are the main trends in results. Secondly, we seek to place greater emphasis on the communication aspect of these nonfinancial actions and aspects. Few studies have focused on determinants of the *level* or *amount* of nonfinancial communication by family firms, and even fewer still have considered communication vs. action in a singular firm.

These mixed findings indicate that the relationship between family ownership and sustainability communication is complex, influenced by governance structures, leadership characteristics, institutional contexts, and stakeholder expectations. Despite growing research, the literature remains fragmented and heterogeneous, using diverse theories, methods, and contexts, which makes it difficult to draw clear conclusions about ESG disclosure determinants and outcomes. A systematic literature review is therefore needed to synthesize existing knowledge, identify patterns, and highlight gaps, providing a clearer understanding of the factors shaping sustainability communication in family-controlled firms.

Purpose of the paper. The purpose of this study is to synthesize and organize the existing academic literature examining CSR and ESG disclosure strategies in family firms. Specifically, the paper seeks to address the following research question:

What do we currently know about sustainability disclosure strategies in family firms, and what factors shape these communication practices?

The study aims to achieve three main objectives.

First, it seeks to provide a comprehensive overview of the academic literature examining sustainability reporting and nonfinancial disclosure in family-controlled firms. By mapping the main research streams and theoretical perspectives employed in the literature, the study aims to clarify how scholars have approached the topic and which explanatory variables have been most frequently investigated.

Second, the study aims to identify the key determinants influencing ESG disclosure practices in family firms. These determinants include family-related characteristics such as ownership concentration and socioemotional wealth priorities, governance mechanisms such as board independence and leadership characteristics, and contextual factors such as institutional environments and regulatory frameworks.

Third, the study seeks to identify gaps and inconsistencies in the existing literature and to propose directions for future research. Understanding how family firms approach sustainability communication is increasingly important in light of evolving regulatory frameworks and stakeholder expectations regarding transparency and responsible business practices.

Methodology. This study adopts a systematic literature review (SLR) methodology in order to synthesize and organize the fragmented body of research examining CSR and ESG disclosure strategies in family firms. Systematic literature reviews are particularly suitable for consolidating dispersed knowledge, identifying research patterns, and highlighting gaps that may guide future scholarly inquiry (Denyer & Tranfield, 2009; Tranfield et al., 2003). Compared to traditional narrative reviews, the SLR approach follows a transparent and replicable process that enhances the rigor and reliability of the analysis.

The literature search was conducted primarily through the Web of Science database, which provides access to a wide range of peer-reviewed academic journals in management, accounting, and business studies. Following the approach adopted in prior sustainability reporting reviews (Brunelli et al., 2024; Mariani et al., 2021), the search strategy combined two groups of keywords. The first group included terms related to family firms (e.g., "family business," "family firm," "family ownership," and "family-controlled firms"), while the second group included terms related to sustainability reporting and nonfinancial disclosure (e.g., "CSR disclosure," "ESG reporting," "sustainability reporting," and "nonfinancial reporting").

The initial search yielded 414 articles. These articles were then screened through a multi-stage selection process. First, the sample was filtered according to journal quality, prioritizing journals ranked above level two in the Chartered Association of Business Schools' Academic Journal Guide (Franco-Santos & Otley, 2018). Special consideration was given to journals specializing in family business research, such as *Family Business Review* and *Journal of Family Business Strategy*, as well as interdisciplinary journals focusing on sustainability and corporate governance.

Second, the abstracts of all remaining papers were carefully examined in order to determine their relevance to the research topic. Articles that did not directly address sustainability practices, ESG reporting, or CSR disclosures within family firms were excluded from the sample. Duplicate entries resulting from the use of multiple keyword combinations were also removed.

Following this screening process, the final dataset consisted of 93 peer-reviewed articles published in academic journals. These studies were subsequently analyzed using thematic analysis, a widely used method for identifying patterns and recurring themes within qualitative datasets (Braun & Clarke, 2006; Jones et al., 2011). Through iterative coding and classification, the reviewed studies were organized into several thematic clusters representing the main areas of research on CSR and ESG disclosure in family firms. We aim to increase our database by repeating the aforementioned process in the Scopus database, thus avoiding selection bias.

In addition to thematic categorization, we briefly describe the sample according to the methodological and geographical distribution of the studies. This descriptive analysis revealed a strong predominance of quantitative research designs, with 69 studies employing quantitative methods, compared to a relatively small number of qualitative, mixed-method, or experimental studies. The geographical distribution of the studies also revealed a concentration of research in Europe, North America, and parts of Asia, with limited representation of firms operating in Africa and Latin America.

Results. The thematic analysis of the literature reveals several key research streams examining CSR and ESG disclosure strategies in family firms.

Ownership structure and disclosure incentives. A substantial body of research investigates how family ownership influences CSR and ESG disclosures. Many studies compare family and non-family firms, highlighting the dual role of socioemotional wealth (SEW) motivations: while long-term orientation and community embeddedness may encourage responsible practices, concerns about privacy, control, and reputation can limit transparency (Arduino et al., 2024; Battisti et al., 2023; Berrone et al., 2010; Biswas et al., 2018; Campopiano & De Massis, 2015; Maggi et al., 2023). Empirical evidence is mixed: some studies find stronger ESG performance but lower disclosure in family firms, while others suggest family ownership may enhance disclosure when reputational concerns are salient (Ardianto et al., 2024; Discua Cruz, 2020; Gavana et al., 2016; Marques et al., 2014; Venturelli et al., 2021). Moderators such as audit committees, non-family shareholders, explicit family firm identity, and institutional context help explain this heterogeneity (Biswas et al., 2018; Cabeza-García et al., 2017; Fuadah et al., 2022; Gavana et al., 2016; Gupta et al., 2025). Lifecycle dynamics also shape strategies, with younger firms often relying more on CSR communication to build legitimacy (Arena & Michelon, 2018; Madden et al., 2020; Manzi et al., 2024).

Governance mechanisms and sustainability disclosure. Governance structures affect strategic priorities, monitoring, and stakeholder engagement, thereby shaping disclosure (Arduino et al., 2024). CEO characteristics such as duality, tenure, and ownership influence ESG reporting, with family ownership often moderating these effects (AL-Duais et al., 2021; Arayssi et al., 2019; Cabral & Sasidharan, 2021; Farooq et al., 2023; Ghinizzini et al., 2025; Seow, 2025). Board size, independence, and diversity also play key roles, generally promoting transparency and higher disclosure levels, though family ownership may strengthen or weaken these relationships (Al Amosh, 2024; Arayssi et al., 2019; Butt et al., 2025; Cuadrado-Ballesteros et al., 2015; Ghaleb et al., 2024; Hunjra et al., 2025; Moisello et al., 2026; Oware et al., 2021; Padungsaksawasdi & Treepongkaruna, 2024; Rubino & Napoli, 2020; Sanad, 2025; Tran & Hamelin, 2025)

Symbolic versus substantive sustainability strategies. Research also examines whether disclosures reflect substantive ESG performance or symbolic signaling (Caccialanza, 2024; Van Gils et al., 2014). Family firms may display smaller gaps between disclosure and performance due to SEW considerations, though outcomes depend on strategic objectives, governance, and generational stage (Bergmann et al., 2025; Chi et al., 2025; Combs et al., 2023; Parra-Domínguez et al., 2021).

Credibility, signaling, and economic implications. Disclosures often function as signals to reduce information asymmetry, yet their effectiveness depends on credibility and stakeholder perceptions (Dhaliwal et al., 2010; Plumlee et al., 2010). Family ownership can provide a credibility advantage or can help reduce skepticism, this effect is especially robust when moderated by assurance mechanisms and board characteristics described in the previous section (Ananzeh, 2022; Elaigwu et al., 2024; Fawad et al., 2025; Ghaleb et al., 2024; Hsueh, 2018; Jaufenthaler et al., 2024; Latif et al., 2023; Martinez-Ferrero et al., 2017; Melati et al., 2023; Stutz et al., 2022). Sustainability disclosure has also been linked to economic consequences, including reduced cost of capital, improved investment efficiency, and stronger market reactions for family firms, though effects vary across contexts (Akhter & Hassan, 2024; Arayssi et al., 2019; Borralho et al., 2022; Cordeiro et al., 2021; Erawati et al., 2021; Gjergji et al., 2021; Natour et al., 2022; Nekhili et al., 2017; Orellana et al., 2025; Sari et al., 2024; Sekerci et al., 2022).

Institutional context. Institutional and regulatory frameworks strongly shape ESG disclosure, influencing the incentives and legitimacy strategies adopted by family firms (Aureli et al., 2020; Brunelli et al., 2024; Coluccia et al., 2018; Sani Khamisu & Ratna Achuta, 2025). Engagement with policymakers can sometimes reduce environmental commitments or result in symbolic compliance (Brumana et al., 2024; Diez-Busto et al., 2021; Fernández-Gago et al., 2024).

Despite substantial progress, three key gaps remain in the literature:

1. The temporal aspect, we see promising results in explaining the heterogeneity present within the field when we account for lifecycle phases of the firm.

2. The alignment between symbolic and substantive strategies requires further study, particularly regarding governance and generational influences.
3. The role of institutional context in moderating disclosure behavior needs more investigation, as most studies focus on specific regions, limiting generalizability. Addressing these gaps can clarify how family firms balance socioemotional wealth preservation, governance, and stakeholder expectations in ESG disclosure.

Research limitations. Despite its contributions, this work in progress review has several limitations. It relies mainly on Web of Science publications and peer-reviewed journals, potentially excluding relevant studies from other databases, practitioner outlets, or grey literature. Most empirical studies use quantitative methods and secondary data, such as ESG databases and sustainability reports, which may not fully capture the complexity of family firms' practices. Qualitative research is needed to explore the motivations and contextual factors behind ESG strategies.

Geographically, the literature is concentrated in Europe, North America, and parts of Asia, leaving Africa, Latin America, and Oceania underrepresented and limiting generalizability.

Future research should expand beyond publicly listed companies to include privately held firms and SMEs, explore alternative forms of sustainability communication (e.g., social media, stakeholder engagement, community initiatives), and examine the alignment between disclosures and actual sustainability practices. Investigating family firm heterogeneity and institutional contexts through cross-country and qualitative studies can provide deeper insights into how family values, governance, and regulatory environments shape ESG communication strategies.

Managerial implications. The initial findings of this review offer several important implications for managers and policymakers involved in family-controlled organizations.

First, the results highlight the importance of aligning **s**ustainability practices with effective communication strategies. Many family firms actively engage in environmental and social initiatives but may not communicate these efforts extensively. Developing structured ESG communication strategies could enable family firms to enhance stakeholder trust, strengthen reputation, and fully capture the strategic benefits associated with sustainability engagement.

Second, our preliminary findings emphasize the role of corporate governance structures in shaping sustainability disclosure practices. Family firms seeking to improve the credibility and transparency of their ESG reporting may benefit from incorporating independent directors, promoting gender diversity within boards, and establishing dedicated sustainability committees.

Finally, policymakers designing sustainability reporting frameworks should recognize the unique characteristics of family firms, particularly SMEs. Providing simplified reporting guidelines and support mechanisms may encourage broader participation in sustainability disclosure while accommodating the specific governance structures of family-controlled firms.

Originality of the paper. This potential study contributes to the literature by providing a systematic synthesis of research examining CSR and ESG disclosure strategies in family firms, an area that has received increasing scholarly attention but remains fragmented across multiple disciplines.

By organizing the existing literature into coherent thematic clusters, the embryonal study clarifies the key determinants of sustainability communication in family firms and highlights the role of family-related motivations, governance structures, and institutional contexts in shaping ESG disclosure strategies.

Furthermore, this work in progress identifies several important gaps in the literature, including the limited focus on privately held family firms, the reliance on formal disclosure data, and the lack of research examining the relationship between sustainability actions and communication practices. Addressing these gaps represents an important opportunity for future research aimed at developing a more comprehensive understanding of sustainability communication in family-controlled organizations.

When Marriage Breaks, Firms Shake: Marital Instability as a Hidden Governance Risk in Family Firms

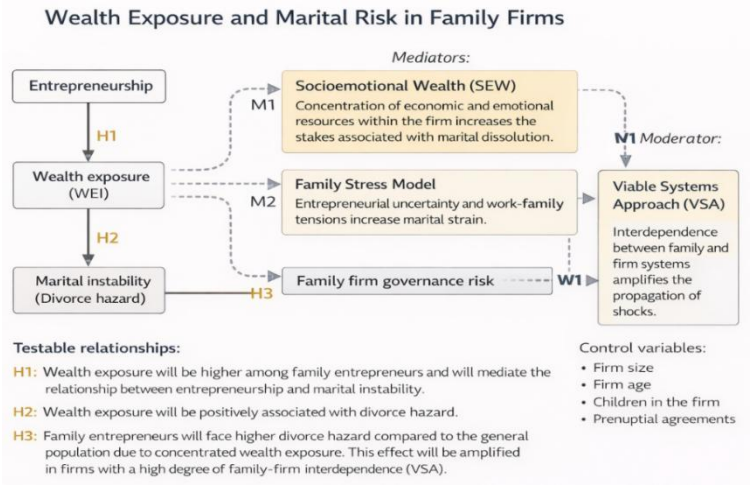
JAIME MURGIA, GIULIO PALMAS, MICHELA FLORIS

Abstract. *Family firms are widely recognized for their long-term orientation, strong relational embeddedness, and commitment to preserving socioemotional wealth (SEW). Yet the same relational foundations that sustain these organizations may also expose them to specific vulnerabilities. One such vulnerability—largely overlooked in the family business literature—concerns the potential relational pressures generated by the strong financial and organizational interdependence between family and firm. In contexts where ownership structures, family relationships, and business governance are deeply intertwined, the concentration of family wealth within the firm may increase the economic and emotional stakes associated with marital relationships, potentially amplifying the consequences of marital instability for both the family and the organization. Rather than treating divorce solely as an exogenous shock to family firm governance, this study explores how the financial and governance arrangements typical of family firms may interact with marital dynamics within business families. Drawing on the Socioemotional Wealth perspective (Gómez-Mejía et al., 2007), the Family Stress Model (Conger et al., 1994), and the Vulnerability–Stress–Adaptation framework (Karney & Bradbury, 1995), the research examines how the financial and governance structures typical of family firms may contribute to relational strain within families involved in the ownership and management of family firms. A central contribution of the study is the introduction of the Wealth Exposure Index (WEI), which captures the degree to which family wealth and firm assets are financially intertwined. The index reflects governance and financing patterns frequently observed in family-controlled firms, such as ownership concentration, reliance on internal family capital, and the use of personal guarantees in corporate financing. Preliminary empirical evidence suggests that family firms characterized by higher levels of wealth exposure may face increased vulnerability to marital instability. By examining how the financial architecture of family firms may shape marital risk within business families, this study contributes to family business research and offers three insights into the relational foundations of organizational stability in family-controlled firms. First, the study highlights how the strong financial interdependence between family wealth and firm assets may represent a structural source of relational pressure within business families, suggesting that governance arrangements designed to protect socioemotional wealth may also carry unintended relational consequences. Second, the study shows how governance and financing choices typical of family firms—such as asset concentration, personal guarantees, and resistance to external equity—may unintentionally increase relational stress within the business family, revealing a potential "paradox of protection" in the preservation of socioemotional wealth. Third, the research integrates insights from family sociology and management studies, demonstrating that changes in family structures and marital stability may have important organizational implications for family-controlled firms, particularly when family wealth and firm resources are tightly interconnected.*

Keywords: *Divorce risk; Wealth exposure; Socioemotional wealth (SEW); Entrepreneurship; Family business governance*

Framing of the research. *Family firms operate through governance structures in which family relationships, ownership arrangements, and business management are deeply intertwined. Unlike widely held corporations, decision-making processes in family firms are frequently embedded in relational dynamics that extend beyond formal organizational boundaries. The classic three-circle model illustrates how the interaction between family, ownership, and business subsystems creates a governance configuration in which personal relationships and economic interests become closely interconnected (Tagiuri & Davis, 1996; Gersick et al., 1997). Within this configuration, family ties often shape strategic choices, leadership transitions, and ownership arrangements. The family business literature has long emphasized that this relational embeddedness represents both a source of advantage and a potential source of tension. On the one hand, strong family ties may foster trust, long-term orientation, and commitment to the continuity of the firm across generations (Miller & Le Breton-Miller, 2005; Zellweger, 2017). On the other hand, the same relational proximity may also generate conflicts that affect governance processes and managerial decision-making (Chrisman, Chua, & Sharma, 2005; De Massis, Kotlar, Chua, & Chrisman, 2014). Consequently, scholars have devoted considerable attention to relational conflicts within business families. Research has extensively explored issues such as succession disputes, intergenerational disagreements, sibling rivalry, and role ambiguity among family members involved in ownership and management (Handler, 1994; Sharma, Chrisman, & Chua, 2003; Jaskiewicz, Combs, & Rau, 2015). These studies highlight how tensions within the family system may influence governance structures, leadership succession, and strategic decision-making in family-controlled firms. More recently, the Socioemotional Wealth (SEW) perspective has provided a powerful framework for understanding why family relationships play such a central role in family firm governance. According to this perspective, family-controlled firms pursue not only financial goals but also non-economic objectives related to the preservation of family control, identity, and dynastic continuity (Gómez-Mejía et al., 2007; Berrone, Cruz, & Gómez-Mejía, 2012). The desire to protect socioemotional wealth often encourages family owners to maintain ownership*

concentration and avoid external equity participation in order to preserve family influence over the firm (Chrisman et al., 2012; Miller & Le Breton-Miller, 2014). While this body of research has significantly advanced our understanding of governance dynamics in family firms, it has primarily focused on conflicts that emerge within the formal governance structure of the firm, particularly those related to succession processes and internal power dynamics among family members. In contrast, relatively little attention has been devoted to relational disruptions that originate within the broader family system but outside the formal governance structure of the firm, despite their potential implications for ownership structures and governance stability. One such disruption is marital dissolution. Divorce has traditionally been examined within sociology, demography, and family studies as a private life event associated with changing household structures and individual life trajectories (Cherlin, 2004; Amato, 2010). However, within business families, marriage may also play an implicit institutional role that extends beyond the private sphere. Marital relationships frequently contribute to the stabilization of relational ties among members of the business family and may support the consolidation of wealth and alliances within the family system. In many cases, marriage indirectly sustains governance arrangements by reinforcing predictable expectations regarding inheritance, ownership continuity, and succession within the firm (Zellweger, 2017; Miller & Le Breton-Miller, 2021). At the same time, contemporary societies have experienced profound transformations in family structures and intimate relationships. Over the past decades, divorce rates have increased across most advanced economies as part of broader demographic changes associated with the Second Demographic Transition (Lesthaeghe, 2010; van de Kaa, 1987). These transformations reflect a broader shift toward individual autonomy, self-realization, and the diversification of family arrangements. Scholars have interpreted these developments as part of a broader transformation in the nature of intimate relationships. Giddens (1992) describes the emergence of "pure relationships," which persist only as long as they provide mutual satisfaction for both partners. Similarly, Beck and Beck-Gernsheim (1995) argue that processes of individualization have transformed romantic relationships into increasingly contingent and fluid arrangements. These changes suggest that marital relationships—once considered relatively stable institutional foundations—have become more uncertain in contemporary societies. For family firms, this transformation raises an important but largely unexplored question: how do changes in marital relationships affect governance structures in family-controlled firms? More specifically, how might the financial and governance arrangements typical of family firms interact with marital dynamics within business families? This question becomes particularly relevant when considering the financial and governance arrangements typical of family firms. Business families often rely on mechanisms that strongly intertwine family wealth and firm resources. Entrepreneurs frequently provide personal guarantees for corporate loans, pledge family assets as collateral, and concentrate a significant portion of their wealth within the firm itself. These governance choices are often motivated by the desire to preserve family control and protect socioemotional wealth (Gómez-Mejía et al., 2007; Chrisman et al., 2012). However, these strategies may also increase the degree of financial and relational interdependence between the family and the firm. Insights from the Family Stress Model suggest that economic pressure can generate relational strain within households, potentially affecting marital stability over time (Conger et al., 1994; Masarik & Conger, 2017). Similarly, the Vulnerability–Stress–Adaptation framework explains marital outcomes as the result of the interaction between enduring vulnerabilities, external stressors, and adaptive processes within couples (Karney & Bradbury, 1995; Randall & Bodenmann, 2017). Taken together, these perspectives suggest that financial pressures associated with business activities may spill over into family relationships, potentially increasing the likelihood of marital instability within business families. Despite these theoretical insights, the potential organizational implications of marital dissolution remain largely unexplored in the family business literature. While prior research has extensively investigated governance conflicts within family firms, limited attention has been devoted to how divorce may reshape ownership structures, alter governance dynamics, and introduce new sources of managerial complexity in family-controlled organizations. Accordingly, this study addresses this gap by examining how the financial architecture of family firms may interact with marital dynamics within business families and how marital instability, when it occurs, may generate organizational consequences for ownership structures and governance processes. By linking wealth concentration, relational stress, and marital outcomes, the study provides an initial step toward understanding divorce as a phenomenon with both relational and organizational implications in family-controlled firms.



Purpose of the paper. *Against this backdrop, this study examines how the financial architecture of family firms may interact with marital stability within business families and potentially influence governance dynamics in family-controlled firms. While prior research has primarily focused on conflicts related to succession and intergenerational relationships, limited attention has been devoted to how divorce may affect ownership arrangements and managerial decision-making.*

Drawing on the SEW perspective and insights from family stress research, the paper examines how the strong financial and relational interdependence characteristic of family firms may shape marital stability and, in turn, generate potential organizational consequences for ownership structures and managerial processes. By doing so, the study explores how governance and financing arrangements typical of family firms—such as the concentration of family wealth within the firm—may indirectly shape marital dynamics within business families, and how marital instability, when it occurs, may have implications for ownership arrangements and governance processes in family-controlled firms.

Methodology. *To investigate the relationship between marital instability and governance structures in family firms, this study adopts a quantitative exploratory research design that combines demographic data on marital dissolution with indicators capturing the financial interdependence between family wealth and firm resources. The objective is not to*

establish causal relationships at this stage but rather to provide an initial empirical exploration of how specific structural characteristics of family firms may be associated with different levels of marital instability within business families and how such relational dynamics may carry potential implications for governance structures in family-controlled firms.

The analysis is grounded in the concept of wealth exposure, defined as the degree to which family wealth is financially intertwined with the assets and financial obligations of the firm. In family-controlled businesses, the boundaries between family assets and corporate resources are often blurred. Business owners frequently rely on mechanisms such as personal guarantees for bank loans, collateralization of family property, reinvestment of family savings into the firm, and high ownership concentration. These practices are widely documented in the family business literature and are often associated with governance choices aimed at preserving family control and protecting socioemotional wealth (Gómez-Mejía et al., 2007; Chrisman et al., 2012; Miller & Le Breton-Miller, 2014). However, these governance strategies may also increase the degree of financial interdependence between the family system and the business system. When family wealth becomes highly concentrated within the firm, economic shocks affecting the business may simultaneously affect the financial stability of the household. Prior research suggests that financial strain and economic uncertainty can generate relational tensions within families and increase the likelihood of marital conflict (Conger et al., 1994; Dew, 2011; Masarik & Conger, 2017). To capture this structural interdependence, the study introduces a composite indicator called the Wealth Exposure Index (WEI). The WEI measures the extent to which family wealth and firm assets are financially interconnected and therefore jointly exposed to economic risk. The index integrates several structural dimensions commonly observed in family firms, including ownership concentration, the use of family guarantees in corporate financing, and the reliance on internal family capital as a primary funding source. These dimensions reflect governance patterns that are frequently adopted by family-controlled firms seeking to maintain control over strategic decisions and limit external interference (Chrisman et al., 2005; Miller & Le Breton-Miller, 2005; Zellweger, 2017). The empirical analysis is conducted using a comparative macro-level dataset combining demographic statistics on divorce with economic indicators related to entrepreneurial activity and family firm ownership structures. The analysis focuses primarily on Italy, where family-controlled firms represent a dominant organizational form, but it also incorporates a comparative perspective including France, Germany, and the United Kingdom. Cross-national comparison allows the study to account for institutional differences in family policies, welfare regimes, and divorce legislation, which may influence marital instability patterns (Esping-Andersen, 2009; Lesthaeghe, 2010). Data on divorce rates and marital transitions are drawn from national statistical agencies and harmonized demographic datasets that provide information on marital dissolution across population groups. Economic indicators related to entrepreneurial activity and family firm ownership structures are integrated into the dataset in order to distinguish families associated with business ownership from other household categories. To analyze the relationship between wealth exposure and marital instability, the study employs a hazard ratio modelling approach, a technique commonly used in demographic and sociological research to estimate the probability that a specific event—such as divorce—occurs within a given time interval (Allison, 2014; Blossfeld et al., 2007). Hazard models allow researchers to estimate how structural characteristics influence the timing and likelihood of marital dissolution. The modelling process involves two main steps. First, the WEI is estimated for different categories of business families based on the structural characteristics described above. Second, hazard ratios associated with marital dissolution are estimated by comparing groups characterized by different levels of wealth exposure with baseline household categories that do not display the same degree of financial interdependence between family and business assets. Finally, to account for cross-country institutional differences, the model incorporates a national adjustment parameter that controls for variations in legal frameworks, welfare systems, and divorce regulations across the four countries considered. This adjustment allows the analysis to identify structural patterns in the relationship between wealth exposure and marital instability while reducing the influence of country-specific institutional factors. While the methodological approach remains exploratory, it provides an initial empirical framework for examining how the financial structures typical of family firms may interact with relational dynamics within business families and potentially influence the likelihood of marital dissolution as well as the broader governance environment of family-controlled firms.

Results. *This section presents the preliminary empirical results of the study.*

Wealth Exposure in Family Firms. A first key result concerns the level of wealth exposure associated with entrepreneurial activity. The construction of the WEI, which measures the proportion of personal wealth concentrated in the firm, reveals substantial differences between family and non-family entrepreneurs. The analysis indicates that family entrepreneurs display significantly higher levels of wealth exposure compared to non-family entrepreneurs. Specifically, the estimated exposure index reaches approximately 0.66 for family entrepreneurs, compared to 0.39 for non-family entrepreneurs, producing a relative exposure ratio of about 1.7. This finding is consistent with the theoretical expectation derived from the SEW perspective, according to which family firms tend to concentrate both economic and emotional resources within the business. Because the firm often represents not only a financial asset but also a repository of family identity and legacy, family entrepreneurs tend to allocate a larger share of their wealth to the firm. From a marital perspective, this concentration of wealth increases the potential economic stakes associated with marital dissolution. In the event of divorce, the division of assets may directly affect the ownership structure and control of the firm, thereby increasing the economic and relational stakes associated with marital instability within business families.

Divorce Hazard and Entrepreneurial Exposure. A second result concerns the relationship between wealth exposure and the probability of divorce. Using hazard ratio modelling, the analysis estimates the relative risk of marital dissolution across different occupational categories. The results indicate that entrepreneurs display a higher divorce hazard compared to the general population. The calibrated hazard ratio for non-family entrepreneurs is estimated at approximately 1.25, indicating a 25% higher probability of divorce relative to the baseline population. However, the effect becomes even more pronounced in the case of family entrepreneurs. The estimated hazard ratio for this group reaches approximately 1.43, corresponding to a 43% higher divorce risk compared to the general population. These findings suggest that entrepreneurial activity itself is associated with increased marital strain, a result that aligns with the Family Stress Model, which highlights how economic pressures and work–family tensions can affect marital stability. However, the significantly higher hazard ratio observed among family entrepreneurs indicates that additional mechanisms may be at play beyond the general stress associated with entrepreneurship and may be related to the specific financial and relational interdependence typical of family-controlled firms.

Decomposing the Excess Divorce Risk. To better understand this difference, the analysis decomposes the excess divorce risk observed among family entrepreneurs into two main components. The results suggest that approximately 62% of the excess risk can be attributed to the baseline risks associated with entrepreneurial activity, including long working hours, financial uncertainty, and role conflicts between work and family life. The remaining 38% of the excess risk, however, appears to be associated with the higher level of wealth exposure characteristic of family firms. Because family entrepreneurs typically allocate a substantial portion of their wealth to the firm, marital dissolution may entail particularly complex negotiations over asset division and ownership rights. This result challenges the idea that divorce risk among entrepreneurs can be explained solely by occupational stress or adverse selection mechanisms. Instead, it suggests that the structural characteristics of family ownership—particularly the concentration of family wealth within the firm—may play an important role in shaping marital outcomes.

Preliminary Interpretation: Wealth Exposure and Family Firm Vulnerability. Findings point to a structural tension within family firms. On the one hand, family ownership structures are often designed to protect family wealth and ensure continuity across generations. On the other hand, the concentration of financial and emotional resources within the firm may inadvertently increase the stakes associated with marital disruption. From the perspective of the Viable Systems Approach (VSA), this dynamic can be interpreted as a form of systemic vulnerability. Because the family and the firm are deeply interconnected, disruptions in one subsystem—such as marital breakdown—can potentially propagate across the broader organizational system. These preliminary results therefore suggest that divorce may have implications that extend beyond the private sphere and potentially affect governance arrangements in family firms. Marital instability may affect ownership structures, decision-making processes, and the firm's strategic continuity, particularly in contexts characterized by high levels of wealth exposure and strong family–firm interdependence. While these findings remain exploratory, they provide initial empirical support for the idea that wealth exposure and family embeddedness jointly shape the relationship between entrepreneurship and marital stability and may indirectly influence the governance environment of family-controlled firms.

Research limitations. *Despite the contributions of this study, several limitations should be acknowledged.*

First, the empirical analysis relies on a preliminary dataset and the results should therefore be interpreted with caution. Although the statistical models provide initial evidence of the relationship between wealth exposure and marital instability among entrepreneurs, further analyses using larger and more diverse samples are needed to confirm the robustness and generalizability of the findings. Second, the study focuses primarily on the economic dimension of divorce exposure, operationalized through the Wealth Exposure Index (WEI). While this measure captures the concentration of personal wealth within the firm, it does not fully account for other important dimensions of marital dynamics, such as emotional conflict, relational quality, or family communication patterns. Future research could complement the current

quantitative approach with qualitative or mixed-method designs in order to better capture the relational mechanisms underlying marital instability within business families. Third, the analysis does not explicitly consider institutional and legal differences across contexts. Divorce regulations, property regimes, and family law frameworks vary significantly across countries and may influence both wealth exposure and divorce outcomes. As a result, the mechanisms identified in this study may operate differently in alternative institutional environments. Comparative cross-country analyses could therefore provide valuable insights into how legal and cultural factors shape the relationship between entrepreneurship, wealth concentration, and marital risk. Fourth, although the study highlights the potential organizational implications of marital instability for family firms, the current analysis does not directly observe firm-level outcomes following marital disruption. Future research could examine how divorce events affect ownership structures, succession processes, strategic decision-making, and firm performance over time. Finally, the conceptual framework integrates insights from socioemotional wealth theory, the Family Stress Model, and the Viable Systems Approach. While this interdisciplinary perspective helps illuminate the mechanisms linking entrepreneurship, wealth exposure, and marital instability, the empirical models test only part of these theoretical dynamics. Additional studies could further explore how emotional attachment to the firm, governance structures, and family–business boundaries interact with marital processes and how these dynamics may influence the stability of family firm governance systems.

Managerial implications. *The findings of this study offer several implications for family business owners, advisors, and governance bodies involved in the management and continuity of family firms. First, the results highlight how marital instability may generate organizational implications in family firms. Because business families often concentrate a substantial share of their wealth in the firm, marital dissolution may have significant implications for ownership structures, control rights, and strategic decision-making. Family business leaders should therefore consider marital stability as part of the broader relational and financial landscape affecting the firm. Second, the findings suggest that wealth concentration within the firm can amplify the economic stakes of marital disruption. For family entrepreneurs, this implies the need to adopt governance mechanisms that can mitigate potential conflicts in the event of divorce. Instruments such as shareholder agreements, prenuptial arrangements, or clear ownership transfer rules may help reduce uncertainty and protect the continuity of the business. Third, the results underline the importance of formal governance structures in family firms. When family relationships and business ownership are deeply intertwined, unexpected personal events—such as marital breakdown—may easily spill over into the organizational domain. Establishing clearer boundaries between family and business roles can help firms maintain stability even when family dynamics change. Fourth, the study suggests that family business advisors—including lawyers, financial planners, and family business consultants—should pay greater attention to the interaction between family dynamics and ownership structures. Integrating marital risk considerations into long-term governance planning may help families anticipate potential conflicts and design more resilient ownership arrangements. Finally, the results point to the broader need for preventive governance strategies in family firms. Rather than addressing marital disruptions only when they occur, family firms may benefit from proactively developing governance frameworks that anticipate potential changes in family relationships. Such an approach can help preserve both family harmony and organizational stability over time and reduce the potential organizational disruptions associated with marital dissolution in business families.*

Originality of the paper. *This study contributes to the family business literature by expanding current understanding of how family dynamics interact with governance structures in family-controlled firms. While prior research has extensively examined governance conflicts related to succession, intergenerational relationships, and role ambiguity among family members involved in ownership and management (Handler, 1994; Sharma, Chrisman, & Chua, 2003; Chrisman, Chua, & Sharma, 2005; Jaskiewicz, Combs, & Rau, 2015; De Massis, Kotlar, Chua, & Chrisman, 2014), comparatively limited attention has been devoted to relational disruptions originating outside the formal governance structure of the firm. In particular, the potential implications of marital instability for family firm governance remain largely unexplored. The originality of this study lies in shifting attention toward the structural conditions within family firms that may shape marital instability within business families. Rather than conceptualizing divorce solely as an exogenous family event, the paper examines how the financial architecture of family firms—particularly the concentration of family wealth within the business—may increase the economic and relational stakes associated with marital disruption. In doing so, the study extends the family business governance literature by highlighting how relational dynamics within the family system may interact with ownership structures and influence the stability of governance arrangements in family-controlled firms.*

A second contribution concerns extending the SEW perspective (Gómez-Mejía et al., 2007; Berrone, Cruz, & Gómez-Mejía, 2012). Prior studies have shown that family owners often prioritize the preservation of family control, identity, and dynastic continuity, leading them to concentrate ownership and avoid external equity participation (Chrisman et al., 2012; Miller & Le Breton-Miller, 2014). This study argues that governance and financing choices aimed at preserving SEW may also have unintended relational consequences. Specifically, the concentration of family wealth within the firm may increase the family system's economic exposure, thereby intensifying the potential consequences of marital instability.

Third, the study contributes by connecting family business research with theories of family stress and marital instability developed in sociology and family studies. The conceptual framework integrates the Family Stress Model (Conger et al., 1994; Masarik & Conger, 2017) and the Vulnerability–Stress–Adaptation framework (Karney &

Bradbury, 1995; Randall & Bodenmann, 2017), suggesting that economic pressures associated with entrepreneurial activity and wealth concentration may spill over into family relationships. By bridging these literatures, the paper highlights how economic structures and relational dynamics jointly shape marital outcomes within business families.

A fourth contribution is methodological. The study introduces the WEI, a composite indicator designed to capture the degree to which family wealth is financially intertwined with firm assets and liabilities. By operationalizing wealth concentration in family firms, the WEI provides a novel empirical mechanism for examining how economic exposure may influence marital risk among entrepreneurs. This approach offers a new analytical tool for investigating the intersection between family wealth structures, entrepreneurial activity, and family stability.

Finally, the study provides preliminary quantitative evidence that family entrepreneurs face a higher divorce hazard compared to both the general population and non-family entrepreneurs. By identifying wealth exposure as a potential mechanism linking entrepreneurship and marital instability, the findings open new avenues for research on how family relationships and governance structures co-evolve in family-controlled firms. More broadly, the study suggests that changes in family relationships may have implications that extend beyond the private sphere, potentially influencing the stability and continuity of family firm governance systems.

Antecedenti, evoluzione ed esiti dell'autenticità d'impresa: una revisione critica della letteratura

ALESSANDRA RUSSO[1], PASQUALE MASSIMO PICONE[2]

Abstract. *Un* leitmotiv *nella letteratura di* strategic management *è che l'autenticità d'impresa rappresenti una risorsa intangibile in grado di supportare l'emergere e la sostenibilità del vantaggio competitivo. Questa consapevolezza ha stimolato un'ampia produzione scientifica sul tema. Se, da un lato, la copiosità della letteratura ha consentito di investigare molteplici e importanti sfaccettature inerenti alla genesi, all'affermazione e al dissolvimento dell'autenticità d'impresa, la ricerca su questo tema rimane teoricamente frammentata. Gli studi esistenti tendono generalmente a esaminare fasi temporalmente distinte connesse all'autenticità d'impresa; pertanto, la letteratura non offre una ricostruzione coerente delle dinamiche temporali che collegano le suddette fasi e, quindi, non spiega compiutamente l'evoluzione dell'autenticità d'impresa. Il presente paper rappresenta il disegno di ricerca di uno studio ancora* in fieri*. La ricerca mira a sintetizzare e reinterpretare l'autenticità d'impresa attraverso una lente interpretativa temporale. La ricerca dovrà proporre un framework concettuale che spieghi come l'autenticità si trasforma nel tempo. In particolare, dall'analisi della letteratura noi abbiamo già identificato le condizioni di field e di categoria, le condizioni di ancoraggio dell'impresa e le condizioni relative alle dotazioni di connessione come antecedenti dell'autenticità d'impresa. Inoltre, lo studio della letteratura esistente consente di mettere in luce come l'autenticità d'impresa evolva sia attraverso sforzi manageriali intenzionali (*i.e., authenticity work*), sia mediante mutamenti non intenzionali. Gli esiti di tali trasformazioni sono rappresentati da nuove condizioni di field e di categoria, nuove condizioni di ancoraggio dell'impresa e nuove condizioni relative alle dotazioni di connessione. Il framework proposto può supportare l'individuazione di nuove direzioni di ricerca e l'identificazione di implicazioni manageriali.*
Keywords: *autenticità d'impresa, authenticity work, temporalità, conformità, coerenza, connessione*

Framing della ricerca. *Negli ultimi due decenni, l'autenticità è divenuta vieppiù centrale nel dibattito di* strategic management*. Le imprese sono sempre più chiamate ad essere percepite come autentiche per ottenere legittimazione, per differenziarsi dai* competitor *e per conseguire il vantaggio competitivo (Kovács et al., 2014; O'Connor et al., 2017). L'autenticità segnala l'appartenenza credibile dell'impresa ad una categoria, la coerenza tra l'identità, i valori dichiarati e le pratiche effettive, o connessioni simboliche con luoghi, persone e tempi (Lehman et al., 2019).*

La letteratura sull'autenticità si è mossa lungo tre principali direttrici. La prima riguarda la questione ontologica stessa dell'autenticità. Per esempio, Wang (1999) ha distinto l'autenticità oggettiva (interpretando l'autenticità come attributo verificabile), dall'autenticità costruita (quindi, l'autenticità come risultato di una costruzione sociale) ed esistenziale (in tal caso, l'autenticità è intesa come potenziale stato esistenziale dell'essere).

La seconda direttrice si è concentrata sulle prospettive interpretative dell'autenticità. Nello specifico, una prima prospettiva denominata audience–based *si concentra su "chi valuta" l'autenticità (Carroll & Kovács, 2021). Una seconda prospettiva denominata* referent–based*, invece, analizza "a che cosa" l'autenticità viene riferita, ossia a quali criteri socialmente condivisi (ad esempio, categorie, identità, valori, tempi, persone, luoghi) l'audience fa riferimento come base valutativa (Lehman et al., 2019).*

La terza direttrice di ricerca che ha caratterizzato il dibattito sull'autenticità è l'analisi dei processi mediante cui le imprese costruiscono l'autenticità (Peterson, 2005), evidenziando tensioni tra parole e azioni (Cording et al., 2014), mutamenti categoriali (Negro et al., 2011; Pozner et al., 2022) e reinterpretazioni di connessioni spazio-temporali (Cappelen & Pedersen, 2021).

Benché l'abbondante letteratura abbia approfondito molteplici dimensioni relative alla genesi, all'affermazione e al dissolvimento dell'autenticità d'impresa, il dibattito scientifico appare ancora caratterizzato da una marcata frammentazione teorica. L'autenticità è usualmente analizzata in momenti discreti o con riferimento a significati isolati (conformità, coerenza, connessione), senza una visione integrata delle dinamiche temporali che collegano gli antecedenti dell'autenticità, la trasformazione dell'autenticità e gli esiti di tali trasformazioni. De facto*, la temporalità, intesa come relazione tra passato, presente e futuro (Schultz & Hernes, 2013), rimane una dimensione limitatamente teorizzata. Tale condizione inibisce la comprensione del perché alcune imprese riescono a trasformare la propria autenticità nel tempo, mentre altre imprese rimangono vincolate agli antecedenti dell'autenticità. Inoltre, da un'analisi della letteratura, noi osserviamo che rimane ambiguo se e come l'autenticità possa simultaneamente abilitare e limitare l'azione strategica delle imprese.*

Scopo del paper. *La presente ricerca – ancora in una fase embrionale – si propone di sviluppare una review della letteratura sull'autenticità d'impresa, reinterpretandola mediante una lente temporale. Il risultato atteso della ricerca*

[2] Full Professor of Management, University of Palermo, email: pasqualemassimo.picone@unipa.it

dovrà essere un framework concettuale che colleghi antecedenti dell'autenticità d'impresa, modalità evolutive dell'autenticità ed esiti della trasformazione dell'autenticità nel tempo.

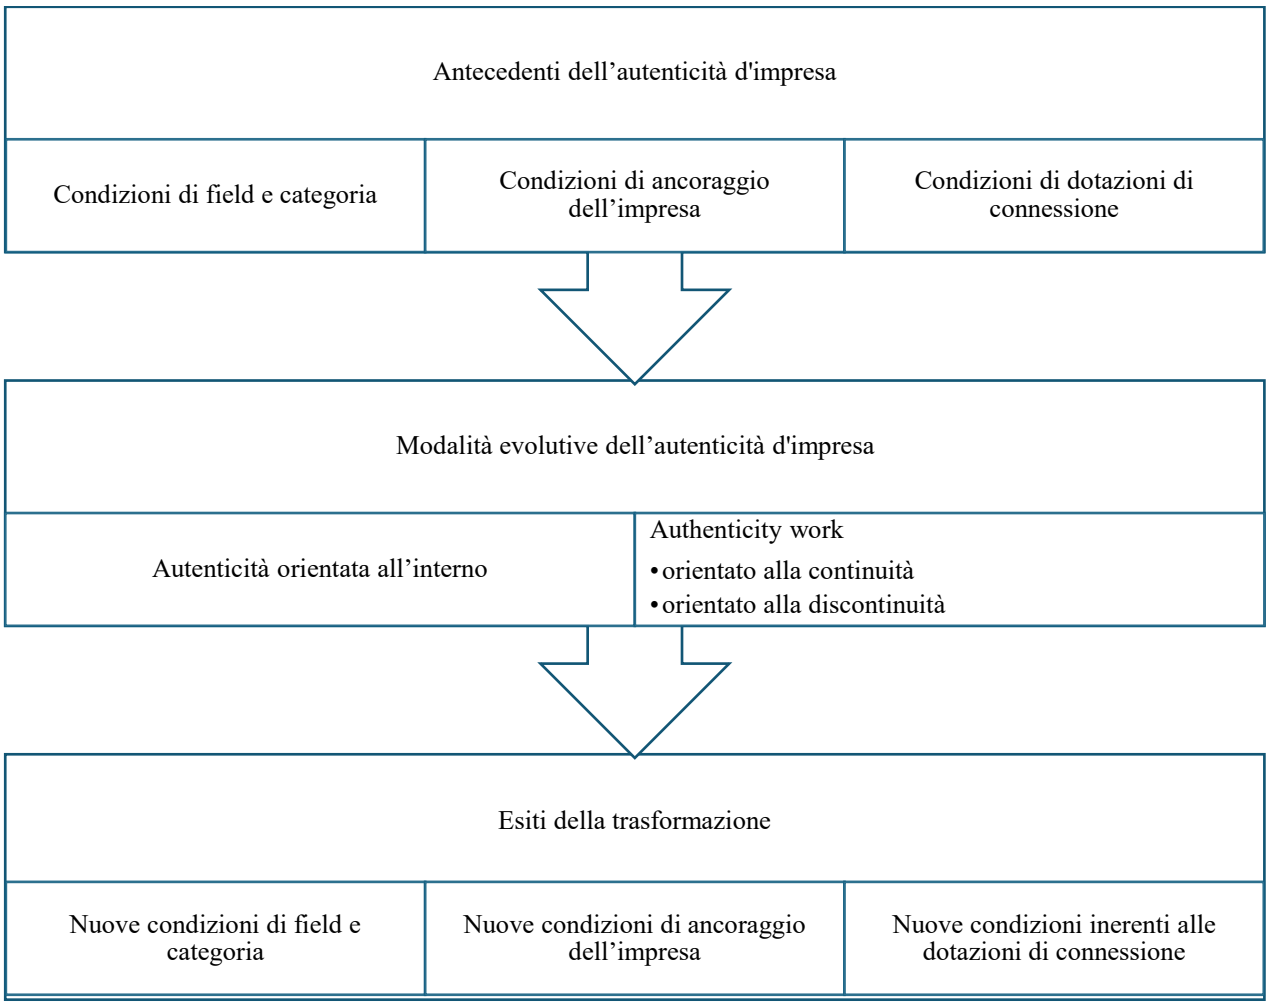
Metodologia. *Questa ricerca adotta un approccio di revisione teorica estensiva della letteratura. La raccolta degli articoli è stata condotta attraverso Web of Science e Scopus (1990–2026) utilizzando il termine "*authentic*" combinato con l'operatore booleano "*AND" "organisation*", "*organization*", "*firm*", "*business*", o "*compan*". Le parole chiave sono state ricercate nel titolo, abstract, parole chiave e sono stati inclusi solo articoli pubblicati in inglese nell'ambito del business e management.*

Per affinare il campione abbiamo applicato un filtro di qualità delle riviste. Sono stati inclusi articoli e review pubblicati in riviste classificate 3, 4 e 4 nell' U.K. Association of Business Schools Academic Journal Guide 2024 all'interno dei seguenti ambiti: entrepreneurship and small business management; ethics, CSR, and management; innovation; international business; marketing; operations & technology; organization & management science; organization studies; strategy. Dopo la rimozione dei duplicati, il dataset comprendeva 700 articoli.*

Coerentemente con l'obiettivo dello studio, l'inclusione di riviste appartenenti ai domini sopra menzionati non implica l'inclusione di tutti i filoni di ricerca che essi comprendono. Ad esempio, sono stati considerati selettivamente gli studi di marketing includendoli soltanto quando i contributi concettualizzano i mercati come sistemi sociali organizzati e istituzionalizzati, piuttosto che come arene di consumo individuale. Di conseguenza, abbiamo escluso gli articoli focalizzati principalmente sulla brand authenticity *(ad es., Fritz et al., 2017; Dwivedi & McDonald, 2018). Sebbene questo filone di ricerca offra importanti contributi in merito alle valutazioni dell'autenticità da parte dei consumatori, la nostra analisi si concentra sui referenti valutativi dell'autenticità dell'impresa. Analogamente, abbiamo considerato in modo selettivo la ricerca nel dominio di Operations & Technology, escludendo ad esempio gli studi centrati sull'autenticità del prodotto focalizzati sugli aspetti tecnologici della blockchain (Pun et al., 2021).*

Inoltre, abbiamo escluso gli articoli che analizzano l'autenticità ad un micro–livello di analisi, come gli studi sui leader (Fladerer et al., 2020), imprenditori (Lewis, 2013), dipendenti (Jean–Baptiste et al., 2025) o altri individui (Lee & Chung, 2025), poiché l'inclusione di tali studi avrebbe introdotto eterogeneità teorica in termini di livelli di analisi, diluendo il focus sull'autenticità come processo collettivo e radicato organizzativamente.

Inoltre, abbiamo integrato il dataset con due articoli che non sono emersi dalla ricerca sopra descritta, ma che sono stati inclusi in virtù della loro particolare rilevanza nella letteratura sull'autenticità. Nello specifico, abbiamo aggiunto Peterson (2005), un contributo fondamentale sui processi di autenticazione, che non era stato incluso nel database originario poiché si concentra più ampiamente sulla costruzione sociale dell'autenticità piuttosto che su come le imprese gestiscono la propria autenticità. Allo stesso modo, abbiamo incluso Lehman et al. (2019), che non era presente nel database iniziale poiché si concentra sui significati dell'autenticità adottando una prospettiva basata sui referenti e, nell'abstract, fa riferimento in modo generale alle "entità" in senso astratto, piuttosto che alle imprese o alle organizzazioni.



A seguito del processo di screening, il campione finale conterrà almeno 100 articoli, che sono stati codificati in base a: (a) prospettiva(e) teorica(e) adottata(e); (b) metodologia; (c) contesto empirico; (d) implicazioni teoriche; ed (e) implicazioni manageriali. Inoltre, seguendo Lehman et al. (2019) secondo cui l'autenticità può avere tre significati, sono state analizzate: (f1) la conformità al field *e alla categoria, che coglie l'aderenza categoriale a norme istituzionalizzate; (f2) la coerenza dell'impresa, che riflette l'allineamento tra l'entità stessa (ossia identità e valori dell'impresa) e le sue espressioni; e (f3) la connessione, fondata sui legami percepiti con luoghi, tempi e persone. Giova osservare che, così facendo, richiamiamo l'attenzione sui referenti valutativi che orientano il modo con cui l'audience valuta le rivendicazioni di autenticità. Un processo iterativo di confronto tra autori ha permesso di identificare antecedenti dell'autenticità, modalità evolutive dell'autenticità ed esiti della trasformazione.*

Figura 1. La selezione della letteratura

Database	Scopus	Web of Science
Arco temporale	Gennaio 1990–Febbraio 2026	Gennaio 1993–Febbraio 2026
Risultati della query di ricerca	3,228 articoli	2,804 articoli
Selezione delle riviste	460 articoli	630 articoli
Articoli aggiunti	2 articoli	
Dataset iniziale	702 articoli	
Criteri di esclusione	Abbiamo escluso quei filoni di ricerca che collocano l'autenticità prevalentemente a livello di tratti individuali, caratteristiche del brand o meccanismi tecnologici di verifica degli attributi del prodotto.	

Risultati. *L'analisi della letteratura fin qui condotta ha consentito di descrivere l'autenticità d'impresa come esito di un processo evolutivo nel tempo. In particolare, identifichiamo tre elementi centrali del processo di evoluzione dell'autenticità d'impresa, segnatamente: (i) gli antecedenti dell'autenticità d'impresa, (ii) le modalità evolutive dell'autenticità d'impresa, e (iii) gli esiti della trasformazione. Il framework concettuale permette di comprendere come l'autenticità venga costantemente trasformata nell'interazione tra passato, presente e futuro.*

Figura 2. Framework concettuale

Fonte: Elaborazione nostra

Di seguito, si analizzano i singoli blocchi che costituiscono il framework proposto in Figura 2.

(i) Antecedenti dell'autenticità d'impresa. *L'autenticità d'impresa non è riconducibile ad un singolo elemento (e.g., coerenza tra espressioni esterne e valori d'impresa o appartenenza ad una categoria), bensì emerge dall'interazione tra condizioni di* field *e di categoria, condizioni di ancoraggio dell'impresa e condizioni di dotazioni di connessione. Le condizioni di* field *e categoria definiscono ciò che è percepito come autentico in un determinato contesto istituzionale. I codici categoriali, le logiche istituzionali e le aspettative dominanti dell'audience forniscono uno "schema" attraverso cui l'audience valuta l'autenticità delle imprese (Lehman et al., 2019). Tuttavia, tali schemi non sono statici. Infatti, la letteratura mostra come mutamenti nella composizione dell'*audience*, nella struttura del mercato o nelle tecnologie possano ridefinire i criteri di autenticità (Negro et al., 2011; Pozner et al., 2022). Ne consegue la natura dinamica dell'autenticità con riferimento alle condizioni di* field *e categoria.*

Il secondo elemento riguarda le condizioni di ancoraggio dell'impresa. Le imprese formulano rivendicazioni su "chi sono", che funzionano da punto di riferimento per le decisioni strategiche (Baron, 2004). La coerenza tra identità, valori dichiarati e pratiche effettive rafforza le percezioni di autenticità (Cording et al., 2014), mentre incongruenze persistenti generano erosione di credibilità.

Il terzo elemento è costituito dalle condizioni di dotazioni di connessione, ossia i legami simbolici che intercorrono tra l'impresa e persone, luoghi e tempi. Ad esempio, connessioni temporali, connessioni con figure fondative e Heritage possono generare rendite simboliche significative (Pecot et al., 2018).

Questi tre elementi, considerati congiuntamente, definiscono gli antecedenti dell'autenticità d'impresa, e costituiscono il punto di partenza per ogni successiva trasformazione.

(ii) Modalità evolutive dell'autenticità d'impresa. *La nostra analisi della letteratura converge su due macro–pattern attraverso cui l'autenticità evolve: autenticità orientata all'interno e* authenticity work*.*

1. **Autenticità orientata all'interno.** *Nel caso dell'autenticità orientata all'interno, l'impresa non "lavora" intenzionalmente per apparire autentica, bensì coltiva coerenza interna e allineamento valoriale (Auster & Freeman, 2013). In questa prospettiva, l'autenticità emerge come risultato di pratiche quotidiane coerenti, piuttosto che operazioni comunicative. Tuttavia, anche in assenza di sforzi intenzionali orientati verso l'esterno, l'autenticità può trasformarsi. Infatti, i mutamenti nelle categorie di mercato, nell'ambiente istituzionale e nei valori sociali possono ridefinire ciò che viene considerato autentico. Alla luce di quanto precede, l'autenticità dell'impresa può essere percepita diversamente anche in assenza di una modifica delle proprie pratiche.*
2. **Authenticity work.** *L'impresa può attivare deliberatamente strategie di* authenticity work *(Peterson, 2005; Voronov et al., 2023), ponendo in essere uno sforzo attivo orientato verso l'esterno per costruire la propria autenticità. L'*authenticity work *può assumere modalità di trasformazione distinte:*
   - **2.1. Authenticity work orientato alla continuità.** *Nell'*authenticity work *orientato alla continuità, l'autenticità dell'impresa evolve integrando elementi innovativi e al contempo preservando la riconoscibilità. Si tratta di un processo di adattamento, in cui la continuità con le categorie, l'identità, i valori e le connessioni iniziali vengono enfatizzate per rendere il cambiamento intellegibile. Ciò avviene enfatizzando l'appartenenza alla categoria (Mathias et al., 2020), allineando la strategia con l'identità e i valori dell'impresa (De Keyser & Langley, 2025) e mobilitando le connessioni con il passato, i luoghi e le persone (Hahl, 2016; Hatch & Schultz, 2017). In questo modo, gli antecedenti dell'autenticità d'impresa funzionano come bussola che orienta il cambiamento.*
   - **2.2. Authenticity work orientato alla discontinuità.** *Nell'*authenticity work *orientato alla discontinuità, invece, l'impresa trasforma in modo più radicale la propria autenticità. Ciò può avvenire attraverso l'estensione e ibridazione tra categorie (Wheaton & Carroll, 2017; Schifeling & Demetry, 2021), il (ri)allineamento tra identità e valori dell'impresa (McKendrick & Hannan, 2014) e la reinterpretazione di connessioni con il passato, i luoghi e le persone (Cappelen & Pedersen, 2021). Anche nel pattern orientato alla discontinuità, la trasformazione dell'autenticità deve apparire chiara all'audience, poiché una rottura dirompente con gli antecedenti dell'autenticità d'impresa rischia di essere percepita come inautentica.*

(iii) Esiti della trasformazione. *Sebbene l'autenticità abbia origine negli antecedenti identificati, essa viene continuamente trasformata nel tempo. In primo luogo, l'autenticità può trasformarsi anche in assenza di sforzi deliberati orientati verso l'esterno da parte dell'impresa (Auster & Freeman, 2014), come nel caso di mutamenti emergenti delle categorie (ossia cambiamenti nelle logiche istituzionali, nei codici delle categorie, o nelle aspettative dominanti dell'audience), di riallineamenti endogeni dei valori (quando mutano i valori sociali precedentemente condivisi), oppure di sedimentazione delle dotazioni di connessione (quando connessioni territoriali diventano date per scontate e non generano più valore aggiunto). Tali dinamiche contribuiscono a trasformare l'autenticità nel corso del tempo.*

*In secondo luogo, la trasformazione dell'autenticità può avvenire attraverso l'*authenticity work *orientato alla continuità o orientato alla discontinuità. L'autenticità dell'impresa non riguarda meramente "essere", bensì "divenire". In un processo radicato nella temporalità, gli antecedenti dell'autenticità d'impresa (passato) vengono trasformati attraverso le modalità evolutive dell'autenticità (presente), e a sua volta conducono verso nuove condizioni di field e categoria, nuove condizioni di ancoraggio dell'impresa e nuove condizioni inerenti alle dotazioni di connessione (futuro). Da un lato, l'*authenticity work *orientato alla continuità può essere mobilitato per abilitare il cambiamento preservando un orientamento stabile verso "chi è l'impresa" (De Keyser & Langley, 2025). In questa prospettiva, l'*authenticity work *orientato alla continuità può attenuare gli effetti vincolanti dell'autenticità e amplificarne la funzione di empowerment. Ad esempio, l'*authenticity work *orientato alla continuità consente di utilizzare valori e identità del passato come punti di riferimento e bussola per orientare la trasformazione, piuttosto che meri limiti al cambiamento. Dall'altro lato, l'*authenticity work *orientato alla discontinuità implica la rottura selettiva e deliberata rispetto agli antecedenti dell'autenticità d'impresa, cercando di mantenere credibilità presso l'audience di riferimento (Younkin & Kashkooli, 2020). In entrambi i casi, le imprese si confrontano con una sfida strategica cruciale: sfruttare l'autenticità come empowerment, limitandone al contempo gli effetti vincolanti.*

Limitazioni della ricerca. *Il disegno della ricerca proposto in questo contributo non è scevro di limitazioni. In primo luogo, il framework concettuale privilegia una prospettiva* referent–based*, concentrandosi sui criteri valutativi attraverso cui l'autenticità viene trasformata nel tempo. Tale scelta analitica lascia in secondo piano l'evoluzione dell'audience. Riconosciamo, dunque, la necessità di adottare una prospettiva complementare che potrebbe indagare come e perché le valutazioni di autenticità cambiano nel tempo, ad esempio in funzione di mutamenti nella composizione dell'audience.*

In secondo luogo, la review adotta una delimitazione precisa del campo di indagine, escludendo contributi focalizzati su brand authenticity*,* product authenticity *e autenticità a livello micro (e.g., leader, imprenditori, dipendenti). Questa scelta è coerente con l'obiettivo di analizzare l'autenticità come processo collettivo e organizzativo, ma comporta l'esclusione di dinamiche individuali e di consumo che potrebbero interagire con gli antecedenti dell'autenticità*

d'impresa. L'integrazione tra livello organizzativo e livello micro rappresenta pertanto una possibile area di sviluppo futuro.

Infine, la maggioranza degli studi analizzati si concentra su contesti organizzativi e imprenditoriali tradizionali e poco esplora la digital authenticity *(Pedersen & Ritter, 2024) e l'impatto delle tecnologie emergenti nella genesi e affermazione dell'autenticità d'impresa. La crescente centralità di ambienti digitali e sistemi basati sull'intelligenza artificiale potrebbe modificare in modo significativo le modalità attraverso cui l'autenticità viene valutata e costruita, dischiudendo nuove linee di ricerca e richiedendo una distinzione analitica tra contesti organizzativi tradizionali e digitali.*

Implicazioni manageriali. *Il framework concettuale proposto offre indicazioni rilevanti per i manager chiamati a gestire l'autenticità d'impresa in contesti caratterizzati da crescente esposizione pubblica e mutamento istituzionale. In primo luogo, la ricerca che stiamo portando avanti indica che l'autenticità può evolvere anche in assenza di interventi deliberati da parte dell'impresa. Ciò implica che i manager non possano considerare l'autenticità come un elemento statico. Giacché la percezione dell'autenticità dell'impresa dipende dai codici categoriali e i valori sociali, che sono in continuo mutamento, le imprese devono monitorare costantemente l'evoluzione degli stessi.*

*In secondo luogo, sottolineiamo che i referenti interni all'impresa (e.g., l'identità dell'impresa) possono evolvere. Tale evoluzione comporta una tensione delicata tra continuità e cambiamento. I manager devono gestire questa tensione evitando che trasformazioni strategiche vengano percepite come rotture incoerenti rispetto alla storia, l'identità e i valori dell'impresa. Nello specifico, l'*authenticity work *orientato alla continuità può consentire il bilanciamento tra il cambiamento e il mantenimento della riconoscibilità, preservando un orientamento stabile rispetto all'identità dell'impresa mentre si introducono elementi nuovi.*

Nel loro insieme, queste implicazioni indicano che la gestione dell'autenticità richiede una combinazione di sensibilità temporale, capacità interpretativa dei cambiamenti e abilità di bilanciare continuità e trasformazione.

Originalità del paper. *Il presente contributo apporta tre principali elementi di originalità teorica. In primo luogo, il disegno della ricerca descritto propone una rilettura della letteratura sull'autenticità d'impresa attraverso una lente esplicitamente temporale. Mentre gran parte degli studi esistenti analizza l'autenticità in momenti discreti o in relazione a specifici significati (e.g., conformità categoriale, coerenza tra identità, valori ed espressioni esterne, connessioni con tempo, luoghi e persone), la presente ricerca integra tali prospettive all'interno di un processo dinamico che collega antecedenti, modalità evolutive ed esiti della trasformazione dell'autenticità d'impresa nel tempo. In tal modo, l'autenticità viene concettualizzata non come un attributo statico, bensì come protagonista di un processo di trasformazione.*

*In secondo luogo, il contributo sviluppa un framework concettuale che mette in relazione tre elementi: condizioni di field e categoria, condizioni di ancoraggio dell'impresa e condizioni di dotazioni di connessione, che insieme formano gli antecedenti dell'autenticità. Tali antecedenti strutturano le possibilità di azione futura dell'impresa attraverso l'autenticità orientata all'interno e attraverso l'*authenticity work*, orientato alla continuità e/o alla discontinuità. Il framework concettuale proposto supera la frammentazione teorica della letteratura e consente di spiegare come differenti antecedenti dell'autenticità d'impresa possano dare origine a modalità evolutive differenti.*

Complessivamente, contribuiamo al dibattito sull'autenticità d'impresa offrendo una prospettiva temporale che integra elementi precedentemente trattati in modo frammentato, fornendo una base per ulteriori sviluppi futuri empirici e concettuali.

Do Packaging Claims Drive Product Performance? Evidence from the Biscuit Category in the Italian FMCG Market

BENEDETTA GRANDI[1], SIMONE AIOLFI[2], DAVIDE PELLEGRINI[3], SILVIA BELLINI[4]

Abstract. *This study investigates the role of packaging claims in explaining product performance in the biscuit category, a context in which front-of-pack messages may be relevant but not universally effective. Building on the idea that packaging claims act as visible and synthetic market signals, the paper examines whether they operate as independent performance drivers or as positioning signals embedded within broader brand identity strategies. The empirical analysis is based on a structured dataset of packaged biscuits in the Italian fast-moving consumer goods market, integrating product-level market performance indicators, brand identity, weighted distribution coverage, and front-of-pack claim categories. Product performance is measured through EURO per point of weighted distribution (EURO PP) and through its year-on-year variation, in order to capture both static performance efficiency and performance dynamics. A stepwise regression approach is adopted to isolate the role of packaging claims from the effects of brand identity and distribution coverage, and to test whether claim effectiveness varies across brands. The results show that some claim categories are associated with product performance when considered in isolation, but their explanatory role decreases substantially once brand effects are introduced. Interaction effects further reveal that claim effectiveness is heterogeneous across brands, while no systematic associations emerge with performance growth over time. Overall, the findings suggest that packaging claims should be interpreted less as universal drivers of market performance and more as brand-contingent positioning signals within an indulgence-oriented food category.*
Keywords: *packaging claims; front-of-pack communication; brand positioning; product performance; biscuit category; FMCG*

Framing of the research. *In fast-moving consumer goods markets, packaging represents a critical communication interface between brands and consumers (Wang et al., 2025), especially at the point of sale, where many decisions are made quickly and under limited cognitive effort (van Ooijen et al., 2017; Steenis et al., 2017; Mehta et al., 2024). In food retail contexts, front-of-pack elements are particularly relevant because they provide highly visible cues that support rapid product evaluation and shape consumers' first inferences about the offer (Steenis et al., 2017). Literature shows that packaging design and front-of-pack communication contribute to consumers' perceptions of quality, healthiness, sustainability, and value. Therefore, packaging functions not merely as a container but as a strategic communication device that helps consumers interpret product meanings in competitive shelf environments (Schifferstein et al., 2021; Spence and Van Doorn, 2022; Mehta et al., 2024).*

Within this communication architecture, packaging claims deserve specific attention because they condense complex product attributes into simple, visible, and immediately accessible signals (Steenis et al., 2017; Schifferstein et al., 2021; Hallez et al., 2023; Zerbini et al., 2023). Nutrition, health, taste, environmental, and origin-related claims may reduce information asymmetry by making otherwise less observable product characteristics more salient to consumers (Hallez et al., 2023; Shahid et al., 2024;). At the same time, prior research suggests that the effects of front-of-pack messages are not always straightforward (Bix et al., 2015). For example, front-of-pack messages have been shown to influence consumers' perceptions of a product, but not necessarily their willingness to buy in a direct way, with nutrition-related messages often proving more effective than environmental or hedonic ones in shaping product evaluations (Biondi and Camanzi, 2020; Tavares et al., 2026). More broadly, prior research as wells as a meta-analysis on front-of-pack labels shows that such cues are generally effective in improving healthier choices and perceptions, but their effects vary depending on context, label format, and outcome considered (Cabrera et al., 2017; Ikonen et al., 2020). Therefore, while many studies show that claims affect perceived healthiness and overall product perception, their impact on willingness to buy or actual purchase behavior is often weaker, context-dependent, or mediated by other factors (Hallez et al., 2023; Zerbini et al., 2023). This gap between perceptual and behavioral effects is particularly important for understanding the marketing role of packaging claims.

A further point emerging from the literature is that claims are interpreted together with other packaging cues rather than in isolation and their effectiveness depends on the broader interpretive context in which claims are embedded (Schifferstein et al., 2021; Hallez et al., 2023; Wang et al., 2025). Specifically, packaging design, wording, image use, and stylistic features may all alter how information is understood and whether it is perceived as credible or misleading (Schifferstein et al., 2021). In particular, short front-of-pack claims can function as heuristics in decision-making, encouraging consumers to generalize from a single positive attribute to broader product evaluations, sometimes

[4] *Dipartimento di Scienze Economiche e Aziendali, Università di Parma, silvia.bellini@unipr.it*

producing halo effects in healthiness perception (Hallez et al., 2023). This is especially relevant because food packages are often processed under low-involvement conditions, where consumers rely on salient and easily interpretable cues rather than on deeper analytical evaluation (Mehta et al., 2024). Since, in realistic shopping environments, consumers do not simply react to claims in isolation, but interpret them in relation to product category expectations, other package cues, and the meaning of the offer as a whole, recent contributions call for studies based on authentic packages, real or quasi-real shopping settings, and actual behavior rather than only self-reported preferences.

The literature also suggests that the effectiveness of claims depends on the broader product category and on the fit between the message and the product's expected meaning (Steinhauser et al., 2019; Hallez et al., 2023). Research comparing different food categories has shown that claim effectiveness is not uniform and varies depending on the perceived healthiness of the product category: nutrition-oriented claims tend to perform better in categories perceived as healthier, whereas hedonic or taste-oriented claims may be more persuasive in indulgence-oriented categories (Steinhauser et al., 2019; Hallez et al., 2023). For instance, Steinhauser et al. (2019) showed how orange juice was bought more often when associated with a nutrition claim, whereas milk chocolate performed better when paired with a taste claim. The same study also shows that, for less healthy or more hedonic products, nutrition and health claims may trigger skepticism, distrust, or a perceived trade-off between health and taste (Steinhauser et al., 2019).

This category-contingent logic is particularly important for the biscuit market. Biscuits are traditionally associated with taste, indulgence, routine consumption, and convenience, yet they are increasingly characterized by the presence of front-of-pack messages related to health, wholegrain content, free-from properties, sustainability, country-origin, and authenticity (McIntyre and Schwanke, 2010; Tarrega et al., 2017). In such a hybrid category, claims are unlikely to work as universally positive cues. Rather, they may act as positioning signals whose meaning depends on whether they fit category expectations and whether they are perceived as coherent with the symbolic and functional associations of the brand. This interpretation is consistent with previous work showing that the persuasive effect of front-of-pack claims depends not only on the claim itself, but also on consumer goals, the broader package design, and the interaction between informational and visual cues (Biondi and Camanzi, 2020; Schifferstein et al., 2021).

This logic is even more relevant in the case of sustainability-related claims. While consumers may value environmentally friendly attributes, the literature also shows that green claims are especially sensitive to trust and skepticism (de Sio et al., 2022; Nugraha et al., 2024). Trust in green claims plays a key mediating role and positively affects intention to buy green food, whereas green advertising skepticism reduces purchase intention indirectly by undermining trust in those claims (de Sio et al., 2022). Similarly, recent reviews on greenwashing in the food industry highlight that sustainability communication can easily become ambiguous, symbolic, or misleading when claims are vague or insufficiently substantiated (Nugraha et al., 2024). Therefore, sustainability claims should not be assumed to generate positive outcomes automatically; rather, their effectiveness depends on perceived credibility and on whether consumers interpret them as trustworthy signals or as symbolic, misleading, or superficial communication devices.

Despite the growing body of research on packaging claims, especially for healthy claims (Xiaotong et al., 2024), an important gap remains in the literature. Existing studies have largely focused on single claim types, perception-based outcomes, or experimental settings (Biondi and Camanzi, 2020; Ikonen et al., 2020; Hallez et al., 2023), whereas less attention has been devoted to the comparative role of multiple packaging claim strategies within real-market product performance data. This gap is particularly relevant in indulgence-oriented food categories, where the effectiveness of claims may depend less on the intrinsic persuasiveness of the message and more on the brand identity within which the claim is embedded (Hallez et al., 2023). In line with this perspective, the present study investigates whether packaging claims explain product performance in the biscuit category independently, or whether they function primarily as positioning signals whose effectiveness is contingent on brand identity and distribution context.

Purpose of the paper. *This study investigates the role of packaging claims in explaining product performance in the biscuit category, a context in which front-of-pack messages may be relevant but not universally effective. More specifically, treating packaging claims as visible and synthetic market signals, the paper examines whether they act as independent performance drivers or as positioning signals embedded within broader brand identity strategies, once distribution coverage is taken into account. The empirical analysis is based on a structured dataset including product-level market performance indicators, brand identity, weighted distribution coverage, and on-pack communication variables for packaged biscuits in the Italian fast-moving consumer goods market.*

Methodology. *The empirical analysis is based on a structured dataset of packaged biscuits in the Italian fast-moving consumer goods market, integrating product-level performance indicators, brand identity, weighted distribution coverage, and front-of-pack packaging claims. In the original dataset, packaging claims were coded as binary variables indicating the presence or absence of specific claims on each product. Since individual products may display multiple claims simultaneously, the dataset was reshaped into a product–claim structure, so that each observation corresponds to a product–claim combination. As a result, products may appear multiple times when more than one claim is displayed on the package. This transformation made it possible to analyse packaging claims systematically as explanatory variables associated with product performance. Claims were then grouped into macro-categories reflecting the main communication strategies observed in the category, namely free-from, wholegrain, health, environment, social, indulgence, Italian origin, and authenticity.*

Two complementary performance indicators were used. Static product performance was measured through EURO per point of weighted distribution, a standardized indicator capturing the efficiency of shelf presence by relating sales value to distribution coverage. This measure makes it possible to compare products with different levels of market availability and therefore provides a more informative indicator than absolute sales values alone. In addition, a dynamic performance indicator was computed as the year-on-year variation in EURO per point of weighted distribution, in order to capture changes in performance over time and not only cross-sectional differences across products.

The empirical strategy follows a stepwise regression approach designed to isolate the role of packaging claims from the effects of brand identity and distribution coverage. In the first step, regression models were estimated using claim categories as the only explanatory variables. This initial specification makes it possible to assess whether packaging claims are associated with systematic differences in product performance when considered independently of brand-related effects. In the second step, brand identifiers were introduced as categorical predictors in order to control for brand-level heterogeneity and brand positioning. This specification allows evaluating whether the explanatory role of packaging claims remains significant once brand identity is taken into account. In the third step, weighted distribution coverage was added as an additional control variable. Although the dependent indicator already standardizes sales value by distribution intensity, including this variable provides a more conservative estimate by capturing possible residual differences in market exposure across products.

To further investigate whether packaging claims operate as universal performance drivers or instead function as positioning signals whose effectiveness depends on brand identity, interaction effects between brand and claim categories were also estimated. This step makes it possible to test whether the same claim category is associated with different performance outcomes depending on the brand displaying it. Given the indulgence-oriented nature of the biscuit category and the central role of brand positioning in this market, interaction effects were interpreted as indicators of brand-contingent claim effectiveness rather than as purely independent claim contributions.

The same modelling sequence was replicated using the performance trend indicator as the dependent variable in order to assess whether packaging claims are associated not only with static performance efficiency but also with product performance dynamics over time. Overall, this analytical strategy makes it possible to distinguish between the independent role of packaging claims, the contribution of brand identity and distribution coverage, and the extent to which claim effectiveness varies across brands within an indulgence-oriented product category.

Results. *The empirical analysis was conducted through a stepwise regression strategy designed to assess whether packaging claims are associated with product performance in the biscuit category and whether their effectiveness varies across brands once brand identity and distribution coverage are taken into account. Results are presented for both static performance efficiency, measured through EURO per point of weighted distribution (EURO PP), and performance dynamics, measured through the variation in EURO PP over time.*

The first model estimated the association between packaging claims and performance without controlling for brand identity. In this initial specification, several claim categories showed statistically significant associations with EURO PP. In particular, free-from claims were positively associated with performance ($p = 0.035$), while wholegrain claims were negatively associated with performance ($p = 0.040$). Environmental sustainability claims also showed a negative and statistically significant association with EURO PP ($p = 0.014$). These results suggest that some claim categories are associated with systematic performance differences when considered independently of brand-related effects.

However, once brand identifiers were introduced into the model, the explanatory role of packaging claims decreased substantially, while brand effects remained strong and statistically significant. In contrast, most claim categories lost statistical significance after controlling for brand identity. Only environmental sustainability claims remained negatively associated with EURO PP ($p = 0.044$), while social sustainability claims showed a marginally significant positive association ($p = 0.051$). Overall, these findings suggest that a substantial share of performance variation is associated with brand-related differences rather than with packaging communication alone.

Weighted distribution coverage was then included as an additional control variable in order to capture possible residual variation in market exposure across products. As expected, distribution coverage did not show a statistically significant association with EURO PP once the dependent variable had already been standardized by distribution intensity ($p = 0.543$), confirming the internal consistency of the performance indicator used.

To evaluate whether packaging claims operate as universal performance drivers or instead function in a brand-contingent way, interaction effects between brand and claim categories were also examined. The interaction analysis revealed substantial heterogeneity in claim effectiveness across brands, indicating that the same claim category may be associated with different performance outcomes depending on the brand displaying it. This pattern is consistent with the interpretation of packaging claims as positioning signals embedded within broader brand identity strategies rather than as uniformly effective category-level drivers.

To assess whether packaging claims are associated with performance dynamics rather than only with static performance levels, the same modelling strategy was replicated using the variation in EURO PP between the current year and the previous year as the dependent variable. The results show that packaging claims are not systematically associated with performance growth once brand identity and distribution coverage are taken into account. None of the claim categories displayed statistically significant coefficients in the trend specification, and distribution coverage also

remained non-significant (p = 0.295). Similarly, brand identifiers did not show consistent associations with performance variation over time.

Taken together, these results indicate that brand-related factors account for a substantial share of performance variation within the biscuit category, while packaging claims display limited independent explanatory power once brand identity is controlled for. The interaction effects further suggest that claim effectiveness varies across brands rather than operating uniformly across the category, supporting the interpretation of packaging claims as positioning signals embedded within brand identity strategies rather than as universal drivers of product-level performance.

Research limitations. *This study presents several limitations that should be considered when interpreting its results. First, the structure of the dataset, based on product–claim combinations derived from packaging information, makes it possible to evaluate the relative role of multiple claim categories within a unified framework, but does not allow testing the effect of individual claims in complete isolation from broader communication architectures. Packaging claims frequently appear simultaneously on product packs and are often embedded within broader brand identity and positioning strategies, making it difficult to disentangle their fully independent contribution to product performance.*

Second, the interaction analysis between brand identity and claim categories suggests that claim effectiveness varies across brands rather than operating uniformly across products. However, the limited number of observations available for some brand–claim combinations constrains the estimation of fully saturated interaction models with strong statistical precision. For this reason, the interaction effects should be interpreted primarily as indicators of brand-contingent positioning patterns rather than as definitive brand-specific causal estimates.

A further limitation concerns the focus of the analysis on the presence of claim categories rather than on the overall structure and complexity of packaging communication. The study should therefore be interpreted as part of a broader research agenda on packaging communication and market performance. The study does not explicitly consider whether performance outcomes may also depend on the concentration or dispersion of informational signals displayed on the package. A relevant direction for future research therefore concerns the role of communication entropy in packaging strategies, investigating whether more focused communication centred on a limited number of claims leads to higher performance efficiency than communication architectures characterized by multiple simultaneous claims. More broadly, future studies could examine whether simplified and coherent communication strategies outperform more complex claim configurations, or whether broader informational richness enhances positioning effectiveness in competitive retail environments.

An additional limitation concerns the scope of packaging information included in the analysis. The study focuses exclusively on front-of-pack claims, as these represent the most visible elements of product communication at the point of purchase and are therefore more likely to influence rapid consumer decision-making in retail contexts. However, packaging communication is typically distributed across multiple informational layers, including side- and back-of-pack content such as nutritional details, certifications, ingredient-related information, and more extended explanatory messages. These elements may also contribute to shaping product perception and positioning, but they were not included in the present analysis. Future research could therefore extend the investigation to the full set of packaging information provided across all pack surfaces in order to assess whether the overall architecture, consistency, and depth of packaging communication further influence product performance and positioning effectiveness beyond front-of-pack claims alone.

Managerial implications. *The findings of this study suggest that packaging claims should not be treated as universal performance drivers in the biscuit category. Once brand-related effects are taken into account, most claim categories lose explanatory power, indicating that shelf-level commercial efficiency depends primarily on brand identity and positioning rather than on the mere presence of front-of-pack messages. This result has an important managerial implication: the inclusion of claims on packaging is unlikely to enhance performance per se unless those claims are coherent with the brand's existing positioning strategy and with the broader meaning that the brand conveys in the market.*

From this perspective, packaging communication should not be designed through imitation of category communication trends or by mechanically adding claims that are currently popular in the market. Rather, claims should be selected and combined according to their strategic fit with brand identity, with the role that the product is expected to play within the brand portfolio, and with the type of associations the company intends to reinforce at the point of sale. In other words, the results suggest that claims are more effective when they contribute to a coherent brand narrative than when they are used as isolated communication devices.

Moreover, the interaction analysis highlights that claim effectiveness is not uniform across brands. The same claim may support product performance for one brand while being ineffective, or even disadvantageous, for another. This implies that managers should evaluate packaging claims not as standardized category-level levers, but as brand-contingent positioning tools whose effectiveness depends on the fit between the claim, the brand, and the competitive context. More generally, the findings indicate that effective packaging communication depends less on the simple presence of multiple claims and more on their consistency with brand strategy and market positioning.

Originality of the paper. *This paper contributes to the literature on packaging communication by providing an empirical assessment of the market performance implications of multiple packaging claims using a real-world product-level dataset from the Italian FMCG market. Unlike much of the existing research, which typically examines single claim categories*

or focuses on perceptual outcomes in experimental settings, the present study evaluates the relative role of different claim types simultaneously within a unified analytical framework. By accounting for brand identity and weighted distribution coverage, the paper shows whether front-of-pack claims act as independent performance drivers or as positioning signals whose effectiveness is contingent on brand-related strategies within an indulgence-oriented food category.

Employee communication as a lever for enablement: Insights from The State of the art of employee communication in Italy

ALESSANDRA MAZZEI[1], CHIARA FISICHELLA[2], ALFONSA BUTERA[3], SILVIA RAVAZZANI[4]

Abstract. *This paper is part of a broader multi-method study investigating employee communication as a strategic business lever for employee enablement within the specific socioeconomic context of Italy. In particular, this paper examines the evolutionary path of employee communication as it transitions toward an authentic strategic role within organizations. It also analyzes the role of management in fostering an environment that enables employees to act as strategic communicators and addresses future challenges for employee communication.*

To explore these topics, the study leverages 16 interviews conducted in Italy in 2025 with consultants and experts in employee communication.

Findings show that employee communication has shifted from an operational function to a real strategic lever for companies and that COVID-19 pandemic served as a catalyst for these changes, although some interviewees remain skeptical about the long-term sustainability of this new importance of employee communication. Findings also indicate that effective employee communication now demands a holistic approach, integrating responsibilities traditionally associated with human resources, information technology, and external communication functions. Additionally, findings show that employee communication serves as an antenna for organizational climate and a control room for employee experience. Key characteristics that enhance the strategic value of employee communication include the shift toward bidirectional dialogue, and the empowerment of employees as active communicators, specifically as ambassadors internally and externally. However, a "Cinderella" status remains, as the function often lacks formal authority and a relevant role in the company governance compared to HR or external communication functions.

While the generalizability of these findings is limited by their specific geographic focus and potential social desirability bias, this study provides unique insights rooted in a specific cultural setting, allowing assessment of the specific configuration and evolutionary patterns of employee communication in Italy.

Keywords: *employee communication; employee enablement; internal communication; strategic communication; employee communication behavior*

Framing of the research. *Employee communication, also known as internal communication, is the area of strategic communication through which organizations engage in dialogue with employees, considered primary stakeholders (Mazzei, 2025b; Mazzei & Butera, 2024; Falkheimer & Heide, 2022; Men & Bowen, 2017; Tkalac Verčič et al., 2012; Welch & Jackson, 2007). It is likely the most important aspect of strategic communication, as without it an organization cannot simply exist and operate (Mazzei, 2025b).*

Routed into the resource theory of the company, employee communication can be defined (Mazzei, 2010) "as a set of interactive processes aimed at generating the catalytic resources that make a company work. These two resources consist of knowledge to fuel working processes and employee engagement that trigger employees to apply their knowledge to company processes" (Mazzei, 2025a, 197-198).

Internal communication begins before employees join an organization and continues after they leave it (Tkalac Verčič et al., 2021). It has three primary aims: aligning employees, activating employees, and fostering engagement and employee voice (Mazzei & Butera, 2024). Aligning employees means ensuring they understand corporate objectives, sharing the organizational culture and values with them, and providing the information they need for organizational functioning. Activating employees involves encouraging voluntary and strategic employee communication behavior that support the organization. Fostering engagement and employee voice entails sustaining the engagement of employees and an open climate that empowers them to express ideas, suggestions and constructive dissent. Moreover, it should be acknowledged that listening is both a prerequisite for and an integral part of all internal communication objectives (Mazzei & Butera, 2024).

Emphasizing that employees are essential for generating intangible resources for competitive advantage (Mazzei, 2010, 2025a), due to the relational nature of this process in organizations, implies that all employees play a key communicative role (Mazzei, 2025b). Employees are individuals who initiate communication flows and send messages to colleagues and managers: in other words, they are active agents of communication within the organizational context (Frandsen & Johansen, 2011; Heide & Simonsson, 2011; Kim & Rhee, 2011; Mazzei, 2010).

To understand employee communication behavior in a comprehensive way, a holistic mapping based on two distinctions has been proposed (Mazzei, 2018, 2025b): the first distinguishes between voice and silence behavior; and

[1] Università IULM, e-mail: alessandra.mazzei@iulm.it
[2] UNINETTUNO University, e-mail: chiara.fisichella@uninettunouniversity.net
[3] Università IULM, e-mail: alfonsa.butera@iulm.it
[4] Università IULM, e-mail: silvia.ravazzani@iulm.it

the second considers the intention behind the communicative actions. In this mapping, voice and silence are viewed as the two opposite poles of a continuum, as both are deliberate and conscious communicative actions expressed in different ways (Mazzei, 2018, 2025b). Considering the intention behind the communicative actions, the holistic mapping of employee communication behavior distinguishes between "procompany communication behavior" and "anticompany communication behavior". These terms express unequivocally that the subject in favor of or against whom the actions of an employee are directed is the company, not society or a social group in general (Mazzei, 2018, 2025b). Therefore, the holistic mapping includes four possible categories of employee communication behavior: voice and silence, each further distinguished by a procompany or anticompany intention (Mazzei, 2025b). Procompany employee communication behavior can be both in-role and extra-role, and are voluntary and discretionary (Mazzei, 2025b). Therefore, they cannot emerge by means of prescriptions and control techniques but rather emerge more indirectly and genuinely through the management of a series of levers. This concept is referred to as enablement (Mazzei, 2014).

The concept of enablement has been incorporated into employee communication as a core element of the consultancy function performed by communication professionals (Zerfass & Franke, 2013), who act as facilitators supporting employees in their communicative responsibilities (Heide & Simonsson, 2011), and are evolving into designers of the overall employee experience (Men, 2021). Consequently, the primary objective of the employee communication department is to create a comprehensive internal experience that shapes perceptions, attitudes, actions, and behavior (Men, 2021), thereby fulfilling a strategic enabling role (Men & Bowen, 2017). Ultimately, employee enablement involves developing communication strategies within a consistent framework of workplace conditions that foster effective and positive communicative engagement (Mazzei, 2025a) while avoiding prescriptions and control mechanisms that would be ineffective (Mazzei & Ravazzani, 2017). Based on the concept of enablement, Mazzei (2014) explored the perceptions of managers about the relevance of employee communicative actions and investigated whether the companies they worked for had implemented specific employee communication strategies. The study found that managers considered employee communication behavior as the basis for company success, specifically for the implementation of the company strategy and as a source of competitive advantage, knowledge creation and sharing, stakeholder engagement, and reputation building processes.

To sustain the active role of employees as communicators, the employee communication function managed by the organization serves as a fundamental lever for engaging the workforce, ensuring they are informed, motivated, and actively contributing to the success of the company: employee communication plays an important role in enabling employees to be strategic communicators (Mazzei, 2025a). Indeed, it provides the context for organizational actions, the meaning of events, knowledge, information, and motivation (Mazzei, 2014). For employee enablement, it is crucial to adopt strategies based on the integration of employee communication with human resource management and relationship-building practices (Mazzei, 2014).

This theoretical framework led to the development of the Enabling Model of Employee Communication (Mazzei, 2025b; Mazzei & Quaratino, 2020). This model highlights specific characteristics of employee communication. First, it is intended to be strategic – supervised by top management, allocated dedicated resources, and recognized as a source of value. Second, it is managed with a managerial approach, using planning and evaluation methods typical of the managerial cycle. Third, it aims to activate employees through supervisor-employee dialogue and by creating environments that encourage the voice and free expression of employees. Fourth, it is open to experimenting with new social arenas that arise from digitization. These characteristics should enhance the generation of the most important intangible resources for competitive advantage, particularly employee engagement as a prerequisite for strategic employee communication behavior.

Purpose of the paper. *This study is part of a broader research project: "The state of the art of employee communication in Italian companies". It investigates employee communication as a strategic business lever for employee enablement within the specific socioeconomic context of Italy and examines the evolutionary path of employee communication. This broad research is the second edition of the one conducted in 2019 and is based on a multi-method approach: first, qualitative research through 16 interviews with experts and consultants and 16 dialogues between academics and practitioners; second, quantitative research through a survey involving a sample of 115 companies; third, comparative analysis of 13 industry reports on employee communication or related topics produced in Italy and abroad in the period 2019-2025.*

The present paper discusses the findings of the first explorative phase based on interviews and it aims at identifying key themes that allow for describing the evolutionary path of employee communication as it transitions toward an authentic strategic role within organizations. It also aims at focusing the role of management in fostering an environment that enables employees to act as strategic communicators, and addresses future challenges for employee communication.

Methodology. *The paper is based on empirical research using the accounts of 16 consultants and experts in employee communication. Qualitative data were collected through 16 interviews conducted between June and September 2025. The sample includes a high concentration of executive leaders from leading communication and consulting agencies. The sample counts 7 CEOs and Presidents, 6 Partners and Managing Directors, 2 independent consultants specialized in internal communication, and 1 Creative Director. Among the interviewees, 4 are women and 12 are men.*

The semi-structured interview guide covered topics including a) the strategic relevance of internal communication and its evolution, b) the use of managerial communication as a strategic lever, c) the involvement of employees as active

communicators, and d) the future challenges for employee communication. The findings are described below according to these themes. It is worth noting that the findings of this qualitative study have been discussed with a group of companies which provided additional insights. These were useful to interpret the data collected through a survey that is part of the broader research within which this qualitative study was conducted and that is not the subject of this paper.

Results.

a) The strategic relevance of internal communication and its evolution. The results show a significant evolution in employee communication within Italian companies. According to the interviewees, it has shifted from a purely operational function to a genuine strategic lever for companies, capable of guiding people as a real asset and influencing leaders in their strategic decisions. This transformation was accelerated by the COVID-19 pandemic, which served as a turning point. During the emergency, employee communication had to bridge physical distance, maintain the corporate community, and reunite teams through constant information flows. Although some interviewees remain skeptical about the long-term sustainability of this new, important role for employee communication, data indicate a general increase in the number of people working in this function and a rise in dedicated budgets.

According to interviewees, using employee communication strategically means going beyond simple alignment with corporate objectives to include culture, values, and the organizational model, thereby stimulating motivation and a sense of belonging. Employee communication acts as an "antenna" that detects the corporate climate and guides people, especially during times of crisis and change. It supports major contemporary transformations, such as digitalization and sustainability, by conveying the meaning of change even before its operational impacts are felt. Furthermore, the purpose of employee communication has expanded, incorporating responsibilities and activities traditionally associated with Human Resources, such as employee well-being, diversity, equity and inclusion and the management of the internal climate; Information Technology, such as Intranet and digital channels management; and external communication, with which it now shares responsibility for company reputation. This expansion into non-traditional responsibilities and functions raises the question of whether the term "employee communication" is still sufficient to describe such a broad business function.

According to the interviewees, in this new strategic vision of employee communication the role of top management is crucial. The strategic role for employee communication is enhanced if the company is viewed as a storytelling community, with the CEO as the primary content curator. However, a cultural challenge persists: many top managers still underestimate the potential of employee communication, involving it only after decisions have been made, which limits its strategic impact. In these cases, top management is unaware of the powerful role employee communication can play, and employee communication has yet to gain authority within the organization. It can be said that it is still often considered as a "Cinderella" when compared to the human resources and external communication functions: even when its strategic importance is recognized, it is not given a significant organizational role in governance and processes, nor are people with leadership and specific skills assigned to this function.

Another fundamental pillar of a strategic employee communication approach is bidirectionality. Employee communication increasingly manages the dialogue between central functions and the organizational periphery and sustains employee participation. People want to participate, trust those who trust them, and have opportunities to express their ideas. Unfortunately, this still conflicts with the Italian business tradition, which has historically favored top-down communication. According to the interviewees, nowadays top managers have a significant need to listen in order to guide the organization, given the speed and complexity of the current environment. However, listening also requires a willingness to engage: when a manager or an organization listens to someone, they must also take responsibility for providing feedback and taking action. It is necessary to accelerate the implementation of actions and responses to requests.

b) The use of managerial communication as a strategic lever. In this process, managerial communication plays a crucial role. In particular, middle management acts as the "transmission belt," according to interviewees. Middle managers are essential for cascade communication, gathering and relaying bottom-up information, and facilitating horizontal communication. They form a "compressed community" between top management and employees, as well as between company objectives and operational tasks. They also foster a sense of belonging and involvement through employee communication. This is especially important in contexts marked by high complexity and significant cultural differentiation, such as companies that have expanded through acquisitions, where integration relies heavily on middle managers. In these cases, while top management is typically already aligned with company objectives, the challenge is to involve the rest of the company population.

In the context of hybrid work, managerial communication is also pivotal for ensuring bidirectionality. The physical presence of employees facilitates informal communication that can partially bypass managerial barriers, but in hybrid contexts informal communication is weakened. Therefore, in such contexts middle managers need to act as facilitators, ensuring communication with remote employees. According to interviewees, another important point is that managers today are communication producers: it is not the internal communication function telling managers what they have to communicate, but rather the managers themselves who express the need. Often, they detect changes and requests faster than the organization does.

c) The involvement of employees as active communicators. The theme of participation mentioned above can be associated to the involvement of employee as active communicators, and in particular according to the interviewees to the concept

of employee ambassadorship, which companies are actively promoting in two main ways: first, organizations seek to involve employees in internal dissemination and to foster people engagement around organizational values; second, they are leveraging the potential of employees for external communication in their role as ambassadors. This approach is highly effective for talent acquisition, especially with Gen Z, and for this reason, according to interviewees, it will continue expanding and being adopted.

To encourage the spread of employee ambassadorship, some companies have also introduced a gamification component as an incentive, for example by offering shopping vouchers to employees who publish posts first or whose posts receive the most likes. However, it is important to emphasize that the process of creating ambassadors should not be forced. Instead, companies should offer employee training to develop the necessary skills and support, for instance by providing tools or repositories of content, graphics, and photographs. This can enable individuals to become active communicators. Related to the role of employees as creators of content, it should be noted that the employee communication function does not necessarily need to develop and distribute content directly, but should instead recognize and amplify the content created by employees, adding value to it. In this sense, employee communication is no longer just a content production center but a control room that coordinates content dissemination.

d) The future challenges for employee communication. The future challenges for professionals in this sector are numerous and complex and can be grouped into activities and objectives, and the professional role itself. Regarding activities and objectives, employee communication will need to act as an agent of cultural change on key topics such as diversity, equity, and inclusion, working closely with the HR department to develop a people strategy aligned with the purpose of the company.

Managing communication in hybrid work environments will be crucial, as physical dispersion can erode the sense of community; in this context, employee communication must act as a unifying force. The ability to measure the impact of employee communication activities through tangible indicators will be equally important, as this will help move beyond the perception of employee communication as merely an overhead cost.

According to the interviewees, another challenge is related to technological evolution, which requires reflection on the role of human intelligence in employee communication: integrating Artificial Intelligence into work activities should focus on personalizing messages without sacrificing the human touch, transparency, and consistency that new generations of workers strongly expect.

Regarding the profession, one interviewee stated that "in any company, communicating is the only job that everyone thinks they can do, because we are born as communicators; we are communicators as human beings". Professional credibility must therefore be earned on the ground, which is more difficult when it does not involve technical expertise. Another challenge is the absence of direct internal reporting to the CEO, while there is a need for direct access to this figure to enable quick action. Additionally, communication teams have become complex and multidisciplinary, requiring the introduction of new mindsets and skills, breaking out of the usual model and encouraging cross-fertilization among teams.

Research limitations. *This study purposely aimed to map the most advanced practices of employee communication in Italy and for this reason the 16 qualitative interviews were conducted within the Italian socioeconomic context, with all interviewees being consultants and experts from leading companies in Northern Italy to provide detailed, nuanced data offering an overview of the state of employee communication in organizations that are well-developed examples of its use. This precise choice implies that despite the insights gained from this study, two main limitations should be acknowledged and addressed in future investigations. First, the sample size could be increased and its composition diversified to represent the average situation in Italy. Second, the qualitative nature of the research relies on the subjective accounts of consultants and experts, introducing the potential for social desirability bias, in which interviewees may emphasize their aspirations rather than the daily operational realities to which they refer in their accounts.*

Managerial implications. *The effectiveness of employee communication is a critical factor in company dynamics and, as noted at the beginning of this paper, is probably the most important aspect of strategic communication, as without it an organization cannot simply exist and operate (Falkheimer & Heide, 2018; Mazzei 2025b).*

First, this research shows that, for employee communication to function as a true strategic lever, companies must move beyond a purely operational approach and top-down communication model, adopting an approach that recognizes the relevance of a bidirectional communication flow and encourages employees to take an active role as communicators. Accordingly, managers should go beyond using employee communication merely for informational alignment but also leverage its role as an "antenna" to detect the organizational climate and support people during times of crisis and change. Organizations should make listening a core activity: collecting feedback should be viewed not as a formality, but as a commitment to rapid, visible organizational action and human-centred engagement.

Secondly, another key managerial implication of the study is the need to legitimate the employee communication function. According to some interviews, this function still holds a "Cinderella" status compared to more established functions, organizations should better value the contribution that employee communication makes to leadership, allocate larger dedicated budgets, and consider establishing direct reporting lines to the CEO to ensure that its strategic impact extends beyond mere dissemination after decisions are made. Only then can employee communication help shape important employee outcomes such as engagement and citizenship behavior.

Third, enhancing interdepartmental collaboration for synergistic interventions, particularly with human resources, information technology, and external communication functions, is crucial, given that today employee communication shares with these functions a range of responsibilities and activities: from promoting employee well-being to managing internal digital channels and governing company reputation.

Fourth, instead of merely producing content, the employee communication function should adopt an enablement approach, equipping employees with training, tools, and repositories that facilitate their role as organic brand ambassadors.

Finally, the leading role of employee communication is especially important in contemporary work settings characterized by hybrid and remote work, where organizations strive to bridge the physical and cultural gaps created by digital transformation. In particular, middle managers are tasked with preserving features typical of traditional, in-person employee communication, such as bidirectionality in manager-employee relationships and informal, serendipitous communication.

Originality of the paper. *While employee communication research has expanded over the last few years, much of the literature still treats communicative dynamics as culturally neutral (Verčič et al., 2025). By analyzing the evolution of employee communication, its challenges, and its role as an enabler within the specific socioeconomic context of Italy, this study provides unique insights rooted in a specific cultural setting, allowing assessment of its specific configuration and evolution patterns in the country.*

Strategic Communication Measurement in GLAM sector

AMELIA NAPOLITANO[1], FABIO GRECO[2], FRANCESCO BIFULCO[3]

Abstract. *Strategic communication has gained prominence in galleries, libraries, archives, and museums (GLAMs) for enhancing audience engagement, digital participation, and public value creation. Yet, evaluation practices remain narrowly focused on media visibility and channel metrics, with limited attention to stakeholder outcomes and firm-level impact. This paper proposes an integrated framework for strategic communication measurement in GLAMs sector, combining Public Value Theory, the RACE model (Research, Action planning, Communication, Evaluation), the Barcelona Principles 4.0 and the AMEC Integrated Evaluation Framework. The framework connects communication planning processes with internationally recognised evaluation standards, positioning measurement as a strategic lever rather than a descriptive reporting activity. Adopting an exploratory qualitative research design, the study applies the framework to two European museums using secondary institutional data. The analysis provides an initial mapping of communication objectives, activities, outputs, out-takes, outcomes and impact indicators within the proposed evaluation architecture. The findings highlight the analytical usefulness of the framework for structuring communication evaluation in cultural firm, while also revealing that publicly available evidence remains concentrated on visibility and engagement metrics, with more limited transparency regarding outcomes and societal impact. The paper contributes to the literature by integrating strategic communication management, communication measurement standards and public value theory within a single analytical structure applicable to the GLAM sector.*
Keywords: *strategic communication; GLAM; public value; communication measurement; Barcelona Principles; RACE*

Framing of the research. The *GLAM sector is operating in an environment which is becoming increasingly complex. Several factors, including public mission, social legitimacy, financial constraints, digital transformation and growing expectations of inclusion and participation, shape this environment. International cultural policy frameworks increasingly expect these institutions to promote accessibility, diversity, audience participation and broad public access, while justifying their public role through visible social and cultural contribution (European Commission, 2014; UNESCO, 2015; European Union, 2019; Council of Europe, 2022). In this context, communication can no longer be understood merely as a promotional or informational lever. Instead, it has been demonstrated to contribute to institutional identity, cultural mediation, stakeholder relationship management, and public accountability (Capriotti, 2013; Centeno, 2021).*

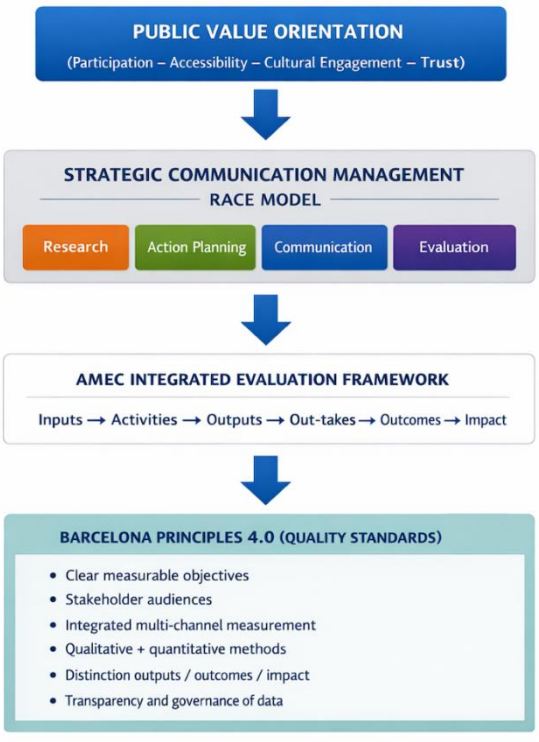
This strategic relevance is particularly evident in GLAMs, where value creation is largely intangible and relational. Effective communication is instrumental in fostering trust, encouraging participation, building reputation, engaging diverse audiences, and establishing legitimacy. These factors collectively influence the institution's ability to attract audiences, secure funding, and garner institutional support (Capriotti, 2013; Zerfass et al., 2020; Falkheimer et al., 2024; Montella, 2024). From this perspective, communication is increasingly recognised as a substantive strategic lever, especially in contexts characterised by resource scarcity, environmental change, competition for public attention and pressure to demonstrate societal impact (Hallahan et al., 2007; Invernizzi & Romenti, 2011; Zerfass et al., 2020; Falkheimer et al., 2024).

Nevertheless, while the strategicity of communication is widely acknowledged, its evaluation remains problematic. This study is primarily anchored in the scholarly stream of strategic communication measurement and evaluation, which examines how communication activities can be systematically assessed against objectives and societal outcomes within broader communication management processes (Siano et al., 2013). Within this field, a growing body of literature has emphasised the need to move beyond output-based indicators and to develop evaluation models capable of capturing the broader effects of communication on stakeholders, performance and public value (Macnamara, 2018; Zerfass et al., 2012; Zerfass & Volk, 2017).In practice, communication is still frequently assessed through media visibility or channel-specific metrics, whereas its effects on stakeholders, performance and public value are much less systematically measured (Gregory & Watson, 2008; Zerfass et al., 2010). This limitation is of particular significance in the cultural sector, where the outcomes of relevance are often concerned with learning, inclusion, participation, trust and community engagement rather than mere exposure or reach. In this sense, the persistence of invalid proxies such as Advertising Value Equivalents (AVE) has further reinforced reductionist approaches that fail to capture the actual contribution of communication (Watson, 2013).

Recent advances in communication measurement have produced internationally recognised evaluation standards, notably the Barcelona Principles 4.0 and the AMEC Integrated Evaluation Framework (IEF). However, these standards are rarely integrated with managerial communication planning models such as RACE (Research, Action planning, Communication, Evaluation), particularly within the GLAM sector. This paper addresses this gap by proposing an

[1] University of Padua, amelia.napolitano@phd.unipd.it
[2] University of Naples Federico II, fabio.greco@unina.it
[3] University of Naples Federico II, francesco.bifulco@unina.it

integrated analytical framework that connects communication planning processes with internationally recognised evaluation standards.



Purpose of the paper. *The present paper aims to address this gap by proposing an integrated framework that responds to three shortcomings identified in the extant literature. Firstly, research on strategic communication in cultural firms is fragmented between managerial planning models and evaluation standards. Secondly, studies on communication in GLAM institutions remain largely tactical or marketing-oriented, with limited attention to the relationship between communication activities and public value creation. Thirdly, the measurement of communication continues to privilege media visibility and channel-based outputs, while stakeholder outcomes and societal impact remain less systematically assessed.*

Against this background, the paper pursues two main objectives. First, it develops a conceptual framework integrating the above-mentioned approaches. Second, it provides an exploratory empirical application of the framework to two GLAM cases to assess its initial analytical usefulness in real-world communication practices. In doing so, the paper conceptualises communication measurement not as an ex-post reporting activity, but as a strategic lever capable of connecting communication objectives, stakeholder engagement, mixed-method indicators and public value creation. The resulting framework is intended to guide future empirical applications and support a more rigorous analysis of communication practices in cultural institutions.

The extant literature on the subject highlights the need for a more systematic integration between strategic communication planning and communication measurement practices in GLAMs. Whilst models such as RACE structure the managerial process of communication planning, measurement frameworks such as the Barcelona Principles and the AMEC Integrated Evaluation Framework provide standards and analytical categories for evaluating communication performance. However, these approaches are rarely integrated into a single framework that supports both communication management and evaluation in cultural firms.

To address this gap, the paper proposes an integrated framework that combines Public Value Theory, the RACE communication management model, and the Barcelona Principles 4.0, operationalised through the AMEC Integrated Evaluation Framework. Within this architecture, Public Value Theory provides the normative orientation linking communication activities to societal outcomes, while the RACE model structures the communication management cycle. The AMEC framework defines the evaluative chain connecting objectives, activities and impact. The Barcelona Principles 4.0 guide the measurement process by emphasising the definition of clear objectives, the identification of stakeholder audiences, the integration of qualitative and quantitative methods, and the distinction between outputs, outcomes and impact. Within the proposed framework, these principles function as quality guidelines ensuring transparency, methodological robustness and the avoidance of invalid metrics such as Advertising Value Equivalents. Figure 1 illustrates the conceptual architecture of the proposed framework.

Figure 1: Integrated framework for strategic communication measurement in GLAM sector

Source: author's elaboration

Methodology. *This study employs an exploratory qualitative research design to test the applicability of the integrated framework proposed in this paper. Exploratory qualitative approaches are particularly suitable when research seeks to investigate emerging phenomena or to develop and test conceptual frameworks in contexts where empirical evidence is still limited (Stebbins, 2001; Creswell, 2013). The purpose of the empirical analysis is not to provide definitive conclusions about communication effectiveness, but rather to explore whether the proposed framework can be meaningfully applied to real-world communication practices in GLAM institutions.*

The development of the integrated framework follows a theory-driven abductive approach, combining conceptual synthesis and iterative alignment across three streams of literature: strategic communication management, communication measurement, and public value theory. Specifically, the framework was constructed through three analytical steps: (i) conceptual decomposition of the core components of the RACE model, the AMEC Integrated Evaluation Framework, and the Barcelona Principles 4.0; (ii) cross-model alignment to identify complementarities and structural connections between planning and evaluation dimensions; and (iii) operational translation into a structured analytical template composed of observable variables (objectives, activities, outputs, out-takes, outcomes, and impact). This process allows the framework to function not only as a conceptual integration but also as an operational and empirically applicable tool.

The empirical analysis focuses on two illustrative cases: the Uffizi Galleries (Italy) and the Rijksmuseum (Netherlands). In particular, the cases serve as empirical settings in which the proposed framework is applied to map communication activities and evaluate their alignment with established communication evaluation principles.

The Uffizi Galleries are among the most prominent museum complexes in Italy, housing world-renowned collections of Renaissance art and attracting millions of visitors annually. In recent years, the museum has developed a highly visible digital communication strategy, characterised by intensive use of social media platforms, informal storytelling formats and audience-oriented narratives aimed at expanding and diversifying publics.

The Rijksmuseum is among the leading European museums in digital cultural communication and open-access strategies. Through initiatives such as Rijksstudio and the large-scale digitisation of its collections, the museum has developed an ecosystem that enables global online access, user participation and the creative reuse of cultural heritage. These initiatives have positioned the museum as an international reference point for digital engagement and open cultural data.

These institutions were selected on three main criteria. First, both institutions belong to the GLAM sector and operate within publicly oriented cultural systems characterised by strong institutional missions and stakeholder engagement. Second, both museums display highly visible communication strategies across multiple communication channels, particularly in digital environments and social media ecosystems. Third, both institutions provide substantial publicly accessible documentation on their communication activities, enabling the reconstruction of communication objectives, initiatives and observable results through secondary sources. The use of a multiple-case study approach allows to explore complex organisational phenomena and to examine the applicability of conceptual frameworks in real-world contexts (Yin, 2018; Eisenhardt, 1989). The selection of two internationally recognised museums with highly visible communication strategies enables testing of the framework in contexts where communication plays a central role in audience development and public value creation.

Data collection is contingent on the use of secondary data sources. Information was gathered from institutional websites, annual and strategic reports, press releases, institutional blogs, and official social media accounts. Further evidence was obtained from press coverage, interviews with institutional representatives, and publicly available presentations. The utilisation of secondary data sources is widely recognised as an appropriate qualitative research strategy for analysing organisational practices and publicly available institutional materials (Bowen, 2009; Johnston, 2014). In circumstances where detailed internal evaluation data has not been publicly disclosed, such sources can be of particular value.

Each case was analysed using a structured analytical template derived directly from the integrated framework proposed in this study. This template operationalises the framework by translating its conceptual components into observable analytical dimensions for examining institutional communication practices. The template maps communication activities to the phases of the RACE model while simultaneously assessing evaluation practices using the analytical categories of the AMEC Integrated Evaluation Framework, including inputs, activities, outputs, out-takes, outcomes and impact. Concurrently, the analysis assesses whether communication practices align with the methodological principles established by the Barcelona Principles 4.0. These principles encompass clear objectives, stakeholder orientation, multi-channel measurement, and the integration of qualitative and quantitative evidence.

The empirical analysis was conducted through a structured qualitative content analysis (Bowen, 2009), applying the analytical template as a coding scheme. Specifically, collected data were systematically coded by assigning observed communication practices to predefined categories derived from the framework. This procedure enables not only descriptive mapping but also analytical interpretation of the degree of alignment between communication activities and evaluation practices, as well as the identification of potential gaps across different levels of measurement (outputs, out-takes, outcomes, and impact).

As the empirical component of this research is currently ongoing, the case analysis presented in this paper should be considered preliminary. The aim is to provide an initial exploratory assessment of how the proposed framework can be applied to the analysis of communication practices in GLAM institutions; future research will further develop the

empirical investigation through additional cases and, potentially, the integration of primary data.

To operationalise the proposed framework for empirical analysis, the study translates its conceptual components into a structured analytical template for examining communication practices in GLAM institutions. The framework integrates the managerial logic of the RACE model with the evaluative structure of the AMEC Integrated Evaluation Framework and the methodological standards of the Barcelona Principles 4.0. By associating each phase of the communication process with specific evaluative categories and indicators, the framework enables GLAM sector to assess communication not only in terms of visibility but also in relation to stakeholder engagement, participation and public value creation.

This operationalisation also enhances the transparency and replicability of the analytical process, allowing the framework to function as both a conceptual model and a diagnostic tool for evaluating communication practices in cultural institutions.

Figure 1 illustrates the conceptual architecture of the integrated framework, while Table 1 summarises its operational structure.

Results. *As said, to explore the applicability of the framework, two illustrative cases were analysed: the Uffizi Galleries and the Rijksmuseum. Both institutions demonstrate robust communication visibility, active utilisation of digital platforms, and unambiguous relevance for audience engagement and public participation.*

Beyond their descriptive relevance, these cases provide analytically suitable contexts to assess the alignment between communication strategies and evaluation practices, particularly across different levels of measurement (outputs, out-takes, outcomes, and impact).

The Uffizi Galleries have adopted a communication strategy strongly oriented toward digital engagement, audience expansion, and institutional storytelling. Their multichannel presence combines website content, press relations and highly visible social media communication on platforms such as Instagram, TikTok and Facebook. The museum has amassed a following of over 1.17 million across various social media platforms, garnering a total of 13.8 million page views and an impressive 2.2 million individual users. The case demonstrates substantial evidence of outputs and audience reactions, while direct outcome and impact metrics are less systematically disclosed.

From an analytical perspective, the case reveals a strong concentration of measurement practices at the level of outputs and out-takes, with limited formalisation of indicators capturing behavioural change, stakeholder relationships, or longer-term public value creation.

Table 1: Integrated framework for strategic communication measurement in GLAM sector

RACE phase	***Managerial purpose***	***AMEC IEF components***	***Barcelona Principles relevance***	***GLAM operational focus***	***Example indicators***
Research	*Understand mission, context and stakeholders*	*Organizational objectives; Communication objectives; Target audiences; Inputs*	*Clear measurable objectives; stakeholder understanding; transparency*	*Define public value goals, map audiences, analyse communication context*	*mission statements, audience segmentation, stakeholder map*
Action Planning	*Translate strategic goals into operational communication plans*	*Planning elements; resources; targets*	*Objectives aligned with measurement; multi-channel planning; mixed methods*	*Define SMART objectives, KPIs, benchmarks and communication channels*	*KPI frameworks, campaign plans, PESO channel mix*
Communication	*Implement communication activities across channels*	*Activities; Implementation*	*Measurement across all relevant channels; qualitative and quantitative data*	*Execute communication initiatives across physical and digital environments*	*content production, media coverage, events, partnerships*
Evaluation (outputs/outtakes)	*Assess immediate communication performance and audience response*	*Outputs; Out-takes*	*Distinguish outputs from outcomes; avoid AVEs*	*Measure reach, engagement, attention and initial audience reactions*	*reach, impressions, engagement rate, attendance*
Evaluation (outcomes/impact)	*Assess broader stakeholder and organizational effects*	*Outcomes; Impact*	*Focus on outcomes and impact; transparency of evaluation*	*Evaluate effects on participation, trust, cultural engagement and public value*	*participation rates, visitor growth, community engagement, reputation indicators*
Learning / feedback	*Integrate evaluation results into future planning*	*Evaluation insights and learning*	*Measurement as continuous governance process*	*Adapt strategies based on evidence and improve future communication planning*	*revised strategies, updated KPIs*

Source: author's elaboration

The Rijksmuseum provides a complementary case study centred on digital openness, audience participation and reuse of cultural content. Through initiatives such as Rijksstudio, the museum enables users to explore, download and creatively reuse high-resolution artworks, thereby extending cultural participation beyond physical visits. The case demonstrates compelling evidence of digital dissemination, user participation and global reach. However, the measurement of broader outcomes and impact remains less transparent in public documentation.

Similarly, while the Rijksmuseum demonstrates advanced practices in enabling participation and access, the explicit measurement of downstream effects—such as learning outcomes, cultural inclusion, or societal impact—remains only partially observable through available data.

The cross-case analysis suggests that the framework is analytically useful for mapping communication practices in the GLAM sector and distinguishing between strategic objectives, communication activities, outputs, out-takes, outcomes and impact. At the same time, the cases confirm that publicly available evidence remains much stronger for outputs and engagement indicators than for more advanced outcome and impact measures.

More importantly, the application of the framework enables the identification of structural gaps in communication evaluation, highlighting a systematic misalignment between strategic intentions (e.g., participation, accessibility, public value) and the metrics effectively adopted by institutions.

Overall, the cases illustrate how the integrated RACE–AMEC–Barcelona framework enables a structured analysis of communication practices in GLAM institutions by linking communication activities to different levels of evaluation, from outputs and audience reactions to broader stakeholder outcomes and public value impact. They demonstrate strong evidence of multichannel communication strategies and measurable outputs, whereas the systematic measurement of outcomes and impact remains less transparent.

Beyond its descriptive function, the framework operates as a diagnostic tool, allowing researchers and practitioners to assess the degree of alignment between communication practices and evaluation standards, and to identify areas where measurement systems remain underdeveloped. In this sense, the findings suggest that current communication practices in leading GLAM institutions are still predominantly oriented toward visibility and engagement metrics, while the transition toward outcome- and impact-based evaluation—central to contemporary communication measurement standards—remains incomplete. This reinforces the relevance of the proposed framework as a mechanism for shifting communication evaluation from a reporting activity to a strategic governance process.

Table 2: Application of the Integrated Framework to the Case Studies

Framework dimension	***Uffizi Galleries (Italy)***	***Rijksmuseum (Netherlands)***
Research (objectives & stakeholders)	*Strategic goal of expanding audiences and increasing accessibility through digital communication and social media engagement. Communication policy explicitly states the goal of promoting heritage, strengthening institutional identity and fostering participation with communities and cultural stakeholders.*	*Strategic objective of connecting global audiences with art and history through digital access and open cultural data. The museum aims to make online experiences as valuable as physical visits and engage global digital audiences.*
Action planning (communication strategy)	*Multichannel communication strategy integrating website, press office and social media platforms (Instagram, TikTok, Twitter, Facebook). Campaigns focus on storytelling, humorous reinterpretations of artworks and audience-oriented narratives targeting younger publics.*	*Digital communication strategy centred on open access and participatory engagement. Initiatives such as Rijksstudio allow users to explore, download and reuse artworks, encouraging creative participation and global digital engagement.*
Communication activities (implementation)	*Extensive social media presence with visual storytelling, meme culture reinterpretations and participatory formats. Communication campaigns regularly involve influencers and digital creators to attract younger audiences.*	*Implementation of digital platforms, apps and interactive online experiences. Rijksstudio enables users to create personal collections and interact with high-resolution artworks from the museum's collection.*
Outputs (observable communication results)	*Strong growth in social media visibility. The museum became the most followed Italian museum online, reaching over 1.17 million followers across social platforms by 2023. Website traffic reached over 13.8 million page views with more than 2.2 million users.*	*Extensive digital dissemination of collections and online platforms. The Rijksmuseum provides hundreds of thousands of digital artworks online and encourages downloading and sharing through its open digital ecosystem.*
Out-takes (audience reactions)	*High engagement levels in comments, shares and user-generated content around artworks. Social media interactions demonstrate active audience participation and digital cultural engagement.*	*Active user participation through Rijksstudio collections and creative reuse of artworks. Digital platforms enable users to curate personal collections and share museum content.*
Outcomes (stakeholder effects)	*Increased international visibility and audience expansion through digital engagement strategies. The museum also became the most visited cultural site in Italy in 2021 with 1.72 million visitors.*	*Strengthened global digital engagement and cultural participation through open access to collections and participatory platforms. Online engagement contributes to extended audience interaction with the museum's collections.*
Impact (organizational and societal effects)	*Strengthened reputation as an innovative museum in digital communication and audience engagement. Communication strategies contribute to expanding cultural accessibility and public participation.*	*International recognition as a leading institution in open digital heritage and participatory museum practices, influencing global standards in digital cultural communication.*

Source: author's elaboration

Research limitations. *The present study acknowledges several limitations, yet concomitantly identifies promising avenues for future research. Firstly, the empirical analysis is dependent on secondary data sources. Whilst this approach facilitates the systematic observation of publicly visible communication practices across institutions, it does not provide access to internal evaluation systems, unpublished KPIs or organisation-specific measurement processes. Consequently, ongoing research is necessary to expand empirical investigation by collecting additional data sources and potentially integrating primary data. Secondly, the empirical investigation focuses on two illustrative cases. The Uffizi Galleries and the Rijksmuseum offer valuable insights into the application of the proposed framework in leading GLAM institutions, characterised by strong communication, visibility and digital engagement. However, future research will extend the analysis to a broader set of cultural firms to test the framework across different institutional contexts and communication environments. Ultimately, given that the empirical element of the research is still in progress, the case analysis presented in this paper should be interpreted as a preliminary application aimed at testing the analytical usefulness of the framework. This exploratory phase is already being complemented by additional case analyses and further empirical refinement to strengthen the framework's applicability and robustness for evaluating communication practices in the GLAM sector.*

Managerial implications. *The framework provides actionable guidance for communication managers in GLAM institutions by translating abstract evaluation principles into operational decision-making tools.*

First, it supports the design of measurement architectures aligned with strategic objectives, encouraging managers to define ex-ante KPIs linked not only to visibility but also to stakeholder outcomes (e.g., participation, trust, inclusivity). For example, instead of relying solely on engagement rates, institutions can integrate indicators such as repeat visitation, co-creation activities, or community partnerships. Second, the framework enables the development of integrated dashboards, where communication activities are systematically linked to outputs, out-takes, outcomes, and impact. This facilitates internal accountability and supports reporting to public stakeholders and funding bodies. Third, by embedding evaluation within the RACE cycle, the framework promotes continuous learning processes, allowing institutions to adapt communication strategies based on evidence rather than intuition.

Compared to existing models used in practice, the proposed framework differs in its ability to: (i) connect planning and evaluation in a single structure; (ii) explicitly incorporate public value dimensions; (iii) provide a replicable template applicable across different GLAM contexts.

Originality of the paper. *This paper contributes to the literature by advancing an integrative, operational framework that goes beyond merely juxtaposing existing models. While prior studies have independently addressed (i) communication planning processes (e.g., RACE), (ii) evaluation standards (e.g., Barcelona Principles), and (iii) measurement architectures (e.g., AMEC IEF), this study systematically connects these dimensions within a single coherent analytical and managerial structure tailored to the GLAM sector. The novelty of the framework lies in three specific contributions. First, it introduces a process–evaluation alignment, linking each phase of the communication cycle (RACE) with corresponding evaluative categories (AMEC IEF), thus overcoming the traditional separation between planning and measurement. Second, it embeds Public Value Theory as a normative anchor, explicitly connecting communication activities to societal outcomes, which remains underdeveloped in existing communication measurement models. Third, the framework provides a practical operationalisation through a structured analytical template, enabling empirical application and comparability across cases. Therefore, this study addresses a structural gap in the literature by transforming fragmented approaches into a governance-oriented measurement system, where communication evaluation becomes an integral component of strategic management and public value creation in cultural institutions.*

Strategy, Experience, Conversation: A Conceptual Model of Corporate Space as Strategic Communication

DENIS ŠIMUNOVIĆ, STEFANIA ROMENTI, ELANOR COLLEONI

Abstract. *Despite substantial research on organizational space from ergonomic, psychological, and corporate identity perspectives, a coherent conceptual framework for understanding the strategic communication function of corporate space remains absent from the literature. This paper addresses that gap by proposing a three-dimensional conceptual model that repositions corporate headquarters as an active strategic communication instrument. The model argues that organizational space operates simultaneously across three communicative dimensions: (1) the strategic dimension, in which space encodes and transmits the organization's strategic trajectory, business model, and competitive positioning across historical phases of capitalism; (2) the experiential dimension, in which space mediates the aesthetic and relational construction of work experience, organizational identity, and the imagined relationship between people, work, and the corporation; and (3) the conversational dimension, in which iconic corporate headquarters function as agenda-building mechanisms in urban public discourse, actively shaping which issues, values, and organizational narratives enter collective attention. Drawing on three intersecting literature streams, organizational studies on space, strategic communication theory, and urban sociology , the paper develops each dimension theoretically and illustrates them through case evidence, including the Nuvola Lavazza headquarters and other international models. The contribution is both theoretical, advancing a multi-dimensional framework for strategic communication scholarship, and managerial, offering communication professionals a model for conceptualizing, designing, and governing corporate space as a consequential strategic communication asset.*

Keywords: *corporate space; strategic communication; organizational identity; agenda-building; work experience; public sphere*

Framing of the research. *Corporate space has been studied from multiple disciplinary perspectives: Among others, organizational behaviour and management have examined how physical environments shape productivity, wellbeing, and culture (Oyedeji, Ko, & Lee, 2025); corporate identity scholarship has treated architectural choices as expressions of organizational identity and legitimacy (Hatch, 1987; Balmer, 2011); sustainability research has highlighted how spatial disconnection from local communities undermines corporate responsibility (Mazutis, Slawinski, & Palazzo, 2021); and urban sociology has documented how corporate buildings reshape city landscapes and civic life (Mozingo, 2014). Cultural, educational, and experiential dimensions of corporate space have also received growing attention as organizations invest in museums, public programmes, and community-facing spaces that exceed purely operational functions.*

Despite this breadth of scholarly and organizational interest, a fundamental gap persists. None of these traditions has yet produced a conceptual framework for understanding corporate space as a form of strategic communication, that is, as a deliberately designed and managed communicative instrument through which organizations pursue their strategic objectives, construct stakeholder relationships, and participate in public discourse. The organizational and managerial literature tells us that space matters, and that it communicates something, but it has not theorized how communication professionals and senior managers can think about, design, and activate corporate space as a coherent strategic communication asset. This theoretical and practical deficit is the motivating problem of the present paper

The strategic dimension of organizational space as communication has been peripherally and in a fragmented manner tackled by several authors. Lefebvre's (1991) theory of the social production of space draws attention to the gap between space as designed and intended by its planners, space as materially inhabited and navigated in practice, and space as experienced and interpreted by its users. This tripartite understanding has been productive in organizational research for revealing how the communicative intent inscribed in architectural design may be affirmed, modified, or resisted by those who live and work in the space (Taylor & Spicer, 2007; Dale & Burrell, 2008). In strategic communication, the Communication Constitutes Organization (CCO) perspective has established that materiality, including physical artifacts, technologies, and spatial arrangements, actively participates in constituting organizational reality rather than merely reflecting it (Bencherki et al., 2021). Andrews (2017) and Bacevice and Wilhoit Larson (2023) have called explicitly for approaches that treat corporate buildings as rhetorical entities that afford or constrain communication practices. Individually, these contributions illuminate different facets of the relationship between corporate space and communication; none, however, has synthesized them into a model that is actionable for strategic communication theory and practice.

Moreover, as hybrid work has disrupted assumptions about the office as a default site of activity, organizations face urgent questions about why, how, and for whom the corporate headquarters should exist. Participating in addressing these questions requires to theories the issue of how can a communication perspective enrich this discussional and bring novel understanding on the functions that corporate space can perform, and that gives managers the theoretical

vocabulary to act on them. The result is a persistent under-exploitation of one of the most powerful and durable communication assets a corporation possesses

Purpose of the paper. *The purpose of this paper is to develop a three-dimensional conceptual model of corporate space as strategic communication. The model is intended to serve both theoretical and managerial functions: theoretically, it integrates disparate literature streams into a framework that advances the field of strategic communication by establishing corporate space as a legitimate and consequential domain of scholarly inquiry; managerially, it provides communication professionals and organizational leaders with a structured way of thinking about how corporate space can be designed, governed, and communicated to achieve strategic objectives.*

Methodology. *This paper adopts a conceptual and theory-building approach. The methodology combines a review of three intersecting literature streams with the development of an original conceptual framework grounded in that review and illustrated through illustrative case example. The literature review encompasses publications from the past thirty years in leading international journals in management, strategic communication, and urban sociology, selected using the Academic Journal Guide rankings. A corpus of 90 articles was mapped enabling identification of the dominant theoretical frameworks, empirical patterns, and persistent gaps that motivate the proposed model (Oyedeji, Ko, & Lee, 2025; Romenti, 2024).*

Results. *The spatial strategic dimension: The first dimension of the model concerns relationship between corporate spatial investment and organizational strategy. The use of organizational space has always been part of the intersection between the discourse on corporate strategy, internationalization, and the projection of corporate positioning within the broader environment. What organizational and strategic communication research has not yet adequately theorized is how corporate space has historically encoded and transmitted strategy, thus how the physical configuration of a headquarters embodies and communicates a particular understanding of what the organization is, what it does, and how it positions itself in competitive, social, and institutional landscapes.*

Corporate spatial strategy has evolved through distinct phases, each corresponding to a particular moment in the history of capitalism and the corporation's understood role in society, and each constituting a distinct chapter in the strategic communication function of organizational space.

In the American post-war industrial phase, the dominant spatial logic was one of containment and consolidation. The insulated suburban campus, exemplified by AT&T Bell Laboratories and the broader typology of the American corporate estate (Mozingo, 2014), communicated stability, self-sufficiency, and institutional authority through its very withdrawal from urban complexity. The communicative message was inward-facing: the corporation as a complete, self-enclosed social world, capable of providing everything its workforce needed and unwilling to be distracted by the turbulence of the city. Space here functioned as a communication of power through separation.

The knowledge economy phase introduced a fundamentally different communicative imperative. As intellectual talent replaced physical labour as the primary source of competitive advantage, corporate space became a tool for attracting and retaining the people organizations most needed, and for signalling membership in the networks that defined innovation and prestige. The proliferation of R&D campuses, innovation hubs, and flagship headquarters was not merely a response to functional needs: it was a strategic communication investment. For example the establishment of WPP's campus model, or the open innovation spaces adopted by major pharmaceutical companies, illustrates how organizations in knowledge-intensive sectors used their physical environments to communicate credibility and proximity to ideas to position themselves spatially within the epistemic geography of their industry. The campus became a material claim about where the future was being made.

A different and particularly revealing communicative dynamic can be spot in the financial sector, where the tension between visibility and secrecy is constitutive of the business itself. Financial headquarters are designed to communicate simultaneously in two registers: outward-facing, they project institutional solidity, trustworthiness, and permanence to markets, regulators, and clients; inward-facing, they maintain the controlled opacity that proprietary operations require. This dual communicative logic, broadcasting stability while concealing process, is legible in the spatial grammar of financial district buildings worldwide, from the monumental lobbies designed to inspire confidence to the windowless trading floors shielded from external observation. Space, in this sector, is not merely a backdrop to the business: it is an active instrument for managing the information environment.

The experiental dimension: The second dimension of the model concerns the role of corporate space in constructing the aesthetic and relational experience of work, the way in which spatial design mediates how organizational members understand, feel, and imagine their relationship to work, to the organization, and to one another. This dimension draws on the rich literature on identity, organizational identification, and the aesthetics of organizational life, while extending it into a specifically communicative register.

Research by Elsbach (2003) established that the personalization of workspaces is directly correlated with organizational identification: the degree to which employees can inscribe their own presence and identity onto the spaces they inhabit shapes the depth of their sense of belonging. This insight has been extended by subsequent research demonstrating how spatial arrangement mediates the formation of organizational culture, the circulation of informal knowledge, and the construction of collective memory (Stigliani & Ravasi, 2012). Space is not a neutral backdrop to these processes: it constitutes them, in the sense that CCO (Communication Constitutes Organization) theory gives to that term

(Bencherki et al., 2021). The aesthetic choices embedded in design — materials, light, colour, scale, atmosphere are not decorative; they are communicative acts that shape the experienced meaning of work and the imagined identity of the organization (Gagliardi, 2006; Strati, 2010).

A critical insight for strategic communication is that the aestheticization of work experience through space is not a neutral process but a corporately mediated one. When an organization invests in the aesthetic quality of its workspaces such as in natural light, biophilic elements, materials of warmth and texture, spatial configurations that support both concentration and encounter it is not merely providing amenities. It is constructing a particular imaginary of work: a vision of what it means to be part of this organization, of the quality of relationship the organization offers its members, and of the kind of future the organization is building. This imaginary is communicated before any word is spoken, through the sensory and spatial experience of simply being in the building, This dimension also encompasses the temporal construction of organizational identity through space. Identity research has established that corporate identity involves the temporal projection of a particular organizational self one that integrates remembered history, present values, and imagined future (Suddaby, Foster, & Quinn Trank, 2010; Balmer, 2011). Space is the materialization of this temporal dimension: it cements the historical development of corporate identity and makes the organization's sense of its own past and future spatially experienceable (Hatch & Schultz, 2017). Buildings that embed and display organizational heritage through architectural references to founding moments, display of historical artifacts, integration of archival materials into the spatial design communicate a particular kind of organizational self-understanding that no verbal or digital communication can replicate with the same durability and immediacy.

The conversational dimension: the third and most theoretically novel dimension of the model argues that iconic corporate headquarters, those invested with deliberate narrative and communicative strategy, function as agenda-building mechanisms in the public sphere (Carroll & McCombs, 2003). This proposition shifts attention from the internal and dyadic communicative functions of space to its role in shaping public discourse at the level of the city, the sector, and the broader cultural environment.

Historically, civic spaces like public squares, parliaments, libraries, cathedrals, and news media institutions were the primary arenas of public agenda formation: the spaces where issues were selected, framed, and brought to collective attention. Corporate buildings have increasingly come to perform an analogous function. A headquarters that is open to the public, hosting global summit, exhibitions, cultural events, educational programmes, and community gatherings, becomes a literal arena in which the corporation acts as gatekeeper, promoter, and framer of the issues and ideas it selects to platform. More diffusely, an architecturally iconic building shapes public discourse through its urban presence, its circulation in media and on social platforms, and the questions it activates in the public imagination about who the organization is, what it stands for, and what role it claims in urban and civic life.

An exemplary case that illustrates all three dimensions operating in coherent integration is Nuvola Lavazza . Across the strategic dimension: the building was designed to externalize Lavazza's business model and brand values architecturally, embedding the product experience,the ritual, warmth, and sociality of coffee, into the sensory fabric of the workspace and inverting the "placelessness" pattern that sustainability research identifies as a strategic liability. Across the experiential dimension: the building functions as a narrative micro-universe where personal and collective stories about the organization and the city accumulate and circulate, constructing organizational memory and identity through the spatial experience of those who inhabit and visit it (Vaara et al., 2016). Across the conversational dimension: the museum, public piazza, events programme, and deliberate architectural narrativization have transformed Nuvola into an active landmark, one that generates 367 average monthly searches by name against 6 for "sede Lavazza", and that activates public curiosity about the organization's history, values, and civic role far beyond what any conventional communication programme could achieve.

Research limitations. *As a conceptual paper, the primary limitation is the absence of systematic empirical testing of the proposed model. The three dimensions are developed through theory-building and illustrated through case evidence; they are not empirically derived from primary data or statistically validated.*

A second limitation concerns the conceptual treatment of the three dimensions as analytically distinct. In practice, the strategic, experiential, and conversational dimensions of corporate spatial communication are deeply interdependent and mutually constitutive: the agenda-building function of a corporate landmark is only achievable when the experiential and strategic dimensions are coherently aligned, and the strategic communication function of space is always mediated by the lived experiences of those who inhabit it. The model's three-part structure is a theoretical simplification that enables analytical clarity at the cost of some phenomenological complexity.

A third limitation is the primarily Western and large-corporation orientation of the empirical cases. The model's propositions are grounded in evidence from Italian and US contexts and focus on large, resource-rich organizations with the capacity to invest substantially in headquarters design and programming. How the three dimensions apply in smaller organizations, different cultural contexts, and non-profit or public sector institutions remains to be explored.

Managerial implications. *The model generates several direct implications for the practice of strategic communication and organizational management. Most fundamentally, it argues that communication professionals must expand their professional remit to include spatial governance: the integration of architectural choices, spatial programming, and narrative investment into the broader communication strategy. Corporate real estate and facilities decisions have*

traditionally been made without communication expertise and the theoretical framework developed here shows why this represents a systematic under-exploitation of a consequential communication asset. With respect to the strategic dimension, managers should ask whether the design and location of their headquarters coherently communicates the organization's strategic positioning and business model, and whether spatial investments reinforce or contradict the narratives the organization is seeking to establish with stakeholders. The evolution of spatial strategy, from operational enclosure to civic embeddedness, suggests that organizations whose headquarters remain spatially insulated from their communities are communicating a strategic posture that is increasingly misaligned with contemporary stakeholder expectations around sustainability, transparency, and civic responsibility.

With respect to the experiential dimension, managers should evaluate the degree to which the aesthetic and relational design of their workspaces communicates the organization's values and identity in ways that are coherent with its verbal and visual communication. This includes attention to sensory coherence between product and space (as in the Lavazza model), to the spatial embodiment of organizational heritage and future orientation, and to the grounding–opening dynamic: whether the building is experienced as an invitation or a barrier by the multiple publics it encounters.

With respect to the conversational dimension, managers should assess whether their headquarters is functioning as an active or passive agenda builder and what investments in narrative, programming, and public accessibility would be required to shift it from one category to the other

Originality of the paper. *The paper makes three original contributions to scholarly and professional knowledge. First, it proposes the first explicit three-dimensional conceptual model of corporate space as strategic communication, an integrated framework that goes beyond the existing literature's treatment of space as an ergonomic variable, identity expression, or employer branding lever, and articulates a multi-register understanding of its communicative functions. By bringing together organizational space studies, strategic communication theory, and urban sociology, the paper creates a conceptual platform for a genuinely interdisciplinary research agenda. Indeed the paper makes an original contribution to the conceptualization of the strategic communication function itself. By demonstrating that corporate space is a consequential site of strategic communication , one that operates across internal, stakeholder, and public sphere levels simultaneously and generates durable communicative effects that exceed those of conventional communication channels, the paper argues for an expanded understanding of strategic communication as a discipline that can draw from architcture, organization studies, and urban studies to advance its own agenda.*

The role of marketing communication strategy and professional expertise in AI adoption: insights from an exploratory study

EMANUELA CONTI[1], ALESSANDRO PAGANO[2]

Abstract. *Artificial intelligence (AI) is increasingly reshaping marketing by enabling firms to automate content creation, personalize communication, and predict customer behavior (Davenport et al., 2020; Huang & Rust, 2021). Although AI technologies are recognised as a fundamental component of the broader technological evolution that businesses must embrace to remain competitive (Chen et al., 2022), existing studies highlight several challenges and opportunities that must be carefully managed for effective adoption, including technological infrastructure, ethical concerns, and organizational readiness (Amin et al., 2025).*

Focusing on organizational readiness, the marketing literature identifies several barriers to effective AI implementation, such as high costs, lack of specialized skills, resistance to change, and difficulties in integrating AI into existing processes (Dwivedi et al., 2021; Elhajjar, 2025). However, there is still limited understanding of how firms - particularly SMEs - operationalize AI adoption in practice, especially in the domain of marketing communication.

This paper aims to shed light on the role of communication strategy and professional expertise in facilitating AI adoption in marketing communication. Specifically, it presents the results of an empirical study examining the extent of AI adoption and its main applications in marketing communication among SMEs, from the perspective of marketing and communication managers. It further investigates whether the level of AI adoption intensity is associated with the presence of a communication strategy. Additionally, the study analyses how firms - grouped according to their level of AI adoption - differ in terms of marketing communication expenditure, the adoption of communication performance measurement systems, and the configuration of human resources dedicated to communication activities (i.e., in-house, outsourced, or hybrid).

In this paper, AI adoption in marketing communication is not viewed merely as the implementation of a technological tool but rather as a strategic decision that can influence firms' strategic choices. From a dynamic capabilities' perspective, firms are required to develop the ability to sense emerging technological opportunities, seize them through strategic integration, and reconfigure their resource base accordingly (Teece et al., 1997; Teece, 2007). Consistent with the resource-based view, the value generated by AI in marketing communication depends on the effective combination of technological resources with complementary organizational capabilities, such as strategy and marketing expertise (Barney, 1991; Wade & Hulland, 2004).

The findings indicate that SMEs characterized by the presence of a marketing communication strategy exhibit higher levels of AI adoption and firms with higher AI adoption levels tend to report greater investment in marketing communication (as a percentage of revenue), a higher incidence of communication performance measurement practices, and a more balanced configuration of communication resources between internal and external solutions.

Overall, the results suggest that Italian SMEs still make relatively limited use of AI in marketing communication. At the same time, the presence of a communication strategy is associated with higher levels of AI adoption, while more advanced adoption is linked to resource configurations characterized by a stronger balance between internal capabilities and external expertise.

Keywords: *Marketing communication; Artificial Intelligence (AI); marketing communication strategy; internal and external communication competences; small and medium-sized enterprises (SMEs), B2C market*

Framing of the research. *The integration of AI into marketing reflects a broader technological transformation that firms must embrace to remain competitive in an increasingly digital marketplace (Chen et al., 2022). AI technologies offer several advantages, including greater personalization, more effective targeting, higher return on investment (ROI), improved efficiency and automation (Kumar et al., 2024). Similarly, Amin et al. (2025), highlight that leveraging AI technologies, enables firms to personalize customer experiences, support decision-making, and streamline operations.*

The ability to analyse vast amounts of data in real time further strengthen customer engagement and optimizes strategic decision-making. Through predictive analytics, machine learning, and natural language processing, AI plays a critical tool in advertising personalization and marketing automation (Casado-Aranda et al., 2023). In this context, machine learning algorithms, allows marketers to align messages more closely to customers' preferences, thereby improving communication effectiveness (Gupta et al., 2020). Additionally, voice recognition applications are gaining increasingly relevance in marketing communication, as they enable more natural, conversational, and personalized interactions between firms and customers, while also reshaping search behaviours, customer journeys, and content delivery strategies (Huh et al., 2023).

[2] Università di Urbino Carlo Bo, Dipartimento di Economia, Società, Politica (DESP), alessandro.pagano@uniurb.it

Overall, AI is reshaping marketing communication by supporting data-driven decision-making, enabling advanced personalization, and facilitating more adaptive and responsive communication strategies (Davenport et al., 2020; Huang & Rust, 2021).

However, despite these benefits, AI adoption in marketing and marketing communication entails several challenges, including technological infrastructure, ethical concerns, and organizational readiness (Amin et al., 2025). Focusing on organizational readiness, a growing stream of literature has examined the conditions that enable the effective integration of AI into marketing communication.

Davenport et al. (2020) state that firms initially deploy AI to support efficiency-enhancing and task-specific applications before moving toward more strategic integration and emphasize that the effectiveness of AI in marketing communication depends on the accurate definition of the target audience, as the quality of AI-driven insights is closely linked to the relevance of input data (Ramos, 2023). In this respect, a clear understanding of the intended audience is essential to ensure meaningful outputs and avoid ineffective or misleading marketing decisions. Alongside audience definition, maintaining a consistent brand voice represents a critical requirement. Misalignment between AI-generated content and established brand identity may lead to inconsistencies in communication, potentially undermining brand authenticity and confusing consumers (Kirkby et al., 2023; Brüns & Meißner, 2024).

From an operational perspective, AI enables a more systematic and data-driven approach to content creation and optimization. Its integration into social media communication allows firms to continuously refine content based on performance data and evolving audience preferences (Bashang & Puttanna, 2023; Haleem et al., 2022). Nevertheless, recent studies highlight that the effectiveness of these processes remains contingent upon data quality and contextual understanding. Limitations such as content inconsistency and difficulties in capturing nuanced brand meaning still require further advancements in machine learning techniques (Kubovics, 2024).

While AI supports the development of more targeted and adaptive marketing communication strategies across multiple channels, contributing to improved customer engagement and marketing effectiveness (Kumar et al., 2019), a deeper understanding of the determinants - particularly those related to organizational readiness - of AI adoption in marketing communication is still needed.

In this regard, the literature has primarily focused on selected elements of marketing communication strategy, such as target audience definition and brand voice, while paying limited attention to other relevant strategic components that may influence AI adoption. These include, for instance, the use of marketing communication performance measurement systems, the level of investment in communication activities, and, more broadly, the presence of a comprehensive communication strategy. Building on the integrated marketing communications (IMC) tradition, which conceptualizes marketing communication as a strategic and integrated process, incorporates key planning elements (Kotler & Keller, 2016), and emphasizes coherence across touchpoints (Porcu et al., 2019), marketing communication strategy can be conceptualized as "an integrated planning framework that aligns objectives, target audiences, messaging, channels, and resource allocation to ensure consistency across touchpoints and enable the optimization of communication approaches to achieve marketing and communication objectives".

Such a strategy is closely linked to a firm's overall strategic positioning, as communication activities are designed to convey and reinforce the brand's distinctive position in the minds of target consumers (Kotler & Keller, 2016; Keller, 2013).

Accordingly, it can be expected that the presence of a marketing communication strategy - whether formal or informal - as well as a clearly defined strategic positioning, is associated with a more intensive (and effective) adoption of AI in marketing communication.

Another relevant factor or organizational readiness facilitating of AI adoption in marketing communication concerns human resources and, more specifically, the governance of competencies. While prior research has emphasized the importance of employee skills and organizational readiness, limited attention has been paid to how firms configure internal and external resources to support AI adoption. Understanding the most effective combination of in-house capabilities and external expertise represents a critical yet underexplored issue, particularly in the context of SMEs.

Beyond skill development, the adoption of AI in marketing communication also raises important questions regarding the governance of resources, particularly the balance between internal marketing capabilities and external expertise. In the marketing literature, this issue has traditionally been framed as the choice between internalizing activities and outsourcing them to specialized partners (Ghosh & John, 1999). Firms must therefore determine which communication activities should remain under internal control and which can be delegated to external consultants, such as communication agencies, digital marketing specialists, or technology providers.

External partners can provide specialized expertise, advanced technological knowledge, and analytical capabilities that may not be readily available within the firm (Florea & Munteanu, 2020). They can offer access to sophisticated data analytics tools, AI applications, and marketing technology infrastructures. At the same time, internal marketing capabilities remain essential to ensure strategic alignment, maintain brand coherence, and coordinate communication activities across channels (Moorman & Day, 2016; Morgan et al., 2018). Internal teams play a central role in defining brand positioning, communication objectives, and the overall strategic direction.

In the context of AI adoption, this balance becomes even more critical. Implementing AI in marketing communication requires not only technological expertise but also the ability to translate data-driven insights into coherent strategies and brand-consistent messages. As a result, firms may increasingly rely on hybrid governance structures, combining internal strategic capabilities with external technological and analytical expertise (Huang & Rust, 2021; Verhoef et al., 2021).

Such configurations can enable firms to leverage external innovation while retaining control over strategic communication decisions and brand management.

Hence, two main gaps related to organizational readiness can be identified, referring to key factors that may facilitate AI adoption in marketing communication. The first concerns marketing communication strategy, including specific elements such as budget allocation and the use of performance measurement systems. The second relates to the composition of human resources, particularly the configuration between internal, external, and a mixed approach.

In this paper, AI adoption in marketing communication is conceptualized not merely as the introduction of a technological tool, but as a strategic choice that can shape firms' communication strategies and marketing decision-making processes. From a dynamic capabilities' perspective, firms need to sense technological opportunities, integrate them into marketing activities, and reconfigure their resources accordingly (Teece et al., 1997; Teece, 2007). Consistent with the resource-based view, the value of AI depends not only on the technology itself, but on its integration with complementary organizational capabilities (Barney, 1991; Wade & Hulland, 2004). Recent marketing research further highlights that effective AI deployment requires the development of new marketing capabilities and the integration of technological resources with organizational expertise (Davenport et al., 2020; Huang & Rust, 2021).

Against this background, this study examines the extent to which SMEs adopt AI in marketing communication and the specific activities supported by AI, based on the perspectives of marketing and communication managers or their collaborators. SMEs represent a particularly relevant context, as their more limited resources and capabilities often make the adoption of new technologies and strategic communication practices more challenging.

More specifically, the study investigates whether AI adoption is associated with the presence of a communication strategy and a clearly defined strategic positioning. It also explores whether firms differ in their configuration of internal and external communication resources. By linking AI use to strategic orientation and organizational capabilities, the study provides insights into how strategy and expertise shape the effective use of AI in marketing communication.

The analysis is based on data from an online survey of SMEs and focuses on three main areas: (1) firm characteristics, (2) the adoption of communication strategies and AI uses, and (3) the configuration of internal and external communication competences.

Given the structural constraints typical of SMEs, understanding how these firms integrate AI into their marketing communication practices is particularly relevant. This study contributes to the emerging literature on AI in marketing by highlighting the role of organizational and strategic readiness in supporting the adoption and effective use of AI-based communication tools.

Accordingly, the study addresses the following research questions:

RQ1: What is the level of AI adoption intensity among SMEs in marketing communication, and of key uses (content creation, data analysis and data personalization)?

RQ2: Is there a statistically significant difference in AI adoption between firms with and without a communication strategy?

RQ3: To what extent do firms, grouped by their level of AI adoption, differ in terms of (a) marketing communication expenditure, (b) the use of performance measurement systems, and (c) the configuration of communication resources (in-house, outsourced, or hybrid)?

Purpose of the paper. *Drawing on the Resource-Based View and the Dynamic Capabilities perspective, this paper investigates the extent and patterns of artificial intelligence (AI) adoption in marketing communication among SMEs. Specifically, the study examines the level of adoption and its main applications from the perspective of marketing and communication managers. It further examines whether differences in AI adoption levels are associated with the presence of a communication strategy.*

In addition, the study explores how firms, grouped according to their level of AI adoption, differ in terms of marketing communication investment intensity, the use of performance measurement systems, and the configuration of communication resources (in-house, outsourced, or hybrid).

Adopting a quantitative and comparative approach, this exploratory study provides insights into the relationship between AI adoption and firms' communication strategies and organizational configurations, thereby contributing to a better understanding of the role of organizational readiness in shaping AI adoption in marketing communication practices.

Methodology. *The study draws on data from an online survey of Italian manufacturing SMEs operating in B2C markets. The questionnaire was developed based on the marketing communication literature and pre-tested through pilot interviews with two entrepreneurs to ensure clarity and relevance.*

The analysis is based on four sections of the questionnaire: (1) firm characteristics; (2) the intensity of AI adoption in marketing communication and key uses ; (3) AI adoption in firms with and without a communication strategy; and (4) the relationship between AI adoption intensity and the marketing communication budget, the presence of a performance measurement system, and the composition of internal and external communication competences.

Communication strategy was defined as "an integrated planning framework that aligns objectives, target audiences, messaging, channels, and resource allocation to ensure consistency across touchpoints and enable the optimization of communication approaches to achieve marketing and communication objectives". The questionnaire included items

measured using a five-point Likert scale, complemented by dichotomous and multiple-choice questions. Descriptive statistics were employed to summarize the data, and ANOVA was conducted to identify significant differences among groups. Data were collected through an email survey administered in November 2025-Januyary 2026 to a panel of firms provided by Sigma Consulting, a consulting firm based in Pesaro (Italy). The final sample includes 151 respondents holding communication-related roles in manufacturing SMEs.

Results and discussion. *The sample of 151 SMEs is heterogeneous, including both small and medium-sized firms, and is broadly representative of Italian manufacturing SMEs in terms of sectoral distribution and geographic origin.*

Table 1. Sample characteristics

Variable	Description	Group 1 (%)	Group 2 (%)	Group 3 (%)	Sample (%)
Size	Small (10-49)	40,4	36,7	48,6	41,1
	Medium (50-249)	59,6	63,3	51,4	58,9
Sector	Furniture, wood and wood products	10,4	10,2	8,6	9,9
	Food and beverages	25,4	30,6	34,3	29,1
	Paper, printing and graphics	4,5	8,2	5,7	6
	Textiles, apparel, footwear and accessories	7,5	12,2	20	11,9
	Home appliances and electronics	16,4	6,1	5,7	10,6
	Chemicals and pharmaceuticals	11,9	16,3	14,3	13,9
	Motor vehicles and transport equipment	10,4	8,2	0	7,3
	Other	13,5	8,2	11,4	11,3
Provenance	Northern Italy	56,7	51	40	51
	Central Italy	26,9	28,6	14,3	24,5
	Southern Italy and Islands	16,4	20,4	45,7	24,5
Revenue (€)	≤ €2 million	20,9	26,5	31,4	25,2
	€2 - 5 million	22,4	14,3	22,9	19,9
	€5 - 10 million	26,9	20,4	25,7	24,5
	> €10 million	29,9	38,8	20	30,5
Revenue trend	Growing	56,7	51	26	47,7
	Stable	32,8	24,5	60	36,4
	Declining	10,5	24,5	14	15,9

To address the first research question, the results indicate (Table 2) that the intensity of AI adoption in marketing communication among the sampled SMEs, measured on a 1–5 Likert scale, remains relatively low. Specifically, respondents report that approximately 56% of firms do not use AI or use it only to a very limited extent, 29.14% report a moderate level of adoption, and only 14.57% indicate a high level of use (i.e., "much" or "very much").

Table 2. AI intensity adoption in marketing communication of SMEs

AI adoption level	Frequency (n)	Percentage (%)
Not at all	56	37.09%
A little	29	19.21%
Moderately	44	29.14%
Much	19	12.58%
Very much	3	1.99%
Total	151	100%

Furthermore, the typologies of AI adoption presented below (Table 3) indicate that AI is primarily used for content creation and data analysis. A substantial proportion of AI use is also dedicated to data personalization. Other activities (n = 3) mainly relate to translation tasks.

Table 3. Key uses of AI in marketing communication

AI uses	Yes (n)	Yes (%)	No (n)	No (%)
Content creation	47	49.47%	48	50.53%
Data analysis	45	47.37%	50	52.63%
Data personalization	32	33.68%	63	66.32%
Other	3	0.00%	92	96.84%
Total	95	100%	95	100%

To address RQ2, the study first shows that the majority SMEs in the sample (55.6%) either do not adopt a communication strategy or only implement it partially (Table 4). It then demonstrates that firms with a formal

communication strategy (Group 1) exhibit a statistically significant higher level of AI adoption intensity compared to those that adopt it partially or not at all (Table 5).

Table 4. Adoption of Communication Strategies among SMEs

Group	Adoption level	N	%
Group 1	Fully adopted	67	44.4
Group 2	Partially adopted	49	32.5
Group 3	Not adopted	35	23.1
Total		151	100.0

Although the overall level of AI use in communication remains relatively moderate on a 1–5 Likert scale, firms adopting a communication strategy (Group 1) reports a significantly higher intensity of AI use (mean = 2.552) compared with Groups 2 and 3 (Table 4).
Furthermore, Group 1 reports a significantly higher perception of strategic positioning (mean = 3.627) compared with the other two groups.

Table 5. Strategic positioning and AI use intensity in marketing communication

	Mean			Dev. St.			ANOVA			
	Group 1	Group 2	Group 3	Group 1	Group 2	Group 3	SumSq	MeanSq	F	p_value
AI use intensity	2,552	2,204	1,657	1,197	1,040	0,938	18,475	9,238	7,750	0,001
Clearly defined strategic positioning	3,627	3,265	2,371	0,982	0,908	0,877	36,394	18,197	20,814	0,000

Finally, to address RQ3, firms characterized by the adoption or not of a communication strategy - and higher versus levels of AI use - tend to rely more on externally managed communication resources (29.9%) and exhibit a stronger preference for hybrid configurations (37.3%) compared to the other groups.

Table 6. Relationship between AI intensity adoption and communication marketing professionals

	Group 1		Group 2		Group 3		Total sample	
BUDGET (% ON REVENUE)								
<1%	7	10,4%	13	26,5%	16	45,7%	36	23,8%
1%-5%	25	37,3%	24	49,0%	10	28,6%	59	39,1%
5%-10%	24	35,8%	9	18,4%	9	25,7%	42	27,8%
>10%	11	16,4%	3	6,1%	0	0,0%	14	9,3%
MEASUREMENT OF MARKETING COMMUNICATION PERFORMANCE								
Yes	47	70,1%	23	46,9%	3	8,6%	73	48,3%
No	20	29,9%	26	53,1%	32	91,4%	78	51,7%
MARKETING COMMUNICATION SKILLS								
In-House	22	32,8%	30	61,2%	28	80,0%	80	17,7%
Externally managed	20	29,9%	8	16,3%	3	8,6%	31	6,8%
A mixed approach	25	37,3%	11	22,4%	4	11,4%	40	8,8%
							151	

The results reported in Table 6 highlight systematic differences across groups of SMEs distinguished by their level of AI adoption in marketing communication. Firms characterized by higher levels of AI adoption (Group 1) report a greater intensity of investment in marketing communication. Specifically, 16.4% of firms in Group 1 allocate more than 10% of their revenues to marketing communication, compared with 6.1% in Group 2, while no firms in Group 3 report such levels of investment. Similarly, the adoption of communication performance measurement practices is more prevalent among firms with higher levels of AI adoption (70.1% in Group 1), compared with firms in Group 2 (46.9%) and Group 3 (8.6%).

More broadly, the findings of this exploratory study provide initial insights into what characterize SMEs with different level of adoption of AI in marketing communication.

Regarding RQ1 the results suggest that its use among SMEs remains relatively limited. AI is predominantly employed in specific key uses, particularly content creation and data analysis, indicating that it is mainly used to support operational tasks rather than being fully integrated across communication processes and strategy. This pattern is consistent with prior research suggesting that firms initially deploy AI to support efficiency-enhancing and task-specific applications before moving toward more strategic integration (Davenport et al., 2020). In this sense, AI in SMEs still appears to function more as an augmentative tool rather than as a fully embedded component of marketing communication strategy. The results suggest that AI is primarily used for content creation and data analysis and prediction, while its application in data visualization appears to be less prevalent. These uses are consistent with the key benefits of AI in marketing communication, particularly in terms of automation, personalization, and data-driven decision-making (Davenport et al., 2020; Huang & Rust, 2021; Casado-Aranda et al., 2023). In particular, content creation is closely associated with the automation of marketing activities and the personalization of communication, while data analysis and prediction support more informed decision-making processes (Gupta et al., 2020; Davenport et al., 2020). By contrast, the lower adoption of AI for data visualization may reflect a more limited use of AI to enhance the presentation and communication of insights, with firms prioritizing applications that more directly support operational and strategic marketing activities.

With respect to RQ2, the findings indicate that firms with a communication strategy exhibit significantly higher levels of AI adoption intensity compared to those that adopt it partially or not at all. This result supports the view that organizational readiness plays a crucial role in enabling AI adoption in marketing communication (Amin et al., 2025). In particular, the presence of structured strategic and organizational elements - such as clearly defined objectives, target audiences, and communication processes - appears to facilitate a more intensive use of AI.

This evidence is consistent with prior research suggesting that the effectiveness of AI depends on the quality of input data and the clarity of strategic orientation (Davenport et al., 2020; Ramos, 2023), as well as on the alignment between AI applications and key communication elements such as brand voice and audience definition (Kirkby et al., 2023; Brüns & Meißner, 2024). More broadly, it confirms that firms with more developed marketing communication strategies - understood as integrated and structured planning frameworks (Kotler & Keller, 2016; Porcu et al., 2019)- are better positioned to integrate AI into their communication activities.

Overall, the results suggest that the presence of organizational and strategic structures not only supports but may also enhance the intensity - and potentially the effectiveness - of AI adoption in marketing communication.

From this perspective, the findings suggest that AI does not substitute strategic marketing thinking but rather amplifies its importance. Firms with clearer communication strategies - articulating targets, messages, and positioning - appear better equipped to leverage AI tools more intensively. This is consistent with the Integrated Marketing Communications (IMC) view, which emphasizes the importance of alignment and coherence across communication elements (Kotler & Keller, 2016; Porcu et al., 2019). In the absence of such clarity, the potential of AI may remain underexploited or lead to inconsistent communication outputs.

Turning to RQ3, the results indicate that differences in AI adoption levels - closely associated with the presence of a communication strategy - are linked to distinct patterns in communication investment, performance measurement practices, and resource configuration. Firms with higher levels of AI adoption invest more in marketing communication, are more likely to adopt formal measurement practices, and rely on a more balanced mix of internal and external resources. These findings extend prior research by showing that, beyond commonly examined elements such as target audience definition and brand voice, other components of marketing communication strategy - such as budget allocation and performance measurement systems - also support AI adoption in marketing communication. This is consistent with the integrated marketing communications (IMC) perspective, which emphasizes the alignment between strategic elements, resource allocation, and performance monitoring (Kotler & Keller, 2016; Porcu et al., 2019).

These findings also align with the resource-based view and dynamic capabilities perspective, which stress that the value of technological resources depends on their combination with complementary organizational capabilities (Barney, 1991; Teece et al., 1997). Higher levels of investment and the adoption of performance measurement practices can thus be interpreted as manifestations of organizational readiness (Amin et al., 2025), enabling a more effective integration of AI into communication activities.

Moreover, the prevalence of hybrid configurations - combining internal strategic competences with external expertise - supports prior research suggesting that AI adoption often requires access to specialized capabilities not fully available in-house (Huang & Rust, 2021; Verhoef et al., 2021), while internal resources remain essential to ensure strategic alignment and brand coherence (Moorman & Day, 2016; Morgan et al., 2018). This balance is particularly challenging for SMEs, where resource constraints may limit both the development of internal capabilities and the effective use of

external expertise, making the achievement of an optimal configuration more difficult.
Overall, AI adoption in marketing communication appears embedded in broader strategic and organizational readiness.

While the results indicate systematic associations, they do not imply causality. Rather, firms with stronger strategic structuring and more developed organizational configurations tend to exhibit higher levels of AI adoption.
At the same time, the limited diffusion of AI among SMEs highlights persistent barriers, including resource constraints, lack of specialized competences, and insufficient strategic formalization. Despite its recognized potential (Kumar et al., 2019; Haleem et al., 2022), AI adoption in marketing communication remains uneven and contingent on firm-specific conditions.

Research limitations. *This study should be interpreted in light of the limitations typical of exploratory research. In particular, the analysis relies on a relatively small sample and primarily descriptive statistics, thus providing an initial empirical exploration rather than definitive conclusions.*

Nevertheless, the study offers valuable and original insights into AI adoption in marketing communication and raises relevant questions for future research. By highlighting the relationship between AI adoption and organizational readiness - specifically the presence of a communication strategy and the configuration of communication competences - the findings open promising avenues for further investigation.

Managerial implications. *The findings offer several implications for managers seeking to adopt AI in marketing communication. First, effective AI adoption requires not only technological skills but also strong marketing communication competences. While AI tools can personalize customer experience, improve decision-making, and streamline operations, their value depends on firms' ability to define clear objectives, understand target audiences, and ensure coherent communication processes.*

Second, the presence of a communication strategy emerges as a key enabling condition for AI adoption. Firms with a well-defined strategic positioning and structured communication processes appear better able to leverage AI across a broader range of activities, particularly in content creation and data-driven decision-making. In this sense, AI should not be viewed merely as a tool for automating operational tasks, but as a resource that can support and reshape communication strategies.

Third, SMEs need to carefully manage the configuration of competences supporting AI adoption. The results suggest that combining internal communication capabilities with external expertise - such as consultants or specialized agencies - facilitates the integration of AI into communication activities. In addition, collaborations with universities and research centers can help firms access advanced knowledge, develop new capabilities, and accelerate AI implementation.

Overall, managers should approach AI adoption as a strategic capability-building process that combines technological knowledge, communication expertise, and organizational learning.

Originality of the paper. *This paper contributes to the emerging literature on the challenges firms face in adopting AI in marketing communication- particularly in terms of organizational readiness - by providing early empirical evidence on how SMEs integrate AI into their communication activities. Although based on a relatively small sample and primarily descriptive statistics, the study offers exploratory insights that can inform and guide the development of more robust future research, both quantitative and qualitative, on the strategic adoption of AI in marketing communication. The originality of the study lies in linking AI adoption not only to technological capabilities but also to strategic communication variables, such as the presence of a communication strategy, a clear strategic positioning, and the use of balanced mix of internal and external expertise in marketing communication activities. Therefore, the research highlights the importance of a strategic approach to marketing communication as a key organizational readiness factor enabling the effective use of AI tools.*

Furthermore, the study opens several avenues for future research. In particular, further studies could investigate how communication strategy influences the scope and intensity of AI adoption in marketing communication and how firms combine internal capabilities and external expertise to support AI-driven communication practices. Future research could also employ larger samples and more advanced quantitative methods to better understand the relationship between strategic communication variables and the effective integration of AI into marketing communication activities. In addition, in-depth case studies are needed to explore how organizational readiness evolves alongside AI adoption over time, providing a deeper understanding of the underlying mechanisms and development processes.

To Err Is Human… and Authentic? Typos and Message Authenticity in the Age of Artificial Intelligence

CHIARA MARINELLI[1], MARCO BALZANO[2], GUIDO BORTOLUZZI[3]

Abstract. *Minor linguistic imperfections are generally considered detrimental to communication effectiveness. However, in a context where AI-generated texts are increasingly widespread and characterized by near-perfect linguistic accuracy, small typos may acquire new interpretative meanings.*

Drawing on signaling theory and cue utilization perspectives, this study intends to examine how the presence of typos influences perceived message authenticity and how this relationship is a) contingent on the formality of the communication and b) shaped by individuals' familiarity with AI-generated content. Because formal communication establishes stronger expectations of linguistic correctness, the authenticity-enhancing effect of typos may weaken when a message adopts a formal tone. At the same time, individuals who frequently interact with AI systems are exposed to highly polished and flawless texts, which may be perceived as algorithmic rather than human. In this context, typos may contribute to higher perceptions of authenticity.

A 2×2 experimental design manipulating message formality and the presence of typos is intended to be employed in order to test the proposed hypotheses. The results of this study could potentially contribute to research on consumer behavior in digital communication contexts by showing that small linguistic cues can influence perceptions of message authenticity. More broadly, it can add a new layer in understanding how the diffusion of AI technologies may reshape the meaning of traditional signals of quality and authenticity in written communication.

Keywords: *AI; communication formality; linguistic typos; perceived authenticity; signaling theory*

Framing of the research. *In digital communication environments, individuals increasingly rely on linguistic cues to evaluate the credibility, authenticity, and reliability of messages (Cox et al. 2017; Kakaria et al. 2023). Because online interactions often lack contextual and interpersonal signals, recipients frequently use surface-level characteristics of communication to infer the quality and authenticity of information they encounter (Berger and Packard 2016). Linguistic elements such as grammar, spelling, and style therefore become important signals shaping message evaluation (Packard and Berger 2024).*

Prior research in communication and marketing has shown that textual accuracy often functions as a heuristic cue, signaling competence and professionalism of the source (Connelly et al. 2011; 2025). Linguistic errors, such as spelling mistakes or typographical errors, can introduce disfluency and signal a lack of credibility or attention to detail (Marinelli et al. 2025), which risks undermining perceived authenticity. As a result, recipients may interpret such small typos as indicators of lower informational quality, thereby reducing positive evaluations of the message.

However, the interpretation of linguistic cues does not occur in a vacuum. The meaning attributed to linguistic elements depends on contextual expectations and communication norms. In particular, the communication register, in terms of more or less formal content, plays an important role in shaping these expectations (Berger and Packard 2023; Kakaria et al. 2023). Formal messages typically convey professionalism, institutional authority, and precision, both online and offline (Yadav 2025). Consequently, audiences expect higher levels of linguistic correctness in formal communication. When errors occur in such contexts, they may represent stronger violations of normative expectations compared to similar errors in informal communication settings.

At the same time, the contemporary marketing communication landscape is undergoing a profound transformation due to the rapid diffusion of AI technologies capable of generating human-like text (Davenport et al. 2019; Desveaud and Pavone 2026). AI-generated communication is typically characterized by high levels of linguistic accuracy, stylistic coherence, and higher levels of grammatical correctness than human-generated text (Illia et al. 2022). While these characteristics often enhance efficiency and clarity, they may also introduce new interpretative dynamics in how audiences evaluate textual content (Zhu and Molnar 2026).

In particular, perfectly polished language may be perceived as a signal of algorithmic generation rather than human authorship. On the web, consumers are used to language mistakes such as typos, for example in online reviews, and may thus perceive perfectly correct language as a byproduct of AI (Cox et al. 2017). As individuals become increasingly familiar with AI, they may more easily detect AI-generated content (Moravec et al. 2024) and start associating error-free language with algorithm-generated communication. In this context, minor imperfections such as typographical errors may paradoxically function as cues of human involvement, spontaneity, or authenticity.

Understanding how audiences interpret small linguistic imperfections as typos in this evolving technological environment represents an important area for research. While previous studies have primarily treated linguistic errors

[2] Research Fellow in Management – DEAMS, University of Trieste, Italy, e-mail: marco.balzano@units.it
[3] Full Professor in Management – DEAMS, University of Trieste, Italy, e-mail: guido.bortoluzzi@deams.units.it

as uniformly negative signals, the rise of AI-mediated communication suggests that their meaning may become more nuanced.

Thus, this study intends to examine how the presence of typographical typos influences perceived message authenticity, and how this relationship is shaped by the register of the message (formal/informal) and individuals' familiarity with AI-generated content. Specifically, in this study we refer to linguistic imperfections as the presence of small typos in communicated information, whose effects may extend beyond basic communication processing.

Purpose of the paper. *The purpose of this ongoing study is to investigate whether and how minor linguistic typos can influence the evaluation of digital messages and how emerging AI-based tools can reshape the meaning of traditional linguistic signals. In particular, this work-in-progress research focuses on the role of typographical errors in shaping perceived message authenticity. Therefore, the study tries to answer the following research questions: does the presence of linguistic typos shape the perceived authenticity of digital messages? Do language formality and people's familiarity with AI technologies moderate this relationship?*

From a signaling perspective, linguistic accuracy is traditionally interpreted as an indicator of competence, professionalism, and careful message construction (Wells et al. 2011). Accordingly, error-free language signaled intentionality and quality control, whereas linguistic imperfections indicated carelessness or lack of effort. As a consequence, textual errors undermined positive evaluations of communication (Cox et al. 2017).

However, we argue that these assumptions may require reconsideration in the age of generative AI. As digitally mediated communication becomes increasingly populated by highly polished and grammatically flawless texts, linguistic perfection may no longer signal only competence. It may also raise the possibility that a message was generated, or at least heavily shaped, by AI rather than written by a human. In this emerging context, minor typographical errors may operate as cues of spontaneity, human presence, and imperfect but genuine authorship. Therefore, although typos have traditionally been viewed as detrimental, in communication environments increasingly shaped by generative AI they may enhance perceived message authenticity by signaling human authorship and reducing the impression of algorithmic generation.

H1: The presence of typos in a message positively affects perceived message authenticity.

Moreover, the impact of linguistic typos may depend on the expectations associated with the communication register (Cox et al. 2017). Formal communication messages typically establish stronger expectations regarding linguistic precision and correctness, due to the higher-level communication register (Flanagin et al., 2020; Yadav 2025). In such settings, errors may represent a more salient violation of expectations and may therefore produce stronger negative evaluations. Conversely, in more informal settings, people would tolerate linguistic imperfections, as communicated information is usually less important and a more easy-going tone is considered acceptable. Therefore, we argue for the following hypothesis:

H2: The positive effect of typos on perceived authenticity is weaker when the message is formal rather than informal.

At the same time, the interpretation of linguistic signals may be influenced by individuals' familiarity with AI technologies (Moravec et al. 2024). AI-generated texts are typically characterized by high levels of grammatical accuracy and stylistic consistency, which often appears of superior quality to human-generated text, especially at the eye of non-experts (Illia et al. 2022). As individuals become more accustomed to interacting with AI-generated content, they may start associating perfectly polished language with machine-generated communication rather than human authorship.

In this context, minor linguistic typos may function as cues of spontaneity and human involvement. Consequently, individuals who are more used to interacting with AI tools may be less likely to interpret typographical errors as negative signals, rather perceiving them as signals of authentic human communication. Thus, we argue for our third hypothesis:

H3: The relationship between typos and perceived authenticity is moderated by individual frequency of AI use, such that the positive effect of typos becomes stronger as the frequency of AI use increases.

Methodology. *To test the proposed hypotheses, the study adopts a mixed-methods design.*

In a first phase, a quasi-experimental design will be employed. Combining experiments and survey studies is an advantageous approach (Lavrakas et al. 2019) and particularly appropriate for examining relationships between communication cues and message evaluations, as they allow researchers to isolate the effects of specific textual features.

The research employs a 2 × 2 experimental design manipulating two aspects: presence of typographical errors (typos vs. no typos) and message formality (formal vs. informal communication register).

Participants are assigned to one of two online questionnaires. Surveys are anonymized and a full informative is available at the beginning on respondents' rights. In one questionnaire, participants evaluate two informal messages that vary in the presence or absence of typographical errors. In the second questionnaire, participants evaluate two formal messages with the same textual manipulation (presence and absence of typos). This structure allows the study to compare the impact of linguistic errors across different communication registers while maintaining consistent message content.

The experimental stimuli consist of short written texts designed to resemble realistic digital communication scenarios. Across conditions, the informational content remains constant, while the communication register and the presence of typographical errors vary systematically. After reading the text, respondents were asked a set of questions replicated for

each of the two scenarios on their perceptions of the message. The last part of the survey contained questions pertaining to individual-level information, such as demographics and habits pertaining to technological and AI-based usage.

The independent variable is the presence of typographical errors, whereby 1 indicates the presence and 0 the absence of typos. Perceived message authenticity represents the main dependent variable. It is measured using a multi-item 7-point Likert scale from Chiu et al. (2012), capturing the extent to which the message appears authentic, believable, and realistic. Two moderators are included in the design: message formality and frequency of AI use. The latter is measured as an individual-level variable capturing how often respondents interact with AI-based tools in their activities. This variable will be included as a second moderator in order to examine whether technological familiarity influences how linguistic imperfections are interpreted.

Additional control variables, including demographic characteristics of the respondents and their general digital experience are collected in the very last part of the survey to account for potential confounding factors.

To test the hypotheses, the data will be analyzed using logistic regression models examining both the direct and interaction effects of the independent variables. Logistic regression allows the study to estimate the probability that a message is evaluated as authentic as a function of the presence of typographical errors, message formality, and individual frequency of AI use. Interaction terms will be included to assess both the moderating role of message formality and the one of AI usage frequency.

The quantitative study will be followed by a qualitative stage based on semi-structured interviews. The interview structure aims at deepening people's perceptions of linguistic typos, how these may affect their information processing and their expectations according to the (in)formality if the message. Moreover, we will interview frequent users of AI-based tools to understand whether frequent users of AI-based tools evaluate the authenticity of messages containing typos differently from other individuals. Interviews will be recorded and transcribed following the procedure by Riessman (2008), with participants' consent, then undergo manual thematic coding to ensure proper collection, interpretation and presentation of the interviews content.

Results. *Since the research is currently ongoing, this section outlines the analytical approach and the expected patterns based on the theorized relationships. First, the analysis will examine the direct effect of typographical errors on perceived message authenticity. In line with the theoretical arguments presented earlier, it is expected that messages containing typographical errors will be perceived as more authentic than error-free messages, consistent with H1.*

Second, the analysis will test the interaction between typographical errors and message formality. Because formal communication contexts establish stronger expectations of linguistic correctness, the authenticity-enhancing effect of typos is expected to weaken when the message adopts a formal tone. Evidence of this moderation would provide support for H2.

Finally, the study will examine the moderating role of frequency of AI use. Individuals who frequently interact with AI-generated content may more readily associate perfectly polished language with machine-generated communication. In this context, typographical errors may be more strongly interpreted as cues of human authorship. Therefore, the positive effect of typos on perceived authenticity is expected to become stronger as the frequency of AI use increases, consistent with H3.

Research limitations. *This study presents several limitations that should be acknowledged.*

First, the study relies on an experimental design using controlled textual stimuli. While this approach allows for strong internal validity and enables the isolation of specific linguistic cues, it may not fully capture the complexity of real-world communication environments. In practice, digital communication often involves multiple simultaneous cues—such as visual elements, contextual information, and source characteristics—that may interact with linguistic signals in shaping message evaluation.

Second, the experiment focuses on short written messages presented within an online survey context. Although this design allows for controlled comparisons across conditions, it may not fully reflect how individuals encounter and process messages in everyday digital environments. Future research could examine similar effects in more naturalistic settings, such as social media interactions, email communication, online reviews, or marketing messages.

Third, the study investigates a limited set of linguistic cues, specifically typographical errors. While this choice allows for a clear and focused manipulation, other forms of linguistic variation—such as stylistic tone, punctuation, grammatical complexity, or conversational style—may also influence how audiences evaluate message authenticity. Future studies could therefore explore a broader range of linguistic features that may signal either human authorship or automated communication.

Fourth, the moderating role of AI familiarity is captured through self-reported frequency of AI use. Although this measure provides a useful proxy for individuals' exposure to AI-generated content, it may not fully capture the complexity of individuals' interactions with AI technologies. Future research could employ more refined measures of technological familiarity, such as objective indicators of AI usage, technological literacy, or attitudes toward AI-generated communication.

Fifth, the empirical setting of the study may limit the generalizability of the findings. The data are collected within a specific geographical context, and cultural differences may influence how linguistic imperfections are interpreted in communication. Norms regarding linguistic accuracy, formality, and communication style may vary across countries and

languages. Future research could therefore replicate the study in different cultural and linguistic settings in order to assess the cross-cultural robustness of the findings.

Finally, the sample used in this study is not randomly drawn from the general population. As is common in experimental research conducted through online surveys, participants are recruited through convenience sampling procedures. Although this approach is suitable for testing causal relationships in experimental settings, it may limit the external validity of the results. Future research could replicate the study using more diverse and representative samples in order to strengthen the generalizability of the findings.

Managerial implications. *The findings of this study may have important implications for organizations, marketers, and communication professionals operating in increasingly AI-mediated environments. As digital communication becomes more automated and AI-generated content becomes widespread, the interpretation of linguistic cues may evolve in ways that challenge traditional assumptions about communication quality.*

Traditionally, organizations have emphasized linguistic perfection and grammatical accuracy as key indicators of professionalism, competence, and credibility. Error-free language has long been considered a hallmark of high-quality communication and a signal of careful message construction. However, the widespread adoption of AI-generated communication tools may alter how audiences interpret these signals. Because AI-generated texts are typically characterized by highly polished and grammatically flawless language, audiences may increasingly associate perfect linguistic accuracy with algorithmic generation rather than human authorship.

In this context, the findings suggest that small linguistic imperfections may function as cues of human presence and spontaneity. When used appropriately, minor typographical errors—particularly in informal communication settings—may contribute to perceptions of authenticity by signaling that the message was produced by a human rather than a machine. This does not imply that organizations should intentionally introduce errors into their communication, but rather that they should recognize the growing complexity of linguistic signals in AI-mediated environments.

More broadly, the study highlights the central role of linguistic choices in shaping perceptions of authenticity in digital communication. Language correctness and register are not merely technical aspects of writing but strategic elements that influence how audiences interpret the credibility of a message and its source. For organizations increasingly relying on automated communication systems, such as chatbots, virtual assistants, and AI-generated marketing content, carefully designing the language aspects of these systems becomes essential (Ozuem et al. 2024). The way chatbots interact with users, including their level of formality, fluency, and conversational naturalness, can significantly influence users' perceptions of authenticity and trust.

In addition, the findings suggest that organizations may benefit from considering consumer heterogeneity in their communication strategies. As frequency of use of AI technologies varies widely across individuals, audiences may interpret linguistic cues differently depending on their level of familiarity with AI-generated content. Consumers who frequently interact with AI tools may be more likely to associate perfectly polished language with machine-generated communication and therefore interpret minor imperfections differently than individuals with limited exposure to AI systems. Segmenting audiences based on their familiarity with AI technologies may therefore help organizations design more effective communication strategies and calibrate their digital communication interactions accordingly.

Finally, the study underscores the importance of aligning linguistic elements with communication context (Cox et al. 2017). While minor imperfections may sometimes contribute to perceptions of authenticity in informal interactions, maintaining high linguistic accuracy remains essential in formal communication settings, where errors may strongly undermine professionalism and credibility. Organizations should therefore carefully balance authenticity cues and linguistic correctness depending on the communication context, the medium used, and the characteristics of the target audience.

Originality of the paper. *This study contributes to the literature on digital communication and message evaluation in several ways.*

First, it advances existing research on linguistic cues by examining how minor textual imperfections influence perceptions of authenticity rather than focusing solely on traditional outcomes such as perceived quality, credibility, or price evaluations (Marinelli et al. 2025). While prior research has largely treated linguistic errors as uniformly negative signals, the present study highlights how their interpretation may vary depending on contextual and technological factors.

Second, the study introduces the role of AI familiarity as a key contextual factor shaping the interpretation of linguistic signals. While previous studies have considered general web or social media experience as determinants of communication effectiveness, this research suggests that familiarity with AI-generated content represents an increasingly relevant dimension influencing how audiences interpret linguistic cues (Zhou et al. 2018). In particular, the findings suggest that individuals who frequently interact with AI tools may interpret perfectly polished language differently from individuals with lower exposure to AI-generated communication.

Third, by integrating signaling theory with emerging research on AI-mediated communication, the paper highlights how technological change may transform the meaning of traditional indicators of communication quality. Traditional communication paradigms have typically associated linguistic accuracy and formal precision with higher credibility and authenticity. However, the diffusion of AI-generated texts may partially challenge these assumptions by introducing new interpretative dynamics in which perfectly flawless language may sometimes be perceived as a signal of algorithmic generation rather than human authorship.

Overall, the study provides new insights into how small linguistic details can produce disproportionate effects on message evaluation in contemporary digital environments (Longa 2004). In doing so, it contributes to a better understanding of how authenticity perceptions are shaped in increasingly automated communication ecosystems.

The study also opens several avenues for future research. First, qualitative approaches such as in-depth interviews or focus groups could be employed to further explore how consumers interpret linguistic imperfections in AI-mediated communication and to better understand the cognitive processes underlying authenticity judgments. Such approaches may provide richer insights into how individuals distinguish between human and machine-generated messages.

Second, future research could examine more granular differences in individuals' interactions with AI technologies. Rather than focusing solely on the frequency of AI use, scholars could investigate how different types of AI engagement—such as using generative AI for work, studying, creative tasks, or everyday information search—shape perceptions of authenticity and trust in digital communication.

Third, future studies could explore how trust in AI technologies moderates these effects. As attitudes toward AI vary across individuals (Zhu and Molnar 2026), the relationship between linguistic cues and authenticity perceptions may depend on broader psychological factors such as trust in technology, perceived algorithmic competence, or concerns about automation.

Last, the rapid evolution of digital communication environments suggests that traditional communication paradigms may need to be reconsidered. As AI-generated content becomes increasingly prevalent, the cues that individuals use to infer authenticity, credibility, and human authorship may evolve over time. Understanding how these signals are reinterpreted in online environments therefore represents an important direction for future research.

Agentic AI Readiness in Italian SMEs: System Integration, Business Model Reinvention and the Intention–Capability Gap in the Post-Globalisation Era

LUCA GIRALDI, MARIA CALIGARIS, ROBERTO LEOMBRUNI

Abstract. *In the era of post-globalisation and agentic AI, SME competitiveness increasingly depends not only on adopting digital tools, but on redesigning the managerial, infrastructural and governance conditions that allow intelligent systems to act across organisational boundaries. Despite growing awareness of AI as a strategic imperative, many SMEs fail to translate this awareness into a structured, governed and integrated capability. The gap between declared intent and actual organisational capability, what we term the Intention-Capability Gap (ICG), remains large and poorly understood, yet is critical to navigate as AI transitions toward agentic architectures that demand deep system integration. This paper investigates the structural conditions that explain the ICG in Italian SMEs, using original survey data collected from 124 Piedmontese (Italy) firms in 2025. We focus on three interlocked dimensions: (1) the nature of the AI benefits that firms seek, predominantly operational efficiency, which technically requires deep system integration; (2) the actual level of digital maturity and system integration achieved; and (3) the governance and training configurations that predict readiness. Our main findings are: the primary expected benefit from AI is operational efficiency (cited by 67% of firms), yet only 16% report high system integration and 43% cite poor AI knowledge as their leading barrier. Mean ICG is +13.7 (normalised to [−100, +100]), with 68% of firms aspiring to more AI than their current infrastructure can support. Digital maturity varies significantly by firm size (Kruskal-Wallis $H = 18.89$, $p < .001$), consistent with the resource-based prediction that organisational scale is a structural precondition for digital infrastructure investment (Guangliang et al., 2025). Training intensity is the dominant predictor of both digital maturity and AI strategic awareness in multivariate analysis; firms adopting a mixed governance model display higher maturity and integration in bivariate analysis, though this advantage is largely mediated by size and training once controls are applied. An exploratory model predicting the ICG from structural firm characteristics yields no significant predictors (adj. $R^2 = -0.010$). This result is interpreted with caution, given the measurement limitations inherent in difference scores derived from single-item ordinal variables. However, it is consistent with the hypothesis that the gap reflects firm-specific dynamics, including legacy infrastructure configuration and leadership-level digital awareness, that vary independently of size, sector, and governance type. The paper argues that AI readiness in Italian SMEs is fundamentally a knowledge and capability challenge, not a financial one. Policy implications favour targeted training support and hybrid governance models over generic investment incentives, and point toward the need for firm-level diagnostic assessment of integration readiness alongside standard categorical support mechanisms. The paper contributes to the conference theme by showing that agentic business model reinvention is constrained less by tool availability than by the managerial capacity to integrate systems, develop knowledge micro-foundations and govern hybrid human–AI transformation in fragmented post-globalisation environments.*

Keywords: *Agentic AI; SMEs; system integration; digital governance; business model reinvention; intention–capability gap; post-globalisation.*

1. Framing of the research. Management is undergoing a structural transition. In the era of post-globalisation, firms face fragmented value chains, geopolitical uncertainty and accelerating technological change; at the same time, agentic AI is shifting digital transformation from the adoption of isolated tools to the orchestration of autonomous, adaptive and cross-functional systems. The dominant paradigm of the past years, AI as a collection of discrete, task-specific tools, is giving way to what researchers and practitioners are calling the agentic economy: an emerging productive order in which AI systems operate as autonomous agents capable of orchestrating multi-step workflows, coordinating across organisational subsystems, and adapting their actions in response to environmental feedback (Rothschild et al., 2025; Tan & Huang, 2025; Huang, 2025). In agentic architectures, a model does not merely answer a question; it perceives context, sets sub-goals, invokes tools, and executes sequences of decisions across time (Huang, 2025). Rothschild et al. (2025) develop this concept at the level of market interactions; this paper applies the framework one level inward, arguing that participation in this emerging market order presupposes a prior investment in intra-firm system integration that most SMEs have not yet made.

This transition has a precise organisational prerequisite: system integration. An agentic AI cannot orchestrate processes it cannot access, extract value from data it cannot read, or act across functions without interoperability among the digital systems on which those functions depend. The infrastructure required, integrated data environments, connected process systems, and accessible APIs, is qualitatively different from what sufficed for isolated AI applications, and most firms have not yet built it.

This is particularly relevant in a post-globalisation setting. Italian SMEs are increasingly required to respond to fragmented supply chains, regionalised markets and volatile coordination demands. Agentic AI could support this transition by improving visibility, automation and adaptive decision-making, but only where firms possess the system integration and managerial capabilities required to connect data, processes and decisions. SMEs account for 99.9% of

Italian enterprises, employ approximately 64% of the private-sector workforce, and generate around 66% of national value added (Istat, 2025; European Commission, 2024); micro-enterprises with fewer than ten employees represent nearly 95% of the total firm population (European Commission, 2021). Italy's competitive trajectory in the agentic economy will therefore be determined largely by whether this vast and heterogeneous population can build the organisational prerequisites for AI integration, not merely deploy consumer-grade AI tools.

The evidence to date is sobering. Approximately 70.2% of Italian SMEs have reached a basic level of digital intensity - broadly in line with the EU27 average range of 58–73% - yet AI adoption remains limited to only 8.2% of firms. For high digital intensity, Italian SMEs substantially underperform relative to EU peers: the EU27 average stands at approximately 27%, pointing to a structural polarisation between widespread basic adoption and a thin tail of genuinely advanced digital capability (Eurostat, 2025). Only 17.8% of Italian firms invest in digital training for their staff, 4.5 percentage points below the EU27 mean (European Commission, 2024).

This paper investigates that distance empirically. Drawing on an original survey of 124 Piedmontese SMEs conducted in 2025, we address three research questions.

RQ1: What structural factors predict digital maturity and AI strategic importance in Italian SMEs, and which are genuinely amenable to managerial intervention?

RQ2: What is the empirical distribution of the mismatch between firms' AI ambitions and their digital capacity, and what does it reveal about their readiness for agentic business model reinvention?

RQ3: Do observable structural characteristics, size, sector, governance model, training intensity, and founding era account for meaningful variation in the ICG, or does the gap vary independently of these characteristics in ways that challenge categorical approaches to AI readiness support?

Purpose of the paper. This paper makes three contributions. It proposes a novel quantitative operationalisation of the Intention-Capability Gap (ICG), a signed, normalised measure on a [−100, +100] scale, as a reproducible diagnostic instrument for SME readiness for agentic AI, building on UTAUT-based precedents that document analogous intention-capability gaps under external shocks (Ranatarisza et al., 2025). It identifies the structural predictors of digital maturity and AI strategic importance through multivariate analysis, distinguishing fixed endowments from actionable factors. Moreover, it reports an exploratory null result in M3: no structural variable significantly predicts the ICG, a finding interpreted with caution given the psychometric limitations of difference scores, but consistent with the hypothesis that integration readiness requires firm-level diagnostic assessment alongside categorical policy instruments.

2. Theoretical Background. Research on AI adoption in SMEs has evolved through two broad phases. The first, still dominant in quantitative surveys, focuses on adoption rates and their structural determinants, firm size, resources, and innovation orientation, within the Technology-Organisation-Environment framework (Tornatzky and Fleischer, 1990). These studies consistently document an adoption deficit among SMEs relative to large firms and identify cost, knowledge, and infrastructure as the primary barriers (Dwivedi et al., 2021). The second, emerging phase shifts the question from whether firms adopt AI to how, with what governance, at what level of organisational integration, and with what structural sustainability (Warner and Wäger, 2019; Verhoef et al., 2021). Our paper contributes to this second phase, and specifically to its least-developed dimension: the organisational conditions that determine whether AI ambition can be translated into structured, governed capability.

A central theoretical anchor for this translation is the role of human knowledge assets. Drawing on the knowledge-based view of the firm and dynamic capabilities perspectives, empirical evidence from private SME contexts demonstrates that internally accumulated digital capabilities are the primary determinants of AI adoption, outweighing the effect of external environmental support, institutional incentives, and generic financial instruments (Arroyabe et al., 2024). In Italian SME settings specifically, intellectual capital, encompassing managerial competence, decision-making skills, and technology-related human capital, has been shown to be the dominant determinant of digital maturity, with strategic and proactive management practices mediating the relationship between knowledge endowments and digital outcomes (Tortora et al., 2024). The underlying cognitive mechanism is consistent with the Technology Acceptance Model (Davis et al., 1989): prior knowledge exposure shapes perceived usefulness, which in turn drives adoption behaviour. In private SME contexts, where formal IT functions are typically absent, and technology decisions rest on a small number of individuals, the digital self-efficacy of those individuals, itself a function of accumulated knowledge and prior training exposure, directly shapes both their technology assessments and their adoption trajectories (Malodia et al., 2023). This dynamic differs from technology adoption in public-sector organisations, where institutional mandates, procurement rules, and bureaucratic incentives intervene between individual attitudes and organisational behaviour (Giraldi et al., 2024); in private micro-enterprises, there is no such organisational buffer, and the cognitive capacity of the owner-manager becomes the binding constraint on digital capability development (Dwivedi et al., 2021). Training intensity is not merely a human resource variable; it is the organisational micro-foundation on which digital capability is built.

Agentic economy, system integration and business model reinvention. The agentic economy changes the managerial problem from whether firms adopt AI to whether they can redesign coordination, decision-making and organisational boundaries around intelligent systems (Tan & Huang, 2025; Huang, 2025). For SMEs, this means that business model reinvention depends less on experimenting with standalone tools and more on building the digital architecture through which AI agents can access data, execute workflows and coordinate with internal and external actors in platform-based, servitised and ecosystemic forms of value creation (Chatterjee et al., 2023; Secundo et al., 2025).

System integration represents the specific, high-leverage dimension of digital maturity that the agentic transition makes newly critical. Contemporary AI applications in business operations share a common architectural requirement: access to structured, real-time data flows from multiple operational systems (Davenport and Ronanki, 2018). This is what enterprise-grade integration provides, and what most SMEs lack. From a dynamic capabilities perspective (Teece et al., 1997), the capacity to build and maintain system integration is a sensing and reconfiguring capability, not a one-time investment. Firms that rely entirely on external expertise for digital governance risk failing to develop the absorptive capacity (Cohen and Levinthal, 1990) needed to assimilate and deploy integrated AI systems over time. The governance model, specifically, who owns digital decisions inside the firm and how that ownership is structured, thus shapes integration outcomes not directly, but through its effect on the accumulation of internal knowledge and organisational learning.

3. Methodology. Data were collected through a structured questionnaire administered to Piedmontese firms between September and December 2025, as part of the OICE research cycle. The instrument covers eight thematic modules: firm profile, human capital and training, process-level digitalisation across five functional areas (administration, sales/CRM, logistics, marketing, production/R&D), digital governance, strategic AI perception, barriers to adoption, public support utilisation, and investment priorities. The full instrument is documented in OICE (2026).

The final sample comprises N = 124 firms that completed at least the human capital section[1]. Table 1 summarises the sample profile.

Table 1 - Sample profile (N = 124). Source: OICE survey 2025–2026, authors' elaboration

Variable / Category	n	%
Firm size		
< 10 employees (micro)	52	41.9%
10–49 employees (small)	35	28.2%
50–249 employees (medium)	27	21.8%
≥ 250 employees (large)	10	8.1%
Sector		
Services	103	83.1%
Manufacturing/industry	21	16.9%
Revenue		
< €1 million	56	45.2%
€1–10 million	44	35.5%
> €10 million	24	19.4%
Founding period		
Pre-2000 (legacy)	65	52.4%
2000–2009	29	23.4%
2010+ (recent / digital-native)	30	24.2%

The sample is dominated by micro-enterprises (42%) and service-sector firms (83%), reflecting the composition of the Piedmontese SME population. Sampling was purposive rather than probabilistic, targeting heterogeneous firm profiles across size, sector, and digital maturity. Results are descriptive of this population rather than population estimates with known precision.

3.1 Key variables. *Digital maturity* is operationalised as the unweighted mean of five Likert-scored items (1–5) measuring the self-assessed level of current digitalisation across five functional areas: administration and accounting, sales and customer management, logistics and supply chain, marketing and communication, and production and R&D. The resulting index (maturita_digitale) has a mean = 2.61, SD = 1.05, N = 101.

AI strategic importance (*ai_importanza_n*) is a single five-level item measuring the perceived strategic centrality of digital technologies and AI for the firm's future (mean = 3.22, SD = 1.23, N = 92). Two features of this measure warrant explicit declaration. The item uses verbal anchors only at the extremes of the scale—"Poco importante" (1) and

[1] Response rates vary by module: N = 124 for training; N = 101 for the digitalisation sub-index; N = 94 for governance; N = 92 for strategic AI importance. All reported bases reflect module-specific respondents.

"Estremamente importante" (5)—with three intermediate levels designated by typographic markers without verbal labels. This partial-anchor design is more susceptible to respondent-level idiosyncratic interpretation of intermediate categories than a fully labelled scale. The 32 firms with missing values on this item correspond to non-response on the AI perception module, which was administered as a branching section contingent on prior engagement with digital governance questions; firms that did not complete the governance section were less likely to reach the AI module.

System integration is a three-level ordinal variable (absent/partial/high) capturing the degree of data connectivity across the firm's digital systems. *Training intensity* is a four-level ordinal variable (none/ under evaluation / occasional / structured). *The governance model* distinguishes internal, mixed (internal + external), and purely external management of digital transformation.

The *Intention-Capability Gap* (ICG) is computed as:

$$ICG_i = \frac{A_i - M_i}{4} \times 100$$

where A_i denotes the AI strategic importance score and M_i the digital maturity index of the firm i, both measured on a 1–5 scale. The denominator 4 normalises the difference to the interval [−100, +100], with positive values indicating AI ambition in excess of current digital capacity. A positive ICG indicates that stated AI ambition exceeds current digital capacity; a negative value indicates the reverse. Mean ICG = +13.7 (SD = 30.2, median = +15.0, N = 92). A psychometric limitation of the ICG must be explicitly acknowledged. The difference scores computed from variables with asymmetric reliability are known to be disproportionately dominated by the measurement error of the less reliable component, in this case, the single-item importance score. The reliability of a difference score is a complex function of the reliabilities of both components and their intercorrelation; when one component is a single ordinal item, the resulting difference score carries substantially greater noise than either input. As a consequence, all ICG-based findings must be treated as exploratory and interpreted with commensurate caution.

3.2 Analytical approach. Bivariate analysis uses Kruskal-Wallis tests with Dunn post-hoc corrections (Bonferroni adjustment) for group comparisons on ordinal variables, Spearman rank correlation for bivariate associations, and chi-square with Monte Carlo simulation (B = 9,999) for contingency tables with small expected cell counts, applicable here to the governance × integration cross-tabulation given n = 11 for the external governance group. Multivariate analysis employs a parallel-specification strategy across three models with identical predictor sets: M1 (OLS, outcome = digital maturity), M2 (cumulative link ordinal logistic, outcome = AI strategic importance), and M3 (OLS with HC3 heteroskedasticity-robust standard errors, outcome = ICG). HC3 robust standard errors are used for M1 and M3. The proportional odds assumption in M2 is assessed via nominal_test; no violation is detected (minimum p = 0.075). VIF values are uniformly below 1.5, ruling out multicollinearity. All analyses were conducted in R 4.3.

The multivariate subset is N = 92, reflecting complete cases on all predictor and outcome variables. This reduction from N = 124 is driven primarily by non-response on the governance module, which was administered as a branching section and disproportionately skipped by micro-enterprises: firms with fewer than ten employees represent 41.9% of the full sample but 35.9% of the multivariate subset. This differential attrition constitutes a form of selection that may attenuate the estimated effects of firm size and partially underrepresent the most resource-constrained segment of the population in the multivariate models.

4 Results.

4.1 The Integration Paradox: a barrier to agentic business model reinvention. The most revealing finding in the data is a structural mismatch between the AI outcomes firms seek and the organisational infrastructure they currently possess, a pattern we term the Integration Paradox and develop theoretically in the Discussion. Operational efficiency is the dominant expected benefit, cited by 67% of respondents (N = 92), nearly twice the rate of the second-ranked benefit (greater data and process visibility: 41%). Operational efficiency delivered through AI, workflow automation, predictive analytics, intelligent process monitoring and agentic coordination requires that AI systems can perceive and act on data from across the firm's operational backbone. This is precisely what system integration provides. However, only 16% of sampled firms report high system integration (N = 93); 62% report partial integration, and 22% report its complete absence. Eighty-four per cent of firms therefore lack the integration level that would make their primary AI aspiration technically accessible at the agentic level. The barrier data confirm the organisational nature of this constraint: poor AI knowledge is cited by 43% of respondents as a leading barrier, integration complexity by 39%, and financial cost, often assumed to be the binding constraint, by only 35%, co-ranked with difficulty identifying concrete use cases.

The ICG captures this tension at the firm level (N = 92). Mean ICG is +13.7 (SD = 30.2, median = +15.0). Sixty-eight per cent of firms exhibit a positive ICG: their stated AI ambition exceeds current digital capacity. Twenty-three per cent exhibit a negative ICG, indicating a digital infrastructure that currently outpaces their declared strategic ambitions, a pattern consistent with underutilised capability. However, it may also reflect deliberate strategic restraint or sectoral contexts with lower AI competitive pressure. The remaining 9% are in approximate alignment. The distribution is near-symmetric (skewness ≈ −0.05), confirming that the ICG captures genuine variance in strategic positioning rather than a ceiling or floor artefact.

4.2 Structural predictors: a size threshold, not a gradient. *Digital maturity* varies significantly across firm size categories (Kruskal-Wallis H = 18.89, p < 0.001), consistent with the resource-based prediction that organisational scale is a structural precondition for digital infrastructure investment (Arroyabe et al., 2024; Guangliang et al., 2025). *Training intensity* is the dominant predictor in multivariate analysis: structured training carries a coefficient of +1.64 points on the

1–5 maturity scale relative to firms with no training programme ($p < 0.001$). The direction and approximate magnitude of this estimate are preserved under parsimonious robustness specifications (binary training indicator; model without founding era controls), as declared in Section 3.2. Furthermore, any engagement with training, even occasional, substantially raises both digital maturity and AI strategic awareness relative to no engagement at all, consistent with a threshold rather than a linear effect of training investment.

Post-hoc Dunn analysis reveals that the size effect is not a smooth gradient but a threshold: the significant contrasts are between micro-enterprises (mean = 2.24) and firms with 50 or more employees (50–249: mean = 3.13; ≥250: mean = 3.57). The gap between micro and small firms (10–49: mean = 2.48) is not statistically significant (p.adj = 1.000). **Digital maturity** improves materially only when firms cross approximately 50 employees, the level of organisational complexity at which integrated process management becomes both operationally necessary and economically feasible.

The ICG pattern is non-monotonic across firm size. Micro-enterprises show the lowest mean ICG (+11.0), not because they are well-aligned, but because their AI ambition is also correspondingly low (mean AI strategic importance: 2.79). Small and medium firms show the highest ICG (+16.9 and +16.4, respectively), reflecting AI aspirations that outpace current capability. Large firms (≥250 employees) show a near-alignment mean of +2.5. The interpretation that larger firms have progressively brought capacity into line with intent is theoretically plausible and consistent with the resource-based view, but cannot be confirmed from this cell size.

4.3 Governance, training, and the mediation structure. Bivariate analysis shows that the governance model is associated with digital maturity: mixed-governance firms report a mean maturity of 2.95, compared to 2.48 for internally governed firms and 2.30 for externally governed firms (Kruskal-Wallis H = 7.52, p = 0.023). Mixed-governance firms also show substantially higher system integration: 23% report high integration, compared to 13% for internal-only firms and 0% for purely external governance. The purely external configuration is particularly revealing: no firm relying entirely on outside providers reports high integration, consistent with the absorptive capacity argument that deep integration requires internal cognitive engagement that cannot be outsourced (Cohen and Levinthal, 1990).

Table 2 presents the parallel-specification results for M1 and M2.

Table 2 — Multivariate results: M1 (digital maturity, OLS) and M2 (AI strategic importance, ordinal logistic). N = 92. M1 reports unstandardised β with HC3 robust SE; M2 reports log-odds ratios with profile SE

Predictor [ref. category]	M1: β	(SE HC3)	M2: log-OR	(SE)
Firm size [ref. <10 employees]				
10–49 employees	0.082	(0.240)	0.471	(0.517)
50–249 employees	0.628*	(0.254)	1.410*	(0.559)
≥ 250 employees	0.650*	(0.275)	0.550	(0.801)
Sector [ref. Services]				
Manufacturing	0.050	(0.290)	−0.306	(0.562)

Founding era [ref. Pre-2000]				
2000–2009	0.112	(0.243)	0.234	(0.515)
2010+	0.250	(0.217)	−0.648	(0.553)
N	**92**		**92**	

*Source: Author's elaboration. Reference: <10 employees, Services, No training, Internal governance, Pre-2000. † p<.10; * p<.05; ** p<.01; *** p<.001. R^2 / Nagelkerke R^2 0.477/0.275. Adj. R^2 for M1 0.405*

The multivariate results in Table 2 clarify the structure underlying these bivariate associations. Once training intensity and firm size are controlled, the mixed-governance coefficient collapses to near-zero in M1 ($\beta = 0.059$, SE = 0.228, $p = 0.798$). The governance advantage observed bivariately is real but mediated: medium-sized firms are disproportionately likely to adopt mixed governance (72% of 50–249 employee firms versus 32% of micro-enterprises), and training intensity covaries strongly with size. The bivariate governance advantage largely reflects these underlying structural confounds rather than an independent governance effect.

Training intensity emerges as the dominant independent predictor across both M1 and M2, a finding whose stability under parsimonious robustness specifications is documented in Section 3.2. In M1, structured training carries a coefficient of 1.641 (SE = 0.250, $p < 0.001$), representing a difference of approximately 1.7 points on the five-point maturity scale, or roughly 41% of the full scale range, relative to firms with no training programme. In M2, the cumulative proportional odds ratio for occasional training is 7.84 (log-OR = 2.059, $p = 0.001$), and for structured training, 7.66 (log-OR = 2.035, $p = 0.002$), indicating that trained firms are approximately eight times more likely to report a higher level of AI strategic importance than untrained firms, holding all other predictors constant. Post-hoc Dunn analysis reveals a structural discontinuity: the significant contrast is between firms with no training and all firms with any training, regardless of intensity. Firms with occasional and structured programmes do not differ significantly from each other (p.adj = 1.000). The first step, even an ad hoc engagement with digital training, produces the largest marginal return. This threshold pattern is theoretically consistent with the digital self-efficacy mechanism identified in private SME contexts (Malodia et al., 2023): the cognitive barrier to engaging with digital technologies is highest before any training exposure, and the marginal return to subsequent investment diminishes once that initial barrier has been crossed.

4.4 The diagnostic value of M3. M3 yields $R^2 = 0.112$ and adj. $R^2 = -0.010$; no predictor reaches significance. As established in Section 3.1, the ICG is a difference score constructed from variables with asymmetric reliability, making it disproportionately susceptible to measurement noise. The adj. R^2 of −0.010 is consistent with this, and the absence of significant predictors should be read as exploratory and inconclusive rather than as confirmed evidence of no structural effect.

Two features of the output nonetheless merit attention. First, the directional pattern is theoretically coherent: all variables associated with higher maturity in M1, structured training ($\beta = -10.327$), mixed governance ($\beta = -10.062$), and digital-native founding era ($\beta = -13.751$), carry negative coefficients in M3, suggesting a tendency to reduce the gap; intermediate size categories carry positive coefficients. Uniform directional consistency of this kind is not expected under pure noise, and suggests the model may be underpowered rather than genuinely uninformative. Second, no predictor approaches even marginal significance (minimum $p \approx 0.12$), consistent with the hypothesis that the ICG reflects firm-specific dynamics, legacy infrastructure, leadership-level digital awareness, not captured by categorical structural variables. This is presented as an exploratory prompt for future research; policy implications follow in the Discussion.

5. Discussion

5.1 Theoretical interpretation. The findings support a reframing of the AI adoption challenge as a management transformation problem. In line with the conference theme, the results show that readiness for the agentic economy is not reducible to technological adoption; it depends on the reconfiguration of managerial knowledge, governance arrangements and system integration capabilities. First, the Integration Paradox documents a previously unnamed form of adoption barrier that is distinct from both financial constraints and strategic inertia. Firms in our sample are not resistant to AI, they actively desire it, with a mean AI strategic importance of 3.22 on a five-point scale and 68% exhibiting positive ICG. Their aspirational trajectory is blocked not by unwillingness but by infrastructural insufficiency: the most desired AI application category is also the most organisationally demanding. This extends Cohen and Levinthal's (1990) absorptive capacity framework to the specific architectural requirements of agentic AI; firms cannot realise value from systems they cannot integrate. The Integration Paradox is therefore the paper's central theoretical contribution to the conference theme. It shows that, in the post-globalisation and agentic economy, business model reinvention is not blocked primarily by the absence of AI tools, but by the absence of the organisational architecture that allows intelligent systems to act across processes, functions and boundaries. Fragmented value chains and volatile coordination demands increase the strategic value of agentic AI. However, these benefits become actionable only when firms possess integrated data flows, interoperable processes and governance routines capable of connecting human and algorithmic decision-making. The connection to Rothschild et al. (2025), Tan and Huang (2025), and Huang (2025) is therefore not only technological but managerial: while these contributions frame the agentic economy mainly at the level of market interactions and AI-agent architectures, the present paper translates that framework inside the firm, showing that SME participation in the agentic economy depends on system integration as a precondition for business model reinvention. This translation from an external market-interaction theory to an internal operational theory is an original theoretical bridge: it implies that participation in the agentic economy is gated not only by strategic intent, but by the underlying infrastructure of intra-firm data connectivity.

Second, the training threshold finding contributes to the dynamic capabilities literature (Teece et al., 1997; Warner and Wäger, 2019) by identifying the knowledge micro-foundation of digital capability in SMEs. Dynamic capabilities are typically conceptualised at the organisational level; our data suggest that in the SME context, where formal IT functions

are absent and technology decisions rest on a small number of individuals, the binding constraint is the knowledge and cognitive capacity of those individuals. Empirical evidence from private SME contexts consistently confirms this mechanism: digital self-efficacy, the accumulated technological knowledge of the owner-manager, directly shapes both technology assessments and adoption trajectories, with professionally led SMEs significantly outperforming on digital transformation outcomes (Malodia et al., 2023). In Italian SME settings specifically, intellectual capital and human capital endowments have been shown to be the dominant determinants of digital maturity, with knowledge-based management practices mediating the relationship between individual competence and organisational digital outcomes (Tortora et al., 2024). This dynamic differs from technology adoption in public-sector organisations, where institutional mandates and bureaucratic incentives intervene between individual attitudes and organisational behaviour (Giraldi et al., 2024); in private micro-enterprises, there is no such organisational buffer. Our finding adds a structural discontinuity to this theoretical picture: it is the transition from no training to any training that matters most, not the subsequent intensity of investment. This lowers the barrier for action for resource-constrained micro-enterprises and implies that the marginal return to a first, modest training initiative is substantially larger than the marginal return to scaling up an existing programme.

Third, the governance mediation finding clarifies a frequently cited but under-specified relationship in the SME digitalisation literature. Mixed governance is positively associated with digital maturity and system integration in bivariate analysis, a result consistent with theoretical predictions about hybrid knowledge structures (Cohen and Levinthal, 1990). However, this advantage disappears in multivariate models once size and training are controlled. The implication is that the governance model is not an independent lever: its effect is contingent on the organisational knowledge base it operates on. Firms that build internal knowledge through training and cross the organisational complexity threshold associated with medium size naturally tend toward mixed governance, not the other way around. Governance follows capability; it does not precede it.

Finally, the exploratory null result in M3, whose directional coherence and psychometric limitations are documented in Section 4.4, is consistent with the hypothesis that the ICG reflects strategic and cognitive dynamics varying as a function of firm-specific legacy infrastructure and accumulated digital architecture rather than class-level structural characteristics. This implies that population-level benchmarks and categorical incentive schemes are insufficient guides for AI readiness on their own: what is needed, in addition to broad-based training and financial instruments, is a diagnostic layer that assesses individual firms' integration gaps before prescribing investment pathways.

Research limitations. Four limitations qualify the interpretation of these findings. First, the sample is non-probabilistic, over-represents service-sector and underestimates micro-enterprise firms; generalisations to manufacturing-intensive regions or the broader Italian SME population require caution. Second, the governance variable shows approximately 25% item non-response due to the branching structure of the questionnaire, reducing the multivariate sample to N = 92 and potentially introducing selection bias. Third, digital maturity is self-assessed; social-desirability bias may compress variance and attenuate true associations. The ICG computation further inherits this measurement uncertainty: all ICG-based findings should be treated as exploratory. Fourth, the cross-sectional design precludes causal inference: the training-maturity association is consistent with both a capability-building interpretation and reverse causality.

The study does not directly measure post-globalisation pressures, business model change, ecosystem positioning or organisational well-being. Its contribution is therefore to identify a readiness condition for agentic business model reinvention, rather than to observe reinvention outcomes directly. Future research should connect ICG measures to longitudinal evidence on business model redesign, supply-chain reconfiguration, organisational resilience and well-being.

Managerial implications and Policy implications. A practical implementation sequence follows from the findings: first, conduct a firm-level integration diagnostic; second, activate low-threshold AI and digital training even before large-scale investment; third, develop hybrid governance arrangements in which external expertise works alongside internal managerial learning; fourth, pilot agentic use cases only where data flows and process ownership are sufficiently integrated. System integration is not a downstream concern to be addressed after AI tools have been selected; it is an upstream prerequisite that determines which AI tools will generate value at the agentic level. Firms currently at partial integration (62% of our sample) should treat the transition to high integration as the primary infrastructure investment before expanding their AI tool portfolio. The exploratory M3 result, where no structural predictor significantly explains the ICG, is consistent with the interpretation that the technical requirements of system integration vary considerably depending on each firm’s legacy infrastructure, historical technology choices, and operational architecture. If this interpretation holds, it implies that sector or size benchmarks alone are insufficient guides for AI readiness assessment: each firm requires a firm-specific diagnostic of its integration gaps and connectivity barriers before a meaningful AI investment roadmap can be designed.

The training threshold finding offers an actionable message for resource-constrained micro-enterprises. The data show that the largest marginal return to training occurs at the first step; any engagement with digital or AI training substantially raises both digital maturity and AI strategic awareness relative to firms with no training at all. The distinction between occasional and structured programmes is not statistically significant. This lowers the barrier for action: a modest, informal training initiative produces organisational returns comparable to a structured programme in this sample.

For policymakers, the findings suggest that AI support schemes should move beyond generic technology subsidies toward capability-building instruments that combine integration assessment, managerial training and hybrid advisory support. This is especially important for micro and small firms, where the first step into training produces the largest marginal benefit.

Originality of the paper. The originality of the paper lies in translating the agentic economy from a broad technological and market-level scenario into a measurable managerial readiness problem at the firm level. This paper offers three distinct original contributions. First, it proposes a novel quantitative operationalisation of the Intention-Capability Gap (ICG) as a reproducible, firm-level diagnostic construct calibrated to the architectural demands of the agentic AI transition. The conceptual terrain of intention-capability gaps is not new: UTAUT-based research has identified and formalised analogous constructs, showing, for instance, how external shocks can decouple behavioural intention from actual technology use when infrastructure and digital literacy gaps intervene (Ranatarisza et al., 2025). What the present paper contributes is not the conceptual invention of the gap itself. However, its specific quantitative operationalisation, a signed, normalised measure on a [−100, +100] scale, is applied to the novel context of SME readiness for agentic AI. Unlike adoption measures (which capture only the presence or absence of AI tools) or maturity indices (which capture capability without reference to strategic intent), the ICG is a measure of strategic positioning relative to the agentic transition.

Second, the paper identifies the Integration Paradox, the systematic co-occurrence of high demand for operational-efficiency AI benefits and low system integration, as a named empirical phenomenon in Italian SMEs. This paradox has not been previously documented in the Italian context and has significant implications for how AI adoption support programmes are designed. The paradox implies that the most desired AI application category is also the most organisationally demanding: it cannot be resolved by tool availability or financial subsidy alone.

Third, the paper makes a methodological contribution through the exploratory null result in M3: no observable structural predictor significantly explains the ICG. This is presented not as proof of absence but as a suggestive pattern pointing toward firm-level architectural heterogeneity, a form of variation that categorical policy instruments cannot adequately capture on their own, and that calls for diagnostic approaches alongside broad-based diffusion instruments. The paper thus contributes to a broader conversation about the governance and capability architecture of the emerging agentic economy.

Allocazione delle risorse, modalità di governance ed esiti cooperativi: coopetizione versus cooperazione nell'industria vinicola

ANNA MINÀ, LEONARDO CORBO, CHRISTIAN LECHNER

Abstract: *La ricerca sulla coopetizione, ancorché copiosa, si è prevalentemente concentrata sulle relazioni diadiche, ossia le relazioni interimpresa che coinvolgono due rivali orientati a collaborare su attività circoscritte, sia temporalmente, sia nei contenuti dell'accordo, (*project-based*). Più recentemente, sia il mondo accademico, sia il mondo delle imprese hanno sottolineato come la coopetizione multilaterale presenti interessanti opportunità, riconoscendone al contempo le peculiarità legate al numero degli attori coinvolti e alla durata della relazione che, diversamente dalla coopetizione diadica, non si esaurisce necessariamente con l'uscita di uno dei soci dell'accordo. Questo lavoro si propone di indagare in che modo le imprese coinvolte in relazioni di multilateral coopetition mantengano l'impegno collettivo pur disponendo, sia dell'autonomia necessaria per affrontare la competizione con gli altri concorrenti, sia dell'opzione di uscita, riconducibile alla possibilità di disimpegnarsi parzialmente o totalmente dall'accordo. Muovendo dall'analisi di tre cooperative vitivinicole, il lavoro confronta diverse modalità di governance collegate alla coopetition multilaterale. Nello specifico, l'analisi rileva la presenza di tre distinti modelli di governance: uno basato sulla pura collaborazione, uno sulla piena esclusività dei soci alla multilateral coopetition e uno sull'esclusività parziale. In quest'ultima forma di governance, i soci dell'accordo multilaterale mantengono la propria autonomia, preservando al contempo l'impegno a permanere nella coopetizione multilaterale. In tal modo, il lavoro propone una nuova forma di coopetizione — la* collective coopetition *— in cui la competizione tra i soci favorisce i risultati collettivi. Il contributo alla ricerca sulla coopetizione consiste nell'avanzamento della teoria sulla coopetizione multilaterale e nella dimostrazione di come le modalità di governance rendano possibile una collaborazione piena e duratura tra competitor.*
Parole chiave: *coopetizione; cooperazione; allocazione delle risorse; modalità di governance; cooperative vinicole; avversione alla perdita*

Inquadramento della ricerca. *Gli studi di strategia hanno tradizionalmente affrontato il tema della rivalità interimpresa considerando la competizione come la principale leva strategica e la cooperazione come una forma — implicita o esplicita — di collusione capace di ridurre, anziché accrescere, il benessere economico collettivo (Hoffmann et al., 2018). Il crescente coinvolgimento delle imprese in relazioni cooperative — anche con imprese concorrenti (Hamel, 1991; Lado, Boyd & Hanlon, 1997) — ha tuttavia fatto emergere la coopetition (Brandenburger & Nalebuff, 2021; Bengtsson & Kock, 2000). In coopetition le imprese collaborano e competono con i propri rivali per condividere risorse complementari e perseguire benefici collettivi, a condizione che la relazione sia adeguatamente gestita (Kostis et al., 2024). Poiché la scelta di cooperare non annulla l'intento competitivo verso il partner (Lorange & Roos, 1991; Hamel, 1991), la presenza di meccanismi di salvaguardia è essenziale per contenere e gestire le tensioni legate a comportamenti opportunistici e alla naturale tendenza a far prevalere l'interesse individuale su quello collettivo (Kale, Singh & Perlmutter, 2000; Khanna, Gulati & Nohria, 1998).*

La letteratura sul tema della coopetition ancorché copiosa, si è prevalentemente concentrata sulle relazioni diadiche, temporanee o project-based (Gnyawali & Park, 2011; Bengtsson & Kock, 2014; Raza-Ullah et al., 2020). Nei fatti la coopetition multilaterale — intesa come la simultanea cooperazione e competizione tra più di due competitor — pone invece sfide qualitativamente differenti (Rouyre et al., 2024), in gran parte riconducibili al crescente numero di attori coinvolti, che intensifica la rivalità, accresce la complessità nella gestione delle complementarità e innalza i costi di coordinamento (Chiambaretto et al., 2020; Lazzarini, 2007). Inoltre, nella multilateral coopetition *l'ingresso o l'uscita di singoli soci non dissolve necessariamente la relazione: le imprese possono disimpegnarsi parzialmente, riallocare risorse o adottare comportamenti opportunistici senza uscire formalmente dall'accordo. Segue l'emergere di nuove riconfigurazioni di* multilateral coopetition *dove la creazione di valore e la distribuzione dei benefici e dei rischi avviene tra le imprese rimanenti (Raza-Ullah et al., 2023) e dove i risultati collettivi, in termini di standard qualitativi, traiettorie innovative, posizionamento settoriale, dipendono dalla partecipazione continua di molteplici competitor.*

Nonostante il crescente interesse dell'accademia a comprendere come funzionano le multilateral coopetition*, e la crescente rilevanza empirica in diversi settori, resta irrisolta una questione centrale: cosa rende il commitment nella multilateral coopetition quando le imprese possono mantenere sia l'autonomia, sia le opzioni di uscita dall'accordo.*

La letteratura di governance interimpresa enfatizza i contratti formali e i meccanismi di controllo e di allineamento degli incentivi per ridurre l'opportunismo tra i soci (Cao & Lumineau, 2015; Gulati et al., 2012; Williamson, 1979). Sebbene rilevanti, questi meccanismi non sono pienamente consistenti con la coopetizione multilaterale, dove by design, i soci hanno autonomia decisionale e dove, di conseguenza, la governance definisce il modo in cui le imprese percepiscono autonomia, rischio e opportunità, orientandone la partecipazione continuativa verso un esito percepito come vincolante, rischioso o strategicamente vantaggioso (Doz, 2019; Raza-Ullah et al., 2024).

Obiettivo del paper. *Questo lavoro esplora in che modo le imprese in multilateral coopetition hanno interesse a mantenere l'impegno collettivo pur disponendo dell'autonomia necessaria a competere con gli altri concorrenti e ad esercitare l'opzione di uscita dall'accordo potendo, dunque, disimpegnarsi parzialmente o totalmente.*

La letteratura esistente evidenzia una dicotomia tra due forme di governance: una non-esclusiva — che preserva l'autonomia a scapito del commitment — ed una, formalmente esclusiva— che garantisce il commitment sopprimendo l'iniziativa competitiva (Bresser, 1988; Birchall, 2011; Chaddad & Cook, 2004). Muovendo dall'analisi di tre cooperative europee operanti sotto diversi assetti di governance cooperativa e competitiva, lo studio intende superare tale dicotomia presente in letteratura proponendo una terza modalità alternativa, definita 'soft exclusivity'*, capace di preservare l'autonomia individuale e commitment collettivo all'interno della multilateral coopetition. La* soft exclusivity*, non impone l'allocazione totale delle risorse ai soci tramite regole vincolanti cosi come non si affida a una partecipazione volontaria priva di salvaguardie, ma sostiene il commitment attraverso incentivi, servizi a valore aggiunto e allineamento volontario, consentendo ai soci di restare legalmente liberi e al contempo avere interesse strategico per una partecipazione continuativa alla cooperativa.*

Lo studio in parola intende offrire tre contributi principali. Primo, si avanza la ricerca sulla coopetizione multilaterale spiegando come il commitment collettivo possa essere sostenuto tra molteplici competitor senza ricorrere né alla piena esclusività né al puro coordinamento di mercato. Secondo, si introduce il concetto di collective coopetition, in cui cooperazione e competizione sono strutturalmente embedded nella governance di un assetto collettivo, anziché bilanciate esternamente. Terzo, si mostra come le modalità di governance plasmino autonomia percepita, costi opportunità e rischio, influendo sulla volontà delle imprese di restare impegnate nella coopetizione multilaterale.

Metodologia. *La natura esplorativa della domanda di ricerca suggerisce l'adozione del metodo dei casi studio (Yin, 2009) con un approccio comparativo (Eisenhardt,1989, 2021) tra tre cooperative vinicole operanti in Francia, Germania e Italia e fondate alla fine degli anni '50. La selezione dei casi rientra nel processo di campionamento teorico tesa a consentire la replicazione analitica - attraverso governance mode distinte nelle politiche di esclusività delle scelte di allocazione delle risorse tra i soci - piuttosto che consentire una generalizzazione statistica (Eisenhardt e Graebner, 2007). Segue come la scelta è coerente con l'obiettivo euristico di comprendere il ruolo della governance e delle decisioni di allocazione delle risorse in multilateral coopetition.*

Le cooperative vitivinicole rappresentano un contesto empirico particolarmente privilegiato. Accordi cooperativi possono riguardare, sia aspetti collegati all'adozione di policy sulla sostenibilità e adattamento climatico (Christ et al., 2017), sia aspetti più strettamente collegati alla produzione, al marketing e alla etichettatura territoriale (Chetty e Wilson, 2003; Taplin, 2010). Le differenti dotazioni dei soci delle cooperative si traducono in differenti benefici e limiti per gli aderenti alle cooperative, acuendo, dunque la necessità di una governance che sia equa e strategicamente coerente (Lazzarini, 2007). La coopetizione verticale multilaterale si configura come una forma di interdipendenza dove la creazione di un common dipende dal continuo e significativo apporto di ciascun socio, nella consapevolezza che l'ingresso, l'uscita e il disimpegno parziale di ciascuno ridefinisce — piuttosto che dissolvere — l'assetto complessivo della cooperativa. Le cooperative vitivinicole mettono a fuoco queste dinamiche in un contesto istituzionalizzato: i soci cooperano come fornitori nei confronti della cooperativa, ma possono agire anche come competitor, sia nei confronti della cooperativa, sia tra di loro nei mercati a valle (Couderc & Marchini, 2011; DiVito & Sharma, 2019). Ciascun socio mantiene autonomia legale e discrezionalità nelle scelte di allocazione delle uve, tra produzione propria e conferimento alla cooperativa. In regime di piena esclusività, i soci conferiscono tutta l'uva alla cooperativa, eliminando di fatto la competizione sul mercato; in regime di non-esclusività, i soci allocano solo una parte della produzione, generando una situazione di coopetition continua. Queste caratteristiche rendono le cooperative un caso analiticamente appropriato per studiare come la governance sostenga la coopetizione multilaterale nel tempo.

La raccolta dei dati è avvenuta tramite interviste con i soci delle cooperative e con i membri dei consigli di amministrazione delle cooperative stesse. Le interviste sono state condotte nel triennio 2022-2025; Il dataset complessivo ammonta a 38 interviste di durata minima di 30 minuti, supportato da materiale opportunamente registrato e trascritto.

Risultati. *Dalla ricerca emergono alcuni risultati interessanti, sia in merito alle forme di governance della* multilateral coopetition*, sia rispetto ai meccanismi che ne sostengono il funzionamento. Un primo dato mette in discussione la visione ottimista della coopetition come riportato dalla letteratura, secondo cui la condivisione delle risorse in coopetition generi benefici reciproci per tutti i partner (Lechner et al., 2019). Lo studio evidenzia come, nelle cooperative non esclusive, i partner tendono a trattenere le uve di qualità superiore per produrre il proprio vino, conferendo quelle di qualità inferiore alla cooperativa. La realizzazione di benefici privati prevale dunque sullo sviluppo di benefici comuni, ed è in questo quadro che le modalità di governance assumono un ruolo discriminante.*

L'analisi identifica tre pattern distinti. Il primo, pure exclusivity*, si fonda su un sistema di incentivi che scoraggia l'uscita e promuove la* retention *attraverso prezzi competitivi, condizioni di pagamento affidabili, accesso a competenze tecniche e infrastrutture condivise, rendendo il conferimento esclusivo delle uve l'opzione più vantaggiosa per i soci. Il secondo,* soft exclusivity*, si basa su un modello orientato ai servizi — assistenza tecnica, supporto alla qualità, logistica e accesso al mercato — per accrescere il commitment volontario senza imporre esclusività formale: i soci restano legalmente liberi di uscire o diversificare, ma sono incentivati ad allocare le migliori risorse al collettivo.*

Il terzo, collective coopetition*, prevede che i soci agiscano come partner attivi, condividendo best practice e specializzandosi per ottimizzare le complementarità del prodotto finale. Questa specializzazione alimenta una*

competizione interna per un riconoscimento qualitativo più elevato, generando un ciclo virtuoso in cui cooperazione e competizione coesistono all'interno del collettivo. Contrariamente alla letteratura che assegna alla fiducia un ruolo centrale, lo studio rivela che in due modalità di governance (esclusività e non-esclusività) è l'avversione alla perdita, non la fiducia, a trattenere i soci. La soft exclusivity*, riducendo strategicamente i rischi percepiti e offrendo costantemente prezzi elevati e servizi premium, allinea gli incentivi individuali al commitment collettivo senza fare affidamento sulla fiducia interpersonale.*

Limiti della ricerca. *I risultati potrebbero essere condizionati dal fatto che i casi studiati interessano cooperative che operano in regioni considerate di alta qualità per la produzione vinicola. Segue come i produttori potrebbero già beneficiare di vantaggi comuni che non richiedono sforzi collaborativi. Inoltre, l'analisi non tiene in considerazione le peculiarità di dotazione di risorse dei singoli soci che possono, dunque, condizionare la valutazione della modalità di governance che prevedere il conferimento esclusivo, o non esclusivo delle uve alla cooperativa.*

La ricerca case study non ha l'ambizione della generalizzabilità: le conclusioni possono essere tratte solo dal caso alla teoria. Sebbene i risultati sul commitment nella coopetition verticale multilaterale siano centrati sulle cooperative vinicole, possono essere estesi a cooperative similmente orientate, specialmente nelle industrie globali food and beverage. Analogamente, le cooperative nel retail, come nell'hardware, articoli sportivi e turismo, affrontano questioni comparabili. Sebbene la discussione evidenzia, dunque, alcune specificità del settore vinicolo, in particolare il ruolo delle connessioni territoriali che vincolano i produttori alla loro cooperativa, limitando le alternative strategiche, studi specifici in altri settori potrebbero estendere la ricerca. Il settore retail, in generale, è soggetto a questioni coopetitive simili: ad esempio, nel settore dell'abbigliamento e nel business della moda, i franchisee locali competono con i flagship store degli stessi brand pur essendo entrambi collegati alla stessa impresa capofila detentrice del brand.

Un ulteriore percorso per la ricerca futura riguarda i meccanismi socio-cognitivi che sono emersi dalla nostra analisi dei casi come concetti promettenti. Concetti come l'identificazione collettiva, l'identità e l'allineamento degli obiettivi possono costituire micro-fondamenta del commitment sostenuto in assetti multilaterali.

Implicazioni manageriali. *Lo studio presenta implicazioni che si estendono oltre i confini del settore vitivinicolo. Sul piano manageriale, contribuiamo al dibattito su trigger, processi e outcome della coopetizione (Bengtsson & Raza-Ullah, 2016; Minà & Dagnino, 2025) distinguendo tra strutture di governance formali — come i contratti di esclusività — e meccanismi di allineamento degli incentivi — come prezzi competitivi e servizi superiori. Le strutture formali assicurano il commitment delle risorse, ma possono inibire il coinvolgimento attivo dei soci delle cooperative; i meccanismi di incentivo, al contrario, conseguono risultati analoghi preservando l'autonomia percepita dei soci. Per chi gestisce le cooperative e la rete, investire in servizi a valore aggiunto e in sistemi di incentivazione può rivelarsi più efficace rispetto ad imporre vincoli contrattuali nel sostenere una partecipazione di qualità nel lungo periodo.*
Più in generale, il lavoro consente le seguenti implicazioni manageriali collegate a come gli attori decidano l'allocazione di risorse simili e che differiscono per livello di qualità e complementarità, scegliendo tra uso proprietario e uso collaborativo in funzione della modalità di governance. Questa impostazione è comune ad altri fenomeni rilevanti, sia in ambito pubblico sia privato. Si considerino, a titolo di esempio, i regimi di proprietà intellettuale che disciplinano le invenzioni universitarie: nei paesi in cui è ammesso il professor privilege*, la proprietà intellettuale è riconosciuta al ricercatore, che può decidere se sfruttare il brevetto in proprio o concederlo al* patent pool *di ateneo (Martínez & Sterzi, 2021). Vi sono evidenze in università europee che hanno dissolto i propri pool di brevetti proprio sotto questo regime, a riprova di come l'assenza di meccanismi di governance adeguati comprometta l'allocazione collaborativa delle risorse. A livello micro, la questione si applica anche alle alleanze di R&S tra concorrenti: un aspetto finora trascurato riguarda quali dipendenti vengano effettivamente allocati — scienziati di punta o ricercatori junior — e come tale scelta sia condizionata dalla governance dell'alleanza (Walter et al., 2015). La ricerca rappresenta dunque un primo passo nell'indagine di una questione più ampia e trasversale: come le decisioni di allocazione delle risorse nelle relazioni coopetitive siano plasmate da forme differenti di governance.*

Originalità del lavoro. *Lo studio fornisce tre contributi principali. In primo luogo, il lavoro consente di arricchire il dibattito emergente sulla coopetition multilaterale spiegando come il commitment collettivo possa essere sostenuto tra molteplici competitor senza ricorrere né alla piena esclusività né al puro coordinamento di mercato. Secondo, il lavoro introduce il concetto di* collective coopetition *come forma avanzata di relazione interimpresa dove cooperazione e competizione sono strutturalmente* embedded *nella governance di un assetto collettivo basato sulle complementarità collettive dei soci e sulla crescente specializzazione. Questa prospettiva estende il lavoro precedente sulle tensioni sottese alla coopetition (Bengtsson et al., 2016; Kostis et al., 2024) spostando l'attenzione dalla gestione delle tensioni relazionali tra competizione e cooperazione a uno* strategizing *collettivo abilitato dalla governance tra molteplici competitor. La* collective coopetition *consente di fare leva sulle tensioni per stimolare cooperazione e competizione sana attraverso la specializzazione. Terzo, il lavoro contribuisce alla comprensione dei meccanismi che favoriscono la cooperazione tra rivali, dove la fiducia non è una condizione necessaria per spiegare l'engagement, mentre l'avversione alla perdita emerge come meccanismo prevalente (*Kahneman & Tversky, 1979, 1992).

Anticipatory Governance in Action: Reframing Organizational Adequacy as a Strategic Infrastructure for Early Risk Detection

DAVIDE LIBERATO LO CONTE♦ MICHELE CAPOZZI♥ GIUSEPPE SANCETTA♠ RAFFAELE D'AMORE♣

Abstract. *Firms increasingly operate under conditions of systemic uncertainty, requiring organizational architectures capable of anticipating and managing emerging risks. This paper reconceptualizes organizational adequacy as an anticipatory governance infrastructure, shifting the focus from compliance-based structures to dynamic systems enabling early risk detection. Adopting an exploratory sequential mixed-methods design, the study integrates qualitative insights with panel data analysis on Italian firms. The findings show that organizational adequacy, captured through governance, structural, and information-system variables, significantly enhances financial stability and reduces distress probability. In particular, information-processing mechanisms emerge as the primary drivers of anticipatory capacity. The study contributes by introducing the notion of anticipatory organizational architecture and offers managerial implications for designing organizations capable of detecting weak signals and sustaining performance in uncertain environments.*
Keywords: *anticipatory governance; organizational adequacy; risk management; financial distress*.

Framing of the research. *Contemporary firms operate within increasingly complex and non-linear environments characterized by persistent uncertainty, institutional plurality, and systemic interdependence. The progressive erosion of stable competitive equilibria and the emergence of continuous disruption have then shifted the locus of strategic advantage from external positioning toward the internal capacity of organizations to process information, anticipate discontinuities, and sustain adaptive responses over time (Gutterman, 2023). Within this context, the design of internal organizational arrangements assumes a central role, not merely as a mechanism of coordination, but as a foundational infrastructure for managing uncertainty and ensuring organizational continuity (Stanikzai and Mittal, 2025). The literature on organizational design has long emphasized that structure constitutes a critical lever through which firms align internal processes with strategic objectives (Chandler, 1962). Organizational structures define the allocation of responsibilities, the distribution of authority, and the architecture of information flows, thereby shaping the organization's ability to coordinate activities and respond to environmental contingencies (Volpe and Vagnani, 2014; Luciano et al., 2026). In particular, the balance between differentiation and integration has been identified as a key design challenge, as it determines the extent to which organizations can simultaneously exploit specialized capabilities and maintain coherence across units (Lawrence and Lorsch, 1967; Goold and Campbell, 2002). However, while this stream of research has extensively explored the relationship between structure and performance, it has predominantly focused on efficiency, coordination, and strategic alignment, leaving relatively underdeveloped the role of organizational architecture in enabling anticipatory capabilities and early detection of systemic risks (Weick, 1993).*

Parallel developments in corporate governance and risk management have partially addressed these issues, yet remain conceptually fragmented. The corporate governance literature, in fact, has traditionally focused on monitoring mechanisms, board composition, and agency cost reduction (Jensen and Meckling, 1976; Fama and Jensen, 1983), with limited attention to the internal organizational infrastructures through which risk signals are generated and interpreted. Similarly, enterprise risk management frameworks have emphasized formalized processes for identifying and controlling risk exposures, often neglecting the broader organizational context that enables or constrains the effective interpretation and escalation of risk-related information (Weick and Sutcliffe, 2015). As a result, existing research provides only a partial understanding of how internal organizational arrangements contribute to the firm's capacity to anticipate and manage emerging instability.

This theoretical gap becomes particularly salient in light of recent regulatory developments at both the European and national levels, which have progressively expanded the scope of corporate governance from ex-post control toward ex-ante risk detection and organizational resilience. Within the European context, directives and regulatory frameworks increasingly emphasize the importance of internal control systems, risk governance, and organizational accountability as key pillars of financial stability and sustainable corporate conduct. In Italy, this evolution has been formalized through the introduction of the requirement for adeguati assetti organizzativi, amministrativi e contabili, which explicitly mandates firms to adopt organizational arrangements capable of ensuring timely detection of crisis signals and preservation of business continuity. This regulatory shift reflects a deeper transformation in the conceptualization of governance, whereby organizational design is no longer viewed solely as an efficiency-enhancing mechanism, but as a legally embedded infrastructure for anticipatory risk management and strategic continuity.

However, despite its growing practical and normative relevance, the concept of organizational adequacy remains theoretically underexplored within management studies. Existing contributions have addressed related dimensions, such as internal control systems and organizational design, but have rarely integrated these perspectives into a coherent framework linking organizational architecture with crisis detection capabilities. In particular, there is a lack of theoretical models that explain how governance structures, information systems, and decision-making processes jointly enable the continuous generation, interpretation, and escalation of weak signals within the firm.

Recent advancements in digitalization and artificial intelligence (AI) further amplify the relevance of this issue. As decision-making processes become increasingly mediated by algorithmic systems, the effectiveness of organizational governance depends not only on data availability, but also on the interpretability, transparency, and controllability of information flows (Raisch and Krakowski, 2021; Brynjolfsson and McAfee, 2014; Raisch and Krakowski, 2021). Emerging research highlights that organizational resilience in data-intensive environments is contingent upon the integration of technological capabilities with governance mechanisms that ensure meaningful human oversight and ethical accountability (Mikalef et al., 2022; Zhang and Sun, 2023). In this perspective, interpretability emerges as a critical governance capability linking technological compliance with cognitive and organizational resilience (Albert et al., 2026). Building on these theoretical premises, this study argues that the notion of organizational adequacy cannot be satisfactorily captured within existing frameworks of corporate governance, organizational design, or risk management when considered in isolation. This fragmentation results in a critical blind spot: the absence of a unifying conceptualization of the firm as an anticipatory system, in which governance structures and decision processes are jointly configured to enable early warning and adaptive response. The core theoretical contribution of this study then lies in shifting the focus from governance as control to governance as organized sensemaking under uncertainty. Specifically, the paper introduces the concept of anticipatory organizational architecture, defined as the integrated configuration of structural arrangements, information systems, and decision protocols that enable the continuous generation, interpretation, and escalation of weak signals related to financial and strategic risk.

Purpose of the paper. *This paper aims to develop and empirically ground a novel conceptualization of organizational adequacy as an anticipatory governance infrastructure, capable of enabling firms to detect, interpret, and respond to emerging financial and strategic risks under conditions of systemic uncertainty. Moving beyond compliance-based and static interpretations of organizational arrangements, the study then seeks to reposition internal organizational design as a central mechanism through which firms build early-warning capabilities and sustain adaptive performance.*

Specifically, the paper pursues two interrelated objectives. First, it develops a theoretically integrated framework that connects organizational design, corporate governance, and risk management into a unified perspective centered on anticipation, information processing, and adaptive decision-making. Second, it empirically investigates how different configurations of internal organizational arrangements influence firms' ability to maintain financial stability and detect early signals of distress. In doing so, the study introduces and operationalizes the concept of anticipatory organizational architecture. This perspective shifts the focus from ex-post control and structural alignment toward a dynamic understanding of organizations as systems designed to process uncertainty and enable timely intervention (Tarafdar et al., 2019). The paper contributes to the literature by advancing a theoretically and empirically grounded framework that extends existing approaches in three fundamental ways. First, it expands organizational design theory by moving beyond the classical "structure–strategy fit" paradigm and introducing the notion of structure–uncertainty fit, whereby organizational effectiveness depends on the ability of internal architectures to process ambiguity and detect emerging disruptions, rather than merely execute predefined strategies. Second, it enriches corporate governance literature by repositioning governance mechanisms from ex-post monitoring devices to ex-ante cognitive infrastructures, capable of shaping how organizations perceive and interpret risk before it materializes. Third, it contributes to the literature on risk management by embedding risk detection within the broader organizational context, demonstrating that early-warning capabilities are not solely the outcome of formal risk systems, but emerge from the interaction between governance structures, information flows, and organizational routines. Building on this conceptual foundation, the paper then addresses the following research questions (RQs):

- *RQ1: How can organizational adequacy be conceptualized as an anticipatory governance infrastructure enabling firms to detect early signals of risk under uncertainty?*
- *RQ2: How do different configurations of organizational arrangements influence firms' capacity for early risk detection and financial stability?*

Methodology. *This on-going study adopts an exploratory sequential mixed-methods design (qual → QUAN), in line with established methodological frameworks for integrating theory-building and empirical testing (Creswell and Plano Clark, 2018; Edmonds and Kennedy, 2017). This design is particularly appropriate when investigating complex and under-theorized phenomena, as it allows the researcher to first inductively identify key dimensions of the construct and subsequently test their empirical relevance (Yin, 2018). The choice of a mixed-methods approach is motivated by three main considerations. First, organizational adequacy, as conceptualized in this study, represents a multidimensional and partially latent construct that cannot be directly observed through quantitative proxies alone. Second, the literature highlights the need for integrative approaches capable of linking organizational, governance, and financial dimensions without relying on purely causal inference. Third, prior research demonstrates that firm-level financial indicators provide*

meaningful signals of organizational conditions and performance, particularly in the context of financial distress and stability (Altman et al., 2017; Barboza et al., 2017).

Accordingly, the research design consists of two sequential phases. The qualitative phase aims to identify and theoretically structure the key dimensions of organizational adequacy, while the quantitative phase tests their relationship with firm-level financial stability and early distress signals. This sequential logic ensures both construct validity and empirical robustness, allowing qualitative insights to inform the operationalization of variables used in the econometric analysis. To ensure consistency across phases, both qualitative and quantitative analyses are grounded in a common empirical domain, focusing on firms operating within a comparable institutional and regulatory environment. This alignment minimizes inferential incongruity between datasets and enhances the interpretability of results (Edmonds and Kennedy, 2019).

Qualitative phase. *The qualitative phase adopts a multiple case study design, which is particularly suitable for theory building in contexts characterized by limited prior conceptualization (Yin, 2018). Case selection followed a theoretical sampling logic, aimed at maximizing variation in organizational configurations, governance structures, and exposure to financial stress. The sample includes firms differing in size, ownership structure, and organizational complexity, allowing both literal and theoretical replication. Data collection involved multiple sources to ensure triangulation and enhance internal validity (Eisenhardt, 1989). Specifically, the analysis draws on:*

- *semi-structured interviews with senior managers, financial officers, restructuring advisors, and governance experts*
- *internal governance documentation, including reporting systems, planning documents, and risk management procedures*
- *publicly available financial disclosures and organizational reports*

Interviews were conducted using a semi-structured protocol focusing on governance mechanisms, information flows, financial monitoring practices, and decision-making processes under conditions of uncertainty. Each interview lasted between 60 and 90 minutes and was transcribed for analysis. Qualitative data were analyzed using thematic coding and pattern-matching techniques, following established qualitative analysis procedures (Yin, 2018). This process led to the identification of four recurrent dimensions of organizational adequacy:

- *governance architecture and accountability mechanisms;*
- *financial monitoring and forecasting systems;*
- *strategic planning and risk assessment processes;*
- *information transparency and reporting infrastructures.*

These dimensions form the basis for the operationalization of organizational adequacy in the quantitative phase (Kroll et al., 2016).

Quantitative phase. *The quantitative phase examines the relationship between organizational adequacy and financial stability using firm-level panel data. The dataset was constructed using the AIDA database (Bureau van Dijk), which provides standardized financial information for Italian firms. The initial dataset included firms operating across multiple sectors, with the aim of capturing heterogeneity in organizational structures. Selection criteria were defined to ensure data reliability and comparability, including:*

- *availability of complete financial statements for at least five consecutive years*
- *active operational status*
- *exclusion of firms in regulated financial industries*

After data cleaning and validation, the final dataset includes approximately 1,000 firms, corresponding to over 5,000 firm-year observations across the period 2018–2024. Multi-year observations were used to reduce idiosyncratic fluctuations and enhance the stability of financial indicators.

Variables and empirical specification

Financial stability, as the dependent construct of the study, is operationalized through a multidimensional set of indicators widely adopted in the financial diagnostics and distress prediction literature (Altman et al., 2017; Wang, 2017) (Table 1).

In line with prior empirical contributions, the construct is captured through a combination of profitability, leverage, and solvency proxies that jointly reflect the firm's ability to sustain its financial obligations over time. Specifically, the Interest Coverage Ratio (EBIT/Interest Expenses) is employed as a primary measure of operating sustainability, complemented by leverage-based indicators such as Debt-to-Equity and Debt-to-EBITDA ratios, which capture the firm's capital structure and debt sustainability. In addition, forward-looking proxies of default risk derived from financial ratios are incorporated to account for the probabilistic dimension of financial distress.

The key independent construct, organizational adequacy, is not directly observable and is therefore operationalized through a set of structural and governance-related proxy variables derived from the qualitative phase of the research. These proxies are designed to capture the multidimensional nature of internal organizational arrangements as theorized in the conceptual framework. In particular, governance-related variables include board size, the proportion of independent directors, and the presence of formal supervisory or control bodies, reflecting the firm's monitoring and oversight capacity. Organizational structure variables capture the internal allocation of managerial responsibilities and resources, including the size of the management team and the existence of dedicated finance and risk management functions. Finally, information system variables are introduced to reflect the firm's capacity to generate, process, and

disseminate relevant information, including the frequency of financial reporting, the adoption of integrated ERP systems, and the time horizon of financial forecasting practices. To isolate the effect of organizational adequacy on financial stability, the empirical model incorporates a set of control variables commonly used in the literature. These include firm size, measured as the natural logarithm of total assets, leverage ratios capturing capital structure effects, sales growth as a proxy for dynamic performance, firm age reflecting organizational maturity, and industry fixed effects to control for sector-specific heterogeneity.

Table 1: Variable Definition and Operationalization

Variable Category	Construct	Operationalization / Proxy	Measurement	Theoretical Rationale
Dependent Variable	Financial Stability	Interest Coverage Ratio	EBIT / Interest Expenses	Operating sustainability and ability to service debt (Altman et al., 2017)
		Leverage Indicators	Debt/Equity; Debt/EBITDA	Capital structure sustainability and financial risk exposure
		Default Risk Proxies	Ratio-based distress indicators	Forward-looking probability of financial distress (Wang, 2017)
Independent Variable	Organizational Adequacy (latent construct)	Governance Structure	Board size; independence ratio; control bodies	Monitoring capacity and oversight effectiveness (Jensen & Meckling, 1976)
		Organizational Structure	Management team size; finance/risk functions	Allocation of responsibilities and decision capacity
		Information Systems	Reporting frequency; ERP adoption; forecasting horizon	Information processing and anticipatory capability
Control Variables	Firm Size	Log of total assets	Continuous (log-transformed)	Organizational scale effects
		Leverage	Debt ratios	Financial structure control
		Sales Growth	% annual change in revenues	Dynamic performance proxy
		Firm Age	Years since incorporation	Organizational maturity
		Industry Effects	Industry dummies	Sectoral heterogeneity
Data Treatment	Preprocessing	Winsorization	1st–99th percentile	Outlier mitigation (Hair et al., 2019)
		Standardization	Z-score transformation	Cross-variable comparability
Estimation Strategy	Panel Model	Fixed-effects regression	(\mu_i, \lambda_t)	Controls for unobserved heterogeneity
		Robustness Checks	Logistic regression; Z-score thresholds	Alternative distress specifications
		Machine Learning	Random Forest	Non-linear relationships and variable importance
		Dimensionality Reduction	PCA	Extraction of latent financial structures

Source: our processing

All continuous variables undergo standard preprocessing procedures to ensure statistical robustness and comparability across observations. Specifically, variables are winsorized at the 1st and 99th percentiles to mitigate the influence of extreme values and outliers, and subsequently standardized using z-score transformation, in line with established practices in multivariate financial analysis (Hair et al., 2019; Wang, 2017). The relationship between organizational adequacy and financial stability is estimated through panel data regression models of the following form:

$$FinancialStability_{it} = \alpha + \beta_1 OrganizationalAdequacy_{it} + \beta_2 Controls_{it} + \mu_i + \lambda_t + \epsilon_{it}$$

where $\mu_i$captures unobserved firm-specific heterogeneity and $\lambda_t$controls for time-specific effects. This specification allows for the isolation of within-firm variation over time while accounting for both cross-sectional and temporal dependencies.

To ensure the robustness of the empirical results, alternative model specifications are employed. In particular, logistic regression models are estimated using binary distress indicators, allowing for the assessment of the probability of financial distress. Additional robustness checks are conducted using alternative distress thresholds based on Z-score

quartile distributions (Altman et al., 2017), thereby capturing non-linearities in financial risk profiles. Furthermore, machine learning techniques, specifically random forest models, are implemented to assess variable importance and explore potential non-linear relationships between organizational variables and financial outcomes (Barboza et al., 2017). Given the relatively high dimensionality of financial indicators in relation to sample size, Principal Component Analysis (PCA) is applied as a dimensionality reduction technique to extract latent financial structures and mitigate multicollinearity issues (Pittelkow and Wilson, 2007; Hair et al., 2019). This approach enables the interpretation of financial indicators as aggregated organizational signals, consistent with the theoretical framing of the study, whereby financial performance reflects underlying governance and organizational configurations. Overall, this empirical strategy ensures a rigorous integration of theoretical constructs and quantitative evidence, allowing for a nuanced analysis of how internal organizational arrangements influence firms' capacity to maintain financial stability and anticipate distress.

Results. *The empirical findings provide strong and consistent support for the theoretical reconceptualization of organizational adequacy as an anticipatory governance infrastructure (Table 2).*

Table 2: Empirical Results. Organizational Adequacy and Financial Stability

Hypothesis / RQ	Relationship Tested	Method	Key Result	Statistical Evidence	Interpretation
RQ1	Organizational Adequacy → Financial Stability	Panel Regression (FE)	Positive and significant effect	$\beta > 0$, $p < 0.01$	Organizational adequacy enhances firms' ability to sustain financial obligations
RQ1	Organizational Adequacy → Leverage Risk	Panel Regression (FE)	Negative and significant effect	$\beta < 0$, $p < 0.05$	Higher adequacy associated with more sustainable capital structures
RQ1	Organizational Adequacy → Distress Probability	Logistic Regression	Negative and significant effect	Marginal effects < 0, $p < 0.05$	Reduced likelihood of financial distress
RQ1	Latent Structure of Organizational Adequacy	PCA	Single dominant factor identified	High explained variance	Adequacy operates as a higher-order capability (sensing & processing)
RQ2	Information Systems → Financial Stability	Panel + Random Forest	Strongest positive effect	Highest variable importance	Information processing is the core driver of anticipatory capacity
RQ2	Governance Variables → Financial Stability	Panel Regression	Positive but conditional effect	Significant with interactions	Governance effective only when supported by information systems
RQ2	Organizational Structure → Financial Stability	Panel Regression	Positive but weaker effect	Lower coefficients	Structural complexity alone is insufficient
RQ2	Interaction Effects (Governance × Information)	Extended Models	Complementarity effect	Significant interaction terms	Anticipatory capacity emerges from system integration
Robustness	Alternative distress thresholds	Z-score models	Results confirmed	Consistent across quartiles	Stability of findings across specifications
Robustness	Non-linear relationships	Random Forest	Threshold effects identified	Variable importance ranking	Effects intensify beyond maturity levels

Source: our processing

Across all model specifications, the results highlight that internal organizational arrangements are not merely background conditions, but constitute a statistically and economically significant determinant of firms' capacity to sustain financial stability and anticipate emerging distress.

With reference to RQ1, which concerns the conceptualization of organizational adequacy as an anticipatory governance infrastructure, the empirical analysis confirms that the construct is both analytically coherent and empirically identifiable. The dimensional structure derived from the qualitative phase is validated through the quantitative analysis, as the selected proxy variables exhibit stable and theoretically consistent patterns across models. In particular, the application of PCA reveals that variables related to governance structures, information systems, and organizational configuration converge into a latent factor that explains a substantial portion of the variance in financial performance indicators. This latent dimension can be interpreted as a synthetic measure of organizational sensing and processing capacity, supporting the notion that organizational adequacy operates as a higher-order capability rather than a

collection of isolated mechanisms. The panel regression results further reinforce this interpretation. The coefficient associated with organizational adequacy is positive and statistically significant across all baseline models when financial stability is proxied through the Interest Coverage Ratio. This indicates that firms characterized by more structured governance systems, more advanced information infrastructures, and more articulated organizational configurations exhibit a systematically higher capacity to sustain operating margins relative to financial obligations. At the same time, the same construct shows a negative and statistically significant association with leverage-based risk indicators, suggesting that firms with higher levels of organizational adequacy tend to adopt more sustainable financial structures and display lower exposure to debt-related vulnerability.

Importantly, these relationships remain robust after controlling for firm size, growth dynamics, capital structure, and industry-specific effects, thereby isolating the independent contribution of organizational variables. The magnitude of the estimated coefficients suggests that organizational adequacy exerts a non-trivial effect on financial outcomes, comparable in scale to traditional financial determinants such as leverage and firm size. This finding provides empirical support for the theoretical argument that internal organizational architectures play a central role in shaping firms' ability to manage uncertainty. The robustness of these results is further confirmed through alternative model specifications. Logistic regression models, in which financial distress is operationalized as a binary outcome, show that higher levels of organizational adequacy are associated with a significantly lower probability of entering distress conditions. The estimated marginal effects indicate a meaningful reduction in distress likelihood for firms positioned in the upper quartiles of the adequacy distribution. Similarly, when alternative distress thresholds based on Z-score quartiles are employed, the results remain consistent, confirming that the relationship holds across different operationalizations of financial risk.

Turning to RQ2, which investigates how different configurations of organizational arrangements influence firms' capacity for early risk detection and financial stability, the findings reveal a differentiated and non-linear structure of effects across the various dimensions of organizational adequacy. Among these, information-related variables emerge as the most influential predictors. Firms characterized by higher frequency of financial reporting, the adoption of integrated ERP systems, and longer forecasting horizons consistently exhibit superior performance across all stability indicators. These variables display the highest statistical significance and effect sizes in both regression and machine learning models. This suggests that the firm's ability to generate timely, forward-looking, and internally integrated information represents the primary mechanism through which anticipatory capabilities are operationalized. From a theoretical perspective, this finding substantiates the interpretation of anticipatory governance as fundamentally rooted in the architecture of information flows. Governance-related variables also display a significant, albeit more conditional, impact. The presence of formal control bodies and higher levels of board independence are associated with improved financial stability; however, their effect appears to be contingent upon the presence of adequate information systems. In models where interaction effects are considered, governance variables exhibit stronger significance when combined with high levels of reporting frequency and forecasting capability. This indicates that governance structures contribute to anticipatory capacity not in isolation, but as part of a broader system of information processing and interpretation. Such evidence supports the reconceptualization of governance as an ex-ante cognitive infrastructure, rather than a purely monitoring mechanism.

Organizational structure variables, including management team size and the presence of dedicated financial functions, display a positive but comparatively weaker effect. While these variables contribute to financial stability, their explanatory power is lower than that of information-related factors. This suggests that structural complexity alone does not generate anticipatory capabilities unless it is effectively coupled with mechanisms for information integration and interpretation. In this sense, the results point to a complementarity effect between structural and informational dimensions, whereby the effectiveness of one depends on the presence of the other. The machine learning analysis provides additional support for these findings by identifying the relative importance of variables in predicting financial outcomes. Random forest models consistently rank information system variables as the most influential predictors, followed by governance indicators, while structural variables occupy a secondary but still relevant position. The non-linear nature of these models also reveals threshold effects, suggesting that the impact of organizational adequacy becomes significantly stronger beyond certain levels of information system maturity and governance formalization.

Taken together, the results suggest that organizational adequacy operates as a systemic and configurational capability, emerging from the interaction between governance mechanisms, organizational structures, and information infrastructures. Firms that exhibit high levels of alignment across these dimensions are characterized by a markedly superior ability to detect weak signals, anticipate financial imbalances, and maintain stability over time. Conversely, firms with fragmented or incomplete configurations display significantly higher vulnerability to financial distress, even when controlling for traditional financial indicators (Williams et al., 2017). From a theoretical standpoint, these findings provide strong empirical support for the transition from a "structure–strategy fit" paradigm toward a structure–uncertainty fit logic. The ability of firms to process ambiguity, integrate information, and anticipate disruptions emerges as a critical determinant of performance in complex environments. Moreover, the results substantiate the reinterpretation of governance as a forward-looking, sensemaking-oriented infrastructure, and of risk management as an emergent property of organizational systems rather than a set of formalized procedures.

Research limitations. *While offering relevant theoretical and empirical insights, the study is subject to several limitations. First, the operationalization of organizational adequacy through proxy variables may not fully capture its latent and multidimensional nature, potentially simplifying complex cognitive, structural, and informational dynamics. Second, the reliance on firm-level secondary data reflects formal organizational arrangements rather than their effective functioning, thus limiting the ability to observe how governance and information systems operate in practice. Third, although the use of panel models with fixed effects enhances internal validity, potential endogeneity issues, such as reverse causality,cannot be entirely excluded. Finally, the focus on the Italian institutional and regulatory context may constrain the generalizability of the findings, suggesting the need for future cross-country and longitudinal research to validate and extend the proposed framework.*

Managerial implications. *The findings carry significant managerial implications by repositioning organizational adequacy from a compliance requirement to a strategic lever for anticipatory decision-making and risk governance. Rather than static structures, organizational arrangements emerge as dynamic information-processing architectures through which firms can detect weak signals and anticipate financial instability. First, managers should prioritize the design of integrated and forward-looking information systems, as reporting frequency, ERP adoption, and forecasting capabilities emerge as key drivers of financial stability. This implies shifting from periodic reporting toward continuous monitoring and real-time signal detection. Second, governance mechanisms should be conceived as cognitive infrastructures, whose effectiveness depends on the quality, integration, and interpretability of available information. Strengthening boards without enhancing information environments is unlikely to improve outcomes. Third, the results highlight the need to align organizational structures with information flows. Structural complexity alone is insufficient unless supported by mechanisms that facilitate rapid signal transmission and escalation. Finally, anticipatory capacity emerges as a configurational capability, requiring systemic alignment between governance, structure, and information systems. In this perspective, regulatory requirements on organizational adequacy can be reframed as an opportunity to build resilience, enhance adaptability, and sustain long-term performance.*

Originality of the paper. *This paper offers a distinctive contribution to the management literature by reframing organizational adequacy as an anticipatory governance infrastructure, thereby bridging a critical gap between organizational design, corporate governance, and risk management. Moving beyond dominant views centered on efficiency and compliance, the study advances a novel perspective of the firm as an anticipatory system, in which governance, structure, and information architectures jointly enable early signal detection and proactive intervention. The introduction of the concept of anticipatory organizational architecture represents a key theoretical advancement, shifting the focus from structure–strategy fit to structure–uncertainty fit and positioning internal arrangements as dynamic capabilities for sensing and responding to emerging disruptions. Finally, the paper strengthens its originality through a rigorous mixed-methods design, combining qualitative theory-building with quantitative validation. In doing so, it moves beyond conceptual abstraction and provides empirically grounded evidence on how organizational configurations shape financial stability, offering a new foundation for understanding firms in conditions of systemic uncertainty.*

Big Data Potenziati dall'Intelligenza Artificiale e Innovazione dei Modelli di Business Sostenibili

FRANCESCO CAPPA[1], CHIARA BARTOLI[2], FRANCESCO FASANO[3], PAOLO BOCCARDELLI[2]

Abstract. *La rapida digitalizzazione degli ambienti di business ha generato una crescita senza precedenti nella disponibilità di dati, rendendo i big data una risorsa strategica fondamentale per le organizzazioni. Allo stesso tempo, la diffusione delle tecnologie di AI ha significativamente rafforzato la capacità delle imprese di elaborare ed estrarre valore da grandi volumi di dati. Sebbene studi precedenti abbiano analizzato separatamente il ruolo dei big data e dell'AI nell'innovazione dei modelli di business, un'attenzione limitata è stata dedicata al modo in cui queste tecnologie possano congiuntamente abilitare l'innovazione sostenibile dei modelli di business e a come le imprese debbano governarle strategicamente. Questo studio affronta tale lacuna analizzando come i big data potenziati dall'AI possano supportare le imprese nella riprogettazione dei propri modelli di business al fine di generare simultaneamente valore economico, ambientale e sociale. Adottando un approccio qualitativo induttivo basato sulla metodologia Gioia, analizziamo dati qualitativi raccolti da 212 CEO e manager iscritti a un Executive MBA presso una prestigiosa business school europea. I risultati mostrano che l'uso congiunto di AI e big data influenza diversi componenti del business model canvas, consentendo alle imprese di migliorare la creazione, la distribuzione e la cattura di valore nelle tre dimensioni della sostenibilità. Allo stesso tempo, l'adozione di queste tecnologie introduce sfide di governance legate ai rischi etici, alla sicurezza dei dati e al consumo energetico. Lo studio contribuisce alla letteratura su big data, AI e innovazione sostenibile dei modelli di business proponendo un framework di governance strategica che spiega come le imprese possano sfruttare i big data potenziati dall'AI per generare valore sostenibile.*
Keywords: *Big data; Intelligenza artificiale; Innovazione sostenibile, Business Model*

Framing of the research. *Negli ultimi anni, la rapida trasformazione digitale degli ambienti economici ha aumentato drasticamente la quantità di dati generati da individui, organizzazioni e infrastrutture digitali. Questa crescita esponenziale della disponibilità di dati ha trasformato i big data in una risorsa strategica che le imprese cercano sempre più di sfruttare per rafforzare la propria competitività e migliorare i processi decisionali (Cappa et al., 2021; Sestino et al., 2020). Si stima che il volume globale dei dati crescerà da 174 zettabyte nel 2024 a oltre 500 zettabyte entro il 2029, evidenziando la crescente importanza delle strategie data-driven per le organizzazioni che operano in mercati sempre più digitalizzati. I big data si distinguono dai dataset tradizionali per alcune caratteristiche specifiche comunemente descritte attraverso il framework delle "5V" (Cappa et al., 2021): volume, velocità, varietà, veridicità e valore. Quando queste dimensioni operano congiuntamente, i big data possono generare significative opportunità per le imprese migliorando le capacità di previsione, supportando decisioni strategiche più efficaci, aumentando l'efficienza operativa e favorendo lo sviluppo di nuovi prodotti e servizi. In questo senso, i big data rappresentano un importante abilitatore dell'innovazione organizzativa e del vantaggio competitivo nelle economie digitali.*

Tuttavia, il valore strategico dei big data non può essere pienamente realizzato senza le capacità tecnologiche necessarie per elaborare e interpretare grandi volumi di informazioni complesse. In questo contesto, l'intelligenza artificiale (AI) è emersa come una tecnologia complementare in grado di potenziare il valore dei big data (Dwivedi et al., 2023; Zhou et al., 2017). Le tecnologie di AI, in particolare le tecniche di machine learning e deep learning, permettono alle imprese di analizzare grandi dataset, individuare pattern nascosti, generare previsioni e automatizzare processi decisionali. Grazie a queste capacità, l'AI consente alle organizzazioni di trasformare i dati grezzi in insight utili per supportare il processo decisionale strategico e l'apprendimento organizzativo. Da una prospettiva strategica, la combinazione tra big data e AI è sempre più riconosciuta come un fattore chiave per l'innovazione dei modelli di business (Acciarini et al., 2023; Ritala et al., 2024). I modelli di business descrivono il modo in cui le imprese creano, distribuiscono e catturano valore attraverso le proprie attività, mentre l'innovazione del modello di business si riferisce ai cambiamenti nell'architettura di tali attività. La trasformazione digitale dei settori industriali ha creato nuove opportunità per le imprese di riprogettare i propri modelli di business sfruttando tecnologie basate sui dati. Ad esempio, aziende come Amazon e John Deer hanno integrato con successo analisi dei dati e tecnologie di AI nelle proprie attività per generare nuove proposizioni di valore e sviluppare offerte innovative basate sui servizi.

Parallelamente, le imprese stanno affrontando una crescente pressione da parte degli stakeholder e della società affinché integrino la sostenibilità nelle proprie decisioni strategiche (D'Angelo et al., 2022; Mostaghel et al., 2023). Le preoccupazioni ambientali, le aspettative sociali e la crescente rilevanza della responsabilità d'impresa hanno spinto le organizzazioni a riconsiderare il modo in cui progettano e gestiscono i propri modelli di business. Questo cambiamento ha portato all'emergere dei modelli di business sostenibili, i quali mirano a creare valore economico affrontando allo

[1] Roma Tre University
[2] Luiss University
[3] University of Calabria

stesso tempo sfide ambientali e sociali (Laasch, 2018; Kılıç e Atilla, 2024). L'innovazione sostenibile dei modelli di business rappresenta quindi una sfida strategica fondamentale per le organizzazioni che intendono conciliare performance economica e obiettivi di sostenibilità. Tuttavia, nonostante il crescente interesse verso i modelli di business sostenibili, i meccanismi attraverso i quali le imprese possono innovare efficacemente i propri modelli di business in direzione della sostenibilità rimangono ancora poco compresi. In particolare, il ruolo delle tecnologie digitali come big data e AI nell'abilitare l'innovazione sostenibile dei modelli di business ha ricevuto un'attenzione limitata nella letteratura. Sebbene studi precedenti abbiano esaminato come le tecnologie digitali supportino l'innovazione dei modelli di business, è ancora poco chiaro come tali tecnologie possano essere governate strategicamente per favorire la creazione di valore sostenibile. Da una prospettiva di governance, l'adozione di AI e big data solleva diverse sfide strategiche. Le organizzazioni devono sviluppare adeguate capacità per gestire le infrastrutture dei dati, garantire l'uso etico degli algoritmi, proteggere la privacy dei dati e mitigare i rischi tecnologici. Inoltre, l'utilizzo di sistemi decisionali basati sull'AI introduce nuove problematiche di governance legate alla trasparenza, alla responsabilità e ai bias algoritmici.

Per analizzare queste dinamiche, il business model canvas rappresenta un utile framework analitico. Il business model canvas concettualizza il modello di business attraverso 9 blocchi (Osterwalder e Pigneur, 2010): segmenti di clientela, proposizione di valore, canali, relazioni con i clienti, flussi di ricavi, risorse chiave, attività chiave, partnership chiave e struttura dei costi. Modifiche in uno qualsiasi di questi elementi possono generare innovazione del modello di business.

Partendo da questo framework, il nostro studio esamina come l'integrazione dell'AI per potenziare i big data possa influenzare le diverse componenti del business model canvas e consentire l'innovazione sostenibile dei modelli di business. A tal fine, adottiamo le prospettive teoriche delle dynamic capabilities e della complexity theory. Le dynamic capabilities evidenziano la capacità delle imprese di individuare opportunità, coglierle attraverso investimenti strategici e trasformare le risorse organizzative in risposta ai cambiamenti ambientali (Bocken e Geradts, 2020; Garud et al., 2011). La complexity theory suggerisce invece che le tecnologie digitali aumentano la complessità organizzativa ma allo stesso tempo consentono di individuare nuove soluzioni a problemi strategici complessi. Combinando queste prospettive teoriche, esploriamo dunque come le imprese possano governare strategicamente i big data potenziati dall'AI per riprogettare i propri modelli di business in modo da generare simultaneamente valore economico, ambientale e sociale.

Purpose of the paper. *L'obiettivo è analizzare come le imprese possano sfruttare l'uso congiunto di AI e big data per realizzare innovazione sostenibile dei modelli di business. In particolare, lo studio affronta la seguente domanda di ricerca:*

Come possono le imprese governare strategicamente i big data potenziati dall'AI per abilitare l'innovazione sostenibile dei modelli di business?

Nel rispondere a questa domanda di ricerca ci auspichiamo di contribuire alla letteratura di strategia e management in diversi modi. In primo luogo, ampliando la letteratura sui big data evidenziando il ruolo strategico delle tecnologie di AI nel potenziare il valore che le organizzazioni possono estrarre dai grandi dataset. In secondo luogo, contribuiamo alla letteratura emergente sull'innovazione dei modelli di business analizzando gli effetti congiunti di AI e big data sulle architetture di creazione del valore delle imprese. Inoltre, arricchiamo la letteratura sull'innovazione sostenibile dei modelli di business mostrando come le tecnologie digitali possano supportare l'integrazione degli obiettivi di sostenibilità nelle strategie aziendali. Dal punto di vista della governance, speriamo anche di fornire indicazioni sulle capacità organizzative e sulle pratiche manageriali necessarie per gestire efficacemente i rischi associati all'adozione di AI e big data.

Methodology. *Per esplorare la domanda di ricerca, adottiamo un disegno di ricerca qualitativo induttivo basato sulla grounded theory (Gioia et al., 2013; Glaser e Strauss, 1967). I dati sono stati raccolti da manager partecipanti a un Executive MBA presso una business school europea accreditata EQUIS, AMBA e AACSB. La raccolta dei dati è stata effettuata attraverso un questionario composto da domande aperte riguardanti l'utilizzo congiunto di big data e AI nelle imprese. Il questionario include domande aperte relative ai 9 blocchi del business model canvas e alle tre dimensioni della sostenibilità: economica, ambientale e sociale. Il questionario è stato somministrato online tramite la piattaforma Qualtrics tra novembre e dicembre 2025. Hanno partecipato allo studio 212 manager provenienti da 34 settori industriali differenti. I dati raccolti consistono in circa 59 pagine di testo. L'analisi è stata condotta seguendo le tre fasi della metodologia Gioia: 1); first order coding; 2) second order themes; 3) aggregate dimensions. Il processo di codifica è stato supportato dal software MaxQDA.*

Results. *I risultati delle risposte aperte dei manager mostrano che l'integrazione tra AI e big data influenza diversi blocchi del business model canvas e favorisce la creazione di valore sostenibile.*

Creazione di valore ambientale. *AI e big data permettono alle imprese di ottimizzare la gestione delle risorse e ridurre il consumo energetico. L'analisi predittiva dei big data consente di anticipare la domanda e adattare i processi produttivi in tempo reale riducendo sprechi e inefficienze. Le imprese possono inoltre progettare prodotti più sostenibili analizzando il ciclo di vita dei prodotti e selezionando materiali con minore impatto ambientale.*

Distribuzione di valore ambientale. *Le tecnologie digitali permettono alle imprese di promuovere comportamenti di consumo più sostenibili tra i clienti. Piattaforme digitali e sistemi di comunicazione basati sull'AI consentono di diffondere informazioni relative alle pratiche ambientali e di coinvolgere i consumatori in pratiche più responsabili.*

Cattura di valore ambientale. *I risultati mostrano tuttavia anche alcune criticità; in particolare, l'elaborazione di grandi dataset richiede elevata potenza computazionale, con conseguente aumento del consumo energetico delle infrastrutture digitali. Le imprese devono quindi bilanciare i benefici ambientali con i costi energetici associati alle tecnologie digitali.*
Creazione di valore sociale. *AI e big data possono contribuire al miglioramento delle condizioni di lavoro e alla promozione dell'inclusione organizzativa. L'analisi dei big data consente di monitorare il benessere dei dipendenti e individuare eventuali disuguaglianze. I sistemi di AI possono far leva sui big data inoltre per identificare segnali precoci di condizioni di lavoro non sicure.*
Distribuzione di valore sociale. *Le tecnologie digitali migliorano anche il coinvolgimento degli stakeholder esterni. I sistemi di comunicazione personalizzati grazie allo sfruttamento dei big data permettono alle imprese di offrire servizi più inclusivi e migliorare la relazione con clienti e comunità.*
Creazione di valore economico. *Dal punto di vista economico, AI e big data migliorano significativamente la capacità decisionale delle organizzazioni. Le imprese sfruttando big data possono identificare opportunità di mercato, migliorare la pianificazione strategica e ottimizzare la gestione della supply chain.*
Distribuzione di valore economico. *L'analisi dei dati consente inoltre una maggiore personalizzazione dei prodotti e dei servizi. I sistemi di customer service basati su AI migliorano la qualità dell'interazione con i clienti e riducono i tempi di risposta.*
Cattura di valore economico. *Infine, l'integrazione tra AI e big data permette di sviluppare nuovi flussi di ricavo basati su servizi data-driven e offerte personalizzate.*
I risultati emersi dall'analisi qualitativa evidenziano dunque che l'integrazione tra AI e big data può influenzare diversi elementi del business model canvas lungo le tre dimensioni della sostenibilità: economica, ambientale e sociale. In particolare, l'uso congiunto di queste tecnologie supporta nuovi meccanismi di creazione del valore, favorisce modalità innovative di distribuzione del valore agli stakeholder e contribuisce allo sviluppo di nuove forme di cattura del valore per le imprese. Allo stesso tempo, l'adozione di tecnologie data-driven può generare alcune tensioni legate ai costi, ai rischi tecnologici e agli impatti ambientali delle infrastrutture digitali.

Research limitations. *Lo studio presenta alcune limitazioni. In primo luogo, i dati si basano sulle percezioni dei manager e non su indicatori oggettivi di performance. Inoltre, il campione è concentrato su manager che hanno seguito lo stesso programma di formazione.*

Managerial implications. *I risultati di questa ricerca offrono diverse implicazioni rilevanti per manager e decision maker che intendono sfruttare i big data potenziati dall'AI per supportare l'innovazione sostenibile dei modelli di business. In particolare, i risultati evidenziano che l'integrazione tra AI e big data non rappresenta soltanto una scelta tecnologica, ma costituisce una decisione strategica che richiede adeguati meccanismi di governance organizzativa.*

Una prima implicazione riguarda la necessità di sviluppare solidi sistemi di data governance. Poiché i big data rappresentano una risorsa strategica sempre più rilevante per le imprese, le organizzazioni devono definire strutture di governance in grado di garantire la qualità, la sicurezza e l'utilizzo responsabile dei dati. In particolare, i manager devono implementare politiche di gestione dei dati che assicurino la trasparenza degli algoritmi, la protezione della privacy e la conformità alle normative emergenti sulla gestione dei dati. Senza adeguati sistemi di governance, l'adozione di tecnologie basate sui dati può generare rischi reputazionali e legali che potrebbero compromettere i benefici derivanti dall'innovazione digitale (Ghasemaghaei e Turel, 2020). Una seconda implicazione riguarda il ruolo dell'AI come capacità strategica organizzativa. I nostri risultati mostrano che l'AI non dovrebbe essere considerata soltanto uno strumento tecnologico operativo, ma una capacità strategica che consente alle imprese di trasformare i dati in insight utili per il processo decisionale. In questo senso, l'integrazione tra AI e big data può supportare le imprese nel migliorare la qualità delle decisioni strategiche, anticipare cambiamenti di mercato e sviluppare nuove opportunità di innovazione del modello di business. Pertanto, i manager dovrebbero integrare le tecnologie di AI nei processi di pianificazione strategica e nelle pratiche di analisi competitiva, al fine di migliorare la capacità dell'organizzazione di individuare opportunità emergenti e di adattarsi a contesti competitivi dinamici (Teece, 2010).

Un'altra implicazione riguarda lo sviluppo delle capacità organizzative necessarie per sfruttare le tecnologie data-driven. L'adozione di AI e big data richiede competenze interdisciplinari che combinino conoscenze tecnologiche, analitiche e manageriali. I risultati suggeriscono che le imprese dovrebbero promuovere la creazione di team interfunzionali che integrino competenze di data science con competenze strategiche e manageriali. Questo tipo di integrazione consente di tradurre gli insight derivanti dai dati in decisioni strategiche efficaci e in iniziative di innovazione del modello di business (Ritala et al., 2024). Un'ulteriore implicazione riguarda il ruolo delle tecnologie digitali nel supportare strategie di sostenibilità aziendale. I risultati mostrano che l'integrazione tra AI e big data può facilitare la creazione di valore sostenibile attraverso il miglioramento dell'efficienza operativa, la riduzione del consumo di risorse e lo sviluppo di soluzioni innovative orientate alla sostenibilità. In questo modo, le tecnologie digitali possono contribuire all'allineamento tra strategie aziendali e obiettivi di sostenibilità (Bocken e Geradts, 2020).

Tuttavia, i risultati evidenziano anche che l'adozione di AI e big data introduce nuove sfide manageriali legate ai rischi etici e tecnologici. Ad esempio, i sistemi di AI possono generare bias algoritmici o produrre decisioni difficili da interpretare, riducendo la trasparenza dei processi decisionali. Inoltre, l'elaborazione di grandi volumi di dati richiede infrastrutture digitali che possono comportare elevati consumi energetici. I manager devono quindi sviluppare pratiche

di governance responsabile dell'AI che includano meccanismi di monitoraggio degli algoritmi, audit dei sistemi di AI e procedure di gestione dei rischi tecnologici (Dwivedi et al., 2023).

Infine, i risultati suggeriscono che l'integrazione tra AI e big data può favorire nuove opportunità di innovazione del modello di business. Attraverso l'analisi dei dati e l'automazione dei processi decisionali, le imprese possono sviluppare nuovi servizi digitali, offerte personalizzate e modelli di business basati sui dati. Queste opportunità consentono alle imprese di migliorare la creazione di valore per i clienti e di sviluppare nuove fonti di ricavo. Tuttavia, per sfruttare pienamente tali opportunità, i manager devono adottare una prospettiva strategica orientata alla trasformazione del modello di business e alla gestione integrata delle tecnologie digitali.

Nel complesso, i risultati indicano che le imprese che intendono sfruttare il potenziale dei big data potenziati dall'AI devono sviluppare un approccio integrato che combini innovazione tecnologica, governance organizzativa e strategie di sostenibilità. Solo attraverso tale integrazione le organizzazioni potranno trasformare le tecnologie digitali in un vero vantaggio competitivo sostenibile.

Originality of the paper. *Lo studio contribuisce alla letteratura integrando tre filoni di ricerca: big data, AI e innovazione sostenibile dei modelli di business. Il contributo principale consiste nell'introdurre una prospettiva di governance strategica per comprendere come le imprese possano sfruttare le tecnologie digitali per creare valore sostenibile. Sebbene ricerche precedenti abbiano analizzato separatamente il ruolo dei big data nell'innovazione organizzativa e l'impatto dell'AI sui processi decisionali, la letteratura ha dedicato minore attenzione al modo in cui queste due tecnologie possano operare congiuntamente per supportare la trasformazione dei modelli di business in chiave sostenibile. Il nostro studio affronta tale lacuna esaminando l'integrazione tra AI e big data come leva per l'innovazione sostenibile dei modelli di business. In particolare, il nostro studio estende la letteratura sui big data mostrando come il valore strategico dei dati possa essere amplificato dall'utilizzo dell'AI, che consente alle imprese di trasformare grandi quantità di informazioni in insight utili per l'innovazione del modello di. In secondo luogo, il lavoro contribuisce alla letteratura sull'innovazione dei modelli di business evidenziando come l'integrazione tra AI e big data possa influenzare diversi blocchi del business model canvas, modificando i meccanismi di creazione, distribuzione e cattura del valore*

Building sustainable development actions by leveraging on values-led collaborations: a comparative case study analysis

FRANCESCA PENNUCCI[1], VERA BENEDETTO

Abstract. *For decades, both business and public organisations have largely oriented their actions towards economic performance and the efficient allocation of financial resources, while social and environmental considerations remained marginal to core decision-making processes. Increasingly, however, organisational purpose and value creation for sustainable development are understood as multidimensional, requiring the integration of economic viability, social equity, and environmental responsibility. Both private and public organisations are therefore called to reimagine their innovation strategies, practices, and monitoring systems in order to secure long-term performance while contributing to the resilience of broader socio-ecological systems in which they exist. In this sense, adopting a collaborative perspective becomes essential to reframing organisational challenges in their contexts and enabling systemic innovation pathways towards problem-solving for complex issues.*

This paper aims at contributing to the ongoing debate on which could be useful configurations of actors to implement changes towards sustainable models by leveraging on values-led public-private collaborations. Four cases are analysed to build a comparative, place-based picture of four innovative initiatives led by public or private actors operating under resource constraints and committed to ensuring multilevel value creation. Focusing on contexts characterised by institutional complexity and limited financial capacity, the study examines how organisations and citizens attempt to balance monetary resource allocation with social inclusion and environmental sustainability criteria to incrementally innovate their practices and solve complex issues. By reframing sustainability as a question of organisational design rather than solely of performance outcomes or indirect impact, the study contributes to debates on values-led collaboration towards sustainability-oriented innovation pathways.

Keywords: *sustainable development; public-private partnership; values-led collaborations; place-based innovation*

Framing of the research. What if the main obstacle to sustainability were not a lack of tools, metrics, or commitment, but the way organisations imagine themselves and their purpose? Much of contemporary management thinking still continues to assume that organisational success is inseparable from expansion, optimisation, and the efficient use of financial resources (Porter, 1985). However, two decades ago Hart and Milstein already underlined the need for a more complex approach in framing the sustainable development of firms and their ecosystems in the current global panorama (Hart and Milstein, 2003).

Growth - of scale, output, and performance indicators - remains too often the implicit horizon against which organisational action is arranged, even when social and environmental concerns are formally acknowledged. Within this imaginary, environmental and social sustainability are tolerated insofar as they can be aligned with efficiency, competitiveness, or innovation priorities, but they rarely challenge the underlying assumption that organisations must ultimately economically grow in order to survive and succeed. As Hart and Milstein (2003) argue, such a constrained understanding of sustainability leaves firms *ill-equipped* to address environmental and social challenges in a strategic manner.

Degrowth scholarship further challenges the classic economic assumptions of organisational activity (D'Alisa et al., 2014). Drawing on ecological economics and political theory, this body of work challenges narratives of "green growth", arguing that they often function as comforting myths, promising to reconcile economic expansion with ecological limits without addressing the structural drivers of environmental degradation and social inequality. From this perspective, environmental sustainability initiatives that remain embedded within growth-oriented rationalities risk reproducing the very conditions they seek to mitigate. Yet, degrowth scholars also acknowledge a sobering reality: abandoning growth as a societal objective without changing politically and institutionally current conditions is implausible (Kallis et al., 2018). In many economies, employment systems, welfare provision, and public revenues remain structurally tied to economic expansion. Under such conditions, a rapid disengagement from growth-oriented frameworks may generate social instability, undermining the very objectives of equity and collective well-being that sustainability agendas seek to advance. Social sustainability, therefore, should not be treated as a residual outcome of either growth or degrowth trajectories (Alexander et al., 2020; Vifell and Soneryd, 2012). Rather, it depends on the reconfiguration of institutional arrangements, redistributive mechanisms, and organisational practices capable of safeguarding livelihoods while operating within ecological limits (Janssen and Basta, 2024).

This tension raises a central question for management and organisation studies: how can organisations balance the interplay between growth and degrowth instances without reducing sustainability to a binary opposition? The challenge lies in developing alternative and more complex imaginaries capable of reshaping the processes through which organisations govern themselves, define value, and make collective decisions under conditions of economic, social and

[1] Interdisciplinary Research Center Health Science, Sant'Anna School of Advanced Studies, Pisa, f.pennucci@santannapisa.it

ecological constraints (Dyck et al., 2019; Engert et al., 2016). From this perspective, sustainability emerges as an organisational problem before it becomes an ideological or economic one. The issue is how organisations structure purpose, responsibility, and accountability when growth and individual performance can no longer serve as the sole and unquestioned sources of legitimacy (Engert et al., 2016).

Indeed, management and organisation studies have increasingly engaged with sustainability, responsibility, and the redefinition of organisational purpose. A growing body of work has examined how organisations incorporate social and environmental concerns into strategies, business models, and performance systems, often emphasising values-led management, stakeholder engagement, and the alignment between economic and societal goals (Bocken et al., 2014; Hart and Milstein, 2003; Pasamar et al., 2023). This literature has contributed important insights into why sustainable development matters for organisations and its stakeholders and how it can be framed as a strategic priority rather than a peripheral concern.

As Freeman already stated, there can be no means without ends (Popa et al., 2015). Redefining values and the value to be achieved is fundamental to introducing transformative pathways in established organisations (Mazzucato, 2018; Seray et al., 2020). In fact, the core values represent fundamental references to develop strategies, organizational models, and adapt operations toward the defined objectives.

Of course, this is also valid if organizations want to orient their actions towards sustainable development. In a context of rapid and often disruptive changes, organizations are called to working on multiple dimensions of value that may conflict. In this context, both public and private institutions need to considering a broader set of resources, actors, and processes to be activated according to a negotiated set of values and desired final goal of their actions (Gray and Jani, 2016; Osborne et al., 2022; Porter and Kramer, 2011). Thus, organizations are called to reimagine their operational models and collaborations to ensure an effective and efficient use of current resources and including others' resources into their network (Cucino et al., 2025; Osborne et al., 2022; Vinaixa et al., 2022).

Once the values and value to be achieved are defined, the translation from theory to practice needs infrastructures, capitals, and procedures to be implemented in balanced configuration of actors and actions (Dai et al., 2024). In this panorama, place-based and collaborative approaches are suited to sustain both private and public organizations in developing alliances with a systematic collaboration funded on a shared set of core values and oriented to a shared achievement of a multidimensional global value (Hofstad et al., 2026; Malmborg et al., 2025).

Despite this growing attention towards integrating complex visions of sustainable development into strategic plans of private and public institutions, two interrelated evidence gaps remain. First, much of the sustainability literature continues to bring evidence on the strategy building as a normative prescription, while limited insights are available on the processes needed to translate sustainability-oriented values into everyday organisational and decision-making activities (Berke and Conroy, 2000; Cortinovis and Geneletti, 2018). Second, while management scholarship has acknowledged the limits of growth-centred models and the shortcomings of technocratic sustainability approaches, sustainable development is often treated as something organisations must comply to - through initiatives, metrics, certifications, or innovations - rather than as something that reshapes how organisations are governed, how value is defined, and how collective priorities are negotiated between stakeholders at different level of actions.

Purpose of the paper. In this paper, we will present a comparative analysis of case studies that represent examples of complex organisational arrangements aimed at balancing different values to building multistakeholder sustainable development pathways. The paper is structured as follows. In the next paragraph, we describe the comparative methodology adopted in the study. The subsequent section presents the findings of the cross-case analysis. Finally, we discuss the implications of our findings for management and organisation studies, and outline directions for future research.

Methodology. The presented research adopts a qualitative multiple case study design to explore how sustainability-oriented transformations develop in practice (Stake, 2006). A comparative approach is particularly suitable for investigating complex organisational arrangements embedded in specific territorial and institutional contexts, highlighting the implemented processes, and identifying recurring patterns across heterogeneous settings and issues. The research focuses on case studies of values-led collaborations built to test innovative solutions within resource-constrained environments.

Case selection and analysis were guided by the sustainable value framework proposed by Hart and Milstein (2003), which identifies four interrelated strategic dimensions:

1. *Resource efficiency and pollution prevention*, reducing operational inefficiencies and environmental harm;
2. *Product stewardship and accountability*, engaging increasingly interconnected civil society actors, responding to growing transparency demands, and incorporating social and environmental expectations into organisational governance and value creation processes;
3. *Clean technology*, investing in future-oriented innovations;
4. *Sustainability vision*, developing long-term strategic orientation towards sustainable development.

These drivers articulate sustainability across both internal–external and short–long term dimensions, offering a dynamic perspective on how organisations can generate economic, social, and environmental value simultaneously.

In this study, the framework is used as an analytical lens to examine how public organisations and their partners attempt to reconcile growth-dependent institutional logics with the need to operate within ecological limits while safeguarding social sustainability.

Cases were selected through a sampling strategy aimed at identifying initiatives that explicitly engage with multidimensional value creation and reflect, at least in part, the drivers outlined in the sustainable value framework. Three cases were retrieved from already established open databases. In particular, we searched the Governance International Case Studies database (https://www.govint.org/our-resources/case-studies) and the Case Collection of the Columbia University (https://www.sipa.columbia.edu/sipa-education/picker-center-executive-education/case-collection). Furthermore, the authors added a case where they have been directly involved with a participatory research approach. Each case refers to a diverse geographical and sectoral contexts, to ensure analytical variation while maintaining a shared focus on sustainability-oriented organisational transformation under resource constraints.

The first case (Case 1) concerns the Proximity Care and the Population Health spoke of the Tuscany Health Ecosystem (THE), developed in remote areas of the Tuscany region (Italy) (https://www.proximitycare.it; https://tuscanyhealthecosystem.it/spoke-10/; anonymised). Coordinated by a Research University and structured as a multi-actor collaboration among regional universities, healthcare authorities, municipalities, third-sector organisations and private foundations, the initiatives promote integrated care models and digital solutions to enhance accessibility and continuity of care. It represents an effort to reconcile economic sustainability, equitable access and environmental considerations within a territorially embedded public healthcare system. The second case (Case 2) examines Partnerships for Parks in New York City (USA), an urban governance initiative led by the NYC Parks Department in collaboration with community organisations and private partners. The project focuses on the regeneration and long-term stewardship of public spaces through collaborative management arrangements integrating public, civic and private actors (https://www.sipa.columbia.edu/sites/default/files/2022-10/Case_Partnerships%20for%20Parks.pdf). The third case (Case 3) analyses off-grid solar initiatives in Uganda, involving public agencies, private energy firms and local communities. These initiatives seek to expand energy access while balancing affordability, market viability and environmental sustainability (https://www.sipa.columbia.edu/sipa-education/picker-center-executive-education/case-collection/offgrid-solar). The fourth case (Case 4) explores the Çiğdemim Neighbourhood Association initiative in Turkey, supported by international development actors such as the UN capital Development Fund (UNCDF) and local entrepreneurs. The project promotes sustainable local development through community-based organising and collaborative resource mobilisation (https://www.govint.org/our-resources/case-studies/case-study/cigdemim-neighbourhood-association-in-turkey-promoting-sustainable-development).

The study relies primarily on the available documental secondary data, including case reports, institutional documents, websites, and policy materials. As already stated, the authors were directly involved in the development of the Proximity Care and THE projects, thus they had access to additional contextual insights and internal documentation.

The authors conducted an in-depth analysis of each case individually aiming at identifying the core elements of each stakeholders configurations, values, and value arrangements. Subsequently, a cross-case comparison was undertaken to identify recurring patterns, shared tensions, and context-specific variations.

Results. The first set of results emerged from the analysis of each case study, according to the predefined categories. Two cases were located in rural or marginalised areas (Case 1 and Case 3), while other two regard public areas and neighbourhoods (Case 2, Case 4).

Each case falls within the strategic dimension of *Product stewardship and accountability,* which is linked to participation and transparency as described. This dimension is concretely introduced through specific transformative imaginaries that mobilise political and collective actions. In this sense, Case 1 activities are built on the idea that remote or marginal areas can function as testing grounds for innovative and sustainable health and social care models. By prioritising investment in these territories, the initiatives develop and pilot new solutions that may later be scaled to more densely populated contexts. In Case 2, a long-standing public–private partnership was grounded in the belief that public parks are central to neighbourhood prosperity and citizens' quality of life. The regeneration and stewardship of urban green spaces are therefore framed as both a civic responsibility and a strategic investment in local well-being. Case 3 is based on a bottom-of-the-pyramid market strategy aimed at developing affordable products and services for economically vulnerable populations. Implemented within the renewable energy sector, the initiative combines environmental sustainability with social inclusion through business models designed to be both financially viable and socially responsible. Finally, Case 4 originates from the citizens-led initiative within a specific neighbourhood who sought to improve their living conditions across multiple domains. Active citizen engagement in voluntary caring for the territory constitutes the driving force of the movement. Moreover, their actions bring forward specific requests for collaboration with public and private actors.

Moving forward to the comparative analysis results, some initiatives originated from collective goals and others from private interests. In both cases, effective collaboration arrangements required the shared definition of values and value to be achieved through integrated actions. In none of the cases did alignment emerge automatically. Rather, institutions and citizens actively mobilised to sharing transformative imaginaries and translating them into concrete initiatives and organizational or governance arrangements. As alignment gradually took shape, actors began to commit both material and immaterial resources in pursuit of collectively defined objectives. Yet collaboration remained inherently dynamic and at times fragile. Recurring barriers included limited trust between public and private actors, scepticism among citizens

or users, complex and often slow decision-making processes, and constraints related to infrastructure and spatial availability. Across cases, development unfolded in a longitudinal and non-linear manner, requiring continuous negotiation of priorities, adjustment and recalibration of collaborative strategies.

> *"All of those groups had representatives who you would meet with on a regular basis. On the one hand it helped expedite certain things through the city process, but on the other hand, it meant that you had to work with five agencies that had very different priorities."* (Case 2)

> *Disparities in quality of solar panels in Uganda threatened the credibility of companies.* (Case 3)

Case 3 illustrates how trust between public and private actors can emerge when roles, responsibilities and risk-sharing mechanisms are clearly defined. It represents a configuration in which economic value creation is explicitly aligned with social objectives through the deployment of environmentally sustainable technologies. Local enterprises operate with a commercial logic, seeking financial returns from the provision of renewable energy products and services. However, market expansion depends on the purchasing capacity of economically vulnerable populations. To address this constraint, firms introduced context-sensitive financial mechanisms, such as *pay-as-you-go* models, enabling affordability while maintaining business sustainability.

> *At the kiosks, users could not only charge their phones or use to connect to the internet, but also receive digital services such as payment service from the franchisee. […] The devices economically empowered a group often denied opportunity in the Uganda labour market. 'Most of the kiosks owners were women'.* (Case 3)

> *By introducing solar-powered water pumps for drinking and irrigation, Innovation Africa helped both to raise the burden of unpaid work off women and to improve community health*. (Case 3)

Across the public–private alliances examined, an effective starting point appears to lie in informal agreements that allow actors to experiment with innovative solutions before formalising shared governance arrangements. These preliminary, flexible forms of collaboration create space for trust-building and mutual learning, reducing the risks associated with immediate institutionalisation.

> *Davis, for one, was adamant about keeping the city's relationship with the Conservancy fluid, eschewing formal contracts or announcements that might suggest the city was receding control of the property to the private sector* "*There was no lease. There was no license agreement. There wasn't anything."* (Case 2)

> *The association organises street parties and other social events […] also to provide a platform for other NGOs […] the neighbourhood plays an important role in 'nudging' the local council to become more forward-thinking.* (Case 4)

All the cases also show that having contemporary bottom-up movements and top-down support is central to ensuring that the experimental phase evolves into ordinary changes. Furthermore, it emerges that individual leaders and collective boards are needed to push forward the collaboration by adhering to and spreading the transformative imaginaries on a local basis.

> *The Proximity care activities needed top-down support in order to achieve concrete changes in health and social care processes. Indeed, the research team was involved in merging the contributions from the territory with the formal actions required to catalyze them.* (Case 1)

> *The most important partnership here is between engaged and passionate citizens and their government.* (Case 2)

> *The U.N. Capital Development Fund (UNCDF) […] Rather than focusing on national governments or corporations, the organization developed expertise in assisting both local governments and private actors. (Case 3)*

Decentralizing responsibilities can also enhance the activation of local resources. This element relates to a devolving power initiative from institutional actors and standard alliances and to open innovation approaches.

> *Engaging local municipalities and citizens in actively collaborating with the public services has been key to guaranteeing successful implementation. Furthermore, it was central to building trust among actors and the targeted territory over time. The higher the rate of participation, the more enlarged set of resources and impacts could be created.* (Case 1)

> *"I learned that there was something, not quite magical but very dramatic, that began to happen when you decentralized authority. Instead of everything having to come to the commissioner, you start pushing it down and creating people in charge of pieces of who a sense of their own, the breadth of authority you're willing… to delegate to them. You begin to have more efficient things begin to happen more innovation."* (Case 2)

Since collaboration is not always for good purpose, we should underline some negative side-effects of the models introduced in the cases. In fact, public-private partnerships can lead to corruption or inequitable access to good quality services and products.

> *The High Line did create a real estate boom. For some, that was a negative. The pace, scale and price range of much of the development adjacent to the High Line raised questions about equity and influence in city planning.* (Case 2)

Overall, it is clear that facilitating or hindering elements have relevance and activate according to specific imaginaries, actors, and infrastructure configurations at the local level. The contingent evolution of shared values and imaginaries seems to give diverse relevance to the elements, thus favouring or impeding the value creation processes. The Uganda case is emblematic in this regard. The growth of the off-grid solar market was driven by the convergence of complementary imaginaries: on the one hand, the bottom-of-the-pyramid approach, which frames economically

vulnerable populations as active market participants; on the other, a vision of socially responsible investment pursued by firms operating in the renewable energy sector.
Public-private partnerships emerged overall as a flexible and adaptable model, while also raising questions about the concrete risk of generating inequity and so diminishing the social sustainability of the solutions. For example, the more active communities could achieve better results just because of their visibility for the public actors. Furthermore, there exist public-private partnerships less performative than others.

> *"Some cities argued that large gifts claimed as tax deductions cost the public pursue needed tax revenues, and benefited already wealthy parks while depriving the general public".* (Case 2)

The Proximity Care and THE initiatives offer a particularly interesting approach to addressing this risk. Rather than concentrating innovation in central and already well-served areas, they encourage centres of research excellence and advanced care provision to engage directly with decentralised and often marginalised territories and populations. In doing so, the projects aim to counterbalance patterns of inequity that are frequently reinforced by conventional models of innovation diffusion, whereby new solutions are firstly implemented in urban centres and only later extended to more remote or underserved areas. Similarly, the New York City parks case reports suggestions regarding *the creation of a Neighborhood Parks Alliance, which would form partnerships between a well-financed conservancy, a "contributing park" and "member parks" in need of more money and support.* In practice, the Central Park Conservancy had already extended its management model to twelve additional parks through an expanded agreement with the city, demonstrating the potential of cross-park resource redistribution within a collaborative framework. At the same time, representatives of the High Line leadership emphasised that public funding alone was insufficient to sustain urban park systems, arguing for broader reinvestment across the city and beyond traditional public–private arrangements. However, the reliance on private funding raises normative concerns. While private contributions can enhance public services, they should not justify reductions in public expenditure without transparent consideration of the distributive and allocative implications of such choices.

Research limitations. Our analysis has many limitations. First of all, the selection of cases was based on a purposive sample according to a specific reference framework. It could be interesting to apply a similar analysis to other cases coming from different data sources and further geographical and cultural contexts. Secondly, we focused our analysis on the explicit value definitions of stakeholders while there could be some covered goals and imaginaries that pushed forward the reported cases. Finally, further research would be needed to better explore the implications of local approaches for the global ecosystems where the stakeholders arrangements are embedded in.

Discussion and Managerial implications. The presented results showed concrete examples of values-led collaborations oriented to sustainable development. The central aspect to be underlined regards the importance of building the process over time and across interests (Ansell and Gash, 2008; Veeman and Politylo, 2003). Collaborative configurations can have moments of turbulence over time. Initial sharing of values needs to be supported by an organizational attitude to seek solutions that adapt step by step to the evolution of contexts. The establishment of iterative shared-value and innovation processes can ensure flexibility if contexts, people, and resources change. To this end, change management practices should be implemented at different decision-making levels (Da Ros et al., 2024).

Ecosystems need continuous effort to stabilize the collaboration over time. Indeed, it could be the case that impact emerges as a "contingency" - which is the project –, thus the joint efforts remain punctual over time and cannot be valued as possible transferable models of action. Managers should always envision a portion of projects dedicated to testing and developing scalability models over time and in other comparable areas (anonymised; Hofstad et al., 2026).

Institutional theory reminds us that organisational change is embedded within broader normative, regulative and cultural-cognitive structures (Scott, 2014). Similarly, research on socio-technical transitions demonstrates that sustainable transformation requires supportive institutional arrangements capable of sustaining new practices beyond isolated experiments (Geels, 2002). Without such support, sustainability initiatives risk remaining fragmented or short-lived.

Capitals are needed for effective and durable alliances. Financial, human, and social capitals are central and should be used with the right intention and sustained over time. Transformative imaginaries are also crucial to orient individual and collective actions towards complex goals, especially when innovations are introduced in contexts with scarce resources or conflicting needs to be merged (anonymised; Bryson et al., 2015; Porter and Kramer, 2011). Surely, a shared value orientation does not eliminate tensions between economic, social, and environmental goals; rather, it provides a normative anchor through which such tensions can be deliberated and governed in the specific places.

Each of the presented cases required a personalized-innovation pathway to ensure the effectiveness of solutions in non-standard territories (Hambleton and Howard, 2013; Kubacki et al., 2017). Managers can take advantage from imagining modular approaches that adapt to local ecosystems. For example, private interests in the Uganda case led to the development of incremental innovations regarding service models adapted to local needs more than disruptive introduction of technologies or big changes.

Public–private efforts integration highlights the importance of mobilising heterogeneous resources, competencies, and capitals across organisational boundaries if the aim is to address complex issues while guaranteeing sustainable development (Stanton and Oliver, 2026). Resource dependence theory suggests that organisations can rely on external actors to access critical resources, thereby shaping patterns of collaboration and power (Pfeffer and Salancik, 1978). More recent work on ecosystems and cross-sector partnerships further emphasises that complex societal challenges require

coordinated action among public, private and third-sector actors (Adner, 2017; Bryson et al., 2015). Indeed, integrating diverse resources expands the capacity to pursue economic viability, social provision, and environmental responsibility simultaneously. As the cases show, institutions need time and space to reduce their prejudices and setting up joint actions.

Regarding the private sphere, common people and communities emerge as concrete protagonists of sustainable development strategies for value creation. Citizen and community engagement reflects the recognition that sustainability challenges cannot be addressed through managerial decision-making alone. Stakeholder theory has long emphasised that organisations are embedded in networks of relationships that shape both legitimacy and performance (Freeman, 1984; Mahajan et al., 2023). More recent work highlights the importance of including diverse actors - including citizens, community groups and civil society organisations - in co-producing public value and negotiating complex trade-offs (Ansell and Gash, 2008; Audretsch et al., 2022; Bryson et al., 2015; Osborne et al., 2022). Engaging communities is therefore not merely a participatory add-on, but a structural condition for redefining organisational purposes in multidimensional terms. If public administrations withdraw into themselves, they miss the opportunity to best bring out or channel the hidden capital of civic activism (Bovaird and Loeffler, 2014; De Rosis et al., 2020; Loeffler, 2021). And they also miss the opportunity to learn new skills, activating open innovation circuits where there is usually stagnation due to bureaucratic rigidity (Audretsch et al., 2022; Cui and Wu, 2016; Hubert, 2011). Companies for their part can build alliances and increase market's trust thanks to actions that on the at a first sight seem only collateral to their core values. Yet these actions may contribute to their reputation and growth in terms of customer and stakeholder relationships while orienting their organizations towards sustainable development, as known. Furthermore, as with the High Line Park example, collaborating to create public value could also bring benefits in terms of private revenues while guaranteeing a balance with social and environmental sustainability (Porter and Kramer, 2011).

Originality of the paper. This work presented a multiple case study analysis to illustrate concrete examples of values-led collaborations towards sustainable development in specific territories. Firstly, we underlined the need for enhancing evidence-based studies regarding the translation of strategic management into sustainable-oriented actions. Secondly, qualitative evidence was used to underline the facilitating and hindering factors to be implemented or addressed when developing alliances towards sustainable development. Finally, we discussed the results by showing the central topics that both public and private managers should consider when working with complex issues by adopting a sustainable development vision. By examining how stakeholders define value, allocate responsibility, and govern trade-offs across economic, social and environmental dimensions, this study aims to contribute to management and organisation scholarship in three ways. First, it shifts the focus from sustainability as outcome to sustainability as process. Second, it advances understanding of how organisations operationalise value pluralism under growth constraints. Third, it unveils the role of collaborative arrangements in enabling transformative pathways towards sustainable development.

Certified management systems as governance infrastructures for ESG assurance readiness

SABRINA RESTANTE[1], ROSSELLA FLORIO[2], EMILIANO TERELLA[3], BERNARDINO QUATTROCIOCCHI[4]

Abstract. *The introduction of mandatory assurance for sustainability information, reinforced by the Corporate Sustainability Reporting Directive (CSRD), has accelerated the diffusion of ESG verification practices while simultaneously highlighting several operational challenges related to data quality, the fragmentation of information processes, and the weakness of internal control systems. Although the literature has extensively examined sustainability reporting frameworks and assurance standards, comparatively less attention has been devoted to the organizational infrastructures that enable their effective and credible implementation.*

This study investigates the role of certified management systems as governance mechanisms supporting ESG assurance, interpreting them as organizational infrastructures capable of structuring information flows, strengthening internal control processes, and improving the reliability of sustainability data. Adopting a comparative qualitative research design, the study analyzes firms characterized by different configurations of ISO 9001 and ISO 14001 certification, comparing certified and non-certified organizations. The analysis is based on a structured protocol derived from international assurance standards and focuses on four key dimensions: ESG data traceability, the formalization of internal control processes, the breadth of the assurance scope, and the level of assurance adopted.

The findings show that certified management systems operate as governance infrastructures that enable higher-quality assurance practices by promoting more reliable data, more structured verification procedures, and a greater organizational readiness to adopt more advanced levels of assurance. The contribution of this study lies in reinterpreting ESG assurance not merely as a technical compliance requirement, but as the outcome of organizational capabilities embedded within management systems. In doing so, the research offers theoretical implications for the literature on sustainability governance and managerial insights for the structural integration of ESG practices into corporate processes.

Keywords. *ESG assurance; certified management systems; sustainability governance; ISO 9001; ISO 14001; ESG data quality; organizational transformation.*

Framing of the research. *The primary goal of the CSRD is to elevate sustainability reporting to the same level of importance as financial disclosure, repositioning ESG disclosure as a structural component of corporate governance rather than a peripheral communication tool. ESG strategies have become critical differentiation factors—not only due to the growing relevance of the triple bottom line (Elkington, 1997), but also because companies face increasingly stringent legislation on non-financial disclosure and intensifying stakeholder expectations regarding corporate social responsibility. In this perspective, sustainability reporting is progressively embedded into strategic and governance architectures, reinforcing its role in value creation and legitimacy-building processes (Eccles, Ioannou, & Serafeim, 2014).*

The directive CSRD imposes two key obligations: (1) annual management reports must include sustainability information aligned with European Sustainability Reporting Standards (ESRS); and (2) all sustainability reports must undergo assurance by an auditor or authorized provider. According to the CSRD (2022), from 2024, large companies already subject to the NFRD are required to publish sustainability statements in accordance with ESRS guidelines, while listed SMEs will progressively enter the scope of application. The directive introduces the principle of double materiality and requires limited assurance as a minimum, with the European Commission mandated to adopt more detailed assurance standards by October 2026.

At the global level, the regulatory landscape has further evolved with the introduction of IFRS Sustainability Standards, consolidating ESG reporting into a transnational governance architecture. Within this context, the most widely adopted sustainability assurance standards are ISAE 3000 (IAASB, 2013) and AA1000AS (AccountAbility, 2020). ISAE 3000 governs assurance engagements other than audits or reviews of historical financial information and is predominantly adopted by accounting-based assurance providers, while AA1000AS adopts a principles-based, stakeholder-oriented approach and is more frequently used by non-accounting providers. Both frameworks distinguish between limited and reasonable (or high/moderate) assurance levels, reflecting different degrees of evidence gathering and confidence.

The assurance process aims to enhance credibility, transparency, and reliability of non-financial information, serving as a strategic instrument to strengthen trust among shareholders, creditors, and broader stakeholder groups. Prior research highlights that assurance contributes to reducing informational asymmetries and enhancing market confidence (Simnett, Vanstraelen, & Chua, 2009; Cohen & Simnett, 2015; Garefalakis et al., 2025). However, two critical issues emerge. First, under stringent regulatory requirements, assurance risks being perceived as a mere compliance exercise—a "tick-box" activity aimed at satisfying legal obligations rather than substantiating authentic ESG commitment. Second, as Doxey and Sealy (2022) suggest, mandatory sustainability reporting and assurance may exacerbate the expectation gap (Porter, 1993) between auditors and users (Deegan et al., 2006), generating discrepancies between what auditors perform and what stakeholders expect in terms of accountability, transparency, and forward-looking ESG performance.

In parallel, ISO Management System Standards represent a structured mechanism for standardizing CSR-related practices, reducing operational risks and costs, and enhancing stakeholder trust (Boiral, 2011). These voluntary frameworks—particularly ISO 9001 (Quality Management Systems) and ISO 14001 (Environmental Management Systems)—formalize managerial routines and embed sustainability into operational processes (Delmas & Montiel, 2009; Heras-Saizarbitoria & Boiral, 2013). Recent bibliometric analyses further highlight the growing role of ISO management system standards within the corporate sustainability literature, emphasizing their contribution to the integration of environmental and governance practices into organizational routines (Ronalter, Poltronieri & Gerolamo, 2023).

ISO 9001 emphasizes process-based approaches, KPI monitoring, and continuous improvement (Fahmi et al., 2021; Hunt et al., 2021; Khan et al., 2020), while ISO 14001 institutionalizes environmental performance monitoring, waste reduction, and emission control (Dewi et al., 2020; Hunt et al., 2021). Through these mechanisms, firms strengthen data traceability, documentation discipline, and internal control routines—core organizational elements potentially underpinning credible ESG assurance.

Moreover, in the evolving European landscape—characterized by the Corporate Sustainability Due Diligence Directive (CSDDD) and subsequent regulatory recalibration through the Omnibus I simplification package—the scope and intensity of sustainability obligations have been strategically adjusted to balance competitiveness and accountability. In such a context, the need for robust, internally grounded assurance practices becomes even more salient, as firms must demonstrate factual social and environmental commitment beyond formal regulatory compliance. Consequently, ESG assurance effectiveness appears increasingly dependent on the maturity of internal governance infrastructures rather than solely on the formal adoption of external standards (De Roeck, Maon, & Haar, 2021; Kuo, Yeh, & Yu, 2022; Adams, 2015; Wang, 2023).

Figure 1. Certified management systems as governance infrastructures enabling ESG assurance readiness (own elaboration)

Purpose of the paper. *Against this regulatory and governance backdrop, the objective of this research is to assess whether and how the adoption of ISO 9001 and ISO 14001 systems improves the quality and effectiveness of ESG assurance according to ISAE 3000 and AA1000AS standards. The study is grounded in the assumption that ESG assurance effectiveness is not merely a function of externally imposed assurance standards but is deeply embedded in organizational governance infrastructures shaped by certified management systems.*

Specifically, the research question guiding this study is: can certified management systems reduce the application-related criticalities of assurance standards and support the transition to higher levels of assurance? By conceptualizing assurance as an integrated management tool rather than an isolated technical requirement, this study aims to bridge the gap between legal obligation and substantive ESG governance.

Building on this framework, three propositions are formulated. First, ISO-certified firms show higher ESG data reliability (P1), as formalized procedures and monitoring systems enhance data traceability and control discipline (Simnett, Vanstraelen & Chua 2009). Second, ISO certification is associated with broader assurance scope (P2), given the structured integration of sustainability processes across organizational functions (Cohen & Simnett 2015). Third, ISO certification is associated with stronger formalization of internal governance and control mechanisms supporting ESG assurance (Wang 2023) (P3). Through this perspective, the paper contributes to the literature on sustainability

governance and management systems by reframing ESG assurance as an organizational capability emerging from structured governance routines rather than as a purely regulatory compliance mechanism.

Methodology

Research design. This study adopts an exploratory comparative multiple-case study design to investigate whether certified management systems function as organizational governance infrastructures supporting ESG assurance readiness. Case study methodology is particularly suitable for examining emerging managerial phenomena characterized by regulatory transformation and evolving governance practices (Eisenhardt, 1989; Yin, 2018). Consistent with case-based research traditions, the objective of the analysis is analytical rather than statistical generalization, aiming to identify organizational mechanisms linking certified management systems to ESG data governance and assurance-related practices (Yin, 2018). Cases were selected through theoretical sampling to ensure variation in governance infrastructures while maintaining sector comparability (Eisenhardt & Graebner, 2007). The sample includes five firms operating in the Italian coffee production industry, a sector increasingly exposed to sustainability pressures related to environmental impact, responsible sourcing, and supply chain transparency. In the analysis of the five coffee sector firms, case selection did not prioritize firm size—while acknowledging its analytical relevance—but rather the materiality of corporate responsibility practices and observed theoretical variation. Consistent with Gioia et al. (2013) and Small (2009), in inductive comparative studies the crucial element is not the number or homogeneity of cases, but the empirical depth of the data, their theoretical relevance, and the quality of the comparison to identify significant ESG organizational patterns. Case selection followed four criteria: sector homogeneity, availability of ESG and sustainability documentation, variation in ISO certification status (ISO 9001 and ISO 14001), and the presence of observable sustainability disclosure practices. The final sample includes three ISO-certified firms and two non-certified firms, enabling comparison between different levels of managerial formalization. Although the firms differ in organizational size and complexity, the analysis does not aim to isolate causal effects but rather to explore whether certified management systems are associated with more structured governance infrastructures supporting ESG assurance processes. The empirical analysis relies on multiple documentary sources to enhance construct validity through data triangulation (Yin, 2018), including sustainability reports and ESG disclosures, corporate governance documents, codes of ethics and compliance frameworks, documentation related to quality and environmental management systems, and publicly available information on sustainability policies and supply chain practices. These materials provide insights into governance routines, ESG data management processes, and disclosure practices relevant to sustainability assurance. Building on prior literature on sustainability assurance and governance infrastructures (Simnett, Vanstraelen, & Chua, 2009; Cohen & Simnett, 2015; Bakarich, Baranek, & O'Brien, 2023), four analytical dimensions were identified: ESG data reliability and traceability, referring to the extent to which sustainability information is systematically measured and documented; formalization of governance and control mechanisms, referring to the presence of structured compliance systems, internal controls, and governance procedures; breadth of ESG disclosure perimeter, referring to the scope of sustainability information disclosed across environmental, social, and supply chain dimensions; and ESG assurance readiness, referring to the degree to which organizational processes and documentation routines appear capable of supporting credible external assurance. These dimensions capture key organizational capabilities that facilitate credible ESG assurance processes (Ruohonen & Kullas, 2024; Sánchez, Zorio-Grima, & Merello, 2026). The analysis followed a two-stage procedure. First, within-case analysis was conducted to map governance structures, ESG disclosure practices, and management routines for each firm. Second, cross-case comparison was used to identify recurring patterns associated with ISO-certified management systems. This analytical strategy follows the logic of pattern matching and replication typical of comparative case study research (Yin, 2018), allowing identification of organizational configurations that may support ESG data governance and potential assurance processes.

Results. *The comparison is conducted between three firms certified under ISO 9001 and ISO 14001(Borbone, Esse Caffe and Kimbo) and two non-certified firms (Dersut and Goppion), suggesting that certified management systems are associated with more structured CSR and ESG governance practices.*

The analyzed sample comprises five firms operating within the same industry (coffee production). The comparison is based on three key dimensions:

- *Environmental attention (CO_2e tons, packaging sustainability, environmental protection initiatives);*
- *Social impact (gender gap and local community engagement);*
- *Governance (presence of Model 231 and Code of Ethics) and Supply chain (sustainable sourcing and certified suppliers).*

A comparative overview of key ESG governance indicators across the analyzed firms is presented in Table 1, in particular:

- ***Environment (E):** The analysis highlights how ISO-certified companies leverage ISO 14001 to translate environmental performance into objective KPIs, thereby facilitating the work of assurance providers;*

- ***Social (S):*** *Non-certified firms tend to focus on ad-hoc, local, and voluntary initiatives. Conversely, ISO-certified firms formalize the 'S' pillar through sustainable procurement procedures, rendering social impact measurable and auditable;*
- ***Governance (G):*** *Governance mechanisms (e.g., 231 Models, Ethical Codes) and Supply chain governance within ISO-certified firms are not treated in isolation; rather, they are embedded within the quality management system. This ensures that sustainability policies are not merely declarative but effectively monitored and enforced.*

Table 1 – Comparative ESG governance indicators between ISO-certified and non-certified firms

Dimension	***Indicator***	***ISO firms (n=3)***	***Non-ISO firms (n=2)***
Environmental management	*Carbon footprint measurement*	*3 / 3 firms*	*0 / 2 firms*
	Sustainable packaging	*3 / 3 firms*	*1 / 2 firms*
	Environmental initiatives	*3 / 3 firms*	*1 / 2 firms*
Social impact	*Women employees (%)*	*20.3%*	*48.5%*
	Local community initiatives	*3*	*4*
Governance structures	*Model 231*	*3 / 3 firms*	*0 / 2 firms*
	Code of ethics	*3 / 3 firms*	*2 / 2 firms*
Supply chain governance	*Sustainable procurement policies*	*3 / 3 firms*	*0 / 2 firms*
	Certified suppliers	*2 / 3 firms*	*1 / 2 firms*

Although firm size remains a relevant contextual factor in the adoption of ISO certifications—often a determinant of resource availability and integration into global value chains—this study focuses specifically on the organizational practices associated with these standards. By holding organizational scale as a backdrop, the analysis isolates the role of certified management systems in structuring governance mechanisms relevant to ESG assurance. The comparative analysis examines five firms operating in the Italian coffee production industry, including three companies certified under ISO 9001 and ISO 14001 and two firms without such certifications. The analysis aims to identify organizational patterns associated with certified management systems and to explore their role in structuring governance mechanisms relevant to ESG assurance.

The evidence provides support for Proposition 1 (P1), which suggests that certified management systems are associated with higher levels of ESG data reliability and traceability. Firms operating under ISO-certified systems systematically quantify environmental indicators, such as carbon emissions, and provide more structured documentation of sustainability-related metrics within their reporting frameworks. In contrast, non-certified firms tend to rely more heavily on descriptive narratives that highlight environmental initiatives without consistently adopting standardized measurement systems or methodological explanations. This difference does not necessarily indicate superior environmental performance; rather, it reflects the presence of more formalized procedures for collecting, monitoring, and documenting sustainability-related information, thereby enhancing the traceability and reliability of ESG data.

The analysis also provides evidence consistent with Proposition 2 (P2), which proposes that certified management systems are associated with a broader scope of ESG disclosure and sustainability practices. ISO-certified firms demonstrate more structured environmental and supply chain initiatives, including sustainable packaging strategies, environmental monitoring systems, and supplier qualification processes incorporating sustainability criteria. These practices indicate that ESG considerations are more systematically integrated into organizational processes and extend beyond internal operations to include elements of supply chain governance. Non-certified firms also engage in sustainability initiatives, particularly through community-oriented activities and local social involvement; however, such initiatives are generally less embedded within formal management systems and therefore more difficult to translate into standardized ESG metrics and structured reporting practices.

Finally, the findings support Proposition 3 (P3), which posits that certified management systems are associated with stronger formalization of governance and internal control mechanisms relevant to ESG management. Firms adopting ISO standards display higher levels of organizational formalization through documented procedures, governance frameworks, and internal monitoring routines that support the management and verification of sustainability-related information.

A significant finding emerges from the comparative analysis: none of the evaluated firms currently adopts external ESG assurance. The sustainability reports and social balance sheets prepared between 2023 and 2024 were not subject to third-party verification under ISAE 3000 or AA1000 standards, as such assurance remains outside current mandatory requirements. Despite the absence of formal external verification, ISO-certified firms exhibit governance structures, monitoring routines, and documentation practices capable of supporting verification processes. This suggests that certified management systems may function as preparatory infrastructures supporting ESG assurance readiness.

In this context, ISO 9001 and ISO 14001 certifications play a significant role in strengthening the credibility of ESG-related practices. Certified management systems operate as verifiable internal managerial tools that signal genuine corporate commitment to sustainability through auditable processes and structured data governance. These characteristics help bridge the assurance gap in voluntary ESG reporting by providing organizational mechanisms that facilitate the generation of traceable and verifiable sustainability information.

Overall, the findings indicate that while ISO certifications do not necessarily determine the substantive level of ESG performance, they contribute to structuring internal governance routines that underpin credible sustainability reporting. Rather than directly improving ESG outcomes, ISO-based systems appear to facilitate the development of internal monitoring mechanisms, standardized documentation procedures, and governance structures that enhance the reliability and traceability of sustainability information.

The evidence indicates that ESG assurance readiness depends not only on using external assurance standards but also on the maturity of internal governance in certified management systems. ISO certifications can help firms move from voluntary sustainability disclosure to more structured and verifiable ESG reporting.

Research limitations. *This study provides exploratory insights into the role of ISO 9001 and ISO 14001 as governance infrastructures potentially supporting ESG assurance readiness. However, some limitations should be acknowledged. First, the small number of cases prevents statistical generalization; consistent with qualitative case study research, the findings should therefore be interpreted as analytical generalizations identifying potential organizational patterns rather than causal relationships (Yin, 2018). Differences in firm size and organizational complexity may also influence governance formalization and ESG disclosure practices; nonetheless, this study intentionally prioritizes the analysis of management practices over scalar differences. Second, the analysis relies on document-based desk research using publicly available sources such as sustainability reports and governance documentation. Although this approach enables data triangulation, reliance on disclosed information may introduce reporting bias and does not allow direct observation of internal processes. Future research could expand the empirical scope through larger cross-sector samples and complementary qualitative or quantitative methods.*

Managerial implications. *The findings of this study provide several managerial insights for organizations facing the increasing institutionalization of sustainability reporting and assurance requirements. In particular, the results suggest that certified management systems such as ISO 9001 and ISO 14001 can function as internal governance infrastructures that support the structuring of ESG information and the development of assurance-ready processes. By formalizing operational procedures, monitoring activities, and documentation routines, these systems facilitate the collection and traceability of sustainability-related data, which are critical elements for credible ESG disclosure. Prior research has highlighted that structured management systems contribute to embedding sustainability practices within organizational processes and strengthening transparency toward stakeholders (Boiral, 2011; Delmas & Montiel, 2009; Heras-Saizarbitoria & Boiral, 2013).*

From a managerial perspective, these findings are particularly relevant in light of the growing regulatory pressure introduced by frameworks such as the Corporate Sustainability Reporting Directive (CSRD), which requires companies to provide more structured, comparable, and verifiable sustainability information. In this context, managers may benefit from leveraging existing management systems not only as operational tools but also as governance mechanisms capable of strengthening internal control environments and supporting the reliability of ESG data. Previous studies emphasize that robust internal governance structures play a key role in enhancing the credibility of sustainability reporting and facilitating external assurance processes (Simnett, Vanstraelen, & Chua, 2009; Cohen & Simnett, 2015).

Integrating ESG indicators within established management systems may help organizations move beyond symbolic sustainability disclosure toward more structured and verifiable practices. Embedding sustainability metrics into existing managerial routines can support more consistent monitoring of ESG performance and reduce the risk of superficial reporting practices often associated with greenwashing. In this sense, strengthening internal governance mechanisms represents a practical pathway for managers seeking to improve the credibility of sustainability commitments and reinforce stakeholder trust in corporate ESG strategies (Busch & Friede, 2018; Eccles, Ioannou, & Serafeim, 2014). The implications of this study transcend the mere analysis of management systems, positioning ESG as a transversal prerequisite for long-term corporate survival. In an increasingly complex regulatory landscape, characterized by the growing demand for external assurance—notably under the CSRD—the adoption of ISO 9001 and ISO 14001 standards functions not merely as a compliance exercise, but as an enabling governance infrastructure. While external assurance remains a future requirement for these firms, the structural 'readiness' provided by ISO certifications suggests that

certified organizations are significantly better equipped to bridge the gap between their ESG performance and the assurance of their sustainability reporting.

The central thesis posits that, in response to sustainability demands necessitating pragmatism and efficiency—consistent with the objectives of the Omnibus I simplification package—certified management systems act as 'complexity reducers'. They enable firms to transition from self-referential narratives to approaches grounded in traceable data and formalized processes. Consequently, the adoption of these standards is not a

procedural shortcut, but a mechanism that enables firms to meet limited assurance requirements—thereby validating their commitment to stakeholders—while simultaneously minimizing information asymmetries and transaction costs associated with external verification. Ultimately, certification serves as an indicator of 'organizational soundness,' allowing firms to navigate the complexities of the sustainable transition and transforming regulatory obligations into a strategic lever for competitive positioning.

Originality of the paper. *This study contributes to the growing debate on sustainability governance by offering a governance-based interpretation of ESG assurance readiness. While existing literature has extensively examined sustainability reporting standards, regulatory developments, and the diffusion of assurance practices, comparatively less attention has been devoted to the internal organizational infrastructures that enable credible ESG assurance. Recent research highlights the role of assurance in enhancing the reliability and credibility of sustainability information (Simnett, Vanstraelen, & Chua, 2009; Cohen & Simnett, 2015; Bakarich, Baranek, & O'Brien, 2023), yet the organizational mechanisms that support these outcomes remain insufficiently explored. The originality of this study lies in conceptualizing certified management systems, specifically ISO 9001 and ISO 14001, not merely as operational or compliance-oriented tools, but as governance infrastructures that structure ESG data management, internal control routines, and organizational processes relevant to sustainability assurance. By examining firms with different certification configurations, the study shows how these systems may contribute to the development of organizational capabilities that facilitate ESG data traceability, formalized governance practices, and broader sustainability disclosure frameworks.*

In doing so, the paper bridges two research streams that have often evolved separately: the literature on sustainability reporting and assurance, and the literature on management system standards and organizational formalization. While previous studies have emphasized the role of ISO standards in improving operational efficiency and environmental management (Boiral, 2011; Heras-Saizarbitoria & Boiral, 2013), their potential implications for ESG assurance and sustainability governance have received limited attention. By linking certified management systems to the structuring of ESG information and assurance-related governance routines, this study reframes ESG assurance not simply as a regulatory compliance mechanism but as an organizational capability embedded within internal management architectures.

Configurations of Resilience in Inter-Organizational Networks

ANNA CABIGIOSU[1] MICHELA BEARZI[2] ENRICO CARLET[3] TIZIANO VOLPENTESTA[4]

Abstract. *This study examines how inter-organizational business networks build resilience in the face of crises. Prior research has mainly treated structural characteristics and coordination mechanisms as separate explanations of resilience. However, we still lack a clear understanding of how these elements combine to influence resilience outcomes across networks with varying characteristics. We adopt a configurational perspective and investigate how these elements jointly shape networks' time to recovery after disruption. Using survey data on 224 Italian formal business networks ("contratti di rete") and fuzzy-set Qualitative Comparative Analysis (fsQCA), we identify configurations associated with both resilience and non-resilience. The findings show that resilience consistently depends on the joint presence of resource complementarity and relational coordination, while the role of formal coordination varies across network configurations. More specifically, we develop a scale-contingent view of inter-organizational resilience: in small, vertically organized networks, resource complementarity and relational coordination can sustain fast recovery, whereas in large, horizontally organized networks, fast recovery requires formal coordination alongside relational practices. Overall, this study advances a configurational understanding of network resilience by showing that fast recovery depends on distinct combinations of network structure and coordination mechanisms, rather than on any one-size-fits-all network design.*
Keywords: *business networks; resilience; formal coordination; fsQCA*

Framing of the research. *Studies on how networks of organizations react to crisis – such as supply chains, innovation ecosystems, humanitarian networks, and trans-organizational systems (Chesley & D'Avella, 2020; Kim et al., 2024; Toufaily & Zalan, 2023) – reveal that inter-organizational resilience cannot be understood as a single capability possessed by individual organizations but as a patterned, collective capacity that allows networks of interdependent firms to sustain or restore functioning when facing external and internal threats.*

Within this literature, a central debate concerns how such resilience is achieved. One stream emphasizes network design, highlighting structural features such as size, structure, and resources as key determinants of resilience (Carnovale et al., 2025; Cobben et al., 2026). A second stream foregrounds collaborative and relational practices, arguing that trust, shared understanding, and coordination routines enable collective recovery even under severe disruption (Kim et al., 2021; Guo et al., 2025). These perspectives are often treated as competing explanations, framing resilience as the outcome of either "more structure" or "more collaboration."

We contend that this opposition may be misleading. Studies on resilient practices and paradoxical organizing show that stability and flexibility, structure and agency, often coexist and interact rather than substitute for one another (Majoor, 2015; Van den Berg, 2021). Similarly, research on ecosystem and supply chain resilience suggests that different combinations of conditions can generate comparable resilience outcomes (Fornasiero & Tolio, 2025; Naderpajouh et al., 2018). Yet, empirical evidence specifying which combinations matter, and under what conditions, remains limited.

Adopting an fsQCA approach for exploring an original dataset of 224 Italian business networks of organizations that signed formal alliances (labelled "contratti di rete"), we identify configurations of network structure and coordination mechanisms that enable networks to recover from crises. Our results show that relational coordination may turn into a liability when it substitutes for resource complementarity or for coordination arrangements suited to larger networks. In doing so, we advance a scale-contingent, configurational theory of inter-organizational resilience: in small, vertically coupled networks, relational and informal coordination can sustain fast recovery, whereas in large, horizontally organized networks, fast recovery requires formal coordination alongside relational practices. By specifying how different configurations of network structure and coordination mechanisms jointly produce resilience, this study contributes to debates on agentic resilience (Kok et al., 2021) and resilient practices (Majoor, 2015) and extends research on inter-organizational systems by moving beyond one-best-way explanations of network resilience.

Purpose of the paper. *This study aims to explain how inter-organizational business networks build resilience in the face of crisis. Specifically, we examine how structural characteristics and coordination mechanisms combine to produce fast recovery, focusing on configurations of network size, verticality, resource complementarity and overlap, and formal and relational coordination. In doing so, we develop a configurational understanding of network resilience. To motivate this objective, we review the literature and identify the gap this study addresses.*

Prior research has highlighted the multiple benefits firms derive from participation in inter-organizational business networks, including enhanced learning and innovation, access to complementary resources, legitimacy, and improved

performance outcomes (e.g., Cabigiosu et al., 2024; Provan et al., 2007). Building on this stream, recent research has increasingly shifted attention toward how such networks respond when confronted with disruptive events and crisis conditions (e.g. Chesley & D'Avella, 2020; Kim & Doerfel, 2024). In this emerging literature, crises are understood not merely as episodic shocks affecting individual organizations, but as disturbances that propagate through interdependencies, making network-level characteristics particularly salient (Ilseven & Puranam, 2021). In this instance, relevant network attributes are, on the one hand, structural and compositional features that affect the extent to which disturbances can be absorbed without systemic breakdown and, on the other hand, coordination and collaboration mechanisms that influence the network's capacity to mobilize resources and support collective recovery. Accordingly, network performance in times of crisis is increasingly conceptualized in terms of resilience, defined as the ability of the network to maintain core functions under stress and to recover its performance trajectory—returning to pre-crisis levels or achieving improved outcomes within a limited time horizon (Hernes et al., 2025).

Concerning the structural characteristics of business networks, resource complementarity—that is, the extent to which partners possess distinct yet interdependent and mutually reinforcing resources—is generally found to be positively associated with network performance (Jin & Wang, 2021). In the context of crises, resource complementarity may be particularly valuable because it enlarges the network's collective repertoire of resources, thereby increasing its capacity to respond to unexpected disruptions through recombination and redeployment. When shocks undermine established routines or render specific resources temporarily unavailable, networks characterized by complementary resource endowments are better positioned to reconfigure activities and sustain functioning (Duchek, 2020; Williams et al., 2017).

Several scholars emphasize that complementarity does not necessarily imply the absence of similarity between partners. Organizations may simultaneously exhibit complementarity in some resource domains and similarity in others, giving rise to resource-based synergies (Tanriverdi & Venkatraman, 2005). Building on this insight, some studies introduce the notion of resource overlap, which captures the extent to which organizations with different resource endowments may nonetheless share similarities in markets, suppliers, processes, or technological domains (Wang & Zajac, 2007). While prior research offers mixed arguments regarding whether such overlap enhances performance by facilitating coordination and mutual understanding or instead generates competitive tensions, in periods of crisis resource overlap may play a distinct role by supporting network resilience. Specifically, overlap can provide a degree of redundancy and substitutability that allows networks to absorb shocks, compensate for temporarily impaired partners, and reduce dependence on single points of failure. At the same time, shared knowledge bases and overlapping operational domains may facilitate rapid coordination and collective sensemaking (Tasic et al., 2019).

A second relevant aspect in defining the structure of a business network is its degree of verticality, defined as the extent to which network partners are positioned at different stages of the value chain. Whereas some studies (e.g. Runge et al. 2022) argue that vertical relatedness may reduce partners' willingness to share valuable knowledge due to concerns over opportunism and the risk of backward integration, others (e.g., Dyer et al. 2018) suggest that many alliances—particularly buyer–supplier relationships—create value precisely through the combination of complementary tangible assets and specialized capabilities. In periods of crisis, vertical ties can facilitate continuity of operations by securing access to key inputs, coordinating production and distribution activities, and reducing exposure to supply-side disruptions. At the same time, verticality may also introduce vulnerabilities. Power asymmetries and dependency relationships can amplify the impact of disruptions if dominant actors prioritize their own survival or if bottlenecks emerge at specific stages of the value chain. Consequently, the effect of network verticality on resilience is likely to be contingent on how vertical relationships are governed.

A third and final structural characteristic concerns the size of the business network, defined as the number of organizations involved. While a larger number of partners may facilitate risk sharing and increase the pool of available resources and capabilities, prior studies examining the relationship between network size and performance report mixed and inconclusive findings (Heidl et al., 2014). Similarly, in periods of crisis, larger networks can enhance resilience by providing access to a wider range of resources and by increasing the likelihood that at least some partners retain operational capacity when others are disrupted. At the same time, an increase in network size can generate coordination challenges that become particularly salient under crisis conditions. As the number of partners grows, decision-making processes may slow down, communication costs may increase, and the alignment of interests may become more difficult, potentially undermining coherent collective responses. Moreover, large networks may experience difficulties in mobilizing collective action when rapid responses are required, especially in the absence of effective coordination mechanisms (Hillmann, 2021).

The second perspective on network and resilience considers the role of formal and informal coordination mechanisms. Regarding informal coordination mechanisms, relational coordination theory emphasizes the importance of high-quality relationships and communication in managing interdependencies within and across organizations (Bolton et al., 2021). Relational coordination is likely to significantly improve resilience capabilities, helping networks to reduce the negative effects of environmental adversities. In particular, timely communication ensures that information is shared as soon as it becomes available, reducing delays in decision-making and action. Accurate communication involves sharing precise and reliable information, which is critical for making informed decisions during a crisis. Problem-solving communication focuses on addressing issues collaboratively. This approach fosters a culture of teamwork and collective problem-solving, which is essential to anticipate and manage adversities.

Regarding formal coordination mechanisms, short- and long-term planning plays a key role in coping with crises as they provide information that helps actors make sense of disruptions, detect anomalies, and reframe assumptions. In

addition, they shape behavioral and organizational responding by guiding action through revised procedures, prioritising recovery interventions, and by (re)defining responsibilities. However, plans and organizational structures may also narrow attention and reinforce rigid responses if over-emphasised and not complemented by a more interactive use in the subsequent phases (Malmi et al., 2023).

Overall, while extant research has disentangled the distinct implications of structural characteristics and coordination mechanisms for business network performance and (more limitedly) for resilience, it has predominantly examined these dimensions in isolation. As a result, we still lack a comprehensive understanding of how resilient business networks are characterized by the joint configuration of these multiple dimensions. This gap is particularly salient in light of the renewed relevance of resilience as a performance variable, as the increasing frequency of high-impact, low-probability events—such as the coronavirus pandemic, geopolitical conflicts, and raw material shortages—is increasingly threatening firms.

Methodology. *We used the Infocamere register of network contracts to identify all network contracts active as of July 3, 2023. On that date, 8,633 networks were recorded, of which 7,493 were neither bankrupt nor dissolved. Contact information was available for approximately 63% of the potential target population (4,720 networks). The effective sample was further reduced by 35% due to compliance with data protection regulations (EU Regulation No. 2016/679, GDPR).*

Data were collected using a mixed-mode design combining CAWI (Computer Assisted Web Interview) and CATI (Computer Assisted Telephone Interview) between mid-September and mid-November 2023. Among firms reached by telephone, approximately 90% agreed to provide an email address to receive the survey link, together with the privacy notice and a cover letter describing the study objectives. By the end of the fieldwork, approximately 18% of the initial population of 7,493 networks had completed the questionnaire. Overall, the survey yielded 224 completed questionnaires, corresponding to about 3% of the initial target population.

The survey was administered to a key informant within each network (e.g., network manager, representative of the lead firm, or member of the governing body), asking respondents to refer to the most recent year of network activity. The survey instrument included multiple sections; for the purposes of this study, we focused on items capturing network structural characteristics, coordination mechanisms, and resilience outcomes.

Network size *was measured as the total number of member firms.* Network verticality *was derived from respondents' classification of the network as vertical, horizontal, or mixed, and calibrated to distinguish predominantly vertical versus horizontal configurations.* Resource complementarity *was measured through a multi-item, 5-point Likert scale assessing the perceived complementarity of tangible resources, managerial experience, and intangible knowledge among partners.* Resource overlap *was captured using items evaluating similarity in products/services, strategic positioning, and overlap in distributors, clients, and suppliers.*

Relational coordination *was operationalized through items capturing informal interaction, collaborative problem-solving, timely and accurate communication, and overall coordination quality.* Formal coordination *was measured through items assessing the presence of formal governance mechanisms, structured planning processes, operational plans, formal agreements, and organizational structures.*

Finally, resilience *was operationalized as time to recovery after major disruptive events, where respondents indicated how long the network took to fully recover from the most severe crisis experienced in the previous three years. This measure was used to distinguish networks characterized by fast versus slow recovery.*

To analyze the data, we employed fuzzy-set Qualitative Comparative Analysis (fsQCA; Fiss, 2011) to examine how network characteristics combine to shape resilience, operationalized as (short) time to recovery after disruption (DesJardine et al., 2019). FsQCA is a configurational, set-theoretic approach that allows researchers to move beyond estimating the net effects of independent variables and instead identify how multiple conditions jointly combine into configurations that are (not) sufficient for an outcome. The method is particularly well suited to capturing conjunctural causation (i.e., outcomes resulting from specific combinations of conditions), equifinality (the possibility that multiple pathways lead to the same outcome), and causal asymmetry (the idea that the configurations leading to the presence of an outcome may differ from those leading to its absence).

In line with this approach, we calibrated fuzzy sets for network size*,* network verticality *(vertical vs. horizontal structure),* resource overlap, resource complementarity, relational coordination, *and* formal coordination *using theoretically informed thresholds. Calibration transformed raw survey data into set membership scores ranging from full non-membership (0) to full membership (1), enabling the assessment of whether a given network belongs to the set of "large networks," "high complementarity networks," or "high relational coordination networks," and so forth. We then constructed truth tables and applied established consistency and coverage thresholds to identify configurations sufficient for fast recovery and, separately, for the negated outcome (not fast recovery), allowing us to assess asymmetric causal patterns.*

In Tables 1 and 2, in which we report our main results, black circles (●) indicate the presence of a condition within a configuration, while crossed circles (⊗) indicate its absence. Blank cells represent "don't care" conditions, meaning that the presence or absence of that element is not decisive in that specific pathway. Following Fiss (2011), core conditions (large symbols) are those appearing in both the parsimonious and intermediate solutions, whereas peripheral conditions (smaller symbols) appear only in the intermediate solution and play a supporting role within configurations.

Consistency values indicate the degree to which networks sharing a given configuration display the outcome (fast or slow recovery), whereas coverage reflects the empirical relevance of each configuration in explaining the observed cases.

As a first step, we conducted the analysis of necessary conditions to identify conditions that are required for the occurrence of the outcome. In fsQCA, a condition is considered necessary (or almost always necessary) when its consistency exceeds the conventional threshold of 0.90. The results show that only the relational coordination index exceeds the 0.90 consistency threshold (consistency = 0.92), indicating that this condition can be considered necessary for the occurrence of the outcome. As a second step, we conducted the analysis of sufficient conditions.

Results. *Table 1 reports the configurations sufficient for resilience (short time to recovery). The analysis identifies three distinct solutions. Across all resilient configurations, two conditions are consistently present: high resource complementarity and strong relational coordination. Differences across configurations concern network scale, network verticality, and the role of formal coordination.*

The first configuration describes small, vertically organized networks. In this setting, fast recovery is achieved when high resource complementarity is combined with strong relational coordination, while formal coordination is absent or irrelevant. This solution suggests that in tightly coupled vertical chains, informal coordination is sufficient to enable rapid adjustment, provided that actors' resources and capabilities are well aligned. In such contexts, complementarity enlarges the collective action space of the network, enabling rapid recombination and redeployment of resources when disruptions occur. Relational coordination, in turn, facilitates timely communication and shared problem-solving allowing actors to respond without relying on formalized structures. The absence of formal coordination does not undermine resilience here; rather, it appears functional in small, vertically organized networks where interdependencies are clear and coordination can be achieved through direct relational ties.

The second configuration also applies to small, vertically organized networks but with higher diversity among members. Here again, fast recovery depends on the presence of resource complementarity and relational coordination, without the need for formal coordination structures. Diversity does not undermine resilience in this context: it appears compatible with fast recovery when informal coordination operates on a shared material base. This finding suggests that heterogeneity does not necessarily hinder collective responses during crises, as long as actors share complementary resources and maintain strong relational ties that mitigate the potential coordination costs associated with diversity.

The third configuration pertains to large, horizontally organized networks. In contrast to the small-network solutions, resilience in this context depends on the joint presence of both relational and formal coordination mechanisms, alongside high resource complementarity. Informal coordination alone proves insufficient at this scale. As network size and horizontal complexity increase, formal coordination structures become necessary to clarify responsibilities and manage interdependencies across a larger number of actors. Formal coordination provides a shared reference framework that supports collective action, while relational coordination complements it by enabling flexibility and problem-solving in the face of unforeseen disruptions. This configuration highlights that, in large networks, resilience emerges not from replacing informal coordination with formal mechanisms, but from their mutual reinforcement.

Table 2 reports the configurations sufficient for the negated outcome, non-resilience (long time to recovery). The first configuration concerns small, vertically organized networks characterized by strong relational coordination but low resource complementarity and no formal coordination. Despite high levels of informal coordination, these networks fail to recover quickly, suggesting that relational strength can mask underlying capability misalignment. The second configuration applies to large, horizontally organized and diverse networks lacking both resource complementarity and formal coordination, even when relational coordination is present. In this setting, diversity combined with weak coordination structures generates fragmentation and inhibits effective recovery. The third configuration describes small, horizontally organized and relatively homogeneous networks in which formal coordination is present, but resource complementarity is absent. Here, formal rules and resource overlap among actors do not compensate for misaligned or insufficient capabilities, resulting in rigid responses and slow recovery.

Research limitations. *The present study is not without limitations, which open up avenues for future research. First, our analysis is based on cross-sectional data collected at a single point in time. Although resilience is conceptualized as the capacity to recover from disruption, our design does not allow us to fully capture its temporal unfolding or to observe how configurations may evolve before, during, and after crises. Future research could adopt longitudinal designs to trace how network structures and coordination mechanisms co-evolve over time, shedding light on whether certain configurations are stable or whether networks shift from one resilience pathway to another as disruptions unfold.*

Second, the empirical setting is limited to 224 Italian business networks formalized through network contracts. While this context offers a unique opportunity to examine formally recognized inter-organizational arrangements, the sample may not be fully representative of the broader population of Italian networks, nor of networked organizations in other institutional environments. Comparative studies across countries, industries, or governance forms could test the robustness of the identified configurations and explore how institutional frameworks and policy regimes shape resilience pathways.

Managerial implications. *This study offers practical guidance for managers and entrepreneurs involved in inter-organizational networks facing turbulent environments. Our findings suggest that resilience requires deliberate alignment between network structures and coordination practices. Managers should therefore avoid replicating governance models across different network structures. In smaller and more tightly coupled networks, investing in strong relational coordination, through trust-building, shared problem-solving, and open communication, may be sufficient to sustain adaptive responses. In larger and more complex networks, however, relational embeddedness must be complemented by clearer formal structures, defined roles, and structured decision-making processes to prevent fragmentation and delays during crises. Moreover, resilience is not only a matter of maintaining relationships but of ensuring that partners bring strategically complementary capabilities. Entrepreneurs entering or designing network contracts should therefore carefully assess how resource interdependencies can be mobilized under adverse conditions. Our results also have implications for policy makers, highlighting the importance to respond to crises with differentiated support strategies. Rather than promoting uniform coordination interventions or providing undirected subsidies, policy makers should help networks strengthen governance arrangements and capability alignment according to their structural characteristics. By supporting both coordination capacity and strategic complementarity, policy initiatives can enhance the systemic resilience of business networks exposed to recurring shocks.*

Originality of the paper. *In this paper, we explored configurations of inter-organizational business networks (contratti di rete) associated with high and low resilience. Structural characteristics and coordination mechanisms of a network are distinct but interdependent aspects that combine in configurations to jointly affect network's capacity to recover from crises. Despite this general wisdom in the resilience literature, studies that explore the combination of those aspects are scant. Consistent with a configurational logic, network resilience does not stem from single optimal design choices, but from distinct combinations of network structure and coordination mechanisms, in which some elements are central while others are absent.*

Drawing on research on inter-organizational networks and resilience, this study advances our understanding of how resilience emerges from the joint configuration of network structure and coordination mechanisms, rather than from isolated structural or relational features. While prior research has emphasized either structural characteristics (e.g., size, verticality, resource composition) or coordination mechanisms in explaining network performance and resilience, our findings demonstrate that neither dimension is sufficient on its own.

First, our findings contribute to resilience studies that conceptualize resilience as a dynamic and multifaceted phenomenon, rather than as a single capability or outcome (e.g., Su & Junge, 2023). While prior studies have identified a wide array of resilience-related capabilities and mechanisms—often emphasizing that resilience entails the development of multiple, sometimes overlapping capacities (Duchek, 2020; Hillmann, 2021)—our configurational results show that resilience does not require the simultaneous presence of all such elements. Instead, fast recovery can emerge

from distinct combinations of structural characteristics and coordination mechanisms, reinforcing the idea of equifinality in resilience outcomes (Shepherd & Williams, 2023).

Second, by focusing on inter-organizational business networks, this study extends predominantly organization-centric models of resilience to a level where interdependencies, coordination, and collective action become central. Our findings empirically substantiate calls to conceptualize resilience as a system-level property that emerges from interactions among actors, resources, and governance arrangements (Chesley, 2020; Naderpajouh et al., 2018). In doing so, we complement multilevel frameworks of resilience by showing how network-level configurations shape recovery trajectories independently of individual organizational attributes.

Third, our results refine capability-based views of resilience (Duchek, 2020) by demonstrating that the effectiveness of resilience-related capabilities is contingent on network structure. Resource complementarity consistently appears as a core condition across resilient configurations, yet its contribution materializes only when embedded within appropriate coordination arrangements. This finding nuances prior claims that emphasize complementarity as universally beneficial, showing instead that its resilience-enhancing role depends on how resources are mobilized and coordinated across the network.

Fourth, the study contributes to ongoing debates on formal versus informal coordination in resilience processes. Our configurational findings reconcile these perspectives by showing that relational and formal coordination are neither universally substitutive nor universally complementary. In small, vertically organized networks, relational coordination alone can sustain fast recovery, whereas in large, horizontally organized networks, resilience requires the joint presence of relational and formal coordination mechanisms. This insight advances a contingency-based understanding of coordination for resilience, aligned with recent work on balancing risk and resilience in complex networks (Carnovale et al., 2025).

Developing Contextual Leadership in Amateur Football: An Action Research Study

CHRISTIAN DI PRIMA[1], SIMONE BEVILACQUA[2]

Abstract. *Leadership plays a critical role in shaping motivation, cohesion, and performance within sports teams. While a substantial body of literature has examined leadership styles in sports contexts, most studies rely on survey-based designs and focus primarily on athletes' perceptions of leadership behaviors. Consequently, relatively little is known about how leadership principles can be intentionally translated into practical interventions and implemented within real-world organizational settings, particularly in amateur sports environments.*

This paper addresses this gap by examining the design and implementation of a contextual leadership intervention conducted within an Italian amateur football club. Adopting an action research approach, the study documents a season-long collaboration between researchers, coaching staff, and players aimed at developing leadership practices capable of supporting motivation, communication, and team cohesion. The intervention included diagnostic activities, leadership development workshops for the coaching staff, individual coaching sessions, and team-wide reflection processes designed to foster a shared understanding of leadership within the group.

The findings highlight how the introduction of structured leadership practices contributed to improving communication, strengthening collective identity, and fostering more adaptive leadership behaviors within the team. While performance outcomes cannot be attributed solely to the intervention, the team experienced a significant improvement in competitive results during the season.

By providing a process-oriented account of leadership implementation in a grassroots sports organization, the study contributes to the literature on sports leadership and highlights the potential of context-sensitive and participatory approaches to leadership development.

Keywords: *leadership; action research; amateur sports; team dynamics; contextual leadership*

Framing of the research. *Leadership has long been recognized as a central factor in shaping individual motivation, group cohesion, and organizational performance across a wide variety of contexts. Over the past decades, leadership research has progressively expanded beyond traditional hierarchical settings to encompass more complex and socially embedded environments, including sports organizations (Day et al., 2014; Northouse, 2022; Di Prima, 2026). In these settings, leadership plays a particularly crucial role because performance outcomes depend not only on technical skills and tactical preparation but also on the psychological climate, interpersonal relationships, and collective identity of the group (Cotterill & Fransen, 2016).*

Within the sports domain, a substantial body of literature has explored how different leadership approaches influence athletes' motivation, well-being, and performance. Transformational leadership, for instance, has been widely studied for its capacity to inspire followers through vision, individualized consideration, and intellectual stimulation (Bass & Riggio, 2006). Empirical studies in sport contexts have shown that coaches who adopt transformational behaviors tend to foster stronger team cohesion, greater intrinsic motivation, and higher satisfaction among athletes (Callow et al., 2009). Similarly, authentic leadership has been associated with trust-building and ethical consistency, emphasizing transparency, relational integrity, and alignment between leaders' values and actions (Avolio & Gardner, 2005). Ethical leadership has also received increasing attention, particularly in contexts where fairness, respect, and moral role modeling shape the quality of interpersonal dynamics within teams (Brown & Treviño, 2006).

In parallel, more recent theoretical developments have emphasized the relational and collective nature of leadership processes. Shared leadership perspectives suggest that influence within groups may be distributed among multiple actors rather than concentrated in a single formal leader (Pearce & Conger, 2003). Within sports teams, this perspective has gained empirical support, as athletes themselves often emerge as informal leaders who contribute to motivation, communication, and coordination during training and competition (Fransen et al., 2014). Similarly, identity leadership theory highlights the role of leaders in fostering a shared sense of "we-ness" within groups, helping members internalize collective goals and align their individual behaviors with the broader team identity (Haslam et al., 2020).

Despite the richness of these theoretical approaches, scholars increasingly acknowledge that leadership styles rarely operate in isolation in real organizational settings. Rather than applying a single "pure" leadership model, effective leaders often combine different behaviors depending on contextual demands, group characteristics, and situational constraints (Yukl, 2013). This perspective resonates with contingency and contextual approaches to leadership, which emphasize that leadership effectiveness depends on the alignment between leadership behaviors and environmental conditions (Fiedler, 1967; Osborn et al., 2002). In complex and heterogeneous contexts, therefore, leadership may be better understood as a dynamic and adaptive process rather than as the application of a predefined style.

[2] Dipartimento di Management "Valter Cantino", Università degli Studi di Torino, Turin, Italy and School of Business, Gnosis Department of Management and Marketing, University of Innsbruck, Innsbruck, Austria, e-mail: simone.bevilacqua@unito.it

These considerations are particularly relevant in the context of amateur sports organizations. Unlike professional teams, amateur clubs typically operate under conditions of limited financial resources, volunteer-based governance, and heterogeneous levels of commitment among participants (Wicker & Breuer, 2011). Coaches and managers often face the challenge of balancing competitive objectives with educational, social, and developmental goals. Players may differ widely in their motivations, ranging from performance-oriented aspirations to recreational participation or social belonging (Allen & Shaw, 2009). As a result, leadership in amateur sports requires a delicate balance between performance management, motivational support, and group cohesion.

Motivation theories provide an important lens through which to understand these dynamics. Self-Determination Theory (Deci & Ryan, 2000), for example, suggests that individuals experience higher levels of motivation and psychological well-being when three fundamental psychological needs—autonomy, competence, and relatedness—are satisfied. In sports environments, leadership behaviors that support these needs can significantly influence athletes' engagement, persistence, and satisfaction (Ryan & Deci, 2017). Coaches who encourage participation in decision-making, recognize individual progress, and foster positive interpersonal relationships are more likely to create a motivational climate that promotes intrinsic motivation and sustainable performance (Mageau & Vallerand, 2003).

Goal-oriented motivational models also contribute to understanding athletes' behavior in team settings. Research on achievement goal theory distinguishes between mastery-oriented climates, which emphasize personal improvement and learning, and performance-oriented climates, which focus on competition and social comparison (Nicholls, 1989). Leadership practices that promote mastery-oriented environments tend to enhance psychological resilience, cooperation, and long-term engagement among athletes (Ames, 1992). In amateur sports contexts, where participation and personal development are often as important as competitive outcomes, fostering such climates can be particularly beneficial.

However, the practical implementation of leadership theories in amateur sports organizations remains relatively underexplored. Much of the existing research relies on survey-based studies examining athletes' perceptions of leadership behaviors (Cotterill & Fransen, 2016). While these studies provide valuable insights into the relationships between leadership and outcomes such as cohesion or motivation, they offer limited understanding of how leadership models can be intentionally designed, implemented, and adapted within real organizational contexts over time.

Furthermore, the majority of studies focus on professional or elite sports environments, where organizational structures, resources, and performance pressures differ significantly from those found in grassroots and amateur settings. This leaves a gap in the literature regarding how leadership theories can be translated into practical interventions capable of supporting coaches and organizations operating in resource-constrained and socially complex environments.

Addressing this gap requires methodological approaches capable of capturing leadership as an evolving, context-sensitive process. Action research offers a particularly suitable framework for this purpose. By combining inquiry and intervention, action research allows scholars and practitioners to collaboratively design and test organizational changes while simultaneously generating theoretically informed insights (Coghlan & Brannick, 2014). Through iterative cycles of diagnosis, action, and reflection, this methodology enables researchers to observe leadership not only as a phenomenon to be studied but also as a practice that can be intentionally shaped and refined within specific organizational contexts.

Against this backdrop, the present study examines the development and implementation of a contextual leadership intervention within an Italian amateur football club. The project was carried out in collaboration with A.S.D. Polisportiva Garino, a team competing in the Prima Categoria league in Piedmont. Over the course of a full competitive season, an academic team worked closely with the club's coaching staff and players to design and implement a hybrid leadership model integrating elements from multiple theoretical perspectives, including transformational, identity-based, and motivational approaches.

By documenting this process through an action research methodology, the study seeks to contribute to the growing literature on leadership in sports organizations by providing an in-depth account of how leadership principles can be operationalized and adapted in a real amateur football environment. In doing so, it also offers broader insights into the role of contextualized leadership practices in fostering motivation, cohesion, and performance within grassroots sports settings.

Purpose of the paper. *The purpose of this study is to explore how leadership principles can be intentionally designed and implemented within an amateur sports organization through a contextual and practice-oriented approach. While the leadership literature has produced a rich array of theoretical frameworks—ranging from transformational and authentic leadership to shared and identity-based perspectives—much of this research remains predominantly conceptual or relies on cross-sectional empirical designs that examine athletes' perceptions of leadership behaviors. Consequently, relatively little is known about how leadership models can be translated into concrete organizational interventions and systematically implemented within real-world amateur sports settings.*

This study addresses this gap by examining the design, implementation, and outcomes of a leadership development intervention conducted within an Italian amateur football club. Specifically, the project involved the co-creation and application of a contextual leadership model aimed at supporting motivation, cohesion, and performance within the team environment. The intervention was developed collaboratively with the organization and implemented over the course of a full competitive season, allowing for continuous observation, feedback, and adaptation.

More precisely, the paper pursues three main objectives. First, it aims to illustrate how leadership concepts derived from the academic literature can be operationalized within a grassroots sports organization through a structured yet

flexible intervention process. By translating theoretical constructs into practical leadership practices, the study seeks to bridge the gap between leadership theory and managerial application in amateur sports contexts.

Second, the study aims to examine how such an intervention unfolds over time within the complex social dynamics of a football team. Leadership in sports teams is inherently relational and context-dependent, involving interactions among coaches, players, and organizational actors. By adopting an action research perspective, the study provides an in-depth account of how leadership practices can evolve through iterative cycles of observation, reflection, and adjustment.

Third, the paper aims to assess the perceived impact of the intervention on key team dynamics, including motivation, group cohesion, communication patterns, and collective identity. While the primary objective of the project was developmental rather than experimental, the study nevertheless offers valuable insights into the mechanisms through which leadership practices may influence team functioning in amateur sports environments.

Overall, by documenting and analyzing a real-world leadership intervention conducted in collaboration with a football club, this study seeks to contribute to the literature on sports leadership and organizational practice. In particular, it highlights the potential value of context-sensitive and participatory approaches to leadership development, emphasizing how academic knowledge can be mobilized to support practical change processes within grassroots sports organizations.

Methodology. *This study adopts an action research approach to examine the design and implementation of a contextual leadership intervention within an amateur football organization. Action research is particularly suitable for studying leadership processes in real organizational contexts because it combines scholarly inquiry with practical intervention, allowing researchers and practitioners to collaboratively diagnose problems, implement changes, and reflect on their effects (Coghlan & Brannick, 2014). Rather than observing leadership as a static phenomenon, this methodology enables the analysis of leadership as an evolving and context-sensitive process shaped through iterative cycles of action and reflection.*

The study was conducted in collaboration with A.S.D. Polisportiva Garino, an amateur football club located in Vinovo, in the Piedmont region of Italy. Founded in 1986, the club has experienced several phases of closure and revival over the decades, ultimately re-establishing itself as a vibrant community-based organization with a strong emphasis on youth development, fairness, and collective identity.

At the time of the study, the club had grown into a well-structured grassroots organization, with multiple youth teams and a senior squad competing in the Prima Categoria, a middle level amateur football in the Italian league system. Despite having a technically competitive team and a supportive local environment, the club had experienced fluctuating results in previous seasons. As a consequence, the leadership—composed of club directors, the coaching staff, and senior players—identified internal cohesion, psychological well-being, and sustained motivation as key areas requiring improvement.

The collaboration with the academic team emerged organically when the team captain, who was attending a university course on performance management and leadership, proposed the idea of applying leadership theories to the team as part of an academic project. This initiative led to the development of a structured intervention aimed at experimenting with a contextual leadership approach within the team environment.

The intervention was designed as a multi-phase leadership development program implemented across the pre-season period and the early stages of the competitive season. The objective was to introduce leadership practices capable of adapting to the specific dynamics of the team, integrating insights from multiple leadership perspectives and motivational theories.

The process unfolded through five sequential phases, each combining diagnostic, developmental, and reflective components.

The project began with an exploratory diagnostic phase aimed at understanding the psychological and relational dynamics within the team. Data were collected through a combination of semi-structured interviews, anonymous surveys, and informal discussions involving players, coaching staff, and club directors. This phase sought to assess players' motivational drivers, perceptions of leadership, communication patterns, and overall team climate. The diagnostic process revealed a heterogeneous motivational environment: while some players were highly engaged and strongly aligned with the team's objectives, others reported lower levels of involvement, often linked to unclear roles, inconsistent communication, or perceived inequalities in decision-making processes. These insights provided the foundation for designing a leadership intervention tailored to the specific needs and challenges of the team.

Following the diagnostic phase, the intervention focused on the coaching staff, who participated in two intensive leadership workshops. These sessions were designed to develop the coaches' ability to adopt a contextual leadership perspective, emphasizing flexibility, situational awareness, and sensitivity to players' motivational needs. The workshops combined theoretical input with interactive activities such as scenario-based discussions, reflection exercises, and simulations of locker-room situations. Particular attention was devoted to themes such as psychological safety, communication strategies, and the relationship between athletes' well-being and performance outcomes. Through these sessions, the coaching staff began to reconsider traditional directive leadership approaches and explore more adaptive leadership behaviors capable of responding to different situations and individual player needs.

In the following weeks, the intervention moved into a more personalized development phase through one-on-one coaching sessions with the head coach. Over a period of approximately six weeks, four structured meetings were

conducted between the academic team and the coach. These sessions focused on reflecting on critical leadership situations that could emerge during the season, such as managing conflicts within the squad, maintaining motivation after defeats, or communicating difficult decisions such as player rotations. Together, the coach and the researchers analyzed potential scenarios and developed leadership strategies aligned with the principles of contextual leadership. This reflective process encouraged the coach to move beyond purely tactical considerations and to pay greater attention to the emotional and relational dynamics influencing team performance.

A further step in the intervention involved the entire team. A collective session was organized to create a shared understanding of leadership principles and to establish common norms for communication, trust, and accountability within the group. Rather than presenting leadership as a top-down concept imposed by the coaching staff, the session encouraged players to actively reflect on their own experiences of leadership in sports teams and to articulate their expectations regarding leadership behaviors. Through guided discussions and group activities, players and coaches collaboratively defined shared principles regarding feedback practices, decision-making processes, and interpersonal respect. This participatory process was intended to foster greater ownership of the leadership model and to strengthen the collective identity of the team.

Once the competitive season began, the intervention incorporated continuous feedback mechanisms aimed at monitoring the evolution of team dynamics and leadership practices. Short anonymous "pulse" surveys and informal focus groups were periodically used to gather players' perceptions of communication quality, cohesion, and motivational climate. These feedback loops allowed the coaching staff and the research team to identify emerging issues and implement timely adjustments. For example, at one point during the season a decline in perceived cohesion was detected, linked to growing tensions surrounding team selection decisions. In response, the coaching staff organized a dedicated meeting to clarify the rationale behind player rotation policies, reinforcing transparency and restoring trust within the group. Through these iterative cycles of observation, feedback, and adaptation, the intervention maintained its contextual character, continuously aligning leadership practices with the evolving needs of the team.

Results. *The action research intervention generated a series of observable changes in the team's internal dynamics over the course of the season. These changes emerged progressively as leadership practices introduced during the intervention were gradually internalized by both the coaching staff and the players. The results can be interpreted across three interrelated dimensions: the evolution of leadership behaviors within the coaching staff, the transformation of communication and trust dynamics within the team, and the overall impact on collective motivation and performance.*

One of the most immediate outcomes of the intervention concerned the leadership approach adopted by the coaching staff. During the initial diagnostic phase, leadership within the team tended to follow a relatively traditional model typical of amateur football environments, where decision-making authority is strongly centralized in the head coach and communication primarily occurs in a top-down manner. Through the workshops and coaching sessions, the head coach progressively developed a more reflexive and situationally adaptive leadership style. Rather than relying exclusively on directive communication, the coach began to place greater emphasis on dialogue, explanation of decisions, and attention to the emotional climate of the group. This shift was particularly evident in situations involving difficult managerial choices, such as player rotations, tactical adjustments, or responses to disappointing match results. The introduction of structured reflection sessions and scenario discussions also helped the coaching staff anticipate potential relational tensions and adopt more proactive communication strategies. As the season progressed, leadership behaviors increasingly reflected a contextual approach in which decisions were not only technically justified but also framed in ways that acknowledged players' perspectives and motivations.

A second major outcome of the intervention concerned the quality of communication within the team. Initial diagnostic data had revealed the presence of several latent tensions, including perceptions of unequal treatment, limited opportunities for open discussion, and uncertainty regarding players' roles within the squad. The team-wide leadership session and subsequent feedback mechanisms played a key role in addressing these issues. By creating a structured space for collective reflection, the intervention allowed players to articulate expectations regarding leadership, fairness, and mutual respect. This process contributed to the development of a shared vocabulary around leadership and team values, facilitating more constructive interactions between players and coaches. Over time, communication patterns became more transparent and less confrontational. Players reported feeling more comfortable expressing concerns and providing feedback, while the coaching staff demonstrated greater willingness to clarify decisions and explain tactical or organizational choices. These changes contributed to a gradual strengthening of interpersonal trust within the group. In addition, the intervention encouraged the emergence of informal leadership roles among players. Certain team members began to take on responsibilities related to maintaining team morale, mediating conflicts, and reinforcing the collective identity of the group. This development reflected the shift from a purely hierarchical leadership structure toward a more distributed form of influence within the team.

Another important outcome concerned players' motivational orientation. At the beginning of the project, the team displayed a heterogeneous motivational landscape: while some players were strongly driven by competitive goals, others showed lower levels of engagement, often due to previous seasons characterized by inconsistent results. As the intervention progressed, several mechanisms contributed to strengthening players' sense of belonging and commitment. First, the emphasis on communication and psychological safety helped reduce interpersonal tensions and created a more supportive team climate. Second, the explicit discussion of leadership principles encouraged players to view themselves as active contributors to the team's development rather than passive recipients of coaching decisions. The growing

alignment between individual motivations and collective objectives fostered a stronger sense of shared identity. Players increasingly referred to the team using inclusive language and demonstrated higher levels of mutual support both during training sessions and competitive matches.

Although the primary objective of the intervention was developmental rather than performance-oriented, improvements in team dynamics were accompanied by a significant positive trajectory in competitive results. Following an initial period of adjustment during which the team struggled to fully internalize the new leadership practices, performances began to improve steadily. The squad developed greater resilience in response to setbacks and demonstrated stronger cohesion during challenging matches. Over the course of the season, the team entered a prolonged positive streak that allowed it to climb the league standings. Ultimately, A.S.D. Polisportiva Garino concluded the season by securing promotion to a higher division. While it would be methodologically inappropriate to attribute this outcome exclusively to the leadership intervention, qualitative evidence from players and staff suggests that the changes in communication, trust, and collective motivation played a significant role in supporting the team's improved performance.

Overall, the results indicate that the contextual leadership approach implemented through the action research process contributed to fostering a more cohesive, communicative, and motivated team environment. These findings illustrate how leadership theories can be translated into practical interventions capable of shaping the social dynamics of amateur sports teams over time.

Research limitations. *This study presents several limitations that should be acknowledged when interpreting the findings. First, the research is based on a single case study conducted within one amateur football club operating in a specific regional and cultural context. While in-depth case studies allow for rich contextual insights, the findings cannot be directly generalized to other organizations, sports disciplines, or competitive levels.*

Second, the study adopts an action research methodology, which implies a close collaboration between the researchers and the organization involved. While this approach enables a deeper understanding of organizational dynamics and facilitates practical change processes, it may also introduce potential biases related to researcher involvement and participants' awareness of being observed. In particular, the presence of the research team may have influenced some behaviors or perceptions within the group.

Third, the evaluation of the intervention relies primarily on qualitative evidence and perceptual data, including interviews, surveys, and participant feedback. Although these sources provide valuable insights into team dynamics, they do not allow for a rigorous causal assessment of the relationship between leadership practices and performance outcomes. The positive competitive results achieved during the season should therefore be interpreted cautiously, as they may also have been influenced by other factors such as tactical decisions, player skills, or external competitive conditions.

Finally, the temporal scope of the research is limited to a single competitive season. Leadership processes and organizational culture often evolve over longer periods, and further research would be necessary to assess the long-term sustainability of the leadership practices introduced during the intervention.

Future studies could build on this work by conducting comparative analyses across multiple amateur sports organizations, integrating longitudinal data and potentially combining qualitative and quantitative research designs to further explore the relationship between leadership practices, team dynamics, and performance.

Managerial implications. *Despite these limitations, the findings of this study offer several relevant implications for practitioners operating in amateur sports organizations and, more broadly, in team-based environments.*

First, the study highlights the importance of adopting a context-sensitive approach to leadership. Amateur sports teams often bring together individuals with heterogeneous motivations, levels of commitment, and personal expectations. In such environments, rigid leadership styles may prove ineffective. Coaches and team managers may benefit from developing flexible leadership behaviors that can adapt to different situations and individual needs.

Second, the results underline the value of structured reflection and leadership development activities even in grassroots sports contexts. The workshops and coaching sessions implemented during the intervention demonstrated that relatively simple initiatives—such as facilitated discussions, scenario analysis, and feedback sessions—can help coaching staff become more aware of their leadership practices and their impact on team dynamics.

Third, the study emphasizes the importance of open communication and psychological safety within sports teams. Providing players with opportunities to express their perspectives, discuss expectations, and understand the rationale behind managerial decisions can contribute to strengthening trust and reducing potential sources of conflict. In amateur contexts, where financial incentives are often limited, these relational factors may play a crucial role in sustaining motivation and engagement.

Finally, the findings suggest that leadership should not be viewed solely as the responsibility of formal leaders such as coaches. Encouraging the emergence of informal leadership roles among players can strengthen the collective identity of the team and contribute to maintaining cohesion during challenging phases of the season.

Overall, the study indicates that leadership development interventions, when designed in a participatory and context-aware manner, can represent a valuable tool for improving the social and motivational climate of amateur sports organizations.

Originality of the paper. *This paper contributes to the literature on leadership in sports organizations in several ways. First, it provides a process-oriented account of leadership implementation within an amateur football team. While much of the existing research on sports leadership relies on survey-based studies examining athletes' perceptions of leadership behaviors, this study documents how leadership principles can be intentionally designed, introduced, and adapted within a real organizational context over time.*

Second, the research contributes methodologically by applying an action research framework to the study of leadership in grassroots sports. By combining observation with direct organizational intervention, the study offers insights into leadership as a dynamic and socially constructed process rather than as a static set of behavioral traits. This approach enables a deeper understanding of how leadership practices emerge, evolve, and interact with the relational dynamics of teams.

Third, the study extends the literature on sports leadership by focusing on the amateur and community-based sport context, which remains relatively underexplored compared to professional and elite sports environments. Amateur teams operate under unique organizational conditions characterized by limited resources, volunteer engagement, and heterogeneous motivational structures. By examining leadership within this context, the study highlights how theoretical leadership models can be adapted to environments where social and motivational factors often play a central role.

Finally, the paper demonstrates the potential of contextual leadership approaches that integrate insights from multiple leadership theories rather than relying on a single prescriptive model. The findings suggest that leadership effectiveness in amateur sports may depend less on adopting a specific leadership style and more on the ability to combine different leadership practices in response to evolving team dynamics.

Innovation Setbacks in State-Led Innovation Initiatives: The Case of Malaysia

JUDY YUEH LING SONG[1], DARIO PEIRONE[2]

Abstract. *Innovation policy plays an important role in economic transformation. Governments invest heavily in science parks, digital corridors, and innovation districts. Many initiatives draw inspiration from models such as Silicon Valley. Many major state-led innovation projects end up neither failing nor succeeding clearly. These cases of persistent underperformance are important for understanding innovation systems. Examining them helps move beyond simple outcome measures. It allows closer analysis of the institutional arrangements, organisational structures, and policy choices that shape innovation trajectories.*

The paper introduces the concept of innovation setbacks which refer to initiatives that continue to operate but do not achieve their original transformative goals. By moving beyond the simple outcome indicators such as patents, firm numbers, or employment growth, the study captures the importances of analysing the institutional arrangements, organisational structures, and policy choices that shape innovation trajectories over time

The analysis focuses on the case of Malaysia's Multimedia Super Corridor (MSC) and Cyberjaya. The study adopts an exploratory case study approach. It combines institutional theory, cluster economics, and systemic innovation failure theory. The case is used descriptively because the research is still in development. The analysis relies mainly on secondary sources and policy documents.

Preliminary findings show that MSC developed infrastructure and attracted multinational firms. However, relational networks and domestic innovation capabilities developed more slowly. These patterns suggest systemic frictions within the ecosystem. The transition to the Malaysia Digital initiative represents a policy response to these challenges.

This work-in-progress paper highlights the value of examining innovation setbacks as a source of policy learning in long-term innovation initiatives.

Keywords: i*nnovation policy, cybercity, Multimedia Super Corridor, innovation setbacks, systemic failure.*

Framing of the research. *Innovation policy has become a central instrument for economic transformation. Over the past three decades, governments have invested heavily in science parks, innovation districts, digital corridors, and smart cities, often inspired by globally illustrious models such as Silicon Valley, Shenzhen, or Singapore's innovation ecosystem. These regions are commonly cited as benchmarks of transformative innovation systems (Wu, Y, 2026; Einhoff & Paunov, 2025; Woo, 2018; Engel, 2015) while projects that are less successful or perhaps stagnant have failed to be studied for their lessons and experiences. This focus on successful ecosystems creates a bias in innovation research by overlooking initiatives that persist but deliver only partial outcomes.*

In practice, many large-scale, state-led innovation projects neither fail outright nor achieve clear success but persist over time with mixed outcomes and limited transformative impact. Despite their prevalence, such cases are often treated as anomalies or policy failures instead of analytically valuable trajectories in their own right.

This paper addresses this gap by introducing the concept of innovation setbacks. Innovation setbacks refer to innovation initiatives that persist over time and generate measurable activity yet fall short of their original transformative ambitions. They are characterised by three core feature like institutional persistence, partial performance and sustained gap between expected and realised outcomes.

Innovation setbacks are different from related concepts. They are not the same as policy failure. They do not mean that a policy halts or collapses. Instead, the policy continues and delivers only partial results. Policy failure usually means that the whole objectives are not achieved. As set out earlier, innovation setbacks refer to situations where an initiative continues to operate only performs below expectations (Brown et.al, 2016; Metcalfe, 2005; Cavalcante, 2024; Björnemalm et.al, 2015). These setbacks also differ from path dependence. Path dependence explains how certain processes reinforce themselves to keep a project on a specific track. In contrast, innovation setbacks describe a situation where a project lasts a long time without fully transforming the system (Pinzón-Camargo et.al., 2021, Henderson, 2019; Veggeland, N., 2008). Similarly, while policy persistence refers to the durability of policy arrangements, it does not capture the sustained gap between expected and realised outcomes, particularly in contexts where policy continues despite recurring limitations linked to governance constraints and uncertainty (Howlett et al., 2015). Innovation setbacks therefore identify a distinct class of long-term initiatives that are durable, resource-intensive, and only partially transformative.

The idea of innovation setbacks provides an alternative analytical lens for analysing complex innovation initiatives by focusing on those with underwhelming performance. It shifts focus from the usual binary success-failure assessments to the organisational, institutional, and policy processes that influence innovation paths across time. This perspective is

[2] Department of Law, University of Turin. Email: dario.peirone@unito.it

especially pertinent to developing and middle-income economies, which have invested extensively in state-led innovation initiatives in the recent decades to stimulate digital transformation, economic upgrading, and integration into the global economy (Hanna, 2024). These initiatives are backed by substantial public investment, specialised regulatory frameworks, and sustained political support, and are typically framed as strategic responses to global competition, technological change, and perceived risks of economic stagnation (UNCTAD, 2025; Trajtenberg, M., 2009; Lerner, 2009).

The outcomes have been uneven across initiatives. Some have failed to meet initial expectations, whereas others evolved into successful ecosystems (UNCTAD, 2025). Many economies face specific challenges that stem from structural and systemic problems. Institutional fragmentation often hinders progress and weak coordination between government agencies creates inconsistent policies and unclear accountability. A heavy reliance on foreign direct investment can also limit domestic growth. Multinational corporations may not share essential technologies or integrate with local businesses. Furthermore, skill mismatches in the workforce prevent the growth of new industries. Rigid regulations often stop innovation projects from adapting to change. These issues create a gap between policy ambitions and realised outcomes. Consequently, these issues provide important lessons for studying innovation setbacks.

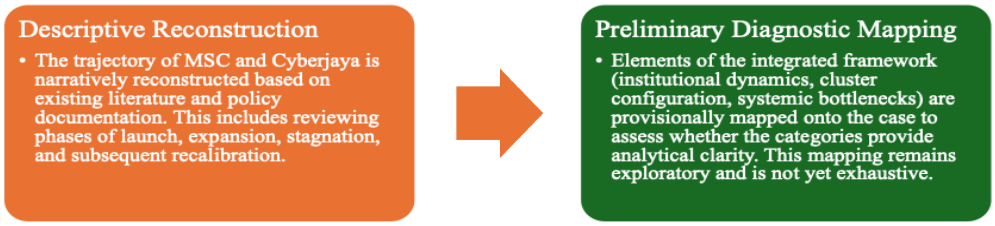
As this stage, the paper examines the case of Malaysia's Multimedia Super Corridor (MSC) and Cyberjaya. The MSC is a long-term project in a middle-income economy that relies on infrastructure. It has attracted investment and sparked technological activity. However, the project has only partially transformed the economy. This makes it a useful case for studying how innovation setbacks happen and how governments respond.

This paper adds to innovation policy research by treating setbacks as a specific category. This approach helps explain why state-led projects often underperform over time. It shows how timing and structural problems shape the results. Finally, the paper provides a system-based method for evaluating long-term innovation policies.

Purpose of the paper. *This paper sets out five interconnected objectives. First; it introduces innovation setbacks as a innovative category for research. This category describes large projects that continue to exist but fail to reach their main goals. Instead of treating them as either success or failure, the paper focuses on cases that fall in between. As discussed earlier, this perspective goes beyond ideas such as policy failure, path dependence, and policy persistence by focusing on initiatives that continue to operate but do not fully transform the system.*

Second, this study emphasises the importance of diagnosing the underlying causes of innovation underperformance. Systemic failure studies provide useful tools for this purpose. Drawing on systemic failure perspectives, particularly the framework developed by Woolthuis et al. (2005), it identifies key bottlenecks such as infrastructural, institutional, and interaction failures within innovation systems.

Third, the paper develops an integrated analytical approach. It combines institutional theory and cluster economics and systemic failure perspectives. In this study innovation setbacks are the main outcome of interest. These theoretical lenses explain why these outcomes happen and how structural problems develop across governance and spatial organisation and capability building.



Fourth, the study applies this framework to the case of Malaysia's Multimedia Super Corridor (MSC) and Cyberjaya. This long-running, state-led initiative provides an empirical setting to examine how innovation setbacks emerge and how system-level frictions persist over time.

Finally, the paper contributes to broader theoretical discussions by proposing a more system-oriented and reflective approach to analysing long-term innovation initiatives, particularly in developing and middle-income economies where persistent underperformance is common but often underexplored.

Methodology. *This study adopts an exploratory and conceptually guided case study approach. At its current stage of development, the research focuses on refining an analytical framework. Case study research is well suited for analysing complex and context-dependent phenomena embedded within institutional and policy environments (Yin, 2018; Flyvbjerg, 2006). Malaysia's MSC and Cyberjaya serve as the primary case for this study. This example is important because the project has continued for a long time with only partial success. It shows how innovation initiatives can persist without reaching their full potential. We use this case to test the practical value of the proposed diagnostic perspective.*

In this developmental phase, the case is not used to test hypotheses. Instead, it serves as a platform for structured analytical reflection. This analysis uses secondary data from government documents, institutional report, macro-level indicators, historical accounts of institutional reforms and policy shifts. It also includes official statistics and academic literature. Other sources include reports from independent organisations and press releases. These materials are triangulated to compare policy goals with actual results across different stages of the project.

The analytical strategy proceeds in two steps, as illustrated in Figure 1. First, a descriptive reconstruction of the MSC trajectory is developed based on existing literature and policy documentation. This reconstruction traces the evolution of the initiative from its inception, through phases of infrastructure-led development in Cyberjaya, subsequent periods of sluggish performance and emerging systemic challenges, and more recent policy recalibration through the transition to Malaysia Digital.

Second, a preliminary diagnostic mapping is conducted. This step applies the analytical framework to the case study. It includes elements like institutional dynamics and cluster configuration and systemic bottlenecks. This process tests the explanatory value of these factors. It also shows how structural frictions emerge and continue through different phases of the initiative.

The study uses an abductive approach. This method combines observations from the data with existing theory. Innovation setbacks are measured using three factors. The concept of innovation setbacks is operationalised through three observable dimensions: persistence of the initiative over time, evidence of partial performance in terms of economic activity, and a sustained gap between policy ambitions and realised outcomes. The analysis also examines systemic frictions. These frictions appear as misalignments between infrastructure and networks and coordination and capability building.

At this stage, the analysis remains exploratory and is intended to assess whether the proposed framework provides meaningful interpretive insights when applied to a long-running innovation initiative.

Results. *At this stage of development, several interpretive patterns emerge from the descriptive analysis of MSC and Cyberjaya. The aim is to assess whether the integrated diagnostic framework offers useful insights when applied to a long-running state-led innovation initiative. The findings are organised around four key patterns.*

i. Imbalance between infrastructure development and relational dynamics. Early studies of MSC describe the rapid establishment of physical and regulatory infrastructure (Ramasamy et al., 2004; Huff, 2002). The initiative introduced broadband access, tax incentives, and formal governance mechanisms. From a systemic perspective, these elements represent essential infrastructural foundations that were largely addressed during the initial policy phase (Edquist et al., 1998; Smith, 1999).

However, the relational aspects highlighted by cluster theory developed less strongly (Porter, 1998; Cooke, 2012). Although firms were co-located in Cyberjaya, evidence of sustained knowledge exchange, university–industry collaboration, and interactive learning remained limited (Ejnavarzala et al., 2008; Edgar & Yusof, 2021). This supports the argument that spatial proximity alone does not guarantee effective innovation networks (Grillitsch & Asheim, 2017).

This imbalance is also reflected in innovation outputs. Despite substantial investment over RM384 billion by 2020, domestic patenting activity has declined in recent years. Between 2018 and 2023, patenting in the heart of MSC-Klang Valley fell by 16.2%, while other regions such as Penang and Johor experienced significant growth. This suggests that strong infrastructural development was not matched by equally robust local innovation dynamics.

While infrastructure grew quickly, softer institutional conditions developed more slowly. These include informal norms and trust-based networks and entrepreneurial culture. These factors are critical because they shape economic behaviour (North 1993; Scott 2001).This pattern shows partial performance. It occurs when visible infrastructure expansion does not match the growth of relationships and interactions within the innovation system.

ii. Limited capacity building and knowledge spillovers. MSC attracted multinational corporations during its early years. Several papers note that much of this activity involved service operations and back-office functions (Brooker, 2013; Salman, 2018). Evidence of sustained local research and development engagement remains limited in some sectors.

Quantitative indicators reinforce this pattern About 85% of patent applications in Malaysia come from foreign companies. This shows that the country still relies on technology from abroad instead of creating its own. Meanwhile, patent output from local creators has dropped since 2014. This decline highlights serious limits in Malaysia's own innovation capacity.

This pattern suggests capability constraints within domestic firms. Innovation system perspectives highlight the role of absorptive capacity in enabling knowledge transfer (Smith, 1999; Malerba, 1997). Where local firms lack sufficient technological capabilities, they may struggle to internalise external knowledge flows, limiting the potential for spillovers from multinational actors.

These dynamics point to a form of interaction or network weakness within the innovation system, where linkages between firms, knowledge institutions, and supporting organisations remain limited (Carlsson and Jacobsson, 1997). As proposed by Woolthuis, Lankhuizen and Gilsing (2005), this type of interaction failure occurs when connectivity among firms, knowledge institutions, and supporting organisations is insufficient to sustain collective innovation dynamics. As a result, measurable economic activity is present, but deeper capability development and knowledge diffusion remain constrained, reflecting a pattern of partial performance.

iii. Talent constraints and entrepreneurial limitations. The development of a dynamic innovation ecosystem also depends on the availability and retention of skilled human capital. In this MSC case study, a constant brain drain has been a major problem. As of 2024, about 1.86 million Malaysians, roughly 5.6% of the population, reside abroad, a rate notably higher than the global average. This outflow reflects both structural push and pull factors, including income differentials, limited career mobility, and constrained research and development opportunities within the domestic economy. We believe that the effects on the innovation system are substantial. Losing skilled professionals means there is less technical expertise available. This makes it harder for local companies to learn new technologies or move from basic services into advanced research.

In fields like tech and engineering, a lack of qualified workers stops companies from growing. These patterns show a big gap between policy goals and real MSC was designed to be a knowledge-based economy hub, positioning Malaysia as a centre for high-value innovation. However, the fact that talent keeps leaving suggests the environment is not yet ready for that change. Because of this, innovation continues at a basic level, but the quality and depth of local skills remain low.

Building a dynamic innovation ecosystem also depends on strong entrepreneurial activity. In Malaysia, a robust "technopreneur" culture has been more limited than first expected. While the MSC aimed to create high-growth, innovation-driven companies, startup survival rates remain low. Only about 38% of these ventures stay in business longer than six years.

The type of work done in Cyberjaya reflects this struggle. Even though the area has many companies, most jobs are in service-oriented roles, such as shared services and outsourcing. There is a lack of high-value, innovation-intensive work. This limits the growth of a startup ecosystem that focuses on experimentation, scaling, and creating new knowledge.

These patterns suggest that entrepreneurial growth has not kept up with the expansion of infrastructure and policy. As a result, while businesses exist and the economy is active, the ecosystem lacks the depth found in highly innovative regions. This leads to partial performance, where the environment for long-term entrepreneurial success remains underdeveloped.

iv. Institutional fragmentation and gradual policy recalibration. Over nearly three decades, MSC has undergone multiple phases of restructuring. Institutional adjustments reflect attempts to refine policy direction and respond to emerging challenges (Weber & Rohracher, 2012). However, repeated restructuring also indicates coordination challenges across policy institutions. Previous studies highlight misalignment between ministries and fragmented implementation processes (Mohan, 2004; Hassan & Abu Talib, 2015).

From an institutional perspective (North, 1993), this suggests that formal policy frameworks have not always aligned with broader governance structures. This lack of coordination makes it difficult to execute a unified strategy, often leading to a gap between high-level policy goals and actual ground-level results.

The initial focus of the MSC matched global ICT priorities of the late 1990s. However, as innovation moved toward fintech, artificial intelligence, and digital platforms, the MSC was slow to adapt. This shows trajectory dependency, where old institutional and technological choices keep the project on a set path (Smith, 1999). Instead of a breakthrough, the system grew through small, layered adjustments.

Recent policy changes show an attempt to fix these limits. In 2022, the government replaced the MSC with the Malaysia Digital initiative. This new strategy expanded the scope of digital policy and created more flexible rules. Significant changes included removing location requirements so that firms no longer must be based in specific zones like Cyberjaya. The government also lowered entry barriers for companies and introduced outcome-based incentives where rewards are linked to actual performance.

These changes also signal a shift away from an infrastructure-centred model toward a more flexible and inclusive approach, particularly for startups and smaller firms, while expanding into emerging sectors such as artificial intelligence and digital platforms. Several supporting initiatives accompany the new policy direction. MyDigital ID provides a national digital identity platform, the DE Rantau program aims to attract global digital talent, and the Malaysia Digital Arrival Card supports digital immigration processing.

Taken together, these patterns point to a trajectory characterised by continuity alongside uneven transformation. The MSC has generated significant outcomes, including investment inflows, firm attraction, and employment creation, proving it is not a policy failure. However, these achievements remain uneven when compared to the original ambition of a Silicon Valley-type ecosystem. While physical infrastructure was built, the softer ecosystem such as the dense innovation networks, entrepreneurial vigour, strong linkages between startups, universities, and investors, remained underdeveloped, reflecting partial performance,

The transition to Malaysia Digital represents a strategic reworking rather than a total reset. By removing geographical constraints, lowering entry barriers and broadening the sectoral focus, the policy is adapting to solve earlier issues of spatial rigidity and limited local capability. Early indicators show progress where the country's digital sector activity continues to expand. Malaysia's digital economy contributed approximately 25% of GDP in 2025 (Gomes, 2025), and e-commerce revenue is projected to reach RM1.64 trillion (The Edge Markets, 2024). Since 2022, Malaysia has attracted RM184.7 billion in approved data centre investments, supporting the Malaysia Digital initiative as the country aims for 2,100 MW of operational capacity by the end of 2026 (Bank Negara Malaysia, 2025).

While these figures demonstrate measurable progress, this shift remains an evolution of existing foundations. Ultimately, this captures the dynamics of an innovation setback: the system is actively evolving and showing signs of

progress, but the gap between the original high-level ambition and the realised structural transformation remains a work in progress. This suggests that while the hardware of policy has been updated, the software of deep systemic change is still being rewritten.

Research limitations. *This study has several limitations. These limits reflect the exploratory and developmental stage of the research.*

First, the analysis relies mainly on secondary sources. These sources include policy documents, academic studies, government statistics, and public reports. While these materials provide valuable longitudinal and institutional insights, they may reflect official narratives and retrospective interpretations, and do not capture the perspectives and practices of key actors within the MSC ecosystem. Future research will include interviews with policymakers, firms, and institutional stakeholders.

Second, the case of MSC and Cyberjaya is used only as an explanatory example. The aim is to explore and refined the concept of innovation setbacks. The interpretations presented here could be enhanced together with full empirical evaluation. A test of robustness for this interpretation through different data sources and analytical approaches would be beneficial

Third, the analytical framework is still evolving. The framework combines institutional theory, cluster economics, and systemic innovation perspective. The operationalisation of these perspectives remains exploratory. Further research should refine the framework, clarify casual mechanisms and assess its explanatory influence more systematically.

Finally, the study focuses on a single case study. Although MSC provides a strong example of a long-running technopole project, it would be useful to capture a diversity of policy contexts and innovation initiatives. Comparative studies across different projects, regions and countries would be useful to strengthen the applicability of this idea of innovation setbacks.

These limitations highlight clear paths for future research, specifically the need for deeper data, broader comparisons, and a more polished theoretical approach.

Managerial implications. *The preliminary findings of this study offer several implications for policymakers and public agencies involved in innovation policy design and their evaluation thereof.*

First, policymakers should adopt a broader diagnostic approach for innovation policies. Many large-scale programs evolve over long periods. Standard indicators such as patents, firm counts, or employment growth capture only part of the picture. Policy evaluation should also consider institutional alignment, network formation, and capability development within the innovation ecosystem. Regular audits would allow governments to better see their investments are translating into innovation or just a surface level growth.

Second, the findings indicate that infrastructure investments itself are not enough. The investments in digital infrastructure and regulatory incentives are important foundations. However, they do not automatically generate vibrant innovation ecosystems. Policymakers need to actively find ways to allow people to connect. This can be done with creating a platform for university-industry collaboration, innovation intermediaries support and creating specific channel for knowledge exchange.

Third, another core priority would be strengthening the domestic capability development. The presence of multinational firms can bring investment and employment. However, knowledge spillovers depend on the absorptive capacity of local firms. In order to strengthen this, a targeted intervention like SME upgrading programs, entrepreneurship initiatives, and R&D support can help local companies to learn new technologies and capabilities.

Fourth, better coordination across policy institutions remains essential. Large projects often involve multiple ministries and regulatory bodies. Weak coordination can produce fragmented implementation and inconsistent policy signals. Creating clear governance structures and shared institutional objectives can improve long-term policy coherence.

Finally, policymakers should treat persistent underperformance as a source of learning opportunities. When long-running initiatives only produces partial outcomes, it usually points to deep rooted structural issues. A diagnostic approach to innovation setbacks can help governments identify structural bottlenecks and adjust policy strategies over time.

Originality of the paper. *The present study makes three interwoven contributions to the growing field of innovation policy research. First, it introduces innovation setbacks as a distinct analytical category, extending beyond binary success and failure frameworks. While systemic failures and policy effectiveness have been widely examined (Edquist et al., 1998; Woolthuis et al., 2005), initiatives that persist institutionally while falling short of transformative goals have received less attention.*

Second, the study adds a temporal dimension to systemic innovation failure. Existing frameworks typically identify bottlenecks in infrastructure, networks, institutions, and capabilities at specific points in time (Edquist et al., 1998; Woolthuis et al., 2005). This paper instead highlights how these structural frictions accumulate and persist over longer periods, shaping the trajectory of innovation initiatives.

Third, the study integrates institutional theory, cluster economics, and systemic innovation failure perspectives to explain how enduring misalignments between governance structures, spatial dynamics, and capability development

influence long-term outcomes. Although these approaches have been applied separately in innovation studies (Porter, 1998; North, 1993), their combined application provides a more comprehensive framework for analysing persistent underperformance in state-led initiatives.

La performance ESG riduce il rischio di crisi e fallimento delle PMI? Il ruolo della dimensione e dei fattori ambientali

FRANCESCO FASANO[1], MAURIZIO LA ROCCA[1], COSTANZA CONSOLANDI[2], ARTURO CAPASSO[3], MARTINA BOCCHINI[3]

Abstract. *L'obiettivo di questo lavoro è stato studiare come la performance di sostenibilità influenzi la probabilità di crisi e di fallimento delle PMI. Abbiamo scoperto che una maggiore performance ESG è associata a una minore probabilità sia di crisi che bancarotta delle PMI, ma questo effetto "protettivo" è concentrato nelle PMI più piccole. Inoltre, l'effetto protettivo è diverso per i 3 pilastri E, S e G e dipende inoltre dalla materialità ambientale del settore in cui opera l'impresa. Infatti, a livello di singole componenti, sono Governance e Social a guidare questo effetto, mentre la dimensione ambientale non mostra effetti significativi. Inoltre, il ruolo protettivo della componente sociale scompare nei settori caratterizzati da elevata materialità ambientale, dove il rischio ambientale è più alto. I nostri risultati evidenziano che la performance ESG nelle PMI non è uniformemente protettiva, ma dipende dalla dimensione dell'impresa e dalle caratteristiche settoriali. Il nostro studio offre una ulteriore importante novità, perché abbiamo utilizziamo i rating ESG per le PMI forniti da CRIF, una fonte di dati autorevole grazie alla quale abbiamo acquisito score di sostenibilità generalmente difficili da ottenere. Inoltre offriamo una prospettiva nuova per il management delle PMI sul ruolo eterogeneo delle componenti ESG e della materialità ambientale nel determinare la resilienza finanziaria di queste imprese.*
Keywords: *ESG; PMI; Crisi d'Impresa; Bancarotta; Ambiente*

Framing of the research. *Vivere a lungo e prosperare. Questo è ciò che tutte le comunità vorrebbero, ma per raggiungere questi obiettivi, devono vivere a lungo e prosperare anche le imprese, che rappresentano una fonte essenziale di benessere per la società (Neumann, 2021). Nonostante ciò, sopravvivere e ottenere buone performance nel lungo periodo è diventato sempre più difficile per le imprese, a causa della crescente complessità dei mercati e della rapidità dei cambiamenti tecnologici (Benito, 2026; Pitelis et al., 2024). Di conseguenza, molte imprese sperimentano situazioni di difficoltà finanziaria e, purtroppo, questo fenomeno è in costante aumento, come sottolineato dal recente report di Allianz Trade, il quale evidenzia: "Secondo il nostro ultimo Global Insolvency Report, il numero di fallimenti globali continuerà ad aumentare nei prossimi due anni: dopo l'aumento del 10% nel 2024, dovrebbero crescere del 6% nel 2025 e del 3% nel 2026. Ciò si tradurrebbe in 5 anni consecutivi di aumento dei fallimenti (2022 - 2026)" (Allianz, 2025). In questo contesto, la capacità di individuare segnali preoci di allerta delle possibili difficoltà finanziarie future rappresenta un elemento cruciale per la continuità aziendale, per prevenire conseguenze negative e piu in generale per limitare la distruzione di valore (Laux & Zheng, 2023). Questa esigenza di previsione preventiva ha attirato l'interesse non solo dei professionisti, ma anche della ricerca accademica, che ha sviluppato nel tempo diversi modelli e negli ultimi anni principalmente modelli basati sull'intelligenza artificiale, dimostratisi più efficaci rispetto ai metodi tradizionali basati su tecniche statistico-matematiche (Barboza et al., 2017). Questi modelli si sono basati principalmente su variabili finanziarie; tuttavia, arallelamente all'adozione di modelli predittivi sempre più sofisticati, è emersa anche la necessità di integrare in questi modelli di previsione del fallimento anche variabili non finanziarie (Grunert et al., 2005). Questo aspetto è particolarmente rilevante poiché la natura storica delle informazioni finanziarie (principalmente i bilanci passati) limita la capacità di cogliere tempestivamente cambiamenti strutturali e strategici che possono condurre al distress, dato che tali informazioni risultano già superate al momento dell'analisi. Tuttavia, sebbene alcuni studi abbiano già affrontato questo tema, l'introduzione di variabili non finanziarie rimane ancora parzialmente un'area inesplorata nella letteratura sulla previsione della crisi e del fallimento. Al proposito, la review di Dasilas & Rigani (2024) evidenzia infatti che quasi tutti gli studi esistenti si basano su indicatori finanziari. In questo filone di ricerca emergente, un fattore non finanziario che potrebbe svolgere un ruolo chiave nella previsione del fallimento è il livello di sostenibilità aziendale e, in particolare, la performance ESG delle imprese. Dalla letteratura emerge sia che l'utilizzo di dati non contabili è ancora limitato, sia che gli studi si concentrano prevalentemente su grandi imprese o società quotate (Sun et al., 2025), mentre viene spesso dedicata minore attenzione al fallimento delle PMI. Il focus sulle grandi imprese è spesso giustificato dal fatto che il loro fallimento comporta conseguenze rilevanti per la società, come dimostrano noti casi di collasso aziendale quali Enron, Lehman Brothers e WorldCom, frequentemente citati negli studi sul fallimento. Tuttavia, è strano che non sia stata prestata particolare attenzione al ruolo delle PMI, poiché il loro impatto complessivo sull'economia è significativo e la loro crisi non può essere ignorata.*

Purpose of the paper. *L'adozione di pratiche sostenibili può influenzare la performance aziendale sia in modo positivo sia negativo e, di conseguenza, incidere anche sulla probabilità di fallimento dell'impresa (Atif & Ali, 2021). La performance aziendale è infatti strettamente legata al rischio di default, come già evidenziato dai contributi seminali di Altman (1968) e Ohlson (1980). Più recentemente, Seefloth et al. (2025) sottolineano che "la ricerca sulla relazione tra performance di sostenibilità delle imprese e rischio di distress finanziario rientra nello studio delle associazioni tra sostenibilità e performance finanziaria". Gli autori evidenziano inoltre che questo filone di letteratura si basa principalmente sulla shareholder theory e sulla stakeholder theory.*

Secondo la prospettiva tradizionale della shareholder theory (M. Friedman, 1970), le imprese dovrebbero massimizzare il valore per gli azionisti e quindi evitare strategie che possano peggiorare la performance finanziaria. Nel contesto della sostenibilità, ciò implica limitare i costi aggiuntivi associati al raggiungimento di livelli più elevati di sostenibilità.

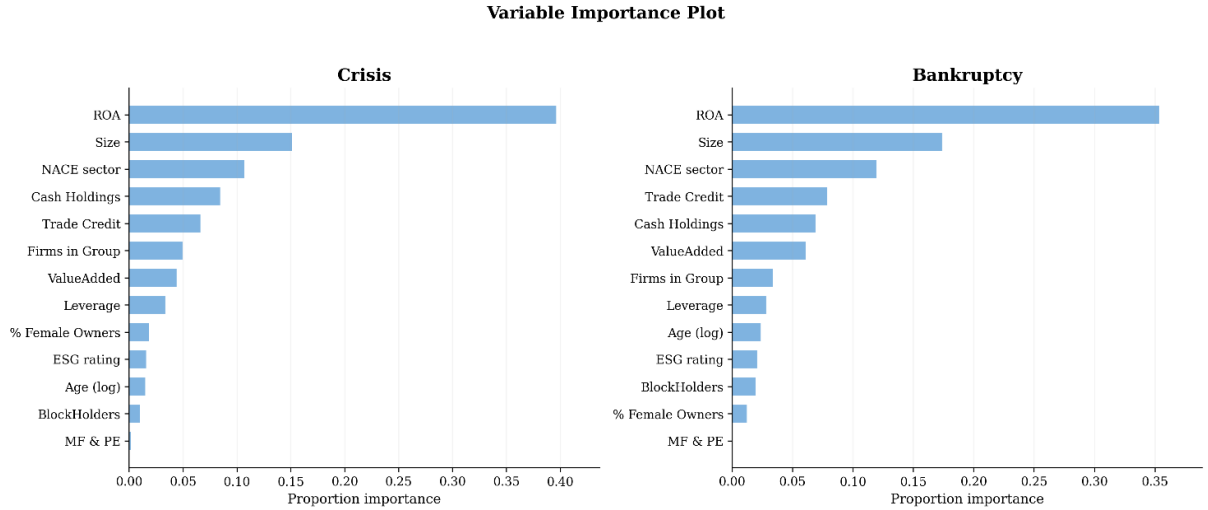
Al contrario, la stakeholder theory enfatizza il ruolo delle imprese nel massimizzare il benessere sociale (Freeman, 1984). Da questa prospettiva, le organizzazioni con elevata performance di sostenibilità hanno maggiori probabilità di essere percepite come legittime dagli stakeholder, grazie al loro impegno credibile verso obiettivi sostenibili. Oggi gli stakeholder svolgono un ruolo cruciale nel determinare la sopravvivenza e il successo delle imprese e mantenere una reputazione positiva nei loro confronti può contribuire a migliorare la performance e ridurre il rischio di fallimento. Questo meccanismo si basa sulla signalling theory, secondo cui gli investimenti in sostenibilità agiscono come segnali osservabili che rafforzano la legittimità dell'impresa e dimostrano la sua volontà di perseguire obiettivi sostenibili. Pertanto, poiché gli investimenti in sostenibilità possono generare sia vantaggi sia svantaggi in termini di performance aziendale, proponiamo due ipotesi alternative.

H1a - La performance ESG (e le sue componenti E, S e G considerate individualmente) è positivamente associata alla probabilità di crisi e default delle PMI.

H1b - La performance ESG (e le sue componenti E, S e G considerate individualmente) è negativamente associata alla probabilità di crisi e default delle PMI.

In linea con la Signalling Theory, sosteniamo che l'impatto della performance ESG sulla probabilità di crisi o fallimento delle PMI possa essere influenzato dalla dimensione d'impresa. Le PMI di maggiori dimensioni inviano al mercato segnali di maggiore stabilità rispetto a quelle più piccole. Inoltre, esse soffrono meno di asimmetrie informative (Fasano & La Rocca, 2023) e risultano finanziariamente più solide, poiché affrontano minori vincoli finanziari (Fasano et al., 2025). Di conseguenza, gli stakeholder reagiscono favorevolmente al comportamento dell'impresa e la probabilità di crisi o fallimento risulta più bassa.

Tuttavia, da una prospettiva alternativa, le PMI più grandi risultano già legittimate dal mercato, poiché la loro dimensione è percepita positivamente dagli stakeholder. Pertanto, quando un'impresa è già ben percepita grazie alla sua dimensione, investimenti eccessivi in sostenibilità e un livello molto elevato di performance ESG potrebbero essere valutati meno favorevolmente. Questo argomento è coerente con l'attention-based view, secondo cui un impegno eccessivo verso la sostenibilità può segnalare agli stakeholder una possibile deviazione dell'attenzione dagli obiettivi di redditività. Alla luce di queste considerazioni, formuliamo due ipotesi alternative.



H2a – La dimensione della PMI modera positivamente la relazione tra la performance ESG (e le sue componenti E, S e G considerate individualmente) e la probabilità di crisi e default.

H2b – La dimensione della PMI modera negativamente la relazione tra la performance ESG (e le sue componenti E, S e G considerate individualmente) e la probabilità di crisi e default.

Methodology. *La nostra analisi si basa su un dataset panel a livello di impresa composto da 1.290 PMI italiane non finanziarie osservate nel periodo 2022–2024, per un totale di 3.371 osservazioni impresa-anno. I dati finanziari e contabili sono tratti dal database Orbis di Moody's. I punteggi ESG sono forniti da CRIF, uno dei principali credit bureau italiani, che valuta ciascuna impresa su una scala da 1 (migliore) a 5 (peggiore) lungo tre dimensioni, Environmental, Social e Governance, e costruisce un punteggio ESG complessivo come media ponderata delle tre componenti. Le due variabili dipendenti utilizzate nel nostro modello sono due variabili dummy. La variabile Crisis assume valore pari a 1 se in un determinato anno l'impresa si trova in una situazione di distress, e 0 altrimenti. La variabile Bankruptcy assume valore pari a 1 se l'impresa è fallita, e 0 altrimenti. Le altre variabili utilizzate sono quelle comunemente impiegate nella letteratura esistente. La principale variabile indipendente, ESG rating, come discusso in precedenza, varia da 1 a 5, dove 5 identifica le PMI più sostenibili. Il moderatore è la variabile Size, misurata come il logaritmo naturale del totale degli asset dell'impresa.*

Results. *Abbiamo stimato un modello di machine learning utilizzando un Gradient Boosting Classifier (scikit-learn) in Python per prevedere la probabilità di distress aziendale. L'analisi dell'importanza delle variabili riportata nella Figura 1, utilizzando Crisis come variabile da prevedere, evidenzia che la redditività, misurata tramite il ROA al tempo t-1, rappresenta di gran lunga il predittore più rilevante. Al secondo posto la dimensione aziendale e poi il settore di appartenenza. Anche ESG sembra avere un ruolo.*

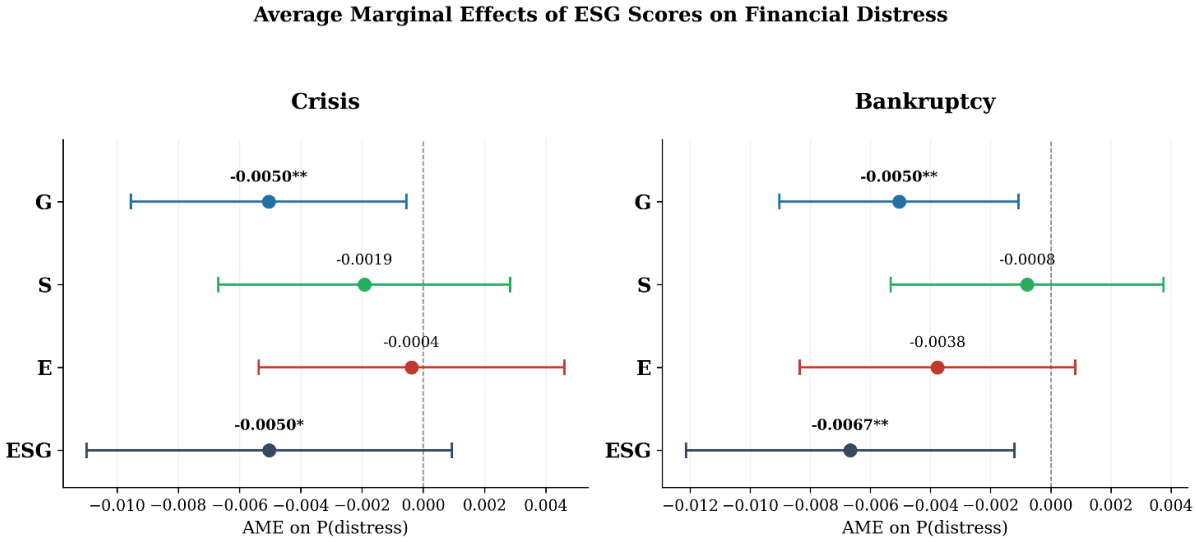
Le colonne (1) e (5) mostrano il modello di base con ESG rating e l'insieme delle variabili di controllo, ma senza Size. Il coefficiente di ESG rating è negativo e statisticamente significativo sia per Crisis (colonna 1) sia per Bankruptcy (colonna 5), indicando che livelli più elevati di performance ESG sono associati a una minore probabilità di crisi e fallimento, supportando l'ipotesi H1b.

Le colonne (2) e (6) introducono la dimensione della PMI (Size) insieme al punteggio ESG. Size presenta in entrambe le colonne un coefficiente negativo e altamente significativo, indicando che le PMI più grandi hanno una minore probabilità di crisi e fallimento. In entrambe le colonne, la significatività statistica del coefficiente di ESG rating si riduce, pur rimanendo significativa, mostrando che parte dell'effetto protettivo è assorbito dal fattore Size. Ciò suggerisce che l'associazione tra performance ESG e distress è in parte legata alle differenze nella dimensione d'impresa.

Le colonne (3) e (7) introducono il termine di interazione tra ESG rating e Size, fornendo l'evidenza principale sul ruolo moderatore della dimensione. In entrambe le colonne, il coefficiente di ESG rating rimane negativo e significativo, mentre il termine di interazione ESG×Size è positivo e statisticamente significativo per la variabile Crisis e positivo ma non significativo per Bankruptcy. Questo indica che la dimensione d'impresa modera significativamente la relazione protettiva tra performance ESG e distress finanziario, supportando l'ipotesi H2a. In particolare, l'effetto negativo, cioè protettivo, dell'ESG sulla probabilità di distress è più forte per le PMI più piccole e si attenua all'aumentare della dimensione d'impresa. In altre parole, la performance ESG agisce come uno scudo contro il distress finanziario principalmente per le imprese più piccole, mentre per le PMI più grandi l'effetto marginale protettivo tende ad annullarsi.

Per illustrare meglio i risultati, includiamo anche la Figura 2, che riporta gli Average Marginal Effects (AME), e la Figura 3, che mostra come l'effetto marginale dell'ESG vari al variare della dimensione d'impresa sia sulla Crisis (sinistra) sia sulla Bankruptcy (destra), evidenziando una riduzione dell'effetto all'aumentare della dimensione della PMI.

Figura 2



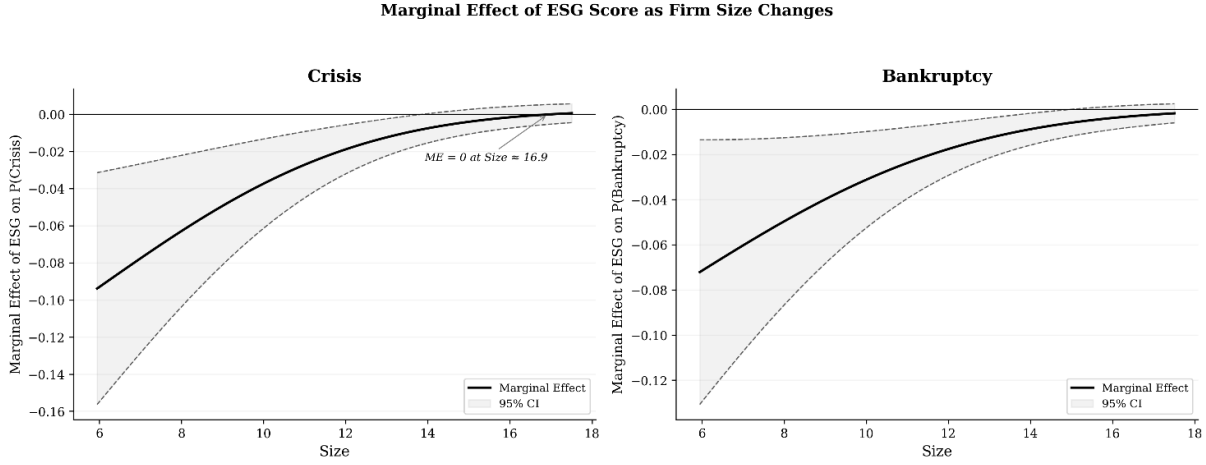


Figura 3

*Per approfondire quali dimensioni della performance ESG guidino i risultati aggregati, stimiamo modelli probit separati per ciascun pilastro: Environmental (E), Social (S) e Governance (G). La tabella è disponibile su richiesta e i risultati mostrano che il pilastro Governance emerge come il predittore più rilevante, con un coefficiente negativo e altamente significativo sia per Crisis (–0.1927***) sia per Bankruptcy (–0.1916***). Il pilastro Environmental non risulta mai statisticamente significativo in nessuna specificazione, mentre il pilastro Social presenta una significatività al limite. Quando viene introdotta la variabile Size, tutti i punteggi dei singoli pilastri perdono significatività statistica, confermando il ruolo dominante della dimensione d'impresa già osservato per il punteggio ESG complessivo.*

È importante notare che, a differenza del punteggio ESG aggregato, i termini di interazione Pillar×Size non risultano statisticamente significativi per nessun pilastro individuale. Ciò suggerisce che il meccanismo di moderazione legato alla dimensione opera a livello del costrutto ESG complessivo, piuttosto che sulle singole dimensioni.

Analisi della materialità ambientale. Alla luce dell'eterogeneità tra i pilastri e dell'assenza di un effetto significativo per il pilastro Environmental, analizziamo se la relazione tra punteggi ESG e distress finanziario vari in funzione della materialità ambientale del settore in cui opera l'impresa. Classifichiamo i settori come ambientalmente rilevanti (E_mat = 1) sulla base del EU Taxonomy Delegated Act 2021/2139. La Tabella, disponibile su richiesta, presenta modelli che includono l'interazione tra ciascun punteggio e la dummy E_mat. Il risultato più rilevante riguarda il pilastro Social. L'interazione S×E_mat è positiva e statisticamente significativa (p = 0.031 per Crisis, p = 0.072 per Bankruptcy), mentre l'effetto principale del pilastro Social è negativo e significativo. Ciò indica che il pilastro Social ha un effetto protettivo nei settori non caratterizzati da materialità ambientale, ma questo effetto scompare completamente nei settori ambientalmente rilevanti, dove l'interazione positiva compensa l'effetto negativo principale. Le interazioni tra ESG, E e G con E_mat non risultano invece statisticamente significative, suggerendo che questa eterogeneità settoriale è specifica del solo pilastro Social.

Research limitations. *I limiti di questo studio riguardano il focus sulle PMI italiane, l'utilizzo di un unico provider di dati ciaoESG e la mancata analisi degli effetti dinamici di lungo periodo*.

Managerial implications. *Dal punto di vista teorico, evidenziamo come il ruolo dell'ESG come segnale verso gli stakeholder sia condizionato dalla dimensione dell'impresa. Mostriamo infatti che le PMI più piccole, caratterizzate da maggiori asimmetrie informative, beneficiano maggiormente dell'ESG in termini di credibilità, mentre per le imprese più grandi tale funzione segnaletica risulta meno rilevante. Sul piano manageriale, suggeriamo che le PMI più piccole dovrebbero considerare l'ESG, in particolare governance e pratiche sociali, come una leva concreta per ridurre il rischio finanziario e rafforzare le relazioni con gli stakeholder. Sottolineiamo inoltre che, nei settori a elevata materialità ambientale, le iniziative sociali devono essere accompagnate da una gestione credibile dei rischi ambientali. Per le PMI più grandi, invece, evidenziamo l'importanza di mantenere un equilibrio tra obiettivi di sostenibilità e performance economica. Infine, sottolineiamo le implicazioni per istituzioni finanziarie e policy maker, suggerendo di non considerare l'ESG come una misura uniforme, ma di tener conto delle sue diverse componenti, della dimensione aziendale e delle caratteristiche settoriali.*

Originality of the paper. *Il presente studio si distingue per diversi elementi di originalità che contribuiscono ad arricchire il dibattito accademico sulla relazione tra sostenibilità e rischio di fallimento. Introduciamo un focus specifico sulle PMI, un ambito ancora poco esplorato nella letteratura ESG, che si è finora concentrata prevalentemente su grandi imprese e società quotate. Questo rappresenta un contributo rilevante, poiché le PMI costituiscono una componente fondamentale del tessuto economico, ma risultano spesso caratterizzate da maggiore vulnerabilità finanziaria e da una minore disponibilità di dati ESG standardizzati.In secondo luogo, il nostro lavoro integra in modo innovativo variabili non finanziarie, in particolare la performance ESG, nei modelli di previsione del distress e del fallimento. In un contesto in cui la maggior parte degli studi continua a basarsi quasi esclusivamente su indicatori contabili, mostriamo come la sostenibilità possa rappresentare una dimensione informativa aggiuntiva e rilevante per comprendere la fragilità finanziaria delle imprese.*

Un ulteriore elemento di originalità risiede nell'analisi delle eterogeneità degli effetti ESG. Dimostriamo infatti che l'impatto della sostenibilità non è uniforme, ma dipende in modo cruciale dalla dimensione d'impresa. In particolare, evidenziamo che i benefici dell'ESG in termini di riduzione del rischio di distress sono più marcati per le PMI di dimensioni ridotte, contribuendo così a chiarire condizioni e limiti dell'efficacia della sostenibilità come leva strategica.

Infine, il nostro studio introduce una prospettiva ancora poco indagata, analizzando il ruolo della rilevanza ambientale del settore. Mostriamo che l'effetto protettivo delle diverse componenti ESG varia in funzione delle caratteristiche settoriali, e in particolare che il contributo della dimensione sociale si annulla nei settori in cui i fattori ambientali sono economicamente rilevanti. Questo risultato evidenzia l'importanza di considerare il contesto competitivo e regolatorio nel valutare l'impatto della sostenibilità.

Beyond productivity: Digital transformation and workers' well-being in warehouse operations

CHIARA SGUIZZARDI[1], BENEDETTA BALDI[1], IVAN RUSSO[1], LORENZO PRATAVIERA[1]

Abstract. *The digital transformation and automation phenomena of logistics workplaces, particularly in warehousing, are posing growing attention to the human element of operations. From a people-centric perspective, while such investments may enhance logistics performance, they may also affect the well-being of logistics workers. Understanding the implications of digital transformation and automation for workers, therefore, remains a crucial issue for logistics research. Despite growing interest in this topic, we still know little about whether and why the same technological intervention may simultaneously reduce workers' physical effort and increase productivity, while also weakening other aspects such as perceived work meaningfulness, social relationships at work, or engagement with tasks. This highlights the importance of examining workers' well-being from a multidimensional perspective. This short paper aims to develop a series of experimental studies (scenario-based and on-field) focusing on a specific warehouse digitalization intervention: the introduction of sensor-enabled vehicle systems designed to guide and partially automate pickers' activities. Semi-structured interviews with managers and logistics workers will first be conducted to inform the design of the experimental studies. This research aims to contribute to the socio-technical systems theory by demonstrating how the technical subsystem of a digitally-transformed warehouse interacts with the social subsystem, represented by pickers' perceptions of their well-being at work. In addition, the study seeks to provide practical managerial guidance on how digitalization initiatives can be implemented while considering their implications for workers' well-being.*
Keywords: *Worker well-being, Productivity, Digital technology, Scenario-based experiment, Field study, Socio-technical systems*

Framing of the research. Over recent decades, the logistics and supply chain management (LSCM) discipline has evolved through several transformative phenomena, from sustainability imperatives to heightened risk management (van Hoek & Wong, 2025), from digitalization and automation to a growing attention for the human element and a people-centric approach (Holmström et al., 2019; Pagell & Wilhelm, 2025). In warehousing in particular, digital transformation and automation have long been perceived as a main driver of future business success, resulting in picking and material-handling activities being increasingly supported by sensors, software, and automated decision aids (Holmström et al., 2019; Winkelhaus et al., 2022). Yet, humans remain a vital part of logistics workplaces as workers continue to shape logistics performance through their decision-making, execution, and interaction with digital systems (Corbett et al., 2024; Kadir et al., 2019; Winkelhaus et al., 2022). Therefore, understanding the implications of digital transformation and automation for workers remains a crucial issue for logistics research, with significant influence on the outcomes of logistics systems.

Digital investments are often justified through promises of effort reduction, increased productivity, and improved operational control. However, extant evidence suggests that these gains cannot be assumed to translate automatically into positive worker experiences (Scott et al., 2021; Westphal et al., 2025). As a matter of fact, digital transformation modifies work characteristics, thus determining changes in individual workers' perceptions and evaluations of their conditions at work (i.e., their well-being at work) (Winkelhaus et al., 2022; Westphal et al., 2025). Logistics workers' well-being has climbed up practitioners' agenda in light of labor shortages and pressures on firms to demonstrate they are behaving in a socially responsible way (Corbett, 2024; Pagell & Wilhelm, 2025). As a result, major international brands have started to perform audits that assess physical dimensions of well-being (Bellingan et al., 2020; Lamb & Kwok, 2016). Likewise, LSCM scholars have been calling for research that examines the role of the supply chain ecosystems in ensuring the health, safety, and well-being of employees and customers (Douglas et al., 2024; Mollenkopf et al., 2024), expanding the traditional logistical mission into one that encompasses social outcomes (Bowersox, 1998). Together with physical dimensions (Cantor et al., 2016; Douglas et al., 2024; Roberts et al., 2024), job satisfaction has frequently been investigated as a proxy for workers' well-being (Autry & Daugherty, 2003; Weiss & Brief, 2001; Winkelhaus et al., 2022). However, recent evidence has highlighted that well-being is much more complex and multi-dimensional, as it includes *hedonic* aspects (e.g., job satisfaction or positive affect at work), *eudaimonic* aspects (e.g., meaning at work), and social aspects (e.g., relationships with peers and leaders) (Bellingan et al., 2020; Fisher, 2014; Martela, 2025).

While existing LSCM studies have examined impacts of technology adoption on human operators mainly through adjacent outcomes such as job characteristics, job satisfaction, safety, or performance (e.g., Cantor et al., 2016; Salanova et al., 2004; Westphal et al., 2025; Winkelhaus et al., 2022), LSCM scholarship now calls for research that places well-being outcomes at the center and recognizes their multi-dimensionality (Mollenkopf et al., 2024). An expanded conceptualization of workers' well-being is relevant as it allows us to shed light on possible trade-offs or misalignments between different well-being dimensions. In fact, digital transformation interventions, intended to reduce effort and

[1] *Department of Management, University of Verona, Verona, Italy*

improve workflow and performance, may still undermine workers' autonomy, thus impacting on one or more facets of workers' well-being (e.g., reducing job satisfaction) (Autry & Daugherty, 2003; Grant et al., 2007; Robert et al., 2020).

We still lack an understanding of how digital transformation and automation in warehouse operations reshape different dimensions of workers' well-being. In particular, we know little about whether and why the same intervention may simultaneously reduce physical effort, eventually increase productivity, while also weakening perceived work meaningfulness, social relationships at work, or engagement with work and tasks. The specific research question is: *how does digital transformation in warehouse operations influence workers' perception of different dimensions of their well-being?* This short paper addresses this gap by developing a series of experimental studies (scenario-based and on-field) on a warehouse digitalization intervention: the introduction of sensor-enabled vehicle systems designed to guide and partially automate pickers' activities.

Purpose of the paper. Building on literature on digital transformation and automation in logistics, and on workers' well-being research, this study aims to examine how multiple dimensions of worker well-being evolve as a result of technology implementation, uncovering positive, negative, and counterintuitive worker responses. Moreover, the research aims at revealing whether trade-offs exist between productivity and well-being perceptions. To reach our aims, we turn to socio-technical systems (STS) theory (Bostrom & Heinen, 1977; Cooper & Foster, 1971).

Workers' well-being. Workers' well-being has emerged as an increasingly important construct across organizational research (Danna & Griffin, 1999; Knight & Haslam, 2010). Within LSCM literature, recent calls for research have highlighted the need to integrate the experiences of people and communities (Pagell & Wilhelm, 2025) and to reframe supply chains as people-centric systems, ones that recognize, encapsulate, and actively promote the well-being of logistics workers. In the broadest sense, employee well-being refers to the overall quality of workers' experience and functioning at work, encompassing how positively they evaluate their job and how well they function psychologically in it (Fisher, 2014; Grant et al., 2007). While job satisfaction has long been the dominant proxy, recent work shows that this indicator is too narrow. Contemporary scholarship distinguishes at least hedonic or evaluative aspects (e.g., job satisfaction), affective states (e.g., approaching work with excitement and joy), and eudaimonic dimensions such as motivation, meaning, and purpose at work. Social and physical dimensions are also increasingly recognized as integral rather than peripheral to well-being (Bellingan et al., 2020; Martela, 2025). This broader understanding is especially relevant in logistics and supply chains, where worker experiences have often been overshadowed by efficiency and performance concerns (Bruccoleri et al., 2014; Roberts et al., 2024). Although LSCM scholarship has begun to address precarious work, safety, and decent work, it still tends to examine workers instrumentally, whose well-being represents an antecedent to retention or productivity (Soundararajan et al., 2021; Wiengarten et al., 2021). Moreover, recognizing workers' well-being as a multi-dimensional concept is useful for logistics contexts because operational and workplace conditions may support some dimensions while undermining others. For instance, warehouse interventions may improve performance or reduce physical effort while still eroding autonomy or satisfaction. Accordingly, studying logistics workers' well-being requires moving beyond single proxies and examining how different aspects of well-being are simultaneously enabled or frustrated by work design changes, such as the adoption of new technologies.

Adoption of automation and digital technologies and work experiences. LSCM research on the impact of automation and digital technologies on logistics workers' experiences has developed across transportation and warehouse operations. In warehouse settings, technology adoption has intensified under the industry 4.0 and industry 5.0 paradigms, yet human labor remains central (Holmström et al., 2019; Westphal et al., 2025; Winkelhaus et al., 2022). Winkelhaus et al. (2022) provide an account of how digital and automation technologies reconfigure work characteristics at varying maturity levels, finding that high automation reduces physical demands but simultaneously turns workers into passive performers, whose knowledge requirements and decision autonomy are reduced. Within the investigation of physical dimensions, a stream of research has examined how technology - from assisted-picking devices to collaborative robots - can reduce physical workload and fatigue (Grosse et al., 2023; Neumann et al., 2021; Pasparakis et al., 2023). While certain forms of digital transformation and automation adoption have been found to reduce physical effort and to improve performance, the evidence on their broader effects on workers' experiences remains fragmented (Pasparakis et al., 2023; Westphal et al., 2025). Beyond physical outcomes, job satisfaction has been the dominant proxy for well-being in LSCM research (Autry & Daugherty, 2003; Maloni et al., 2017), and it has also been explored under digitalization shifts (Bala, 2013; Winkelhaus et al., 2022). Winkelhaus et al. (2022) show that automation technology can indirectly have both positive and negative effects on workers' job satisfaction, depending on system design and employees' preferences. Westphal et al. (2025) sharpen this picture through a field study, showing that algorithmic task assignment suppresses self-determination needs to the point where workers develop informal coping strategies, and that even an intervention intended to restore autonomy can paradoxically reduce job satisfaction if it disrupts such coping responses. Collectively, these contributions reveal an important gap: while studies have individually examined outcomes such as physical effort and safety, job satisfaction, or productivity and performance of warehouse technologies, they have not jointly examined how multiple well-being dimensions are simultaneously – and potentially divergently - affected by a single technology implementation. Understanding these dynamics can yield a more comprehensive understanding of the impacts of technology adoption on a multi-dimensional conceptualization of well-being, while revealing whether trade-offs exist between productivity and workers' well-being perceptions.

Socio-technical systems theory. Socio-technical systems (STS) theory proposes that work system performance depends on the alignment of technical structures with the requirements of social actors and the external environment (Bostrom &

Heinen, 1977; Cooper & Foster, 1971). Early STS studies observed that employee behavior and work design were so intertwined that technical processes could not be understood without understanding social processes (Emery, 1959; Kull et al., 2013). The supply chain field has used aspects of STS theory to investigate, among others, social reactions to factory automation (Susman & Chase, 1986), logistics workers' resistance to the implementation of electronic log-book systems (Cantor et al., 2009), and the engagement of drivers on sharing economy platforms based on platform design attributes (Saunders et al., 2025). Overall, STS theory allows generating critical insights into the relationships among people, technology, and outcomes (Griffith & Dougherty, 2001; Kull et al., 2013).

Drawing on STS theory, we conceptualize digitally-transformed warehouses as socio-technical systems and examine how the alignment between technical (digital and automation technology integration) and social (pickers' preferences and behaviors) subsystems influences workers' perception of different dimensions of their well-being. By integrating structural elements of warehouse structures with pickers' preferences, we gain a more comprehensive understanding of the factors influencing logistics workers' job experiences.

Methodology. We will collect data through a series of complementary and sequential research methodologies. Following a three-step research design, we will first conduct semi-structured interviews with managers and logistics workers employed in a warehouse where a digitalization intervention is being introduced. Building on the insights obtained from the interviews, we will then conduct a scenario-based experiment to test the impact of the digitalization intervention on workers' well-being in a controlled environment and establish internal validity. Finally, drawing on the findings of the previous studies, we will conduct a field experiment to validate the findings and examine the external validity of the results in a real operational setting.

Semi-structured interviews with managers and logistics workers will help us gain a detailed understanding of warehouse working procedures before and after the digitalization intervention. The interviews will help identify the intended opportunities of the intervention as well as potential behavioral issues arising in the workplace. We expect to gain detailed insights into existing workflows and formal operational processes, allowing us to accurately capture the key perceptual and behavioral dimensions and design realistic experimental scenarios (Gioia et al., 2013; Grant et al., 2023; Salanova et al., 2004).

Next, we will conduct an online, scenario-based between-subject experiment with logistics workers as the target participants. The methodology provides a valuable approach for studying individual decision-making, in which varying versions of a scenario convey information about different levels of the manipulated variable to participants (Eckerd & Bendoly, 2011; Knemeyer & Naylor, 2011). It is particularly well-suited for isolating causal effects that may be difficult to observe in complex real-world environments. Participants will be presented with a warehouse work scenario describing either the presence or absence of the digitalization intervention in the warehouse. Participants will be randomly assigned to one of the treated conditions. Data will be collected via the Prolific Academic crowdsourcing platform, and the survey instrument will be developed in Qualtrics. Prior to the main experiment, we will conduct pretests to ensure scenario realism and to conduct manipulation checks (Bachrach & Bendoly, 2011). Respondents will receive a fixed compensation for their participation. In the experiment, respondents will be asked to imagine a warehouse work situation representing a simplified and controlled version of the real operational setting, which will later be examined in the field experiment.

Although scenario-based experiments provide strong internal validity, they primarily capture individuals' perceptions and behavioral intentions rather than actual behavior. To address this limitation and enhance external validity, we will therefore conduct a field experiment in a logistics warehouse. This study will examine whether the digitalization intervention affects logistics workers' well-being in a real operational context. Conducting field research allows us to observe behavior within existing systems of human interaction and operational processes. It offers a unique opportunity to uncover dynamics, such as interactions among workers, managers, and digital systems, that may not emerge from scenario-based data alone. Grounding the research in a real-world setting strengthens external validity (Ibanez & Staats, 2018) and enables us to identify operational and behavioral factors affecting worker well-being that might otherwise remain hidden and to analyze actual productivity data. In this study, we examine people-centric operations by analyzing how logistics workers interact with digitalized systems and adapt their behavior within warehouse processes. The field study will be conducted in the warehouse of a logistics service provider operating in Western Europe.

Measures of logistics workers' well-being and productivity. The dependent variables investigated in the scenario-based and field experiments will be workers' perceived well-being and productivity. Logistics workers' perceived well-being will be measured along the three dimensions proposed in the literature (Fisher, 2014; Martela, 2025): affective, evaluative, and conative well-being. Affective well-being (Van Katwyk et al., 2000) refers to the affective experiences employees have at work that tend to range along a continuum from positive to negative (Warr, 2013). The most common way to measure affective well-being is to examine how much positive affect and how much negative affect the worker is experiencing. Some workers might approach their work with excitement and joy; others may feel that their work gives rise to anxiety, frustration, and sadness. Evaluative well-being refers to general feelings and assessments employees make as regards how positively they evaluate their work, and is typically measured through job satisfaction and meaningful work (Rothausen & Henderson, 2019). Job satisfaction is defined as an overall evaluative judgment workers have about their job, focusing on its favorability. Meaningful work is conceptualized as the extent to which the employee finds their work personally significant and valuable. Conative well-being refers to the quality of the worker's motivation toward one's work, thus focusing on types of motivation felt as positive, where work feels attractive and intrinsically motivating,

and the employee feels drawn toward and excited about one's work (Deci et al., 2017). Conative well-being can be mainly measured by positive constructs, such as work engagement – defined as a motivational state of dedication and absorption – and negative constructs, such as job burnout, characterized by loss of energy and enthusiasm (Rivkin et al., 2018).

Logistics workers' job productivity measures will be defined consistently with KPIs adopted in the warehouse that represents the context of the study; such measures will be shared by the logistics service provider implementing the digitalization intervention.

Results. This research is conducted at the individual (worker) level of analysis to capture the little-known perspectives of logistics workers (specifically, pickers) and explore the influence of digital transformation and automation adoption in warehouses from a more micro perspective, thus contributing to a deeper understanding of how transformative phenomena such as Industry 5.0 might influence worker perceptions and behavior when conducting dynamic tasks.

Our expected results shed light on positive, negative, or counterintuitive changes of multiple dimensions of logistics workers' well-being (namely, job satisfaction, affective well-being, and meaning at work) as a result of a digital transformation intervention in a warehouse. Moreover, we expect to reveal whether trade-offs exist between productivity and well-being perceptions.

Our contribution to STS theory lies in demonstrating how the technical subsystem of a digitally-transformed warehouse interacts with the social subsystem (pickers' perceptions of their well-being at work). This interaction may shape the overall logistics system's effectiveness, particularly in terms of pickers' productivity. Moreover, well-being perceptions may have an impact on further job-related outcomes such as turnover intention, absenteeism, and motivation. By applying STS principles to a warehousing context, we highlight the importance of aligning technical platform design with the preferences of the workers.

Research limitations. This research presents some inherent limitations. First, from a methodological perspective, scenario-based experimental methods, while strong in internal validity, often suffer from lower external validity. We intend to assess this limitation by complementing the scenario-based experiment with a field study. Second, this study focuses on a single digital transformation intervention in a warehouse. This may limit the applicability of findings to other warehousing contexts, considering that a great variety of digital and automation technologies may be implemented and integrated. Further research may examine whether other human-technology interaction designs yield comparable results.

Managerial implications. This research aims to provide critical knowledge and timely guidance to managers in logistics and warehousing contexts, for increasing worker-related outcomes such as well-being, while maintaining operational productivity. Furthermore, increased perception of well-being may indirectly lead to a reduction of workforce turnover intention and absenteeism. Specifically, our results potentially provide insights into how firms can reduce negative job-related outcomes by aligning digital and automation technology design inside warehouses with the preferences of a heterogeneous logistics workers' population, in a way that fosters individual workers' perception of well-being.

Originality of the paper. This research contributes to LSCM literature by examining how digitalization and automation technologies shape multiple dimensions of workers' well-being in logistics operations, an outcome that remains underexplored despite its growing importance. Moreover, the research adds behavioral insights to the literature on digital transformation in logistics contexts. Finally, it extends the application of STS theory to digital transformation in the warehousing context.

Designing Shock-Ready Agrifood Supply Chains

PAOLO COPPOLA[1], MARIA ANTONELLA FERRI[2], MARCO VALERIO ROSSI[3], MARIA PALAZZO[4]

Abstract. *Systemic shocks such as the pandemic, geopolitical conflicts, energy price volatility and climate-related disruptions have exposed structural weaknesses in agrifood supply chains. Traditionally configured according to cost-efficiency and lean management principles, these networks have proven fragile when confronted with simultaneous and prolonged disruptions. In this context, resilience must be embedded in the strategic design of supply chain networks rather than treated as a reactive capability. This study develops a network-oriented decision framework to identify the most critical resilience drivers in agrifood supply chains and to determine which strategic resilience approach should be prioritized under systemic shocks. An integrated Analytic Network Process (ANP) and Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) methodology is adopted. ANP captures interdependencies among resilience drivers, while TOPSIS ranks alternative resilience strategies based on weighted criteria. Findings indicate that digital supply chain visibility, strategic logistics outsourcing governance, network diversification and dynamic business continuity planning are the most influential resilience drivers. Among strategic alternatives, agility emerges as the most appropriate resilience orientation in shock-prone environments. The study contributes to the supply chain management debate by integrating digitalization, logistics governance and network configuration into a structured decision-support framework for designing shock-ready agrifood supply chains.*
Keywords: *supply chain resilience; systemic shocks; agrifood logistics; ANP; TOPSIS; agility*

Framing of the research. *Over the past two decades, supply chain management (SCM) has progressively shifted from an efficiency-oriented paradigm toward a resilience-based perspective. Lean production, just-in-time practices, and global sourcing strategies were designed to reduce costs and increase competitiveness. At the same time, these configurations reduced slack and inventory buffers, increasing exposure to systemic disruptions (Durach et al., 2015). Recent shocks highlight this structural fragility. The COVID-19 pandemic disrupted labor mobility, transport capacity, and demand stability worldwide. The Russia–Ukraine conflict subsequently altered trade flows, restricted access to key agricultural inputs such as fertilizers and grains, and generated sustained volatility in energy prices affecting logistics networks (Zakeri et al., 2022; Mottaleb et al., 2022). Competition over critical minerals—including lithium, cobalt, and rare earth elements—has further concentrated supply chains in a limited number of producing countries, increasing strategic vulnerability across industries (Liu et al., 2025). Agrifood supply chains are particularly exposed to these risks. Perishability, seasonality, reliance on transport and cold-chain infrastructure, and fragmented primary production increase operational vulnerability (Koufteros and Lu, 2017). Because agrifood systems are closely linked to food security, disruptions in fertilizer markets or energy-intensive logistics can rapidly translate into food price volatility (Mehibel et al., 2025). Climate stress further amplifies commodity volatility (Marn-Rodríguez et al., 2025). In response, resilience has become a central concept in SCM research. It refers to the capacity of supply chains to anticipate, absorb, and recover from disruptions while maintaining operational continuity (Durach et al., 2015). Recent contributions emphasize agility and flexibility as key capabilities enabling adaptation to persistent shocks (Fayezi et al., 2017; Mishra et al., 2022; Mishra et al., 2024). Moreover, extant research has increasingly framed supply chain resilience as a systemic capability emerging from the interaction between network structure, governance mechanisms and information flows across interconnected actors (Ivanov, 2026). Rather than being interpreted solely as the ability to recover from disruptions, resilience is progressively conceptualized as a proactive capability embedded in supply chain design, enabling organizations to anticipate, absorb and adapt to systemic shocks through coordinated network responses (Faggioni et al., 2024). From this perspective, resilience does not depend exclusively on individual firm capabilities but on the configuration of the broader supply network, including the alignment of partners, the distribution of decision rights, and the availability of shared information infrastructures. Within such networked systems, scholars also identified intangible resources and forms of intellectual capital as crucial in enabling coordinated responses to disruption (Mubarik et al., 2022). Elements such as relational capital among supply chain partners, shared knowledge bases, trust-based governance mechanisms and collective learning processes contribute to strengthening adaptive capacity across the network (Yu et al., 2023). Consequently, resilience increasingly emerges as a knowledge-intensive and relational capability embedded in the intellectual capital of the supply chain ecosystem rather than solely in the operational assets of individual firms (Rossi et al., 2026). In complex sectors such as agrifood systems, where multiple actors interact under strong environmental and regulatory constraints, resilience therefore becomes an emergent property of the supply chain network rather than a firm-level attribute (Faggioni & Rossi, 2025).*

Contemporary resilience literature identifies multiple interconnected drivers spanning technological, relational, and structural dimensions. Transport infrastructure endowment influences supply chain performance and adaptive capacity (Agnusdei et al., 2022a). Coordination mechanisms, information sharing, and social capital enhance relational resilience. Digital transformation has emerged as a foundational resilience enabler. IoT-enabled monitoring systems, blockchain traceability, predictive analytics, digital twins, and AI-driven risk forecasting strengthen real-time visibility and proactive disruption management (Agnusdei et al., 2022b; Belhadi et al., 2024; Adama et al., 2024; Gomaa, 2025).

Logistics outsourcing governance represents a critical resilience dimension. Outsourcing can either increase vulnerability through supplier concentration or enhance resilience through collaborative alignment and strategic integration (König and Spinler, 2016; Liu and Lee, 2018; Laari et al., 2024; Alsmairart, 2025). Third-party logistics providers increasingly serve as adaptive partners capable of reconfiguring routes and capacities under disruption.

Structural diversification strategies also contribute to resilience. Supplier dispersion and network diversification mitigate concentration risk and reduce dependency on single regions. Nearshoring and reshoring initiatives reflect deliberate strategic reconfigurations driven by geopolitical risk mitigation rather than cost optimization (Qureshi and Ali, 2025; Robinson and Dolfsma, 2025).

Dynamic business continuity planning frameworks further strengthen adaptive capacity. Rather than relying on static contingency manuals, organizations increasingly adopt scenario-based, data-driven, and analytics-supported planning systems to enhance preparedness (Kaneberg et al., 2025). Inventory planning systems and adaptive resource allocation mechanisms also influence resilience outcomes (Swink et al., 2025).

Given the multiplicity of resilience drivers and the presence of competing objectives, structured decision-support approaches have gained relevance. Multi-criteria decision-making (MCDM) frameworks provide systematic methods for integrating technological, relational, and structural dimensions. Hybrid ANP–TOPSIS models have been applied to supplier selection, risk prioritization, and strategic evaluation contexts (Chen, 2021; Abdel-Basset et al., 2018; Mukherjee et al., 2024; Kayouh and Dkhissi, 2025). These approaches allow modeling interdependencies among criteria while transparently ranking strategic alternatives under uncertainty.

Purpose of the paper. *Despite the substantial growth of the supply chain resilience literature over the past decade, several conceptual and methodological limitations persist.*

To illustrate, resilience drivers are frequently examined in isolation. Technological capabilities, relational governance mechanisms, and structural network configurations are often treated as separate analytical dimensions, without adequately accounting for their systemic interdependencies. However, supply chains increasingly operate as complex adaptive networks in which digital visibility influences coordination routines, outsourcing governance affects vulnerability exposure, and diversification strategies interact with business continuity mechanisms. Recent network-oriented perspectives explicitly call for resilience research that incorporates multiple stakeholders and interlinked system components rather than firm-level isolated factors (Hong et al., 2023). The absence of integrative analytical frameworks capable of capturing such feedback mechanisms therefore represents a significant limitation in current resilience research.

In addition, sector-specific resilience dynamics remain underexplored. Although general resilience frameworks provide valuable conceptual foundations, agrifood supply chains exhibit distinctive characteristics that challenge standard models. Biological production cycles, perishability constraints, regulatory compliance requirements, energy dependency in cold-chain logistics, and fragmentation of upstream actors generate resilience patterns that differ substantially from those observed in manufacturing or high-tech sectors. Empirical evidence from agri-food systems confronted with compounding shocks highlights the need for context-sensitive approaches capable of addressing sectoral particularities (Murphy et al., 2023; Coluccia et al., 2025). A contextualized analysis is therefore required to account for the structural and institutional peculiarities of agrifood networks.

Moreover, existing contributions often lack structured and transparent decision-support methodologies. While qualitative taxonomies and conceptual discussions are widespread, managers and policymakers frequently lack operational tools for prioritizing resilience investments under resource constraints. Recent contributions emphasize the urgency of developing structured frameworks to guide strategic choices in the face of global disruptions (Bamia and Bamia, 2025). However, few studies provide multi-criteria decision models capable of explicitly incorporating trade-offs among competing objectives, such as cost efficiency, service level, adaptability, and risk mitigation, within a coherent analytical structure. Fourth, the trade-off between resilience and efficiency remains insufficiently specified. Although resilience is widely recognized as desirable, its implementation entails tangible costs associated with redundancy, diversification, digital infrastructure and coordination mechanisms. The balance between adaptive capacity and operational efficiency is inherently context-dependent and may vary across industries and shock typologies. Recent analyses underline the need for more rigorous evaluation of resilience strategies capable of mitigating disruption while preserving competitiveness (Phukan and Kumar, 2025). Yet empirical clarification of how different strategic orientations perform under systemic shock conditions remains limited.

In light of these gaps, the objective of this paper is twofold.

First, it aims to identify and prioritize the most critical factors shaping agrifood supply chain resilience in the presence of systemic shocks. These factors include digital transformation, logistics outsourcing governance, network diversification, energy dependency management and dynamic business continuity planning.

Second, the study seeks to determine which resilience strategy should be prioritized among four alternative approaches: robustness, agility, flexibility and risk-oriented governance.

The research questions are therefore:

RQ1: Which factors most significantly influence resilience in agrifood supply chains under systemic shocks?

RQ2: Which resilience strategy best aligns with the prioritized resilience drivers?

By answering these questions, the study contributes to the ongoing debate on supply chain configuration under uncertainty and provides operational guidance for managers and policymakers responsible for agrifood logistics systems.

Methodology. *To ensure a rigorous and structured evaluation of resilience strategies in agrifood supply chains exposed to systemic shocks, the methodological framework was developed through a sequence of clearly defined steps (Figure 1).*

The methodological process was structured into four main phases:

1. *Identification and validation of resilience drivers.*
2. *Structuring of the ANP network and weighting of criteria.*
3. *Ranking of resilience strategies using Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS).*
4. *Sensitivity analysis.*

Each phase progressively refined the analytical framework and ensured alignment with the research objectives (Coluccia et al., 2024; 2025a).

Figure 1 – Methodological workflow

Source: Authors' Elaboration

Phase 1 – Identification of the criteria or resilience drivers. *The first phase focused on identifying the resilience drivers to be included in the evaluation framework.*

An initial list of potential drivers was derived from the literature on supply chain resilience, systemic shocks, agrifood logistics, digital transformation, and governance mechanisms. Particular attention was given to contributions addressing technological capabilities, network diversification, outsourcing governance, and adaptive planning mechanisms.

To ensure contextual relevance to agrifood systems, a structured expert consultation was conducted. The panel consisted of 18 experts, including university scholars in supply chain management and practitioners operating in agrifood logistics networks. Eligibility required at least five years of professional or academic experience in supply chain risk management, logistics coordination, or agrifood operations.

The identification process unfolded in two stages:

- *First, experts reviewed and refined the preliminary list of drivers derived from the literature.*
- *Second, overlapping constructs were consolidated and definitions were clarified to avoid redundancy.*

At the end of this process, eleven resilience drivers were validated and grouped according to technological, structural, and relational dimensions:

Table 1 – Criteria of the study

Code	*Resilience Driver*	*Description*
(C1)	***Digital supply chain visibility***	*Capability to monitor inventory flows, transport status, supplier performance and disruptions in real time through digital platforms, control towers and data-sharing systems, reducing information asymmetry and enabling rapid response.*
(C2)	***Advanced analytics and AI adoption***	*Use of predictive analytics, artificial intelligence and data-driven forecasting tools to anticipate disruptions, optimize routing decisions and support adaptive planning under uncertainty.*
(C3)	***Strategic logistics outsourcing governance***	*Ability to design and manage outsourcing relationships with logistics providers through collaborative contracts, performance-based agreements and joint contingency planning mechanisms.*
(C4)	***Network diversification and nearshoring***	*Structural configuration of supply networks through geographical dispersion of suppliers, multi-sourcing strategies and selective regionalization to reduce concentration and geopolitical risk exposure.*
(C5)	***Inventory buffer strategy***	*Adoption of safety stock policies and strategic inventory reserves to absorb short-term disruptions and mitigate supply volatility.*
(C6)	***Energy dependency management***	*Capability to reduce vulnerability to energy price volatility and supply constraints through diversification of energy sources, efficiency measures and renewable integration within logistics operations.*
(C7)	***Cybersecurity readiness***	*Implementation of cybersecurity protocols and digital risk protection systems to safeguard interconnected supply chain infrastructures from cyber threats and data breaches.*
(C8)	***Human capital coordination***	*Organizational capability to coordinate cross-functional teams, align decision-making processes and enhance adaptive behavior among supply chain actors during disruptions.*
(C9)	***ESG and regulatory integration***	*Alignment of supply chain strategies with environmental, social and governance standards, as well as regulatory compliance requirements, reducing institutional and reputational risks.*
(C10)	***Dynamic business continuity planning***	*Development of scenario-based, data-supported and continuously updated contingency plans designed to ensure operational continuity during systemic shocks.*
(C11)	***Relational trust and information sharing***	*Degree of collaborative trust, transparency and structured information exchange among supply chain partners to enhance collective resilience and coordinated response.*

Source: Authors' Elaboration

These drivers constitute the criteria of the multi-criteria evaluation framework.

Stage 2: Analytic Network Process (ANP). *Given the presence of interdependencies among resilience drivers, the Analytic Network Process (ANP) was adopted to determine their relative importance (Kumar and Pant, 2023; Chung et al., 2005).*
Unlike hierarchical approaches, ANP allows the modeling of feedback and reciprocal influence among criteria. A network structure was defined using SuperDecision software. The eleven resilience drivers were organized within interconnected clusters reflecting technological, structural, and relational dimensions. Interdependencies among drivers were explicitly modeled through pairwise comparisons. A panel of 20 experts (partially overlapping with the previous consultation phase) conducted pairwise comparisons using Saaty's 1–9 scale. The scale ranged from 1 (equal importance) to 9 (extreme importance) (Saaty, 2004).
The comparison process generated:

- *An unweighted supermatrix*
- *A weighted supermatrix*
- *A limit supermatrix*

The weighted supermatrix was raised to successive powers until convergence was achieved, producing the limit supermatrix. The values contained in the limit supermatrix represent the global weights of each resilience driver.
To ensure reliability, a Consistency Ratio (CR) was calculated for each pairwise comparison matrix (Chu and Liu, 2002). A threshold of $CR \leq 0.10$ was adopted. When this threshold was exceeded, experts were asked to revise their judgments. The resulting global weights were subsequently used in the ranking phase (Apostolou and Hassel, 1993).

Stage 3: TOPSIS. *After deriving the global weights of the resilience drivers through the Analytic Network Process (ANP), the TOPSIS method was applied to rank four alternative resilience strategies (Fayezi et al., 2017): A1 – Robustness; A2 – Agility; A3 – Flexibility; A4 – Risk-oriented governance.*
TOPSIS is a distance-based multi-criteria decision-making method that identifies the alternative which simultaneously maximizes performance across benefit criteria while minimizing its distance from the least desirable configuration (Yoon

and Hwang, 1981). In this study, the method was used to determine which resilience orientation best aligns with the prioritized resilience drivers identified through the ANP analysis (Krstić et al., 2022; Coluccia et al., 2025b).
A decision matrix was constructed in which each resilience strategy was evaluated against the eleven resilience drivers. The evaluation scores were obtained from the expert panel, reflecting the perceived contribution of each strategy to strengthening specific resilience dimensions within agrifood supply chains exposed to systemic shocks.
To ensure comparability across criteria, the decision matrix was normalized in order to eliminate scale effects. Since all resilience drivers were treated as benefit criteria, higher values indicated better performance. The normalized scores were subsequently multiplied by the global weights derived from the ANP analysis, generating a weighted performance matrix that integrates both the relative importance of each resilience driver and the effectiveness of each strategy.
Following this, a positive ideal solution and a negative ideal solution were identified. The positive ideal solution represents a hypothetical strategy that achieves the best possible performance across all resilience drivers, whereas the negative ideal solution represents the lowest performance levels across the same criteria.
The distance of each resilience strategy from both the positive and negative ideal solutions was then calculated. These distances measure, respectively, how close each strategy is to the optimal configuration and how far it is from the least desirable scenario.
Finally, a relative closeness coefficient was computed for each alternative. This coefficient expresses the extent to which a strategy approaches the ideal solution while distancing itself from the negative benchmark. The resilience strategies were ranked in descending order according to their closeness coefficients, with higher values indicating superior overall alignment with the prioritized resilience drivers.
The integration of ANP and TOPSIS ensures that interdependencies among resilience drivers are captured through the network-based weighting process, while the final ranking of strategic alternatives is obtained through a structured and transparent distance-based evaluation procedure.

Stage 4: Sensitivity analysis. *To verify the robustness of the ranking results, a sensitivity analysis was conducted (Miškić et al., 2023; Coluccia et al., 2025).*

Three alternative scenarios were developed. In each scenario:

- *The weight of the most influential resilience driver was reduced by 15%, 30%, and 50%, respectively.*
- *The reduced weight was proportionally redistributed among the remaining drivers to maintain the total weight equal to 1.*

For each scenario, the TOPSIS procedure was repeated and the ranking of alternatives was recalculated.

This approach allows verification of ranking stability under different weight configurations and assessment of the influence of dominant criteria on the final ordering of resilience strategies.

Results. *The ANP analysis indicates that digital supply chain visibility is the most influential resilience driver within the network structure. This result highlights the central role of real-time monitoring systems, data-sharing platforms, and integrated control mechanisms in enhancing responsiveness under systemic disruptions (Agnusdei et al., 2022b).*

Strategic logistics outsourcing governance ranks second, suggesting that the management structure of outsourced logistics relationships significantly affects resilience outcomes. Previous research has shown that outsourcing may either amplify vulnerability or strengthen adaptive capacity depending on the quality of coordination and information integration (König and Spinler, 2016; Liu and Lee, 2018).

Network diversification and nearshoring emerge as the third most relevant driver, confirming the importance of geographical dispersion and reduced concentration risk in shock-prone environments.

Dynamic business continuity planning and human capital coordination also receive relatively high global weights, indicating that organizational and managerial capabilities complement technological and structural dimensions in shaping overall resilience (Svensson, 2004).

Regarding the ranking of strategic alternatives, the TOPSIS results show that agility achieves the highest closeness coefficient. This suggests that strategies emphasizing rapid sensing, adaptive reconfiguration, and flexible response mechanisms exhibit the strongest alignment with the prioritized resilience drivers (Fayezi et al., 2017; Mishra et al., 2022).

Risk-oriented governance ranks second, reflecting the continued relevance of structured monitoring and mitigation systems. In contrast, robustness and static redundancy-based approaches obtain lower scores, indicating comparatively weaker alignment within the evaluated multi-criteria framework (Durach et al., 2015).

Research limitations. *This study is subject to limitations. First, the analysis relies on expert judgments rather than large-scale empirical or archival data. Although consistency ratios were verified within the ANP procedure and structured evaluation was applied in TOPSIS, subjective bias cannot be fully excluded.*

Secondly, the empirical focus on agrifood supply chains may limit the generalizability of the findings to other industrial sectors characterized by different structural configurations or demand dynamics.

Finally, the model adopts a cross-sectional perspective. Resilience, however, is inherently dynamic. Future research could incorporate longitudinal datasets, simulation-based stress testing, or system-dynamics modeling to evaluate how resilience drivers evolve under prolonged or sequential shocks.

Managerial implications. *The findings indicate that designing shock-ready agrifood supply chains requires a strategic shift from cost-centric optimization toward resilience-oriented network configuration.*

In particular, managers should prioritize investments in digital visibility infrastructures that enable real-time tracking of inventory levels, transport flows, and supplier performance. Enhanced information transparency reduces asymmetry and improves response coordination (Johnson et al., 2013). Logistics outsourcing arrangements should move beyond transactional cost efficiency and incorporate resilience-oriented performance indicators, collaborative governance mechanisms, and joint contingency planning structures (Liu and Lee, 2018). Moreover, geographical diversification strategies, including selective nearshoring, can mitigate exposure to geopolitical fragmentation and climate-related concentration risks. Finally, business continuity planning should evolve from static emergency protocols to dynamic, scenario-based frameworks supported by predictive analytics and continuous monitoring systems (Svensson, 2004).

Originality of the paper. *This study contributes to the supply chain management literature in three main respects. In particular, from the prior side, it updates the conceptualization of resilience drivers in light of recent systemic shocks, explicitly integrating digitalization, cybersecurity, energy dependency, and geopolitical fragmentation within a unified analytical framework.*

At the second stage, it applies a hybrid ANP–TOPSIS methodology that captures interdependencies among resilience drivers while simultaneously ranking alternative strategic orientations in a structured decision-support environment.

Finally, it reconceptualizes resilience not as a reactive buffer-based capability but as a strategic outcome of network configuration choices, offering a formalized decision framework for designing shock-ready agrifood supply chains within the Logistics and Operations domain.

Human Judgment relevance for forecasting in time of AI: a cluster analysis of scientific papers

FILIPPO DI LORENZO[1], VIVIANA D'ANGELO[2], VALERIA BELVEDERE[3]

Abstract. *This study reports the outcomes of a literature review aimed at depicting the state of the art of studies that adopt the human judgment perspective in contexts where AI-based solutions are implemented. Our analysis highlights three main clusters of papers. One adopts an industrial perspective to explore the role of quantitative forecasting methods and the way in which domain experts can interact with AI-based forecasting system. The second cluster is mostly based on studies that cope with retail environments and the features of markets, events and products. The third cluster is focused on quantitative forecasting techniques and specifically on AI and machine learning solutions, with the aim of unveiling the features of such methods that can drive their effectiveness, especially in comparison with domain experts.*
Keywords: *demand forecasting; artificial intelligence; judgmental forecasting; literature review; bibliometrix.*

Framing of the research. *Demand forecasting represents a critical process in supply chain management, involving the prediction of future customer demand to inform operational and strategic decisions. According to Hyndman e Athanasopoulos (2018), demand forecasting is defined as the estimation of future sales or consumption levels based on historical patterns, market trends, and external factors, serving as a foundational element for inventory control, production planning, and resource allocation. This definition aligns with the broader operations research perspective, where forecasting is not merely a statistical exercise but a mechanism to mitigate the uncertainty embedded in volatile markets (Hofmann and Rutschmann, 2018). Grando et al. (2021) emphasizes that effective demand forecasting integrates both internal data, such as past sales records, and external information, like economic indicators, to produce actionable insights that improve supply chain efficiency and effectiveness. Similarly, Lee et al. (1997) conceptualize demand forecasting as a challenging task that requires a synthesis of numerous and diverse data sources to improve accuracy, particularly in complex supply chain environments where demand fluctuations can disrupt logistics. These definitions emphasize the complex nature of demand forecasting, positioning it as an indispensable tool for balancing supply and demand while minimizing costs and risks (Feizabadi, 2022).*

The literature delineates a comprehensive spectrum of methods for demand forecasting, broadly categorized into quantitative, qualitative and mixed approaches, each suited to different contexts based on data availability and uncertainty. Quantitative methods dominate when historical data is abundant, relying on statistical and algorithmic techniques to extract patterns. For instance, statistical approaches such as time-series models, including exponential smoothing and ARIMA, are highlighted for their ability to decompose trends, seasonality and cycles in demand data (Box et al., 2015). Babai et al. (2022) provide an in-depth review of aggregation and hierarchical forecasting techniques within this category, noting that these methods aggregate data at various levels (e.g., individual product, product family, geographic region) to reconcile forecasts and reduce errors in hierarchical supply chain structures. Early studies demonstrated the applicability of machine learning (ML) as a powerful subset of quantitative methods, leveraging algorithms like neural networks and random forests to handle non-linear relationships and large datasets, showing competitive performance compared to traditional models. Feizabadi (2022) further explores how ML-based demand forecasting enhances supply chain performance by improving prediction accuracy and responsiveness to dynamic market conditions.

Qualitative methods, in contrast, are employed when historical data is scarce or unreliable, drawing on expert opinions, market research, and Delphi techniques to incorporate subjective insights. Goodwin and Fildes (2022) describe qualitative forecasting as essential in judgmental scenarios, where domain experts assess unstructured information to anticipate demand shifts driven by qualitative factors like consumer preferences or geopolitical events. Lawrance et al. (2006) go even further by advocating for structured qualitative approaches, such as the Delphi method, to aggregate expert judgments and mitigate biases in forecasting processes. These methods are particularly valuable in innovative or nascent markets where quantitative data is limited (Wright and Goodwin, 2009).

Mixed methods combine the rigor of quantitative models with the intuition of qualitative inputs, offering a hybrid framework. Grando et al. (2021) outlines how mixed approaches integrate statistical baselines with managerial adjustments to address gaps in purely data-driven predictions. Hofmann and Rutschmann (2018) extend this by proposing that mixed methods can incorporate big data analytics (BDA) alongside human insights, creating a synergistic process that refines forecasts through experts' validation.

The choice among these methods depends on factors like data quality, forecast horizon and organizational resources, with quantitative methods excelling in stable environments, qualitative in uncertain ones, and mixed providing flexibility

[3] Università Cattolica del Sacro Cuore, valeria.belvedere@unicatt.it

across scenarios (Hyndman and Athanasopoulos, 2018; Petropoulos et al., 2022).

Judgmental forecasting, involving human adjustments to quantitative forecasts, plays a central role in enhancing accuracy, particularly in environments undergoing structural changes or presenting incomplete data. Goodwin and Fildes (2022) define judgmental forecasting as the application of human expertise to modify or generate predictions, emphasizing its benefits in capturing nuances that statistical models cannot capture, such as sudden market disruptions. Key methods include dampening adjustments, where forecasters reduce the impact of recent anomalies to prevent overreactions and analogical forecasting, which draws parallels from similar past events (Armstrong, 2006). Evidence from controlled experiments demonstrate that well-calibrated judgmental adjustments can substantially reduce forecast errors compared to unadjusted statistical models, especially in intermittent demand scenarios (Fildes et al., 2009), (Syntetos et al., 2010). Armstrong (2006) further its attention on the possible drawbacks of judgmental methods, advocating for rule-based adjustments to minimize common biases such as overconfidence or anchoring. Babai et al. (2022) further evidence the benefits in hierarchical contexts, where judgmental adjustments at aggregate levels spread to disaggregated forecasts, improving overall coherence and accuracy. However, challenges persist; Goodwin and Fildes (2022) warn of shortcomings like optimism bias, recommending training and software tools to standardize adjustments. Schoemaker (1995) highlights practical methods, such as scenario planning in judgmental forecasting, which allows forecasters to simulate demand under various conditions, thereby enhancing resilience in supply chains. Collectively, the literature demonstrates that judgmental forecasting not only increase quantitative outputs but also fosters organizational learning, with empirical studies showing sustained performance gains when integrated thoughtfully (Fildes and Goodwin, 2007

The advent of AI, machine learning, and big data analytics has revolutionized demand forecasting by enabling the processing of vast, unstructured datasets to uncover hidden patterns and improve predictive precision (Choi et al., 2018). Feizabadi (2022) explains how ML algorithms, including deep learning models, outperform traditional statistical methods in supply chain by adapting to real-time data streams, resulting in enhanced inventory turnover and reduced stockouts. Hofmann and Rutschmann (2018) offer a conceptual analysis of BDA's integration in the demand forecasting process, defining it as the application of advanced analytics to high-volume data from sources like IoT sensors, social media, and transaction logs. This framework illustrates how BDA enhances forecasting by fusing internal supply chain data with external signals, to create more granular predictions. Integration of AI/ML with existing processes requires notable technological investments, as noted by Hofmann and Rutschmann (2018), who emphasize that BDA initiatives must align with operational levels: tactical for short-term planning and strategic for long-term trends. They also suggest that AI-driven methods can automate bias corrections traditionally handled judgmentally, though human oversight remains crucial for interpretability. Babai et al. (2022) discuss hierarchical AI applications, where ML hierarchies reconcile top-down and bottom-up forecasts, minimizing discrepancies in multi-level supply chains. Grando et al. (2021) positions AI as a transformative force that scales forecasting capabilities, yet underscores the need for hybrid systems to incorporate domain knowledge. Overall, these advances promise greater efficiency, but their success hinges on data quality and infrastructural readiness (Hofmann and Rutschmann, 2018).

Purpose of the paper. *As AI proliferates across forecasting domains, the relevance of human judgment in forecasting has come under scrutiny. The tension between automation and human intuition underscores a research gap: how scientific literature clusters around themes of judgment's role in AI-augmented demand forecasting. As aforementioned, traditional demand forecasting encompasses quantitative methods (e.g., ARIMA, exponential smoothing), qualitative approaches (e.g., Delphi, expert surveys), and mixed techniques that integrate both. Recent advances in AI, ML and BDA have enhanced predictive power but often overlook human judgmental adjustments, which address biases, contextual events, and overconfidence in volatile markets.*

This study wants to address this condition by conducting a bibliometric literature review to map the evolution of research on the integration of these instruments (i.e., quantitative, qualitative, mixed methods, judgmental adjustments, AI/ML/BDA) in demand forecasting. Employing scientometric tools like Multiple Correspondance Analysis (MCA) and Cluster Analysis, we aim at identifying thematic clusters, tracing temporal shifts in literature and eventually reveal gaps to be addressed by future literature.

Methodology. *We retrieved the articles used in this study from the ISI Web of Science database, a reliable source for conducting literature reviews (Singh et al., 2021). The keyword combinations used to retrieve the articles were identified by surveying recent reviews on judgmental forecasting and artificial intelligence. The resulting search string comprised the following terms: artificial intelligence, AI, large language model, LLM, machine learn*, human-machine*, demand*, sale*, sales and operations plan, S&OP, judgment*, judgement*. To make sure to include only articles that were published in the best peer-reviewed journals with an impact factor, we selected the Social Sciences Citation Index (SSCI), Science Citation Index (SCI), and Emerging Sources Citation Index (ESCI) collections in Web of Science. This approach yielded 349 documents.*

Then we refined our search by filtering the documents by time period, categories, sources, and language. First, we included only documents published until 2025. Second, we filtered out the results to exclude articles published in journals not pertaining to the fields of business, management, and operations management. Third, we included only peer-reviewed journal articles (excluding books, book chapters, and conference proceedings) and we excluded literature reviews, in line

with previous studies (Marzi et al., 2025). Fourth, we filtered the documents by language (English). This process of refinement led us to exclude 30 documents.

The final search string can be summarized as follows: TS=(("artificial intelligence" OR AI OR "large language model" OR LLM* OR "machine learn*" OR "human-machine*") AND (demand* OR sale* OR "sales and operations plan*" OR S&OP) AND (judgment* OR judgement*)).*

The authors then examined each title and abstract to ensure that each article was pertinent to the topic of the use of AI for judgmental forecasting. Indeed, the keywords utilized to retrieve the documents from ISI Web of Science allowed us to broaden the spectrum of papers included in the search so as to be sure that every possible relevant article for our study was included. However, this approach also led us to a considerable number of papers which were actually unrelated to our topic. Thus we manually screened the dataset proceeding as follows. First, we examined article titles to identify those clearly aligned with the focus of our study. For the remaining papers, we proceeded by reviewing the abstracts. Those articles which presented a clear connection to our topic, were included in the final dataset while the rest were discarded. Following this procedure, we excluded a total of 172 articles, resulting in a final dataset consisting of 147 articles.

To identify the thematic areas of the articles, we performed a Multiple Correspondence Analysis (MCA) based on keywords plus co-occurrence, an approach that enables the reduction of the dimensionality of a large dataset and allows its visualization in a two-dimensional space. The reason MCA was performed using keywords plus is due to the capacity of keywords plus to represent the themes covered by the articles more effectively than the authors' keywords. They are generated by the Web of Science and are words or phrases that frequently appear in the titles of an article's references.

Compared with authors' keywords, keywords plus provide a better representation of the themes covered by the articles, as they are automatically generated to enhance the indexing and retrieval of articles. Factor analysis is a valid approach to cluster large datasets, as it reduces the dimensionality of the data and represents it in a low-dimensional space. The factorial analysis was performed on keywords plus co-occurrence. Given the size of our sample, we set the algorithm to obtain three clusters. The analysis was performed using Bibliometrix, an R package developed for the analysis of scientific knowledge structures (Aria and Cuccurullo, 2017).

Results. *We first report some descriptive statistics to provide an overview of the research field. Figure 1 reports the distribution of articles over time and, surprisingly, it shows that the first article appeared in 1994, although a continuous and growing interest in the field has begun in 2013, with significant increase after 2024.*

Figure 1 – Distribution of publications by year

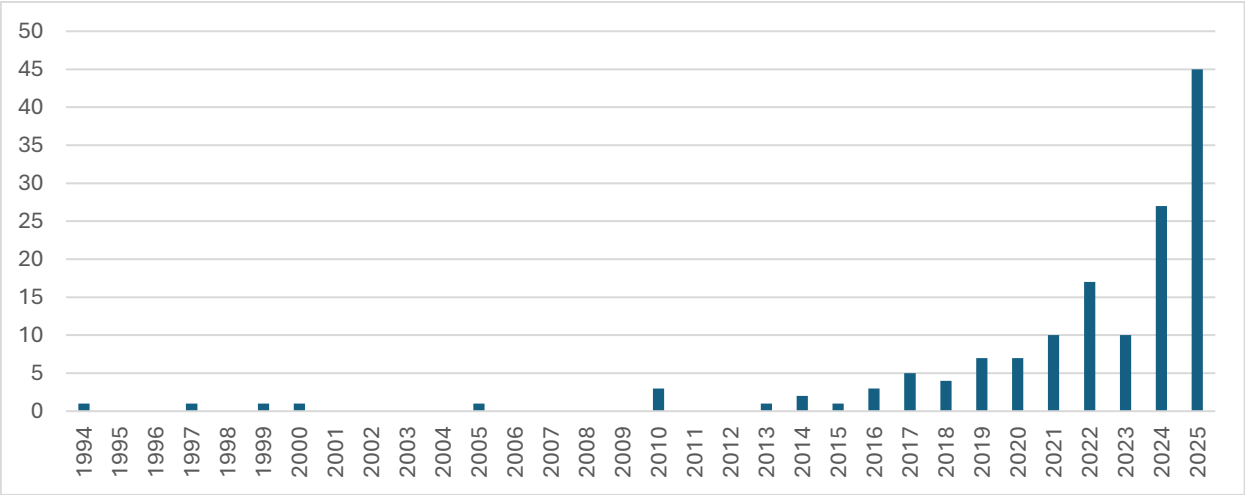

Table 1 shows the journals that have published more than one articles. The most attractive scientific journal is International Journal of Forecasting, which has published the highest number of articles (five articles), suggesting that forecasting and predictive analytics play a central role in the literature analyzed. This highlights the importance of predictive modeling approaches within the research domain. Both the European Journal of Operational Research and the International Journal of Production Economics contribute three articles each. These journals are strongly associated with operations research and production systems, indicating a significant methodological and applied orientation in the field. The inclusion of the Journal of Consumer Research (two articles) suggests that the topic is not limited to technical or engineering disciplines but also extends into behavioral and consumer research.

Table 1 - Distribution of articles by journal

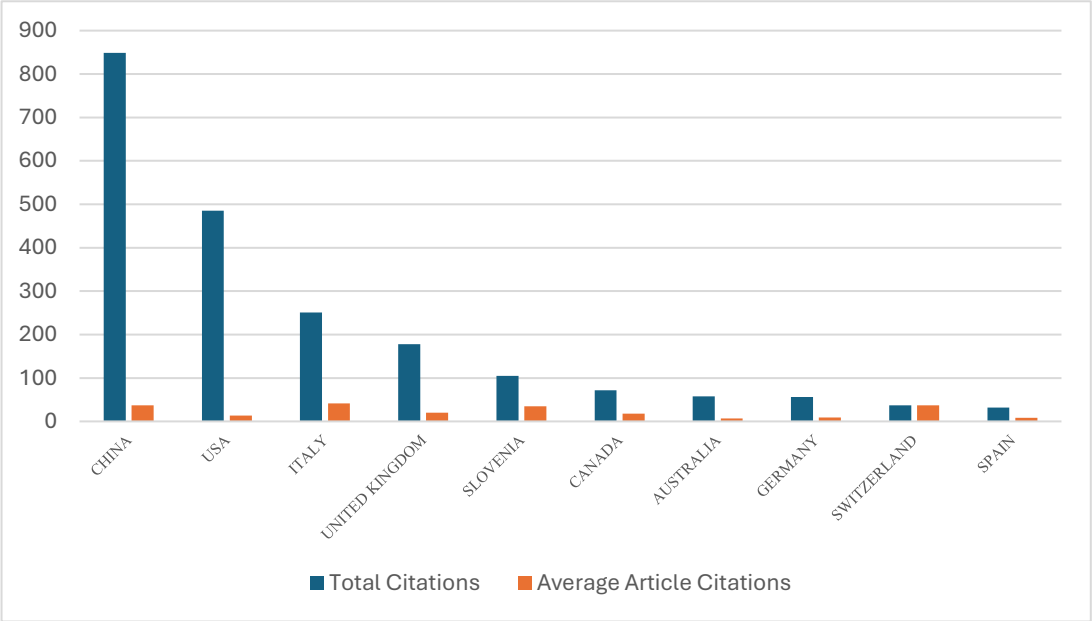
Figure 2 reports the distribution of citations by country. China shows the highest research impact in terms of total citations with more than 800 citations. The United States follows with over 400 citations, indicating another major contributor to the influence of the research field. Although China leads in total citations, Italy shows the highest average citations per article (41.8), suggesting that Italian publications tend to achieve particularly strong academic impact on a per-paper basis. Overall, the data reveals a geographically diverse distribution of research influence. While China and the United States dominate in total citation volume, several European countries such as Italy, Switzerland, and Slovenia achieve higher citation impact per article, highlighting differences between productivity and average research influence.

Figure 2 – Distribution of citations by country



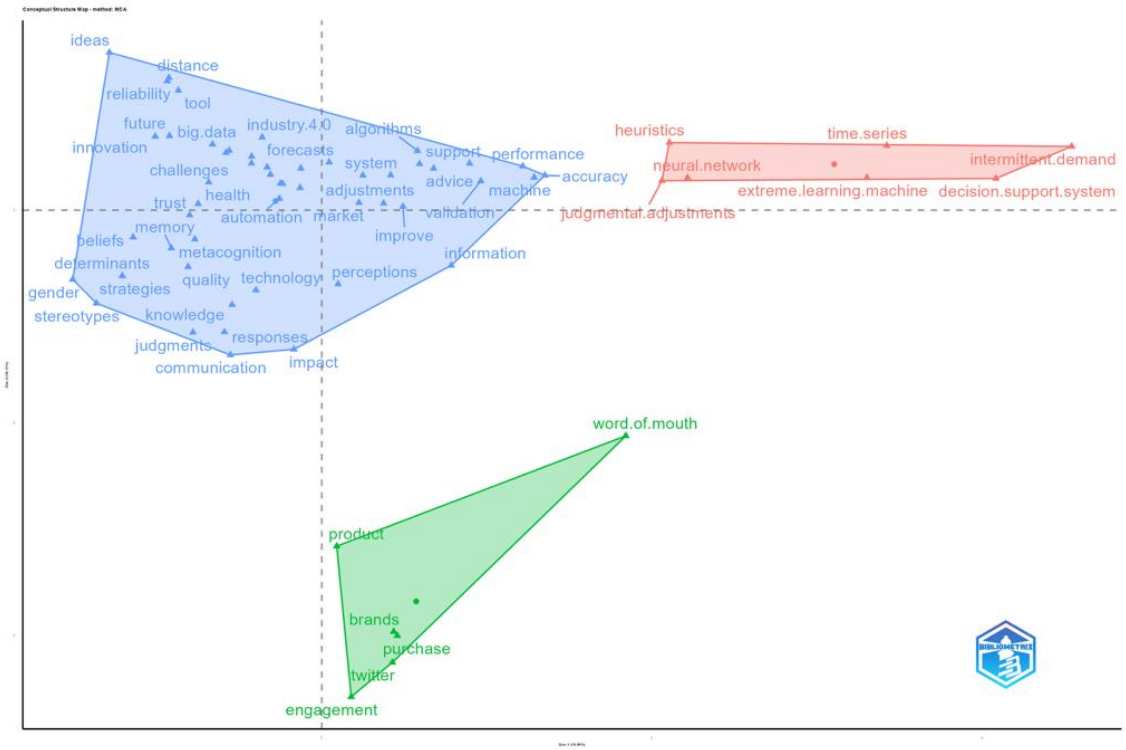


Figure 3 reports the results of the MCA. Keywords that are close to each other in the bi-dimensional plan, mean that they often appear together in same articles and, therefore, are similar. This means that similar words express the same concept. Their vicinity led to the definition of a specific number of clusters, which is automatically generated by the program, in our case Bibliometrix (Aria and Cuccurullo, 2017). The clusters of keywords plus represented in Figure 3 correspond to three distinct thematic areas in which Bibliometrix divided the literature on AI and judgmental forecasting.

The blue cluster (cluster 1) includes 75 articles that spread over a quite wide number of topics. One remarkable area refers to the traditional systems based on time series analysis, with a focus on data composition and on the management of seasonal or intermittent patterns. In this regard, scholars focus on the development of sound parameters enabling superior accuracy and on the comparison among different models, such as regressions or exponential smoothing (Boutselis and McNaught, 2019; Özden and Gürlek, 2020). An evolution of this stream refers to solutions able to cope with massive databases where traditional models fail to provide reliable forecasts. Literature in this regard mainly discusses model architectures computing capacity. Within this stream, Nikolopoulos (2010) compares the effectiveness of artificial neural networks, multiple linear regression and nearest neighbor in demand forecasting in case of special events. Nearest neighbor approaches are adopted also in studies concerning sporadic demand (Nikolopoulos et al., 2016), while bayesian networks are suggested to predict the demand of spare parts for machineries (Boutselis and McNaught, 2019).

Figure 3 – Clusterization of articles through MCA

Another remarkable feature of this cluster relies on its focus on demand forecasting mostly from B2B and industrial perspectives. Lauer et al. (2019) discuss industrial demand planning, providing insights on the factors that influence the human acceptance of algorithms. The case of forecasting in the car manufacturing industry is addressed by Salais-Fierro et al. (2020), while Boutselis and McNaught (2019) delve into the problem of forecasting of spare parts for machineries. Van Belle et al. (2021) study the problem of demand forecasting for manufacturers belonging to a multi-echelon supply chain.

This cluster also addresses the problem of human-machine interaction. Brau et al. (2023) present an experimental study dealing with such an interaction in forecasting and demonstrate that its effectiveness depends on the integration method. Empirical evidence shows that such an integration increases in the upstream sections of the supply chain, while at the retail level quantitative methodologies are more popular (Brau et al., 2024). Several other studies provide similar insights (Zajec et al., 2021; Abolghasemi et al., 2025; Cassenti and Hawkins, 2024); Nair and Huchzermeier, 2024).

The green cluster (cluster 2), including 21 papers, is mostly based on studies that cope with retail environments and the features of markets, events and products, which can affect the effectiveness of statistical methods and of judgmental ones. Moss and Edmonds (1997) discuss the relevance of the nature of the market, showing that quantitative context-dependent models can outperform traditional statistical ones, even though they require less data to be run. Hewage et al. (2025) delve into the specificities of developing countries, where the unavailability of extensive data and poor data quality, coupled with the need to predict the demand across multiple geographical and products hierarchies, can thoroughly hinder forecast accuracy. In these environments, hybrid models, based jointly on machine learning approach and on human expertise, seem to be more effective.

Another aspect that has gained remarkable attention in this cluster refers to the nature of the external events that can influence the demand from the market. Abolghasemi et al. (2020) distinguish between systematic (e.g., promotions) and non-systematic events (e.g., sudden climate change), maintaining that statistical models should incorporate the formers while the latter should be addressed by domain experts. This study further develops an earlier intuition, concerning the possibility to embed systematic events in prediction models that leverage artificial neural networks (ANNs), multiple linear regression and nearest neighbor approaches (Nikolopoulos, 2010).

The nature of the product has a great relevance to demand forecasting: industries affected by high product innovation rates cope with a considerable level of complexity of the forecasting task (Fildes et al., 2022). In this regard, Willcox et al. (2019) explore the topic of sales forecasts for new products, with a focus on the fashion industry, where the phenomena of product variety and variability pose serious challenges to demand planners. Their empirical evidence shows that sales forecasts developed by AI-based methods largely outperform the ones of human groups composed of fashion-conscious millennial women, even though the latter technique is commonly considered quite appropriate for these kinds of environments. Also Nair and Huchzermeier (2024) dive into the problem of predictions for fashion products and show that machine learning systems enjoy a high accuracy compared to domain experts; however, the best overall performance is achieved by a mixed human-machine approach. Focusing on the relevance of specific product features as driver of

forecasting accuracy, Khosrowabadi et al. (2022) have conducted a study on data provided by a European retailer concerning 30 million forecasts at the SKU-store-day level, showing that adjustments made by planners on an AI-based forecasting model are influenced by some product characteristics, namely price, freshness, and discounts, leading sometimes to a worse level of accuracy, especially when large positive adjustments are made.

The red cluster (cluster 3), including 16 papers, is more focused on quantitative forecasting techniques and specifically on AI and machine learning solutions, with the aim of unveiling the features of such methods that can drive their effectiveness, especially in comparison with domain experts. In this regard, Abolghasemi et al. (2025) have conducted an experiment with 123 human forecasters and five LLMs—namely, ChatGPT-4, ChatGPT3.5, Bard, Bing, and Llama2, to compare their accuracy in sales forecasting. The outcome of the study does not lead to a clear superiority of one system over the other. Feuerriegel and Gordon (2019) use machine learning on a large database of financial news to extrapolate information about the macroeconomic climate and predict the dynamics of macroeconomic indicators, showing a remarkable reduction of the forecast error compared to alternative forecasting approaches. An interesting perspective in this cluster concerns the features that an AI-based forecasting system must have to be considered trustworthy by the decision makers. In this regard Marusich et al. (2025) review such features, namely transparency, explainability and uncertainty visualization, and call for research to improve confidence measures in AI systems. Following this approach, Khosrowabadi et al. (2025) investigate about the role of supervisors who must choose between the AI-based forecast and the one adjusted by the planner. They outline the effect of providing information such as improvement probabilities of adjustments, direction and magnitude of the adjustment on the final choice of the supervisor. Hélie and Pizlo (2022) introduce a psychological perspective in the study of AI-based approaches, claiming that the analysis of the way in which humans develop heuristics could help in developing more parsimonious AI algorithms, characterized by lower computational complexity and shorter computation time, which could enable real-time feedback in case of complex problems.

Research limitations. *The literature review that we discuss in this study offers various perspectives from which the integration between human judgment and machine-based forecasts can be observed. This study can be improved through a higher focus on more specific perspectives, which could refer for instance to the level of the supply chain (e.g., manufacturer vs. retailer) where the forecasting process is carried out. Another interesting perspective refers to the nature of the papers under scrutiny, which could be divided into case-based, purely quantitative and based on experiments.*

Managerial implications. *This paper can help managers in getting an overview of the main techniques that can be used in demand forecasting, with specific attention to the factors that can drive the effective integration of experts' knowledge and AI-based systems. Based on the common traits highlighted by the clustering process performed, practitioners could adopt a contingent approach when deciding on the correct method. Aspects such as the occurrence of systematic or non-systematic events in the past, the availability of high quality data, the sporadic or continuous nature of the demand, the novelty of the product whose demand needs to be forecasted, should all be taken into consideration by management when choosing the right approach. All in all, there is no universally right or wrong approach; the correct approach depends on the specific situation.*

Originality of the paper. *This paper represents an attempt to describe the state of the art on the topic of integration between human judgment and AI in the sales forecasting process. The outcomes of this analysis can help in identifying future research directions in this field.*

Innovative packaging solutions for sustainability across the supply chain: key themes and trade-offs in global firm experience. A text mining analysis.

ALESSANDRA DOMINIJANNI[1], FRANCESCA CELIO[1], ALESSANDRA COZZOLINO[1], FRANCESCO RICOTTA[1]

Abstract. *Sustainable packaging has become a strategic priority for firms facing increasing regulatory pressure and growing consumer demand for environmentally responsible solutions. However, existing research has provided limited large-scale empirical evidence on how firms frame packaging innovation for sustainability and how sustainability is embedded within corporate innovation narratives. This study addresses this gap by analysing a global corpus of packaging innovation projects submitted to the WorldStar Packaging Awards between 2023 and 2025. Using text-mining techniques combining Structural Topic Modeling and dictionary-based analysis, the study identifies the dominant thematic domains of packaging innovation and examines how sustainability is embedded across different strategic orientations. The results show that sustainability is more strongly embedded in logistics-oriented packaging innovations, while marketing-oriented projects place comparatively less emphasis on sustainability.*
Keywords: *packaging innovation; sustainability; supply chain; logistics; marketing; text-mining*

Framing of the research. *Environmental packaging sustainability has emerged as a strategic imperative, driven by regulatory frameworks such as the EU Packaging and Packaging Waste Regulation (PPWR, effective February 2025)[2] and growing consumer environmental awareness. The green packaging market demonstrates this momentum, projected to expand from USD 362.01 billion (2025) to USD 732.33 billion (2034), with Europe maintaining 32.08% market share[3].*

Despite this trajectory, firms struggle to manage packaging innovation toward sustainability due to inherent trade-offs between incompatible requirements—performance versus cost, economic versus environmental outcomes, operational efficiency versus market communication (Pålsson and Hellström, 2023). These tensions become particularly pronounced when considering packaging's fundamental strategic duality: it must simultaneously fulfil logistics functions (protection, transport efficiency, supply chain optimization) addressing primarily B2B stakeholders, and marketing functions (brand differentiation, consumer appeal, purchase influence) targeting end-consumers who process packaging information rapidly and heuristically at point-of-sale.

This duality generates what we conceptualize as a "Visibility-Integration Paradox" in sustainable packaging innovation. The trade-off emerges because sustainability appears to be more substantively integrated in logistics-oriented innovations—those less visible to final consumers—than in marketing-oriented innovations designed for maximum consumer visibility. This counterintuitive pattern reflects two competing integration mechanisms operating across different strategic orientations.

In logistics-oriented innovations, sustainability objectives exhibit structural alignment with operational performance goals. Material reduction simultaneously achieves environmental benefits (lower resource consumption) and economic advantages (reduced costs, improved transport efficiency). Mono-material designs enhance both recyclability and supply chain standardization. This alignment transforms sustainability from an additional constraint into a core performance dimension, rendering environmental vocabulary pervasive within innovation narratives as it describes functionally integrated improvements rather than separate attributes (Hellström & Nilsson, 2011; Pålsson, 2018).

Conversely, in marketing-oriented innovations, sustainability must compete with other attributes within severely constrained cognitive space. Consumer research demonstrates that shoppers dedicate merely 3-7 seconds to packaging evaluation, during which visual elements dominate textual environmental information (Rettie & Brewer, 2000). Sustainability communication competes with brand identity, aesthetic differentiation, premium positioning, and convenience signals for limited consumer attention.

From an institutional perspective (DiMaggio & Powell, 1983), logistics innovations face coercive pressures—regulatory compliance, B2B specifications, carbon targets—rendering sustainability a condition for operational legitimacy. Marketing innovations face normative pressures from consumers, weakened by the documented attitude-behaviour gap where environmental preferences inconsistently translate into purchase behaviour when conflicting with price, convenience, or aesthetics (Carrington et al., 2010). Signalling theory (Connelly et al., 2011) further suggests that logistics contexts generate

[1] Sapienza University of Rome, Department of Management
[2] *https://environment.ec.europa.eu/strategy/circular-economy_en*
[3] *https://www.fortunebusinessinsights.com/green-packaging-market-105113*

credible sustainability signals verified through operational metrics, while marketing contexts lack immediate verification mechanisms, potentially enabling superficial environmental communication.

Building on this theoretical understanding, we examine whether logistics-oriented packaging innovations exhibit higher sustainability intensity than marketing-oriented innovations, reflecting the structural integration versus communicative competition mechanisms theorized

Purpose of the paper. *Packaging (primary, secondary and tertiary) affects the climate both directly—e.g., packaging material—and indirectly, e.g., via the amount of product waste and transport efficiency; minor changes in the design and material selection of consumer and transport packaging have major impacts on sustainable development and climate change, both positive and negative (Pålsson and Hellström, 2023). Despite this, businesses in all industries struggle to employ packaging improvement initiatives toward sustainability because it is difficult to manage the packaging innovation process and its trade-off. Trade-offs that are present between various incompatible requirements on packaging (Pålsson and Hellström, 2023; Pålsson, 2018): i.e. related to packaging performance, such as trade-offs between packaging cost and sales attributes, or between economic and environmental performance), as well as those related to the organisation of packaging development.*

Extant research has focused on packaging innovations and environmental sustainability (Danvers et al., 2026; Cozzolino and De Giovanni, 2023; de Koeijer et al., 2017; Niero and Hauschild, 2017). However, previous academic studies mainly focused on single cases (i.e. Dominic et al., 2015; Toniolo et al., 2013), and very few on multiple cases (i.e. Vernuccio et al., 2010) or larger data (i.e. Cozzolino and De Giovanni, 2023), but almost every of them consider only specific aspects of sustainable packaging for circularity at a time – specific practices (i.e. Zhang et al., 2015), specific performances (i.e. Ross and Evans, 2003), specific materials (i.e. Niero et al., 2016), specific sectors (i.e. Saraiva et al., 2016), specific countries (i.e. Cozzolino and De Giovanni, 2023), etcetera.

Prior research has so far not adequately explored at large empirical level and with a broad perspective how firms innovate effectively in packaging for the sustainability.

Considering the importance of the topic at the global level with its potential contribution to sustainable development targets for firms and considering the academic literature gap emerged from our analysis, this study investigates the following research questions (RQs).

***RQ1:** What thematic domains structure packaging innovation narratives globally, and how is sustainability embedded within these domains?*

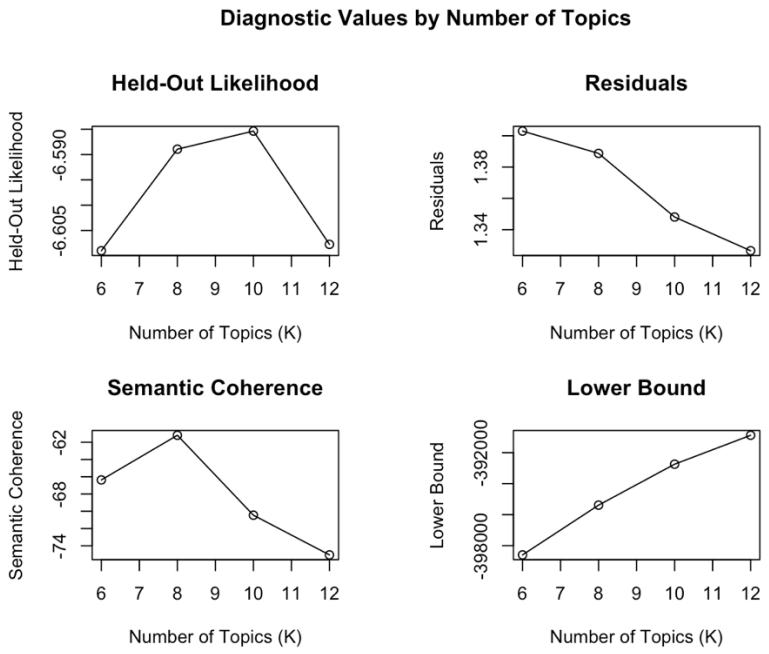
***RQ2:** Do logistics-oriented innovations exhibit higher sustainability intensity (green density) than marketing-oriented innovations, consistent with the visibility-integration paradox?*

The objectives of this paper are investigated in the present research considering hundreds of awarded packaging innovation projects developed by firms operating at global level and included in the winners' initiatives selected by the World Packaging Organization (WPO).

Methodology. *The empirical analysis relies on a corpus of packaging innovation projects submitted to the WPO - WorldStar Packaging Awards between 2023 and 2025, covering all the five continents inhabited. The textual data were collected from the official website and consist of the innovation descriptions provided directly by the firms as part of their award applications. Because these texts are authored directly by the companies and accepted by the WPO website, they represent corporate narratives through which firms frame and communicate the innovative characteristics of their packaging solutions within the international competitive recognition context.*

In this study, text mining techniques were implemented in the R programming environment – Rstudio (Kwartler, 2017) to preprocess and analyse the textual data. Text mining techniques are widely used to extract knowledge from unstructured textual data (Talib et al., 2016). In line with this approach, the dataset used in this study was constructed by extracting textual information from the website. Similar methodologies have been adopted in previous research analysing company information available on corporate websites and on environmental topics through text mining techniques (Spinder et al., 2023).

Data referring to the last three years were imported and merged after harmonizing variable formats across years. The resulting dataset initially contained 690 project descriptions (details on the dataset in Appendix A[4]). In addition to textual descriptions of packaging innovations, the dataset includes structured information on the geographical location of the companies submitting the projects, and the industry categories to which the innovations belong. Descriptive statistics on the distribution of projects across countries and packaging categories are reported in the Appendix B[5]. Text preprocessing followed standard natural language processing procedures. The corpus was converted to lowercase, while punctuation, numbers and English stop words were removed. Stemming was not applied in order to preserve lexical interpretability and maintain semantic transparency. A custom stop words list was introduced to remove domain-generic terms frequently



[4] The appendix can be requested to the authors.
[5] The appendix can be requested to the authors.

appearing in award descriptions but offering limited discriminative value, such as "packaging", "product", "innovation", "project" and "award". Low-frequency terms were filtered using a minimum occurrence threshold of 10. After preprocessing, the final corpus consisted of 685 innovative packaging projects, 1,378 unique terms and 45,846 tokens.

The empirical analysis is structured into two complementary studies.

Study 1 identifies the latent thematic architecture of packaging innovation narratives using Structural Topic Modeling (STM). Alternative topic solutions were estimated for different values of K (6, 8, 10 and 12) and evaluated using diagnostic statistics including held-out likelihood, residual dispersion, semantic coherence and lower bound. As reported in Figure 1, semantic coherence reaches its maximum at K=8, while higher values generate increasing thematic fragmentation (Mimno et al., 2011). The eight-topic specification was therefore selected as the optimal balance between statistical performance and interpretability.

Figure 1 – Topic model diagnostics for alternative numbers of topics

Source: our elaboration

These topic-level patterns provide an initial descriptive indication that sustainability discourse may be more structurally embedded in operational and logistics-related innovation domains. To examine whether this pattern also emerges when considering firms' strategic orientation, we next analyse sustainability intensity across logistics-oriented and marketing-oriented packaging innovations. Indeed, Study 2 examines how sustainability is embedded within these narratives across different strategic orientations. Sustainability intensity, operationalized as green density, is measured through a dictionary-based text analysis approach capturing the relative frequency of sustainability-related keywords within each project description, following established dictionary-based approaches to textual analysis (Loughran & McDonald, 2011). All supplementary material can be found in the Appendix C[6]. Specifically, for each project description i, green density is computed as:

$$GreenDensity_i = \frac{Green\ Hits_i}{Word\ Count_i}$$

Where:

- *$GreenHits_i$ denotes the number of matches to the predefined sustainability keyword dictionary in description i.*
- *$WordCount_i$ denotes the total number of words in the cleaned description*
- *$GreenDensity_i$ represents the relative frequency of sustainability-related terms in description i, obtained as the ratio between dictionary matches and total word count.*

[6] The appendix can be requested to the authors.

This proportional normalization ensures comparability across texts of varying length and captures the relative narrative emphasis placed on sustainability within each innovation description, as term frequencies are commonly normalized by document length in text analysis (Manning et al., 2008).

Strategic orientation is determined using a dictionary-based classification approach that compares marketing-related and logistics-related keyword densities within each description.

Projects are assigned to the orientation with the higher relative keyword density. Applying this classification procedure, 422 projects are classified as marketing-oriented, 193 as logistics-oriented, and 70 as balanced. Balanced cases, which represent approximately 10% of the corpus, occur when marketing-related and logistics-related keyword densities are equal. Because these projects do not display a clear strategic orientation, they are excluded from the regression analysis in order to avoid classification ambiguity. The final regression sample therefore consists of 615 observations. The distribution of projects across strategic orientations is reported in Table 1. Logistics orientation serves as the reference category in the regression models.

Table 1- Strategic orientation distribution

Orientation	***N***
Marketing - oriented	*422*
Logistics - oriented	*193*
Balanced	*70*

Source: our elaboration

To account for heterogeneity in packaging domains, the regression models include product-category fixed effects corresponding to the original WorldStar classification structure. Differences in sustainability intensity across orientations are estimated using the following ordinary least squares model:

$$GreenDensity = \beta_0 + \beta_1 Marketing_i + \gamma Category_i + \varepsilon_i$$

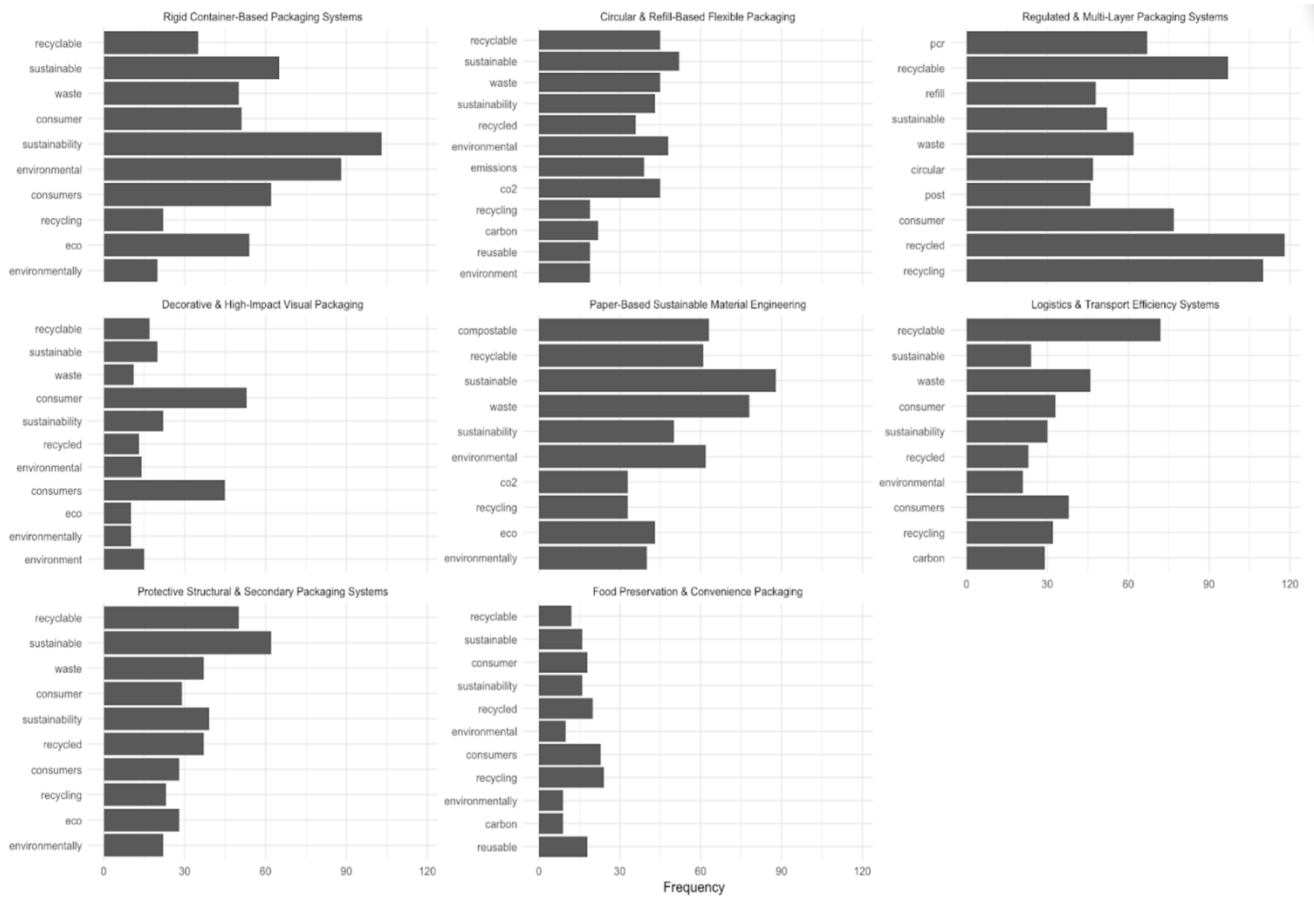
Where:

- $marketing_i$ *is a binary indicator equal to 1 if the project is classified as marketing-oriented and 0 if logistics-oriented,*
- $category_i$ *represents product-category fixed effects,*
- *and* ε_i *denotes the error term.*

Given the relatively small range and approximately continuous distribution of the dependent variable, ordinary least squares provide consistent and easily interpretable estimates for assessing differences in sustainability emphasis across strategic orientations.

Results. *The results are presented following the analytical sequence of the study, moving from the identification of the thematic architecture of packaging innovation narratives to the analysis of sustainability embeddedness across topics and strategic orientations.*

The STM analysis identifies eight interpretable macro-topics describing the thematic architecture of packaging innovation narratives submitted to the WorldStar Awards. The identified topics capture distinct technological and functional domains of packaging innovation, including rigid container-based packaging systems, circular and refill-based flexible packaging, regulated and multi-layer packaging systems, decorative and high-impact visual packaging, paper-based sustainable material engineering, logistics and transport efficiency systems, protective structural and secondary packaging systems, and food preservation and convenience packaging.



Topic prevalence analysis reveals a non-uniform thematic distribution across the corpus. Protective structural and secondary packaging systems represent the most prevalent domain (0.204), followed by decorative and high-impact visual packaging (0.171). Circular and refill-based flexible packaging accounts for 0.136 of the corpus, while paper-based sustainable material engineering represents 0.127. Regulated and multi-layer packaging systems and food preservation and convenience packaging each account for approximately 0.10 of the documents. Logistics and transport efficiency systems represent 0.092 of the corpus, while rigid container-based packaging systems appear as the least prevalent domain (0.069).

The identified thematic architecture provides initial empirical support for the visibility-integration paradox. Topics emphasizing logistics and operational functions—"logistics and transport efficiency systems," "protective structural and secondary packaging systems," and "paper-based sustainable material engineering"—collectively represent substantial portions of the corpus. These domains align with contexts where structural integration mechanisms predict higher sustainability embedding, contrasting with "decorative and high-impact visual packaging" where communicative competition mechanisms suggest sustainability faces trade-offs with aesthetic differentiation objectives.

Overall, the results indicate that packaging innovation narratives are primarily organized around functional and structural packaging configurations rather than abstract innovation paradigms.

To further investigate how sustainability is embedded within the thematic structure identified in Study 1, sustainability-related terms were mapped across the dominant topic of each document. Figure 2 illustrates the most frequent sustainability-related terms observed within each macro-topic.

Figure 2 – Distribution of sustainability-related vocabulary across STM topics

Source: our elaboration

Figure 2 reveals systematic variation in sustainability vocabulary distribution consistent with theoretical predictions. Paper-based sustainable material engineering and circular flexible packaging exhibit the highest density of sustainability-related terms, reflecting structural integration where material innovation inherently embeds environmental performance. Logistics and transport efficiency systems similarly demonstrate strong sustainability vocabulary presence, validating predictions that operational efficiency contexts facilitate sustainability integration. Critically, decorative and high-impact visual packaging exhibits markedly lower sustainability terminology, supporting the communicative competition mechanism where environmental attributes compete with aesthetic differentiation for limited discursive space.

The analysis reveals that sustainability discourse is unevenly distributed across technological domains. The strongest presence of sustainability-related vocabulary appears in the topics related to paper-based sustainable material engineering and circular flexible packaging, where terms such as recyclable, compostable, recycled, and environmental frequently occur. Sustainability language also emerges within logistics and transport efficiency systems, typically associated with carbon emissions reduction and material waste optimization. In contrast, sustainability-related terminology appears less frequently in visually oriented domains such as decorative and high-impact visual packaging, suggesting that environmental attributes in these cases may function more as complementary communicative elements rather than as core technological drivers.

The second part of the analysis examines differences in sustainability intensity across strategic orientations of packaging innovation. In particular, a lemma-based analysis of the keywords was conducted in order to reconstruct the thematic areas emerging from the analysed corpus. The associated terms were treated as weighted descriptors based on their frequency distribution and summarized through a word cloud representation (Figure 3).

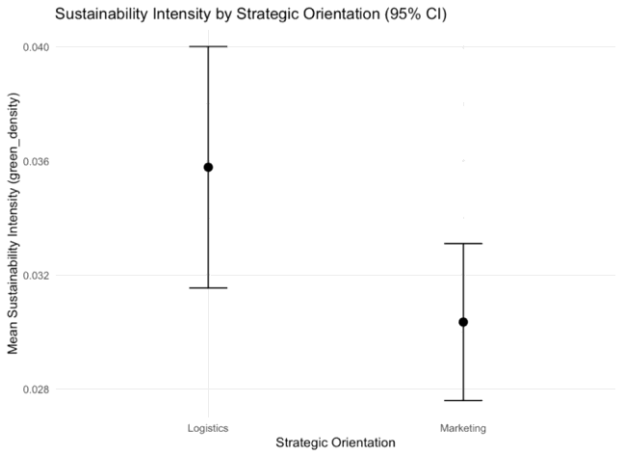


Figure 3 – Word cloud of keywords in packaging innovation narratives

Source: our elaboration

Sustainability intensity, measured as green density, ranges from 0 to 0.205 across the corpus, with an average value of 0.0321 (SD = 0.0293). Logistics-oriented innovations exhibit a higher mean sustainability density (0.0358, SD = 0.0303) compared to marketing-oriented projects (0.0304, SD = 0.0287). The regression results, illustrated in Figure 4, confirm that marketing-oriented innovations display significantly lower sustainability intensity than logistics-oriented ones when controlling for product category. The estimated coefficient indicates that marketing-oriented projects include approximately 0.83 percentage points fewer sustainability-related words relative to logistics-oriented innovations. Given the sample mean sustainability intensity, this difference corresponds to roughly a 26% reduction in sustainability emphasis. This difference indicates that sustainability language occupies a substantially smaller share of the narrative space in marketing-oriented innovations compared with logistics-oriented ones.

Figure 4 – Predicted sustainability intensity by strategic orientation (95% confidence intervals)

Source: our elaboration

The regression results provide strong empirical validation of the visibility-integration paradox. Marketing-oriented innovations exhibit significantly lower sustainability intensity, representing approximately 26% reduction in green density relative to logistics-oriented innovations when controlling for product category. This substantial effect confirms that sustainability is structurally integrated within logistics-oriented innovation narratives, where environmental vocabulary pervasively describes functionally integrated improvements, while marketing-oriented narratives exhibit lower sustainability intensity consistent with communicative competition constraints. The magnitude suggests fundamental rather than marginal variation in how firms frame environmental innovation across strategic orientations.

The empirical evidence therefore suggests that sustainability integration is not merely a communicative attribute but often emerges as a structural property of operational packaging innovation processes

The effect remains statistically significant in alternative model specifications without category controls. Figure 5 compares the estimated effect of marketing orientation across model specifications, showing that the negative association

persists even when category controls are excluded, indicating that the observed difference is not driven by sectoral composition.

Figure 5 – Effect of marketing orientation on sustainability intensity across model specifications

Source: our elaboration

Overall, these findings suggest that sustainability is not uniformly articulated across packaging innovation narratives. Instead, its discursive prominence varies systematically across strategic orientations, appearing more strongly embedded within logistics-oriented innovations than within marketing-oriented ones. This pattern is consistent with the visibility–integration paradox proposed in the theoretical framework.

Research limitations. *Although this study provides novel insights into packaging innovation and the role of sustainability within corporate innovation narratives, limitations should be acknowledged.*

First, the empirical analysis relies on textual descriptions of packaging innovation projects submitted directly by the companies to the WorldStar Packaging Awards. While these narratives represent valuable sources of information on how companies frame and communicate their innovation initiatives, they may reflect strategic communication choices rather than the full set of technical or environmental characteristics of the innovations themselves. Consequently, the analysis captures the discursive emphasis on sustainability, rather than directly measuring the actual environmental performance of the packaging solutions. Second, sustainability intensity and strategic orientation are operationalized through dictionary-based text analysis. Although this approach enables the systematic analysis of a large corpus of innovation narratives, dictionary methods may not fully capture contextual nuances in language use and may overlook implicit sustainability references that are not expressed through the selected keywords.

These limitations also suggest promising directions for future research, involving direct engagement with managers overseeing innovative packaging projects through interviews, focus groups, or more grounded analytical methods. Moreover, future studies could replicate the analysis using alternative innovation datasets, investigate sector-specific packaging innovations, or extend the concept of sustainability to include broader social and technological innovation dimensions within packaging systems.

Managerial implications. *The findings of this study offer several managerial implications for firms engaged in packaging innovation and sustainability initiatives.*

First, the results suggest that sustainability in packaging innovation is rarely framed as an isolated design objective, but rather emerges as an embedded component within broader technological and operational configurations. Managers involved in packaging development should therefore consider sustainability not only as a marketing attribute but as an integrated element of packaging systems, including material selection, logistics efficiency, and structural design.

Second, the evidence indicates that sustainability discourse is more strongly embedded in logistics-oriented innovation initiatives. Improvements in transport efficiency, packaging weight reduction, material optimization, and damage protection appear to generate innovation narratives where sustainability becomes structurally integrated. This suggests that supply chain and logistics managers can play a central role in advancing sustainable packaging strategies by aligning environmental objectives with operational performance improvements.

Third, the analysis highlights a potential tension between marketing-oriented packaging innovation and sustainability emphasis. While visually differentiated and brand-oriented packaging solutions may enhance consumer appeal and shelf

visibility, they appear to incorporate sustainability narratives less intensively. Managers should therefore carefully balance marketing objectives with environmental considerations, ensuring that packaging communication strategies remain aligned with substantive sustainability improvements.

Overall, the results indicate that effective sustainable packaging innovation requires cross-functional coordination between marketing, logistics, and product development functions. Firms that integrate environmental objectives into both operational design and market communication strategies are more likely to develop packaging solutions that simultaneously enhance sustainability performance and competitive positioning.

Originality of the paper. *The present study contributes to the literature on sustainable packaging innovation by providing a large-scale empirical analysis of corporate packaging innovation initiatives at the global level. While prior research has often relied on single case studies or focused on specific industries, materials, or practices, this research analyses hundreds of international awarded innovation projects. By examining firm-authored innovation narratives across a broad range of sectors and technological domains, the study offers a comprehensive perspective on how companies frame and communicate packaging innovation for sustainability.*

Methodologically, the paper utilises text mining techniques, combines structural topic modeling with dictionary-based text analysis, to investigate both the thematic architecture of packaging innovation narratives and the relative emphasis placed on sustainability within them. This approach allows the identification of latent innovation domains and the measurement of sustainability intensity within corporate innovation discourse.

Finally, the study provides novel insights into the relationship between strategic orientation and sustainability in packaging innovation. By distinguishing between logistics-oriented and marketing-oriented innovation narratives, the research highlights how sustainability is embedded differently across operational and market-facing innovation logics. In doing so, the paper advances understanding of the trade-offs and complementarities that characterize sustainable packaging innovation along the supply chain.

Logistics Service Providers' Specialized Capabilities for Fine Art: Evidence from a Case Study.

ALESSANDRA DOMINIJANNI[1], ALESSANDRA COZZOLINO[2]

Abstract. *The logistics activities regarding the movement of fine art have grown considerably in value, volume and complexity at global level, confirming its strategic and economic importance. This "movement" is not simply a physical transfer, but a set of essential activities for the protection, promotion, and international presence of a nation's cultural and artistic heritage. Fine art logistics is increasingly emerging as an enabling activity for the functioning of the entire cultural and artistic ecosystem, both nationally and internationally. In this setting, the role played by logistics service providers offering fine art services is crucial. However, academic contributions studying this field remain very few and fragmented. This study addresses this gap by analysing how logistics service providers develop their capabilities to offer fine art specialized services. To address this research question, we built on the dynamic capabilities' theory, distinguishing among sensing, seizing, and reconfiguring processes. This research design relies on the action research approach and the empirical investigation, due to the exploratory context of this original study, is focused on a case study analysis. The selected case is an historical Italian leading logistics service provider that offers specialized fine art logistics services. The findings suggest that dynamic capabilities in fine art logistics are deeply embedded in micro-level practices and are continuously enacted throughout project-based operations. As such, this study contributes to the dynamic capabilities literature by highlighting how these capabilities unfold in highly customized, non-standardized environments, where traditional assumptions of routinization and sequential processes may not fully apply.*
Keywords: *fine art logistics; logistics service providers - LSPs; dynamic capabilities theory; case study; action research*

Framing of the research. *The evolution of the concept of cultural heritage – marking the transition from the static protection of the art object "per se" to the valorization of the asset through the broad and effective enjoyment of its value – determines a progressive expansion in the need for mobility of the works themselves (Cozzolino et al., 2021; Barile & Cozzolino, 2022). This need for mobility, in turn, impacts the derived demand for fine art logistics, which provides the practical implementation of such movement (Canali &, Puglisi 2005). Consequently, in recent decades, the role of logistics within the cultural and artistic sector has undergone a significant transformation (Barile & Cozzolino, 2024). It contributes not only to the preservation – through the protection – of unique and delicate assets during transport, but also to the valorization of cultural and artistic heritage and its wider accessibility to the public (Florian, 2023; Barile & Cozzolino, 2022). In this context, "valorization" refers to the potential to transform all assets so designated into instruments for increasing the social and economic well-being of a country, taking into account the direct and indirect spillover effects generated (Cerquetti & Montella, 2024; Montella, 2012, 2016, 2020; Golinelli, 2012; Belmondo, 2019; Montella & Petraroia, 2016).*

The logistics supporting cultural and artistic heritage constitutes a highly specialized, complex, and delicate activity. The assets involved in such movements possess exceptional characteristics that necessitate bespoke solutions throughout every phase of the logistical process: from specialized packing and crating to transit, storage, on-site installation at the destination facility, and potential de-installation for return shipment in the case of temporary exhibitions. Furthermore, each stage of the logistical chain must adhere to rigorous quality standards and, critically, to specific national and international regulatory frameworks. In comparison with general commercial logistics and freight transport, fine art logistics requires a superior degree of organizational and technological specialization. Consequently, these operations should be entrusted to industry specialists capable of ensuring seamless handling, thereby preserving the absolute physical integrity of the object and guaranteeing its optimal accessibility and fruition. This requirement is essential whether logistical activities are managed internally by the institution (e.g., a museum) or outsourced to external logistics providers (LSPs) dedicated to these specialized services.

In recent years, both the demand for and the supply of outsourced logistical services have experienced rapid growth in terms of market value and volume. Globally, the fine art logistics segment is experiencing modest but steady growth. According to MarketResearch.com estimates, the Fine Arts Logistics market is valued at $3.6 billion in 2024 and could reach $4.3 billion by 2030, with a compound annual growth rate of 2.6%. Art transportation represents the largest component of the sector, estimated at $3.1 billion by 2030, while specialized packaging is experiencing more modest growth rates[3]. In Italy in particular, art logistics is defined as a "precious niche" within the broader logistics sector[4].

[4] https://www.nomisma.it/il-valore-dellindustry-dellarte-in-italia/ (accessed on December 10, 2025).

According to Nomisma's research[5] conducted for the Apollo Group in collaboration with Intesa San Paolo, the art logistics market is expected to be worth €70 million in 2023 – stable compared to 2019 – with €51 million generated for clients such as museums and foundations, and €19 million for clients such as modern and contemporary art galleries, auction houses, and, to a lesser extent, antique dealers, art dealers, and private individuals (within the broader logistics sector, which is worth approximately €80 billion). For Italian art logistics the key numbers are: 1,200,000 movements/year, €40 billion in insured value, 500 direct employees, and 4,000 domestic clients, including museums and foundations[6].

These data highlight the economic and cultural importance of the circulation of works of art. This circulation is not simply a physical transfer, but a set of essential activities for the protection, promotion, and international presence of a nation's cultural and artistic heritage. Logistics for cultural and artistic assets is increasingly emerging as an enabling activity for the functioning of the entire cultural and artistic ecosystem, both nationally and internationally.

Purpose of the paper.

Research question. Despite the growth in volume and value of logistics for cultural and artistic heritage offered by logistics service providers and its crucial role in the entire cultural and artistic sector, academic contributions studying this field remain few and fragmented.

In fact, in most cases where the management of museums or art collections or the economics of culture is discussed, logistics activities are not explicitly referred to. Fine art logistics is only mentioned in a few articles on art or cultural management, and in these contexts, it is only briefly mentioned: for example, in the recent volume dedicated to the economics of art by Negri-Clementi (2023 p. 139), there is a short paragraph on "Packaging, transport, delivery, installation, handling"; in this contribution, logistics activities are only "ancillary" to the other topics presented.

There are few contributions that dedicate attention to fine art logistics, even proposing in the title itself evidence of the importance of this activity, albeit with a predominantly technical and less managerial approach: Fratelli (2017), Powell (2016), Carboni (2018), Kolakowski (2017), and Cannon-Brookes (1986), to name a few. Other contributions are extremely specific on certain aspects, such as the volume "Art in Transit: Studies in the Transport of Paintings" commissioned by the Smithsonian Institution, which focuses on paintings, or the contribution by Loddo et al. (2022), which focuses on movement in warehouses in the Netherlands. Studies that present fine art logistics from the perspective of LSPs within cultural heritage management volumes or journals are rarer. An early contribution is that of Canali and Puglisi (2005). A more recent stream of contributions in this direction is developed by Cozzolino et al. (2021), Barile et al. (2022), and Barile and Cozzolino (2024; 2022). In particular, these latest works highlight the contribution made by logistics service providers in this sector, not only for the protection function, but also and above all for the valorization of cultural heritage through their movement thanks to specific capabilities. But, how LSPs compose and propose their own value proposition specifically for this specific sector valorizing their specialized capabilities is not clearly explained.

Therefore, given the importance of logistics in the protection and, above all, valorization of cultural and artistic heritage and its concrete contribution to the actors in the supply chain, and the limited theoretical exploration of the topic in the existing academic literature, this study aims at addressing the gap and it examines the following research question (RQ):

RQ: How do logistics service providers develop their capabilities to offer fine art specialized services?

To address this research question, we built on the dynamic capabilities' theory by Teece et al. (1997), which considers the importance of organizations' ability to adapt to changing needs and environments by integrating and reconfiguring resources (Teece, 2007). The dynamic capabilities' theory seems to be the appropriate theoretical lens for the investigation of our research aims on specialized capabilities for fine art logistics because it allows to take into account the different needs of customers, the evolutionary changes in the sector, the new technological and digital challenges and even environmental sustainability goals. In particular, in the logistics industry, the dynamic capabilities' theory is increasingly adopted to explain and predict how firms confront technological advancements and evolving customer demands (Prataviera et al., 2026; Dovbischuk, 2022; Sandberg, 2021). The literature lacks research on dynamic capabilities for fine art logistics specialization.

Dynamic capability perspective as theoretical lens. Originally conceptualized by Teece and Pisano (1994), dynamic capabilities theory provides a framework for understanding how organizations navigate and thrive within dynamic conditions. Dynamic capabilities – deeply rooted in managerial expertise and ingrained organizational processes – can enable an enterprise to upgrade its ordinary capabilities and direct these, and the capabilities of partners, toward high-payoff endeavours and this requires developing and coordinating – or "orchestrating" – the firm's (and partner firms') resources to align with a changing business landscape or, even, to shape changes in the marketplace, or the business environment more generally (Teece, 2018; Teece et al., 1997). To better analyse these mechanisms, Teece (2007) categorizes dynamic capabilities into three core functions: sensing, seizing, and reconfiguring. Sensing involves the proactive identification and evaluation of market shifts and opportunities; seizing focuses on capitalizing on identified

[6] https://www.nomisma.it/il-valore-dellindustry-dellarte-in-italia/ (accessed on December 10, 2025).

prospects or neutralizing potential risks; reconfiguring entails the ongoing synchronization of the organization's portfolio, so that firms can renew and ensure their resources are in line with the detected changes and sensed opportunities (Helfat et al., 2007).

Methodology.

Approach. *This research design relies on the action research (AR) approach (Näslund et al., 2010). This method fits best to respond to our research question, as it permits application in real settings to address real-world managerial and organizational challenges (Näslund, 2002). By addressing real-world organizations and managerial problems, AR increases the emphasis on relevance (Ellis & Kiely, 2000). Because of this qualitative methodology, both the researchers' team and organizational agents collaborate by sharing ideas and reflections. Moreover, due to the exploratory context of this original study, a case study is a useful instrument for the empirical part of the research, which facilitates an in-depth understanding of complex phenomena (Yin, 2003) and provides a better understanding of events with concrete context dependent knowledge (Ridder, 2017). The importance of this methodology in management and social science research has been widely recognized (Eisenhardt, 1989; Eisenhardt & Graebner, 2007). This recognition is also confirmed by logistics and supply chain management researchers as a method of approach in scientific investigations (Ellram, 1996; Aastrup & Halldorsson, 2008; Seuring, 2008).*

Data collection and analysis. *The selected case is an historical leading company in fine art logistics and belongs to the Italian logistics industry; it has been chosen because of its interest (Stake, 2005) and relevance for theoretical reasons (Eisenhardt & Graebner, 2007).*

We adopt a team-based approach, which is strongly encouraged to increase reliability, through investigator triangulation (Benbasat et al., 1987), with professionals as part of the case study. The top managers and professionals of the LSPs investigated actively participated during the discovery, descriptive, mapping and managing phases of the research. For some years, the research team collaboratively conducted multiple steps in the research process, in particular, refining a focus, conducting reconnaissance, reflecting on progress, planning for action, implementing and observing action, and reflecting and evaluating change (Townsend, 2013).

Data were collected through different initiatives that cover the entire research project along years (to present) – that is still in a work-in-progress phase – and rely on participants generating data through narratives, field notes, and for the next period also semi-structured interviews. This flexibility in data collection, typical of AR research, takes advantage of new emergent themes to improve resultant theory (Näslund, 2002; Eisenhardt & Graebner, 2007). The empirical investigation was based on meetings within the LSPs and their suppliers and customers; moreover, internal presentations and reports of the companies, external documents and participants' informal comments were tracked in the participants/observers notes and then examined to triangulate data and provide rigor to the study (Yin, 2003). A field analysis through active meeting participation was necessary because no other studies have specifically addressed the objective of this research project. We consider these documents and the meeting transcripts and participant notes to be sufficient because they are posed to those directly involved in the project.

Coding procedures followed the approach proposed by Gioia et al. (2013). We collected first-order concepts from the informants, aggregated them in more conceptual categories as second-order themes, and then grouped in the three dimensions of the Teece's (2007) categorization of the dynamic capabilities' theory: sensing, seizing, and reconfiguring.

In this short paper version, due to the limited space, we present only the results of arising from the public materials of the LSP investigated.

Results. *Fine art logistics is characterized by the peculiar focus on a special object to be moved, that is, works of art: delicate, unique, often of inestimable economic and cultural value, bound by ministerial practices of export/import authorization, accompanied by relevant loan/sale and insurance contracts. It is a "special" logistics, extremely critical and complex to carry out, which requires very high specialization, safety and competence to guarantee the necessary qualitative excellence of the service in coherence with the goods moved. Fine art logistics activities require extremely high competence, quality and specialization, with safety and integrity as priorities, both when they are managed internally and when they are entrusted to logistics service providers dedicated to such activities: transportation, packaging and storage management, as "core" activities, but with great relevance, also other activities of significant importance, such as insurance, customs procedures, loan agreement coordination, certifications, consultancy, armed bodyguards, appraisal management, emergency response services, etc. – which make up complete solutions for the needs of the actors involved in the cultural and artistic offering system.*

The basic services offered by logistics operators for art are, in general, those of (a) transport, which deals with moving the work from one point to another, (b) packaging, which takes care of the best way to store the work for handling and/or storage, and (c) storage, which involves the more or less permanent storage of the works in a warehouse/deposit location. Each of these basic services has specific characteristics peculiar for art and is composed of a series of other specialized activities - as well as resources and skills that are also specialized - that carry out the specific service and need specialized capabilities; furthermore, alongside these activities there are many others that make up the offer with complementary elements and/or accessories of primary importance. Just to name a few, below are some concrete examples that make up the basic services (Barile and Cozzolino, 2022).

With reference to transport activity (a), the informants consider the importance of insurance contracts and the related activity of assessing the value to be insured, or the completion of import/export customs procedures. The means of transport must, for example, be equipped with a system of adequate anti-shock shock absorbers, temperature-controlled interiors and with anti-theft alarm devices. The driving staff must have knowledge and experience in the movement of art; the permanent presence of a courier is often foreseen who follows the route of the works of art as they travel from the lending museum to the hosting one.

With reference to packaging activity (b), the informants consider the importance of the status-check of the conditions of the works of art and the design of custom-made crates (even the crate system). The packaging must, for example, be fireproof, permeable and shockproof. Packaging and logistics experts, but also chemists and physicists must study the environment appropriate to the risk profile and technical characteristics of the work for the entire duration of the journey.

In reference to the storage activity (c), the informants consider the importance of the cataloguing/compilation of the checklist of the goods and the sophisticated security systems. In the deposits there must be, for example, shelves, fixed boxes and air-conditioned vaults. Experts in the manipulation of the works take care of the storage and/or transit of the art works.

While the above activities describe the core and complementary services characterizing fine art logistics, they do not fully capture the underlying the complex of capabilities required to deliver such highly specialized operations. In particular, these services are enabled by a set of micro-level practices and decision-making processes through which logistics providers interpret complex contexts, mobilize resources, and adapt execution in real time.

To unpack these underlying mechanisms, we analyse the empirical evidence through the lens of the dynamic capabilities' framework, distinguishing among sensing, seizing, and reconfiguring processes. Following a Gioia-inspired approach, first-order evidence from the empirical material is interpreted into second-order themes (micro foundations), which are then aggregated into the three dimensions of dynamic capabilities.

In line with prior literature, our findings confirm that sensing involves the ability to identify relevant signals and anticipate potential risks, seizing reflects the capacity to mobilize and deploy resources effectively, and reconfiguring captures the continuous adaptation of processes and structures. However, unlike prior studies that often conceptualize these capabilities in relatively structured and repeatable environments, the fine art logistics context reveals a much higher degree of variability and uncertainty. In this setting, sensing is not limited to market or technological scanning, but extends to the detailed interpretation of physical, spatial, and human-related constraints. Similarly, seizing does not only involve resource allocation, but also the selective acceptance or rejection of projects to preserve service quality. Finally, reconfiguring emerges as a pervasive and continuous process, rather than an occasional adjustment, as operations must be constantly customized for each project and inside each project adjusted in real time and.

These findings suggest that dynamic capabilities in fine art logistics are deeply embedded in micro-level practices and are continuously enacted throughout project execution. As such, our study contributes to the dynamic capabilities literature by highlighting how these capabilities unfold in highly customized, non-standardized environments, where traditional assumptions of routinization and sequential processes may not fully apply.

The capabilities required in fine art logistics emerge from the continuous interaction of these micro foundations, rather than from standardized routines. In this context, sensing, seizing, and reconfiguring do not unfold as sequential phases, but rather as tightly intertwined processes that are activated simultaneously throughout project execution. This reflects the project-based and highly customized nature of fine art logistics, where each operation requires context-specific interpretation, tailored solution design, and ongoing adaptation under conditions of high uncertainty. As such, the dynamic capabilities perspective provides a useful lens to explain how logistics providers are able to ensure reliability and quality despite the absence of standardization.

The findings can be meaningfully interpreted in light of prior studies on dynamic capabilities in logistics service providers, particularly recent work by Prataviera et al. (2026). While this stream of research highlights how sensing, seizing, and reconfiguring capabilities enable logistics providers to respond to technological changes, our research shows how such capabilities operate in a context characterized by extreme asset specificity, non-standardization, and project-based operations.

Research limitations. *This paper is not free from limitations, but they also suggest promising directions for future research. The main limitation is that the paper is still at a work-in-progress step of development, even if at a good point for its finalization. Moreover, the empirical analysis relies on just one qualitative Italian case study, so that future research may consider multiple cases, or even develop the investigation into a quantitative direction, also mapping other countries in the overall analysis.*

Managerial implications. *The findings of this study offer several managerial implications for firms engaged in fine art logistics, for cultural entities and institutions, and for policy makers both in the cultural and logistical areas. In fact, the growth and development of the cultural heritage logistics sector, within an art market that is also growing and developing, highlights the strategic and economic importance of these services, with great current and prospective potential, with direct implications for the competitiveness of the individual players involved, their supply chains, and the entire cultural heritage system, as well as having repercussions on numerous other players and operational areas that represent a significant scope extension, such as tourism.*

Originality of the paper. *The present study contributes to the literature on dynamic capabilities in logistics service providers by providing an original focus on how such capabilities operate in a context characterized by extreme asset specificity, non-standardization, and project-based operations. Furthermore, the topic itself – fine art logistics – is a very original research area in academia even if the business context moves very high values and volumes in the area with concrete impact on economy, finance and social settings. Moreover, the research contextualises the dynamic capabilities theory for fine-art logistics services; and, methodologically, this paper adopts an action research approach focused on a case study: these elements are both original in the investigated field, there are no research references that use these typologies to analyse dual contributions for research and practitioners.*

Opening the black box of Olympic logistics: a qualitative study of logistics management decision-making in a temporary mega-event

SILVIA BLASI[1], BARBARA GAUDENZI[2], LORENZO BRUNO PRATAVIERA[3]

Abstract. *Logistics plays a critical role in the Olympic Games; however, existing research has primarily focused on the key steps of planning and system design, leaving managerial decision-making only partially explored. This research aims to open the black box of Olympic logistics by examining how logistics managers make decisions within the complex organizational context of the Milan–Cortina 2026 Winter Games. Based on Temporary Organization Theory and research on strategic decision speed in high-velocity environments, this study investigates Olympic logistics as a time-bounded organizational system characterized by institutionalized termination, structural temporariness, and intense temporal pressure. Milan–Cortina 2026 represents a theoretically revealing case due to its geographically dispersed configuration, encompassing both urban and mountain venues and relying on heterogeneous, partially temporary infrastructures. In this context, logistics extends beyond the optimization of material flows to include the spatial and organizational coordination of flows of people, resources, athletes, and vehicles during the event. Furthermore, the finite duration of the Olympic organization, combined with fixed deadlines and limited opportunities for iterative learning, amplifies the role of decision speed and reshapes how managers balance urgency, resource coordination, sustainability, and security. The temporary nature of the Olympic organization and the absence of repeated learning cycles further imply that decisions are made under stringent material constraints, high uncertainty, and limited reversibility. Based on in-depth qualitative interviews with key informants from Fondazione Milano Cortina and Citec, this study investigates how managerial decision-making unfolds in Olympic logistics, with particular attention to the enabling factors, organizational barriers, and collaborative mechanisms that shape strategic decision speed and its implications for optimizing key performances.*

Keywords: *Logistics management; Olympic Games; Qualitative research; Urban context; Uncertainty*

Framing of the research. *Logistics has long been recognized as a critical component of Olympic mega-events, given the scale, complexity, and visibility of the operations required to stage the Games. Existing research has primarily conceptualized Olympic logistics from the perspective of system design, planning, and coordination, focusing on the optimization of flows, infrastructure deployment, and organizational arrangements (Minis et al., 2006; Pott et al., 2024). Most of the literature has emphasized strategic choices related to outsourcing, warehousing, transportation, security and venue logistics, often drawing on ex post evaluations of past Olympic editions (Essex and Chalkley, 1998, 2004; Minis et al., 2006; Pott et al., 2024; Preuss, 2004). While this body of studies has significantly advanced our understanding of how Olympic logistics can be planned and implemented, it has largely adopted a normative perspective. As a result, much of the literature in this field considers logistics as a technical and functional aspect, implicitly assuming that once appropriate systems, processes, and governance structures are in place, operations will unfold as intended (Christopher, 2016; Minis et al., 2006; Pott et al., 2024). However, this perspective fails to consider the opportunities related to a proactive optimization of logistics to achieve better performances in terms of efficiency, resilience, and sustainability. In particular, little attention has been paid to how logistics managers make strategic decisions under conditions of temporal pressure, structural constraints, and organizational complexity (Bonn and Rundle-Thiele, 2007).*

This gap becomes particularly salient when considering the organizational characteristics of the Olympic Games. The Games are organized through temporary organizational structures established for a limited duration, operating under fixed and non-negotiable deadlines and dissolving shortly after the event concludes. As Lundin and Söderholm (1995) argue, temporary organizations are characterized by time-boundedness, task orientation, team configuration, and transition, with action rather than decision serving as their organizing principle. These four dimensions are especially consequential for logistics: fixed and non-negotiable deadlines to take decisions; task orientation around delivery; team configurations focused on specialized actors; risk exposure toward knowledge discontinuity across different phases and organizational interfaces. The fixed temporary organizational structures fundamentally reshape managerial behavior, as actors cannot rely on long-term routinization. Bakker et al. (2016) further emphasize that temporary organizational structures engage in continuous negotiation with permanent institutions and public actors, generating potential tensions at the interfaces between short-term action and enduring institutional arrangements.

Within such temporary settings, decision-making cannot be understood solely as the outcome of formal planning structures. Instead, temporariness heightens the relevance of time and intensifies the potential consequences of delay (Bakker et al., 2016; Grabher, 2002; Lundin and Söderholm, 1995). Research on strategic decision speed in high-velocity environments further suggests that rapid decision-making is often associated with superior performance when

organizations face dynamic and uncertain conditions (Baum and Wally, 2003; Judge and Miller, 1991). In such contexts, decision speed does not necessarily imply weak analysis; rather, it may reflect the ability to integrate real-time information, manage multiple alternatives simultaneously, and coordinate effectively under pressure (Eisenhardt, 1990).

The Milan–Cortina 2026 Winter Games amplify these theoretical concerns. Unlike many previous Olympic editions concentrated within a single metropolitan area, Milan–Cortina is geographically dispersed across urban and mountain venues spanning multiple regions and relying on heterogeneous and partially temporary infrastructures. This spatial dispersion increases coordination demands and limits the feasibility of incremental adjustments. In a temporary organization operating under non-negotiable deadlines, the speed of logistical decisions may directly affect not only operational reliability but also broader urban and inter-organizational coordination. Prior research on decision speed indicates that environmental dynamism and organizational structure shape both the pace and quality of strategic decisions (Baum and Wally, 2003; Judge and Miller, 1991). In the Olympic context, temporariness itself functions as a structural driver of urgency, potentially magnifying the impact of enabling factors and organizational barriers to rapid decision-making. Accordingly, Milan–Cortina offers a particularly suitable setting in which to examine how decision speed is conditioned by the interaction of temporariness (fixed deadlines and institutionalized termination) and spatial dispersion (multi-venue interdependence), rather than by environmental velocity alone.

Given these considerations, this study aims to address the following research question: "How do organizational and geographic characteristics impact logistics decision-making in an Olympic event?"

Purpose of the paper. *The purpose of this paper is to develop an empirical qualitative study that explains the mechanisms of logistics management decision-making in temporary mega-events. Specifically, the study adopts the lens of Temporary Organization Theory (Bakker et al., 2016; Lundin and Söderholm, 1995) with research on strategic decision speed in high-velocity environments (Baum and Wally, 2003; Eisenhardt, 1989; Judge and Miller, 1991) to examine how structural temporariness shapes the pace and configuration of logistical decisions. Hence, rather than positioning decision speed as an independent organizational attribute, the paper treats it as structurally conditioned by the temporal architecture of temporary organization.*

Temporary Organization Theory conceptualizes mega-events as organizations characterized by time-boundedness, task orientation, team configuration, transition. In such settings, time is not merely a constraint but a structuring dimension that shapes authority, coordination, and accountability (Bakker et al., 2016; Lundin and Söderholm, 1995). Time-boundedness compresses decision windows; task orientation sharpens goal-driven prioritization; team configuration intensifies cross-functional interdependence; and transition introduces risks of discontinuity in knowledge and responsibility. Rather than treating decision speed as a static organizational capability, the study conceptualizes Olympic logistics decision-making as evolving across temporally distinct phases: preparation, Games-time, and closure; each characterized by different configurations of constraints, enabling mechanisms, and performance implications in terms of efficiency, resilience, and sustainability. In particular, performance implications will be examined not only from the perspective of the Games' time cycle but also in relation to the post-event phase, investigating whether and how a legacy-oriented perspective influences logistics decision-making. Specifically, the study explores whether legacy considerations constitute a strategic priority in logistics decisions, for instance with regard to the potential reuse of logistics infrastructures after the conclusion of the Games.

While prior research on Olympic logistics has primarily focused on system design and operational planning, and decision speed research has largely examined corporate settings (Baum and Wally, 2003; Minis et al., 2006; Pott et al., 2024), little is known about how decision speed unfolds within geographically dispersed temporary organizations operating under institutionalized termination and non-negotiable deadlines. This study addresses that gap by conceptualizing Olympic logistics as a time-bounded organizational arena in which temporariness interacts with spatial dispersion and structural interdependence to condition the enactment of decision speed.

Hence, the study underlines the salience and determinants of decision speed vary across the life cycle of the event. During the preparation phase, structural arrangements and planning routines dominate; during Games-time, decision speed reaches peak criticality as spatial dispersion, real-time coordination, and material irreversibility converge; and during the closure phase, governance and knowledge transfer mechanisms reshape decision priorities. In this phase-contingent view, speed is not uniformly desirable; rather, its meaning and consequences shift with the configuration of constraints and coordination demands. In this perspective, temporariness is not simply a descriptive feature of mega-events but a structural dimension that actively configures managerial decision-making by compressing time horizons and limiting opportunities for revision

Therefore, the framework shifts attention from isolated antecedents to the temporal structuring of decision conditions, proposing that structural temporariness, environmental dynamism, and spatial dispersion interact differently during preparation, Games-time, and closure phases. In doing so, the study explores how urgency, coordination intensity, sustainability and security converge during the peak event phase, altering both the mechanisms enabling rapid decisions and the barriers constraining them.

The study explores these topics through qualitative interviews with several logistics decision-makers of the Milan–Cortina 2026 Winter Games, under the lens of Temporary Organization Theory. At the same time, it extends research on strategic decision speed by demonstrating that in geographically dispersed and dynamic mega-events, decision speed emerges not simply from organizational structure or environmental velocity, but from their interaction with temporariness as a funding characteristic. In this sense, the study positions temporariness as a moderating structural condition in the

relationship between environmental dynamism and decision speed, thereby advancing both literatures beyond their traditional empirical domains.

Methodology. *This study adopts a qualitative case study design (Yin, 2018) to investigate managerial decision-making in Olympic logistics within the temporary and geographically dispersed setting of the Milan–Cortina 2026 Winter Games. A single-case design is appropriate because Milan–Cortina constitutes a theoretically revelatory case: it embodies the defining characteristics of temporary organizations—time-boundedness, institutionalized termination, and task-based coordination (Lundin and Söderholm, 1995) while simultaneously exposing decision-makers to high environmental dynamism, structural interdependence, and immovable deadlines. In line with Temporary Organization Theory, the case also enables observation of how team configuration and transition dynamics unfold as the organization moves across phases. The case thus provides a unique opportunity to examine how temporariness and velocity interact in shaping decision speed.*

The data collection is still in progress. Data are collected through semi-structured, in-depth interviews with purposively selected key informants (Patton, 2002) occupying both strategic and operational roles within the Organizing Committee and partner organizations responsible for logistics functions (e.g., transport coordination, venue logistics, warehousing, cross-functional integration, security, sustainability, and all the associated services). The sampling strategy ensures heterogeneity in hierarchical position, functional responsibility, and phase involvement across the event life cycle (preparation, test events, Games-time, and closure). Recruitment proceeds until thematic saturation is reached with respect to phase-specific decision conditions and enabling mechanisms. The expected number of interviews is eleven.

The interview protocol is structured around phase-based logic consistent with the theoretical framework. Respondents are first invited to describe their role and responsibilities, followed by a reconstruction of their involvement across the preparation, test event, Games-time, and closure phases. Emphasis is placed on eliciting detailed accounts of concrete decision episodes characterized by urgency, high impact, interdependence, or constrained reversibility. Rather than focusing on abstract perceptions of speed, the protocol encourages respondents to reconstruct specific situations in which rapid decisions were required, how alternatives were evaluated, how coordination unfolded, and what constraints shaped the available courses of action. To strengthen comparability across interviews, respondents are prompted to locate each episode in time (phase), specify the decision arena, identify involved actors, and describe escalation pathways and coordination channels.

The protocol explicitly probes: 1) how temporal pressure was perceived and managed; 2) how structural arrangements (governance, reporting lines, planning routines) enabled or constrained decision speed; 3) how spatial dispersion across venues affected coordination intensity; 4) how trade-offs between speed, accuracy, and risk mitigation were handled; 5) how decision conditions differed across phases of the event life cycle, also considering the post-event perspective. This episode-based approach reduces retrospective bias by anchoring accounts to specific incidents and allows decision-making to be examined as embedded in temporally bounded organizing processes. Interviews are recorded and transcribed. All interviews follow informed consent procedures and are anonymized to protect respondents operating in a highly visible institutional setting.

To enhance construct validity, interview data are triangulated with documentary sources, including internal planning documents, organizational charts, governance guidelines, and publicly available reports concerning logistics preparation and venue coordination. These materials are used to corroborate timelines, structural arrangements, and decision responsibilities described by informants.

Data analysis follows an abductive strategy (Timmermans and Tavory, 2012), iteratively moving between empirical material and theoretical constructs derived from Temporary Organization Theory and strategic decision speed research. The coding process unfolds in multiple iterative stages and follows the principles of the Gioia methodology (Gioia et al., 2013). In the first step, we conduct open coding aimed at preserving informant-centric terms and expressions (first-order concepts), allowing managerial accounts of decision episodes to emerge without imposing theoretical structure. In the second step, these first-order concepts are progressively grouped into second-order themes that captured emerging patterns in how decision dynamics were described across phases of the event life cycle (preparation, Games-time, closure) and across different decision arenas. This stage involves iterative movement between data and theory in line with an abductive logic. In the third step, aggregate theoretical dimensions are developed by relating second-order themes to sensitizing constructs derived from Temporary Organization Theory and strategic decision speed research.

Expected Results. *Drawing on Temporary Organization Theory (Lundin and Söderholm, 1995), it is reasonable to anticipate that the time-bounded and task-oriented nature of the Olympic organization progressively reshapes authority structures, coordination patterns, and tolerance for risk as the event approaches Games-time (see Table 1). In the preparation phase, decision processes are likely to be more formalized, planning-oriented, and embedded in negotiated inter-organizational arrangements. Decision speed in this phase may be moderated by the need for alignment, consensus-building, and procedural legitimacy across multiple stakeholders. Here, temporariness manifests primarily through anticipatory structuring rather than immediate urgency, allowing decision speed to be balanced against coordination breadth and procedural robustness.*

As the organization transitions into Games-time, temporal compression and irreversibility are expected to intensify, shifting decision-making toward more rapid, centralized, and action-oriented processes, consistent with research on strategic decision speed in high-velocity environments (Eisenhardt, 1989; Judge & Miller, 1991; Baum & Wally, 2003).

Under these conditions, coordination is expected to rely on tighter integration mechanisms, reduced consultation cycles, and simplified decision frames, reflecting the increased costs of delay and heightened systemic interdependence. However, consistent with the decision speed literature, acceleration is anticipated to be effective only when supported by integrative mechanisms that sustain cross-functional coherence and prevent fragmentation across dispersed venues.

During the closure phase, decision priorities are expected to shift again, emphasizing accountability, demobilization, and knowledge transfer, thereby reconfiguring speed and risk considerations. Risk tolerance may decrease relative to Games-time, and decision processes may become more documentation-driven and compliance-oriented as institutional responsibilities come to the forefront. In this phase, the transition dimension of temporary organizing is expected to become salient, with decision speed subordinated to governance stabilization and formal knowledge codification.

Overall, the study is expected to support the development of a phase-contingent model of decision speed in temporary, geographically dispersed mega-events. Specifically, temporariness is anticipated not merely to increase urgency, but to alter the configuration of authority, coordination intensity, and risk orientation across phases. Decision speed in Olympic logistics is therefore expected to emerge from the interaction between institutionalized deadlines, spatial dispersion, and structural interdependence, rather than from environmental dynamism alone. In addition, the study is expected to contribute to the understanding of performance management and prioritization in Olympic logistics, considering both the Games' time cycle—measured in terms of efficiency, timeliness, and sustainability—and the post-event phase from a legacy-oriented perspective.

Table 1: Framework

Phase	***Organizational Characteristics***	***Spatial Configuration***	***Decision Speed Drivers***	***Performance***
Preparation	Formalization; centralization	Space as planned configuration (venue planning; macro-scale coordination)	Alternative generation	Efficiency
Games-Time	Institutionalized termination	Space as practiced coordination across scales (micro–meso–macro)	Real-time information; simultaneous alternatives	Resilience
Closure	Transition	Reconfiguration of spatial scales; re-embedding in permanent space	Integration across decisions	Sustainability

These expectations remain theoretically grounded but empirically open. The qualitative analysis will assess whether, and under what conditions, these anticipated phase-based shifts in decision dynamics are observable in managerial accounts.

Research limitations and future research. *This study presents several limitations that open avenues for future research. First, it relies on a single revelatory case, which enables in-depth exploration of decision-making within a temporary mega-event but limits statistical generalizability beyond the specific institutional and territorial configuration of Milan–Cortina 2026 (Yin, 2018). While the objective is analytical rather than statistical generalization, the findings remain embedded in a particular governance model and spatial architecture. Future research could adopt comparative designs across different Olympic editions or other large-scale temporary events to examine whether phase-contingent decision patterns remain stable across governance structures, degrees of centralization, and levels of spatial dispersion.*

Second, the study primarily draws on interview-based reconstructions of decision episodes, which may be affected by retrospective sensemaking and ex-post rationalization, particularly under high-pressure conditions. Future research could incorporate longitudinal or real-time observational methods during peak operational phases to capture decision speed dynamics as they unfold, thereby reducing reliance on retrospective accounts and strengthening causal inference regarding temporariness and temporal compression.

Third, although the framework emphasizes phase-contingent shifts in decision conditions, the empirical design does not allow for direct measurement of performance outcomes associated with faster or slower decisions. Subsequent studies could examine how variations in decision speed across phases affect operational reliability, coordination effectiveness, and risk exposure, thereby linking temporal dynamics to performance implications.

Finally, while the study focuses on managerial actors within the temporary organization, future research could explore multi-level dynamics by examining how political authorities, local institutions, contractors, and international governing bodies influence decision processes across phases. In particular, investigating how external institutional pressures interact with internal temporariness could further refine our understanding of how decision speed is structurally conditioned in mega-event settings.

Managerial implications. *This study offers several implications for organizers of temporary and geographically dispersed mega-events. First, the findings suggest that decision-making structures should not be designed as static arrangements but calibrated to the evolving temporal phases of the event. In temporary organizations, time-boundedness implies that coordination architectures must anticipate phase transitions rather than merely support steady-state operations. During preparation, managers should prioritize clarity in roles, escalation pathways, and inter-organizational coordination mechanisms, creating a stable architecture that can absorb future temporal compression. Formal governance design in this phase should reduce ambiguity before urgency peaks.*

As Games-time approaches, formal planning routines should be complemented with mechanisms that support rapid commitment to action and coordinated execution, such as cross-functional briefings, shared situational awareness tools, and pre-defined decision boundaries. Consistent with research on decision speed in high-velocity environments, organizations should simplify information flows, shorten consultation chains, and empower clearly defined decision authorities to avoid analysis paralysis under temporal compression.

Moreover, in geographically dispersed events, particular attention should be devoted to boundary-spanning roles and real-time communication infrastructures that connect spatially distant clusters. Given the structural interdependence across venues, mechanisms that ensure rapid vertical and horizontal alignment become critical during peak operations.

Finally, recognizing that temporariness limits the consolidation of routines, organizers should implement structured knowledge-transfer processes during the closure phase to avoid the loss of experiential learning and enhance preparedness for future editions. Because institutionalized termination disrupts organizational memory accumulation, formalized debriefing protocols and codification of decision logics are essential to mitigate the structural discontinuity inherent in temporary mega-events.

Originality of the paper. *This paper advances research on Olympic and mega-event logistics by moving beyond structural design and planning models toward a temporally grounded analysis of how decision speed unfolds within a temporary organizational form. While prior studies have conceptualized Olympic logistics primarily as a system-design problem (e.g., infrastructure deployment, process optimization, governance configuration), this study reframes it as a phase-contingent decision environment in which temporariness actively reshapes the conditions of managerial action.*

By integrating Temporary Organization Theory with research on strategic decision speed in high-velocity environments, the study proposes a novel theoretical synthesis. Rather than treating temporariness as a contextual backdrop and decision speed as a static capability, the paper conceptualizes their interaction as structurally generative: institutionalized termination, fixed deadlines, and spatial dispersion jointly configure the pace, coordination intensity, and risk orientation of decisions across phases.

Empirically, the study contributes by subjecting this theoretical integration to qualitative examination within the geographically dispersed configuration of Milan–Cortina 2026. Importantly, the framework does not assume that phase-based shifts in decision dynamics necessarily occur; rather, it advances theoretically grounded expectations that remain empirically open. The qualitative analysis assesses whether, and under what conditions, temporariness translates into observable shifts in authority structures, coordination mechanisms, and decision speed across the event life cycle.

In doing so, the paper contributes to Temporary Organization Theory by specifying how institutionalized termination influences not only coordination but the temporal logic of managerial decision-making. At the same time, it extends research on strategic decision speed beyond corporate high-velocity markets to the underexplored domain of geographically dispersed mega-events.

More broadly, the study demonstrates the value of combining organization theory and strategic decision research to illuminate decision dynamics in temporary, high-stakes, and spatially complex settings—an area that has remained theoretically fragmented and empirically underexamined.

Returns Management in E-Commerce: The Role of Sustainability in Shaping Customer Satisfaction

BRAVI LAURA[1*], ALESSIO TRAVASI[1], FABIO MUSSO[1], ELISABETTA SAVELLI[1], VINCENZO GISSI[1]

Abstract. *The rapid growth of e-commerce has led to a significant increase in product returns, making returns management a critical component of the customer experience and a major challenge for firms in terms of logistics efficiency and environmental sustainability. While reverse logistics has been widely investigated from an operational and environmental perspective, limited empirical research has jointly examined sustainable returns management and customer satisfaction from the consumer point of view.*

This paper investigates the relationship between sustainable returns management practices and customer satisfaction in the e-commerce context, focusing on consumers' return behaviors, sustainability perceptions, and post-purchase evaluations. Adopting a consumer-oriented perspective, the study aims to explore how sustainable initiatives implemented within the returns process, such as eco-friendly packaging, digital return labels, and product refurbishment, are perceived by consumers and how they influence satisfaction and behavioral intentions.

The research adopts a quantitative methodology based on a structured online questionnaire administered to consumers with prior experience in online shopping and product returns. Data collected from 250 respondents were analyzed using descriptive statistical techniques to examine purchasing and return behaviors, awareness of the environmental impact of returns, and attitudes toward sustainable return practices.

The results show that returns are perceived as a normalized component of the e-commerce experience and that convenience-related factors, such as ease of return and refund speed, remain the primary determinants of customer satisfaction. Sustainability emerges as a relevant but secondary driver, positively influencing satisfaction only when integrated into efficient and user-friendly return processes. Packaging-related sustainable practices and digital return labels are particularly valued, while willingness to accept economic or behavioral trade-offs for sustainability remains limited. The findings also reveal generational differences in sustainability awareness and acceptance of circular economy practices, such as refurbished products. In conclusion, the study contributes to the literature by providing empirical evidence on the sustainability–convenience trade-off in returns management and by highlighting the strategic role of sustainable returns as a lever for customer satisfaction and long-term value creation in e-commerce.

Keywords: *e-commerce; reverse logistics; returns management; sustainability; customer satisfaction; circular economy.*

Framing of the research. *The rapid expansion of e-commerce has profoundly reshaped consumption patterns and supply chain configurations, leading to a substantial increase in product returns. In online retailing, returns have become an intrinsic component of the overall customer experience and represent one of the most critical and complex reverse flows affecting logistics performance, operational efficiency, and customer satisfaction (Robertson et al., 2020). Therefore, reverse logistics and returns management have gained growing strategic relevance, moving from a purely operational concern to a key managerial issue for firms operating in digital markets.*

Recent industry evidence further confirms the scale and strategic relevance of this phenomenon. According to the National Retail Federation (2025), online return rates are expected to account for 19.3% of total e-commerce sales, corresponding to nearly $850 billion in returned merchandise, while recent industry analyses by Optoro (2024) further highlight the growing economic and environmental burden associated with returns processes. These data reinforce the need for firms to treat returns management as a strategic business issue rather than merely an operational cost.

From a literature perspective, this study is positioned within the stream of consumer-centric supply chain management, which recognizes consumers as active actors shaping logistics and post-purchase processes (Esper et al., 2020; Baldi et al., 2024). In this perspective, the focus is specifically on returns management in the post-purchase phase of e-commerce, rather than on broader end-of-use reverse logistics flows.

More specifically, the study considers consumer returns generated by dissatisfaction, product mismatch, damages, or change-of-mind decisions, consistently with the classification proposed by Abdulla et al. (2019). This focus allows the paper to investigate how sustainable return practices and return policy design influence customer satisfaction and behavioral intentions.

From an environmental perspective, the management of returns generates significant negative impacts, particularly in terms of transportation emissions, packaging waste, and resource consumption. These impacts are exacerbated in the e-commerce context, where consumers benefit from flexible return policies and the inability to physically inspect products prior to purchase, resulting in higher return rates and inefficient reverse flows (Frei et al., 2022). Accordingly, companies face increasing pressure to redesign returns processes to mitigate their environmental footprint while maintaining high service levels.

In parallel, sustainability has emerged as a central paradigm in supply chain and logistics research. The growing emphasis on the Triple Bottom Line approach has encouraged firms to pursue economic, environmental, and social objectives simultaneously, fostering the adoption of sustainable and circular supply chain models (Nogueira et al., 2023). Within this framework, reverse logistics plays a pivotal role by enabling product recovery, reuse, refurbishment, and recycling, thus contributing to waste reduction and more efficient resource utilization (Biancolin et al., 2023).

At the same time, consumers are no longer passive recipients of products but active participants whose purchasing and return behaviors directly influence logistics flows and environmental outcomes (Robertson et al., 2020). Recent studies highlight that return behaviors are driven not only by product-related issues but also by psychological factors, expectations regarding convenience, and perceptions of risk, making returns management a multifaceted challenge for firms (Rintamäki et al., 2021; Lysenko-Ryba & Zimon, 2021).

In this context, return policies have become a critical determinant of customer satisfaction and loyalty. Transparent, simple, and flexible return procedures reduce perceived risk and enhance the overall shopping experience, positively influencing repurchase intentions. However, overly permissive return policies may generate excessive operational and environmental costs, creating a tension between customer-centric strategies and sustainability objectives (Zhang et al., 2023; Abdulla et al., 2025).

Despite the growing body of literature on reverse logistics and sustainability, empirical research jointly addressing sustainable returns management and customer satisfaction from the consumer perspective remains limited (Kiba-Janiak et al., 2024). Against this background, the present research adopts a consumer-centric supply chain management lens to explore how sustainable approaches to returns management can reduce environmental impacts while simultaneously enhancing customer satisfaction and supporting long-term value creation for firms.

Purpose of the paper. *The purpose of this paper is to investigate the relationship between sustainable returns management practices and customer satisfaction in the context of e-commerce. Specifically, the study aims to analyze consumers' return behaviors, their perceptions of the environmental impact generated by product returns, and the importance attributed to sustainable practices implemented within the returns process.*

By adopting a consumer-oriented perspective, the research seeks to identify which sustainable initiatives in returns management, such as eco-friendly packaging, digital return labels, and product refurbishment, are considered most relevant by consumers and how these practices influence customer satisfaction and behavioral intentions. In doing so, the paper addresses the trade-off faced by firms between offering convenient and flexible return policies and pursuing sustainability objectives.

Furthermore, the study aims to contribute to the existing literature by providing empirical evidence on the role of sustainability in shaping customer satisfaction in reverse logistics processes. Through the analysis of primary data collected via a structured questionnaire, the research offers insights into how sustainable approaches to returns management can simultaneously reduce environmental impacts and support customer-centric strategies, thereby fostering long-term value creation for e-commerce firms.

Methodology. *The study adopts a quantitative research design aimed at investigating the relationship between sustainable returns management practices and customer satisfaction in the e-commerce context, from the consumer perspective. Consistent with prior research on reverse logistics and consumer behavior, a survey-based methodology was chosen as the most suitable approach to capture perceptions, attitudes, and behavioral intentions related to online purchasing and product returns (Ball, 2019; Rintamäki et al., 2021; Robertson et al., 2020).*

Primary data were collected through an online questionnaire administered using Google Forms. The use of an online survey is particularly appropriate in e-commerce research, as it allows direct access to consumers who regularly engage in online shopping and returns activities (Nguyen et al., 2018). The questionnaire was distributed through digital channels, and participation was voluntary and anonymous.

The target population consisted of consumers with prior experience in online shopping and product returns. The final sample included respondents with heterogeneous socio-demographic characteristics in terms of age and gender, allowing for an exploratory analysis of different consumer profiles. This approach is consistent with previous empirical studies on customer returns and reverse logistics, which emphasize the importance of capturing diverse consumer behaviors and perceptions (Lysenko-Ryba & Zimon, 2021).

The questionnaire was structured into multiple sections: the first focused on respondents' general online shopping behavior, including frequency of online purchases, preferred e-commerce channels, and product categories most commonly purchased. This section aimed to contextualize respondents' familiarity with e-commerce environments. The second section investigated consumers' return behavior, examining the frequency of product returns, the main motivations for returning items (e.g., size issues, product mismatch, quality concerns), and prior experiences with return processes. These items are consistent with established literature identifying customer returns as a critical element of the post-purchase phase (Robertson et al., 2020). The third section addressed sustainability-related aspects of returns management. Respondents were asked to evaluate the perceived environmental impact of returns and to assess the importance of specific sustainable practices, such as reusable or right-sized packaging, digital return labels, and product refurbishment for resale. This section builds on previous studies highlighting the growing relevance of sustainability perceptions in reverse logistics processes (Zhang et al., 2023; Biancolin et al., 2023). The fourth section focused on customer satisfaction in relation to returns management. Respondents were asked to express their level of satisfaction

with return procedures and to indicate how sustainable practices influence their overall evaluation of the e-commerce experience. Five point likert-scale items were used to measure attitudes and perceptions, in line with common practice in customer satisfaction and logistics research (Rintamäki et al., 2021). The final section collected socio-demographic information, including age and gender, to support descriptive analysis and facilitate the interpretation of results across different consumer groups. The collected data were analyzed using descriptive statistical techniques. Frequency distributions and summary statistics were employed to examine consumers' purchasing and return behaviors, perceptions of sustainability, and satisfaction levels.

Results. ***Sample characteristics and online purchasing behavior.*** *The final sample consists of 250 respondents aged between 18 and 75 years. The majority belongs to Generation Z (18–27), representing 58.4% of the sample, followed by Millennials (28–43) with 24.8%, Generation X (44–60) with 13.6%, and Baby Boomers (61–75) with 3.2%. The sample is predominantly female (60.4%), while males account for 39.2%. In terms of education, 46% of respondents hold a high school diploma, while 44.8% have a university degree (bachelor's, master's, or postgraduate qualification), indicating a generally high level of education. Almost half of the respondents are students (46.4%), followed by employees (37.6%).*

Online shopping appears to be a consolidated habit among respondents. In fact, 43.6% report purchasing online "often" and 38.8% "sometimes", while only 14% purchase rarely. Younger generations show a significantly higher purchasing frequency: all respondents who declared purchasing online "always" belong to Generation Z or Millennials, whereas the few respondents who rarely shop online are from older age groups.

When evaluating the factors influencing online purchase decisions, product quality emerges as the most important element (mean = 4.30), followed by free shipping (mean = 4.24) and product price (mean = 4.21). Conversely, the company's environmental reputation ranks among the least influential factors (mean = 3.29), although with high variability, indicating heterogeneous attitudes toward sustainability. This pattern is consistent across age groups, except for Baby Boomers, who assign higher importance to environmental reputation (mean = 4.50).

Delivery preferences and sustainability in last-mile logistics. *Home delivery is by far the most frequently used delivery method (mean = 4.29), regardless of age. Alternative options such as pick-up points (mean = 2.34) and click-and-collect services (mean = 2.08) are used significantly less, despite their potential environmental benefits. This preference highlights a clear dominance of convenience over sustainability considerations in last-mile logistics choices.*

Regarding sustainable delivery practices, respondents attribute relatively high importance to order consolidation into a single shipment (mean = 4.13) and route optimization (mean = 4.02). Packaging-related initiatives, such as the use of recycled materials (mean = 4.02) and packaging reduction (mean = 3.82), are also positively evaluated. Conversely, delivery to parcel points to reduce traveled kilometers is considered less important (mean = 3.18), reflecting coherence with the widespread preference for home delivery.

Age-related differences emerge clearly: Baby Boomers consistently report higher average scores across all sustainable delivery practices, particularly route optimization (mean = 4.75), indicating greater environmental sensitivity compared to younger generations.

Return frequency and motivations. *Despite high online purchasing frequency, most respondents return products infrequently. Specifically, 64% declare that they return items "rarely", and only 4% report returning products "often" or "always". Younger consumers show slightly higher return frequency than older ones, although returns remain generally limited across all age groups.*

Women tend to return products more frequently than men, especially in the categories "often" and "always", while men are overrepresented among those who never return products.

The primary motivations for returning items are functional and product-related. The most relevant reason is receiving a damaged product (mean = 3.90), followed by incorrect delivery (mean = 3.48) and dissatisfaction with product quality (mean = 3.41). Opportunistic behaviors, such as returning products after finding a better price elsewhere or ordering items only to try them, are among the least important motivations (means below 2). These findings confirm that returns are largely driven by operational failures rather than strategic consumer behavior.

Older consumers, particularly Baby Boomers, attribute significantly higher importance to all return motivations, with extremely high scores for damaged products and need for repair (mean = 4.75), suggesting lower tolerance toward product defects.

Return policies and customer satisfaction

Return policies play a crucial role in shaping customer satisfaction and purchase decisions. Most respondents (57.2%) consider return conditions before completing an online purchase, highlighting the strategic relevance of transparent and customer-friendly policies.

The most important return policy attributes are full refund (mean = 4.66), free returns (mean = 4.61), and the possibility to return products online (mean = 4.33). These factors show very low variability, indicating strong consensus among consumers. Conversely, in-store returns (mean = 3.68) and the availability of a return label (mean = 3.94) are considered less critical.

A positive return experience strongly influences repurchase intentions: 88.8% of respondents state that they would purchase again from the same company after a satisfactory return process. This percentage is consistently high across genders, confirming the pivotal role of returns management in customer loyalty.

Awareness and evaluation of sustainable return practices. *Consumers' awareness of the environmental impact of returns is moderate and uneven. Only 38.4% declare full awareness, while 34.8% are partially aware and 26.8% are not aware at all. Awareness increases slightly with age, reaching 50% among Baby Boomers.*

Willingness to pay a higher price for sustainable return policies is limited and uncertain. While 30.4% of respondents are willing to pay more, 31.6% are not, and the largest group (38%) remains undecided. This uncertainty suggests insufficient knowledge about the environmental benefits of sustainable returns.

Nonetheless, almost half of the sample (46.8%) considers sustainable return practices "fairly important", and 10% consider them "very important". Younger consumers, especially Generation Z, show relatively higher sensitivity toward sustainability in returns. Among specific sustainable initiatives, packaging-related solutions receive the highest evaluations. Reusable packaging for returns (mean = 4.33), right-sized packaging (mean = 4.20), use of sustainable materials (mean = 4.19), and digital return labels (mean = 4.14) are the most appreciated practices. Conversely, peer-to-peer returns (mean = 3.26), refunds without returning the product (mean = 3.23), and returns without packaging (mean = 3.33) are perceived as less relevant.

Refurbished products and circular economy practices. *Half of the respondents (50.4%) are willing to purchase refurbished products originating from returns, while 27.6% remain uncertain and 22% are unwilling. Younger consumers show higher acceptance, whereas resistance increases with age. The main drivers of refurbished product adoption are price convenience (mean = 4.29), availability of all accessories (mean = 4.34), detailed information on product condition (mean = 4.34), warranty (mean = 4.26), and return possibility (mean = 4.15). Sustainability-related motivations, such as contribution to the circular economy, are considered moderately important (mean = 3.60), confirming that functional and risk-reduction factors prevail over environmental considerations.*

Research limitations. *Despite the contributions of this study, some limitations should be acknowledged. First, the composition of the sample represents a constraint, as the majority of respondents belong to Generation Z, while older age groups, particularly Baby Boomers, are underrepresented. This imbalance may limit the generalizability of the findings across different generational segments. Second, the sample size, although adequate for an exploratory analysis, does not allow for more advanced inferential or multivariate statistical techniques that could further strengthen causal interpretations. Third, the study relies on self-reported data, which may be affected by subjective biases and social desirability effects, particularly regarding sustainability-related perceptions. Finally, the analysis is based on descriptive statistics; future research could extend this work by employing larger and more balanced samples, longitudinal designs, or multivariate methods to further investigate the relationships between sustainable returns management, customer satisfaction, and behavioral intentions.*

Managerial implications. *From a managerial perspective, the results provide several actionable insights for e-commerce firms. First, companies should recognize that return policies and procedures represent a critical determinant of customer satisfaction and loyalty. The descriptive evidence suggests that satisfactory return experiences may support repurchase intentions, highlighting the importance of designing return processes that are simple, transparent, and reliable. Investments aimed at improving refund speed, clarity of procedures, and free return options are therefore likely to contribute positively to customer retention.*

Second, the findings suggest that sustainability initiatives in returns management should prioritize practices that are both environmentally effective and highly visible to consumers. Packaging-related solutions, such as reusable packaging, right-sized packaging, and the use of sustainable materials, emerge as particularly valued by customers. These initiatives not only contribute to reducing environmental impacts but are also easily perceived by consumers, increasing their potential to positively influence satisfaction and brand perception. Similarly, digital return labels represent a low-complexity intervention capable of delivering both environmental and experiential benefits.

Third, the results underline the importance of targeted communication strategies. The moderate and uneven level of consumer awareness regarding the environmental impact of returns indicates that many customers are not fully informed about the sustainability implications of their return behavior. Firms can address this gap by transparently communicating the environmental benefits of sustainable return practices, for example through dedicated sections on websites, during the return process, or via post-purchase communications. Improved awareness may enhance consumers' acceptance of sustainable solutions and reduce resistance to potential trade-offs.

Fourth, the evidence on refurbished products suggests the potential relevance of circular economy practices within returns management, although these findings should be interpreted with caution. While a substantial proportion of consumers express willingness to purchase refurbished products, uncertainty and perceived risk remain significant barriers. Moreover, prior literature shows that consumer perceptions of products derived from circular economy practices are often heterogeneous and context-dependent (Russo et al., 2019). Managers should therefore focus on risk-reduction mechanisms, such as warranties, certifications, detailed product condition information, and clear return options. In line with previous studies, these elements appear to play a relevant role alongside sustainability-related motivations, whose influence may vary depending on product category and perceived risk.

Finally, the observed differences across age groups suggest that a one-size-fits-all approach to sustainable returns management may be ineffective. Younger consumers tend to show higher sensitivity toward sustainability initiatives, whereas older consumers place greater emphasis on reliability, guarantees, and transparency. Managers may therefore

benefit from adopting differentiated strategies, tailoring communication and return solutions to specific target segments in order to balance sustainability goals with customer expectations.

Originality of the paper. *The originality of this paper lies in its integrated approach to reverse logistics in e-commerce, which jointly considers consumer behavior, service design, and environmental performance within the post-purchase phase. While existing studies have mainly examined operational efficiency or sustainability outcomes separately, this research positions reverse logistics as a customer-facing service experience, where environmental objectives and user acceptance are closely intertwined.*

By focusing on the post-purchase stage, the study addresses a critical yet underexplored moment in the customer journey, shedding light on how perceived effort, uncertainty, and risk shape consumers' willingness to engage with sustainable return solutions. In doing so, the paper explicitly conceptualizes the trade-off between sustainability and convenience, offering a theoretical framework that connects behavioral responses with service design choices.

Furthermore, by adopting a generational perspective centered on Millennials and Generation Z, the paper extends the literature on reverse logistics by highlighting the role of transparency, trust, and information quality in fostering sustainable behaviors among younger consumers.

Slowing the loop: repair as a supply chain service or obligation?

ILENIA CONFENTE[1], BENEDETTA BALDI[2], VALENTINA MAZZOLI[3], IVAN RUSSO[4]

Abstract. *Central to the circular economy paradigm, repair represents a key strategy for delaying resource extraction and waste generation by "slowing" material flows and extending product lifecycles. This research investigates how firms can strategically design and communicate repair initiatives to encourage consumers to choose repair service over replacement. Drawing on Attribution Theory, we propose that internally driven repair strategies embedded in the supply chain configuration as a customer service are more effective in fostering consumer engagement than those positioned as compliance-driven responses to external pressures. This effect is expected to be particularly pronounced when repair services are delivered in-house, as internal service provision strengthens perceptions of service quality. Using a series of scenario-based experiments, this study contributes to the literature on circular supply chain management and the slowing loop debate, while also advancing research in service management. In doing so, it offers actionable managerial insights on how to structure and position repair initiatives to support circular economy objectives and consumer involvement.*
Keywords: *Product repair; Slowing the loop; Circular economy; Service; Experimental design*

Framing of the research. The circular economy (CE) has emerged as one of the most promising paradigms for redesigning business models in pursuit of sustainable development (Geissdoerfer et al., 2017; Ghisellini, Cialani, & Ulgiati, 2016; McPhail et al., 2022). It is widely regarded as a critical lever for achieving net-zero targets by 2050 (IEA, n.d.; Meseguer-Sánchez et al., 2021). Engaging in CE, however, requires capabilities that extend beyond incremental operational efficiencies. As Rovanto and Virtanen (2025) argue, firms must develop capabilities to slow resource loops—through reducing virgin material use, enhancing product durability, and promoting repair and refurbishment—and to close loops through recycling and energy recovery (Bocken et al., 2016; Kirchherr, Reike, & Hekkert, 2017). In line with the 4R hierarchy (reduce, reuse, recycle, recover), slowing resource loops should take precedence, as it directly addresses material throughput and resource intensity (Kirchherr et al., 2017). Unlike closing loops, which focus on end-of-life management, slowing loops entail systemic transformations in production and consumption patterns. In the slowing loop, the life of products can be extended through appropriate design for a longer lifespan or through life-prolonging procedures (Mrad et al., 2025).

The economic potential of the circular economy is substantial, with estimates suggesting up to $4.5 trillion in value creation by 2030 (Goldman Sachs, 2022). Central to this transition are business models that extend product lifespans through reuse, repair, regeneration, and recycling (European Commission, 2020). Among these strategies, repair plays a distinctive role: rather than reintroducing materials into the production cycle, repair delays resource extraction and waste generation, effectively "slowing down the loop" and extending products' life cycle (Bradley & Persson, 2022; Munten & Vanhamme, 2023).

Items that can be repaired are often thrown away. This results in 35 million tonnes of waste and 261 million tonnes of greenhouse gas emissions in the EU each year. The cost to consumers of replacing (rather than repairing) products is estimated at almost €12 billion per year (European Union, 2025). Ensuring product repairability has therefore become a cornerstone of sustainable consumption policy (Manwaring, 2024). Survey data indicate strong public support for repairability, with 79% of EU citizens advocating mandatory ease of repair and 77% preferring repair over replacement (European Parliament, 2022). In response, the European Commission's 2023 Proposal for a Right to Repair Directive introduces common EU rules aimed at strengthening consumer repair rights. The proposal includes obligations for manufacturers to repair certain product categories within reasonable time and cost conditions, ensure access to spare parts and repair information, provide loan replacements, extend liability periods after repair, and establish repair information platforms and financial incentives (European Commission, 2023; European Parliament, 2022). These measures signal a regulatory shift: repair is no longer solely a consumer responsibility but increasingly embedded within institutional and supply chain structures, which should be redesigned to offer the repair service as a strategy to prolong products' lifespan (Mrad et al., 2025; Roskladka et al., 2023).

Despite strong normative and policy support, repair practices remain constrained by significant barriers. Accessibility to repair services is often limited (Bridgens et al., 2018), and economic disincentives persist due to the relatively low price of new products, shortened product lifespans, complex designs, unavailable spare parts, and rising labor costs (Cooper & Salvia, 2018; Svensson-Hoglund et al., 2022). From an economic standpoint, repairing electronic household products may not always be rational despite environmental benefits (Bovea et al., 2017). Furthermore, consumer competence and confidence in repair are limited; only a minority reports prior experience repairing common household

electronics (Hankammer et al., 2019). Time-related barriers and "mental depreciation" further diminish repair intentions as products age (Makov & Fitzpatrick, 2021).

At the same time, repair is not solely driven by economic logic. Altruistic and community-oriented motivations have been observed in grassroots repair initiatives such as Repair Cafés (Keiller & Charter, 2014; Terzioğlu, 2021), suggesting that repair can generate social and symbolic value beyond financial considerations. Legislative initiatives—such as France's repairability index, EU ecodesign standards, U.S. Federal Trade Commission enforcement, and local repair subsidies (Federal Trade Commission, 2021; Lechner et al., 2021; Right to Repair Europe, 2021)—further shape the institutional landscape of repair.

Nevertheless, research on repair behavior remains underdeveloped compared to studies on other circular economy strategies, such as recycling or remanufacturing (Roskladka et al., 2023), and mainly focuses on consumer "in-home" repair behavior rather than at producers' or retailers' places (Mrad et al., 2025). Although several brands across sectors—furniture (IKEA), luxury fashion (Louis Vuitton, Burberry), sportswear (Decathlon), and electronics (Apple, Samsung)—have invested in repair services, the effectiveness of these initiatives ultimately depends on consumer engagement (Godfrey, Price, & Lusch, 2022). Repair requires supply chain reconfiguration and after-sales integration, yet it may also enhance repurchase intentions, positive word-of-mouth, and customer loyalty (Mashhadi et al., 2016).

Right to repair: Toward a Product-Service-System. A crucial conceptual distinction emerges: should repair be framed as a producer duty within a sustainable paradigm, or as a service embedded within business models? Recent scholarship suggests that the European Right to Repair may function not only as a normative instrument but also as an infrastructural catalyst for service-based models, particularly Product-Service Systems (PSS), which structurally integrate maintenance and repair into their value proposition. Within such models, repair is shifted from an individual burden to a provider-managed function.

Rooted in access-based consumption (Bardhi & Eckhardt, 2012) and the functional economy (Mont, 2002), PSS redefine value creation by emphasizing performance over ownership. Consumer adoption of such models depends on perceived value, understood as the trade-off between benefits and sacrifices (Zeithaml, 1988). Benefits or gains may include economic savings, functional reliability, emotional reassurance, and symbolic alignment with sustainability (Sweeney & Soutar, 2001; Tukker, 2004; Kim & Hwang, 2021). However, PSS also entails multiple forms of perceived risk or losses—performance, financial, psychological, social, privacy-related, and dependency risks (Dowling & Staelin, 1994; Catulli, 2012; Lutz et al., 2017)—which may undermine adoption if not mitigated through trust (Mayer et al., 1995; Gefen et al., 2003; Chen & Chang, 2012).

From a behavioral standpoint, the well-documented intention–behavior gap (Ajzen, 1991; Sheeran, 2002) suggests that pro-repair attitudes alone are insufficient. Convenience—defined as the reduction of time and effort required for acquisition, use, and maintenance (Brown & McEnally, 1993; Berry et al., 2002)—becomes pivotal. By embedding maintenance, repair, and end-of-life management within contractual arrangements, PSS can reduce cognitive and physical burdens, potentially making sustainable behavior the most convenient option. Yet this transformation introduces new relational and systemic risks associated with service performance, loss of ownership, and data governance.

Purpose of the paper. This research seeks to answer the following question: ***"How can companies incentivize individuals to choose repair services for their products rather than purchasing new ones?"***

Specifically, we examine how firms should design and communicate repair initiatives, focusing on (1) producers' approach to repairability strategies based on service offering (internal driven) versus a law-oriented duty (external driven) and (2) supply chain configurations for repair service provision, comparing in-house versus externalized repair services, via online platforms (internal vs external).

Drawing on Attribution Theory (Kelley, 1973; Weiner, 1985), this paper argues that consumers evaluate corporate repair initiatives by inferring the underlying motives that drive such actions. Attribution theory suggests that individuals seek to determine whether an observed behavior is caused by internal dispositions or external situational pressures. In the context of repair strategies, when a company frames repair as an internally motivated service strategy, consumers are more likely to form dispositional attributions, interpreting the initiative as a reflection of the firm's intrinsic commitment to customer value and sustainability. In contrast, when repair is framed as compliance with external obligations or regulatory requirements, consumers are more likely to generate situational attributions, perceiving the initiative as driven primarily by external pressure rather than genuine organizational intent.

These differing attributional processes have important behavioral implications. Dispositional attributions, which signal authentic commitment and long-term orientation, are expected to foster more favorable consumer responses. Consequently, we posit that consumers will be more inclined to repair rather than replace a product when the repair strategy is framed as a proactive service offering rather than as a reactive form of duty compliance. Hence, the first hypothesis we aim to investigate is the following one:

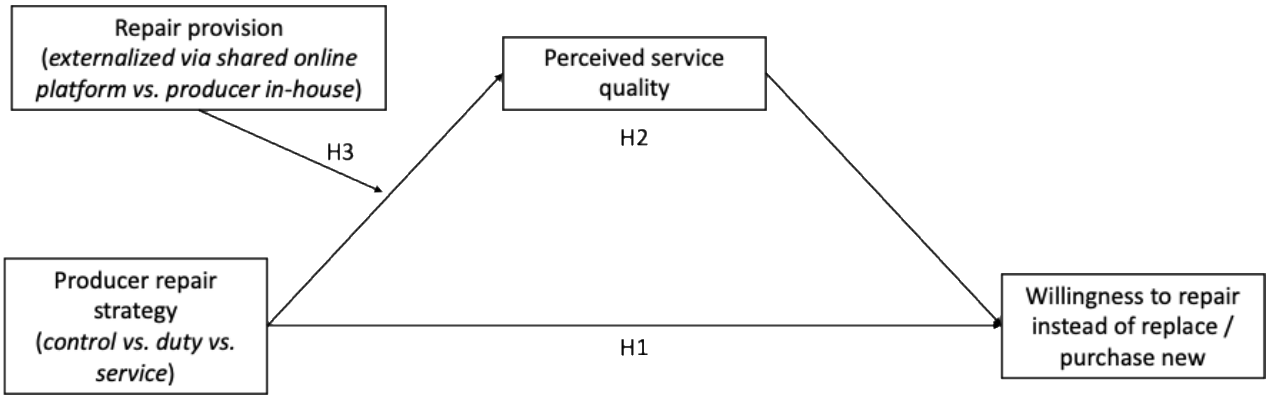
H1. Consumers' willingness to repair rather than replace a product will be higher when the producer's repair strategy is framed as a service offering rather than as duty compliance.

Furthermore, the attribution process is expected to influence consumers' perceptions of service quality. When repair initiatives are interpreted as internally driven, the stronger commitment attributed to the company should enhance perceived service quality. In turn, higher perceived service quality is likely to strengthen consumers' engagement and

behavioral intentions toward repair. Thus, perceived service quality is proposed to function as an underlying psychological mechanism linking repair strategy framing to consumers' willingness to repair.

We posit that:

H2. Perceived service quality positively mediates the relationship between the producer's repair strategy and consumers' willingness to repair rather than replace the product.



In addition, we propose that the configuration of the repair supply chain acts as a diagnostic cue that shapes consumers' attributional reasoning. Specifically, in-house repair provision may strengthen dispositional inferences by signaling organizational investment, control, and long-term commitment—consistent with Kelley's (1973) augmentation principle, whereby the presence of additional effort reinforces internal attributions. Conversely, externalized repair provision may introduce alternative explanations, such as cost efficiency or risk transfer, thereby weakening intrinsic motive attributions—consistent with the discounting principle.

Because dispositional attributions convey stability, authenticity, and genuine intent, they are expected to translate into stronger behavioral intentions toward repair. Accordingly, supply chain configuration should moderate the effect of repair strategy framing on perceived service quality. Hence, our last hypothesis reads as follows:

H3. Supply chain configuration for repair service provision positively moderates the relationship between the producer's repair strategy and perceived service quality, such that in-house repair provision strengthens the positive effect of repair-as-a-service framing on perceived service quality.

Figure 1 summarizes our hypotheses in a conceptual model.

Figure 1. Conceptual model.

Methodology. We test the causal relationship proposed in our conceptual model by using a series of between-subjects scenario-based survey experiments (Rungtusanatham et al., 2011). The methodology provides a valuable opportunity to investigate consumers' decision-making, in which varying versions of a scenario convey information about different levels of the manipulated variable to participants (Eckerd & Bendoly, 2011; Knemeyer & Naylor, 2011). It is particularly well-suited for isolating effects that are difficult to observe in noisy environments. Study 1 will employ a 3 (producer repair strategy: control vs. duty vs. service) x 1 full factorial between-subjects design to investigate the causal effects of producers' approaches to repair strategy on individuals' willingness to repair their product instead of replacing it. Study 2 will employ a 3 (producer repair strategy: control vs. duty vs. service) x 2 (repair provision: externalized via shared online platform vs. producer in-house) full factorial between-subjects design to investigate the moderating role of repair provision design. The industry sector will be electronics. Study 3 will validate the findings by testing the relationship in the field across different industry sectors, such as fashion and sports gear.

Data for the scenario-based survey experiments will be collected via the Prolific Academic crowdsourcing platform, where consumer participants will receive a flat compensation for their participation. The survey will be developed in Qualtrics. Before the main experiment, pretests will be conducted to ensure scenario realism and to conduct manipulation checks (Bachrach & Bendoly, 2011).

Beyond the variables and relationships specified in the conceptual model, additional constructs will be measured to capture individual personality traits and other relevant characteristics. These variables will allow for the examination of potential alternative explanations, serve as control variables, and help rule out competing accounts of the observed relationships. Incorporating these supplementary constructs will strengthen the internal validity of the study and provide a more comprehensive understanding of the mechanisms underlying the proposed model.

Expected results. We will test the hypothesized direct relationship using one-way ANOVA, while the mediating and moderating effects will be tested using the PROCESS macro for SPSS (Hayes, 2018). We expect the findings to suggest that positioning repair not as an obligation but as a well-structured, consumer-oriented service offering can significantly

enhance consumers' acceptance and engagement with this circular initiative. We expect this relationship to be explained by perceived service quality, which serves as a mediator, coherently with the attribution theory. Moreover, we expect the in-house repair provision to strengthen the effect of repair strategy positioning on perceived service level, such that the perceived service level will be higher when repair is offered as a service and the provision is internally offered by the producer.

Research limitations. This research is not without limitations. First, the study is currently in the early stages of design and development, which provides opportunities for further refinement prior to data collection. Second, the use of a scenario-based experimental methodology entails inherent limitations, particularly its reliance on measuring consumers' stated intentions rather than observed behavior. To mitigate these concerns, we plan to complement the scenario-based experiments with a field study aimed at assessing external validity and examining whether the findings generalize across different industry contexts. This additional step will strengthen the robustness of the results and enhance their practical relevance.

Managerial implications. From a managerial standpoint, this research offers practical insights into how firms can strategically design and communicate repair offerings to increase the likelihood that consumers will repair their products rather than replace them. Specifically, by shifting the narrative of repair strategy from moral obligation to value-creating service provision, the study seeks to clarify the organizational and communicative conditions under which slowing-loop supply chains can be successfully operationalized in pursuit of circular economy objectives. Moreover, the insights regarding repair service provision will inform managerial decisions about supply chain configurations. In particular, we expect the results to provide guidance on whether firms should internalize repair activities to signal commitment and service quality, or rely on external repair solutions facilitated through shared online platforms.

Originality of the paper. This ongoing research aims to contribute to the circular economy practices in the supply chain management literature by examining consumer participation in slowing-loop initiatives. It contributes to this literature in three main ways. First, it contributes to the literature on slowing-the-loop approaches by investigating different firm-side factors (i.e., producer repair strategy, repair provision, and product type) that affect the design of circular processes. Moreover, it extends the literature on the drivers of consumer participation in circular economy initiatives (Mrad et al., 2025; Terzioğlu et al., 2021). Second, it contributes to the literature on the strategic approach to circular economy initiatives, focusing on repair-as-a-service rather than a duty approach. Our findings will potentially extend and integrate the literature on service-based models, particularly Product-Service Systems, which structurally integrate maintenance and repair into companies' offerings. Third, it expands the literature on circular supply chain management by adopting a consumer-centric approach via an empirical investigation of our circular economy loop (Baldi et al., 2024). It then examines supply chain repair service configurations, extending the synergies between marketing and supply chain practices to enhance the effectiveness of circular supply chain initiatives.

Unpacking Circular Supply Chains: A Systematic Review and Research Agenda of SCM Processes and Actors in Circularity

OLIVIA IBEH[1], ILENIA CONFENTE[2], IVAN RUSSO[3], BENEDETTA BALDI[4]

Abstract. *Research on the circular economy (CE) in supply chain management has accelerated in recent years, driven by the increasing need to transition to circular supply chains. Supply chains have increasingly become complex as we move towards a circular supply chain, especially in an era of post-globalization and a multi-actor dependent economy. Existing reviews on the topic commonly organize evidence by practices (such as recycling, manufacturing) or sectors. This may obscure the logic of the loop being enabled (e.g., closing, slowing, narrowing), the core SCM processes being configured or those that still remain unconfigured, and which the actors in the supply chain (especially beyond the focal firms) drive or may constrain circular transition and outcomes. Thus, we propose to conduct a systematic literature review from a supply chain management perspective, treating the CE transition and circular supply chain management as an organizational and inter/intra-organizational transformation problem where firms must redesign the supply chain processes across multiple actors in the supply chain in order to reduce resource dependencies and to enable scalable circular loops. This short paper presents the preliminary findings from an ongoing systematic literature review that maps circular supply chain management (CSCM) studies across three core lenses (loops, processes, and actors). Using Scopus and Web of Science search databases, restricted to leading SCM/OM/logistics journals and a structured coding procedure, we identified a final sample of 166 papers (both empirical and conceptual papers) published till 2026. The preliminary results show a dominance of closing-loop strategies in closed-loop supply chain research, a methodological concentration in qualitative case studies and underexplored intersections clusters and will propose a process-oriented research agenda that will guide future empirical and managerial work.*
Keywords: *Circular economy*; *circular supply chain management; Circular economy loops actors; supply chain processes and governance; systematic literature review*

Framing of the research. The circular economy has become central in organizing processes and mechanisms for the grand challenge of sustainability transitions. CE rather than treating production and consumption as classically linear, it aims to keep products, components, materials, and other resources in use through multiple value retention loops, and thereby reducing virgin resource extraction and waste generation. Within supply chain management (SCM), this ambition has translated into growing attention to circular supply chain management (CSCM), closed-loop supply chains (CLSC), open-loop configurations (where recovered resources flow into different value chains), and emergent circular ecosystems (Farooque et al., 2019; Zhang et al., 2021). Early CLSC scholars provided a business oriented foundation for profitable value recovery and emphasized that this domain evolved from narrow operational problems to a recognized SCM subfield (Guide & Van Wassenhove, 2009). More recent work highlights that circularity is not limited to the dominant reverse logistics and that it requires redesigning the supply chain structures, the relationships, and decision processes across the product life cycle (Govindan & Hasanagic, 2018).

Despite these advances in literature, CSCM research still encounters a synthesis challenge. This is due to circularity being multifaceted, and reviews often group studies by specific practices (like recycling, remanufacturing, reverse logistics) (e.g., Mahmoudi & Parviziomran, 2020; Suzanne et al., 2020; Wang et al., 2017), specific sectors (such as food, apparel, electronics, and batteries) (e.g., Denizel & Schumm, 2024; Do et al., 2021; Zhu et al., 2025), or looking at drivers and barriers (e.g., Gebhardt et al., 2022; Govindan & Hasanagic, 2018). Although this approach helps organize a rapidly expanding CE field, it can also obscure the underlying loop logic that links circularity strategies to the relevant supply chain processes and actor configurations involved in this evolution. This short paper frames three main constitutive elements of CE in supply chain management: loop logic, SCM process reconfiguration, and multi-actor circularity; and uses them jointly as the organizing lenses (three-dimensional perspective) for the review.

On the Loop logic. The Loop logic is a widely used CE lens which distinguishes between: (1) close loops (e.g., take-back, remanufacturing, recycling), (2) slow loops (e.g., repair, refurbishment, aftermarket services, rental and product-service systems), and (3) narrow loops (e.g., reducing material intensity, increasing recycled content, process efficiency), (4) intensifying loops (intensive product usage, maximizing value from materials), (5) dematerializing loops (e.g., reducing physical products to reduce raw material use, software implementation and service systems as substitutes) (Bocken et al., 2016; Geissdoerfer et al., 2018). In reality, these CE strategies are not interchangeable because they carry different operational requirements and trade-offs in performance. For instance, closing loops tends to emphasize reverse flows, acquisition/sorting/disposition decisions, and recovery operations (Dukovska-Popovska et al., 2025; Batista et al.,

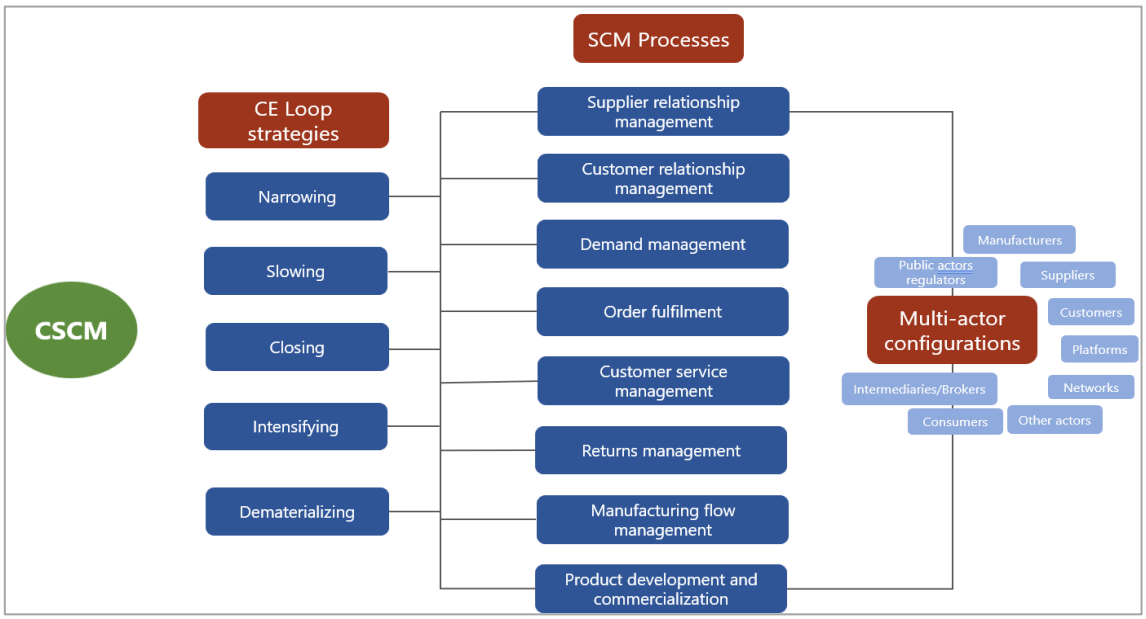
[1] Department of Management, University of Verona, olivia.ibeh@univr.it
[2] Department of Management, University of Verona, ilenia.confente@univr.it
[3] Department of Management, University of Verona, ivan.russo@univr.it
[4] Department of Management, University of Verona, benedetta.baldi@univr.it

2019; Sgarbossa & Russo, 2017). Slowing loops tend to depend on product durability, service design, and distributed repair or refurbishment networks (Gatenholm et al., 2021; Nilsson & Hazen, 2025). While narrowing loops appears to strongly rely on design for circularity, procurement of secondary inputs, and process innovations (Cozzolino & De Giovanni, 2023; Danvers et al., 2026).

The SCM processes reconfiguration. In order to make the loop choices systematically tractable within the SCM, Hazen et al. (2021) propose a process-based perspective and connect CE loops (e.g., closing, slowing, intensifying) with eight core SCM processes (supplier relationship management, customer relationship management, demand management, customer service management, order fulfillment, manufacturing flow management, product development and commercialization, and returns management) (Hazen et al., 2021; Lambert, 2008). This process view is valuable because it indicates that, in practice, circularity is not confined to a single SCM process, such as returns management, but that it can be enabled or constrained by more mainstream SCM processes, such as procurement, demand management, and product development.

The multi-actor nature of circularity. In reality, circular systems are rarely controlled by a single firm. These circular systems depend on multiple actor coordination among manufacturers, suppliers, customers/consumers, logistics service providers, repair networks, recyclers/manufacturers, intermediaries, digital platforms, public actors (such as policy makers and municipalities), and many others (Elnourani et al., 2026; Farooque et al., 2019). However, orientation towards the focal firm still remains very common in empirical papers (Dadsena et al., 2026; Hung Lau & Wang, 2009). Whenever they consider actor heterogeneity, they are mostly treated as context rather than as theoretical variables that shape circular outcomes through governance, incentives, legitimacy, standards, capacity building, and information sharing (Bressanelli et al., 2019; De Vass et al., 2023).

In the present systematic literature review, we map CSCM research simultaneously by (a) loop logic and configuration, (b) the SCM processes being reconfigured, and (c) the actors who enact, coordinate, or resist these changes. The remainder of this short paper will report the research aim, preliminary findings of our ongoing research from such a mapping, and propose an initial research agenda.



Working definitions of the CE loop logics used in this review (from Bocken et al., 2016; Geissdoerfer et al., 2018), with their potential associated SCM processes (from Lambert, 2008), are presented in Table 1. For further clarity, indicative practices and some exemplary studies have also been outlined.

Table 1. CE Loops and SCM Processes

CE Loop logic	Definition	Exemplar activities enabling CE loop	SCM processes potentially involved	Exemplar studies combining CE loops with SCM processes
Closing loops	Returning products, materials, or components back into the supply chain through recovery operations	Take-back, remanufacturing, recycling, sorting	Returns management, manufacturing flow management, supplier relationship management	Dukovska-Popovska et al. (2025); Batista et al. (2019); Insanic & Gadde (2014); Östlin et al. (2008)
Slowing loops	Extending the product life cycle and the product usage life cycle	Repair, refurbishment, aftermarket services, rental, and product-service systems	Customer service management, customer relationship management, product development & commercialization, order fulfilment	Gatenholm et al. (2021); Werner-Lewandowska et al. (2025); Nilsson & Hazen (2025)
Narrowing loops	Reducing material or resource intensity in production and consumption	Increasing recycled content in products, redesign of packages and products, and process efficiency	Product development & commercialization, manufacturing flow management, supplier relationship management	Cozzolino & De Giovanni (2023); Danvers et al. (2026); Field & Sroufe (2007)
Intensifying loops	The more intensive use of products or assets in order to get the maximum value	Enabling sharing or access models, resource pooling, and rental models	Demand management, customer relationship management, order fulfillment	Nilsson & Hazen (2025); Laukkanen et al. (2026)
Dematerializing loops	Reducing physical products or components in products through digital or software substitution	Software implementation and service systems, digital traceability infrastructures	Customer relationship management, product development & commercialization	Do & Stevenson (2026)

An overview of the conceptual framework for mapping CSCM research is shown below (Figure 1). Circular economy loops are expected to be applied within different SCM processes that involve different actors/actor.

Figure 1: Preliminary conceptual framework

Source: Extended from Hazen, B. T., Russo, I., Confente, I., & Pellathy, D. (2021). Supply chain management for circular economy: conceptual framework and research agenda. The International Journal of Logistics Management, 32(2), p. 527

Purpose of the paper. The ongoing literature review aims to describe the evolution of the CSCM research field across leading SCM/OM/logistics journals in terms of methodological and theoretical profiles, and to offer a preliminary overview of thematic clusters in the literature. Moreover, the research aims at presenting a synthesizing framework organized by loop type, SCM process, and actor, and to identify underexplored research areas and translate them into a structured research agenda.

In accordance with this purpose, the review aims to address the following research questions:

RQ1: Which themes are most frequently investigated and what research methods and theoretical lenses are most frequently adopted?

RQ2: Which circular economy loop types (closing, slowing, narrowing, intensifying, dematerializing), SCM processes reconfiguration, and actors dominate the CSCM research?

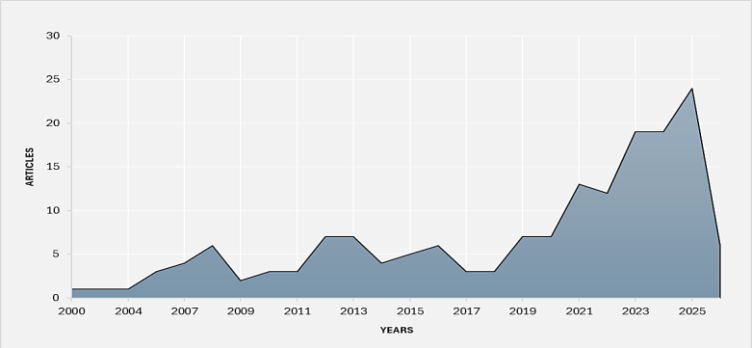
RQ3: What future research opportunities emerge from the gaps identified in the existing CSCM literature?

These research questions guide this ongoing systematic literature review.

Methodology. The systematic review process follows established SCM and operations systematic literature review guidelines (Denyer & Tranfield, 2009; Durach et al., 2017; Tranfield et al., 2003). Consistent with these guidelines, we structured the review in four steps: (i) framing our review and research questions, (ii) locating the studies through database searching, (iii) screening and eligibility assessment, and (iv) analysis and synthesis through structured coding (Seuring & Gold, 2012).

In the second step of locating the studies, we conducted searches in Scopus and the Web of Science Core Collection database. The search string combined CE and circularity terms with SCM and logistics terms. In order to ensure disciplinary comparability, the search was restricted to a predefined list of 15 core SCM and logistics journals: Journal of Supply Chain Management; Journal of Business Logistics; International Journal of Logistics Management; International Journal of Production Research; Journal of Purchasing and Supply Management; International Journal of Operations and Production Management; Journal of Operations Management; International Journal of Physical Distribution and Logistics Management; Supply Chain Management; Transportation Research Part E: Logistics and Transportation Review; European Journal of Operational Research; Production and Operations Management; International Journal of Production Economics; Decision Sciences; Operations Research.

After the journal restriction, the search was conducted applying the abstract and keywords search query using: ("circular economy" OR "circular*" OR "closed*loop" OR recycl* OR repair* OR reus* OR refurbish* OR remanufactur* OR recover*) AND ("supply chain*" OR "supply chain management" OR "SCM" OR logistics OR operations OR procurement OR manufacturing). The search was run across all published papers through February 2026 in order to capture a comprehensive representation of CLSC work. The results were then limited to peer-reviewed articles, and we excluded papers such as editorials, conference papers, and commentaries. This resulted in 2091 articles from Scopus and 2321 from Web of Science Core Collection. After removing all the duplicates, the first sample comprised 2663 articles.



For the third step, several screening processes were conducted on each of the articles to ensure they fit with the purpose of the research. The first process involved title and abstract screening, which resulted in 353 papers. The second screening process involved a full-text screening that was conducted on the remaining articles to ensure suitability and a relevant scope for the review. The inclusion criteria applied for the screening were: first, papers must engage substantively with CE-related circularity (not just using its elements as a background), and secondly, the papers must address SCM, its decisions, relationships, or processes. The exclusion criteria removed purely technical optimization or algorithm studies, studies that were outside SCM, and conceptual papers outside the scope of CSCM were also excluded. After the second screening process, the final sample resulted in 166 papers, consisting of 32 conceptual papers and 134 empirical papers.

The fourth step of coding and synthesis involved coding the papers involved capturing bibliographic information (year and journals), methods (e.g., case study and surveys), and stated theoretical lens. The content coding will focus on primary variables strictly related to CSCM, including the loop types, the SCM process, actors involved, and the themes that emerge. This coding scheme will be refined during preliminary coding to ensure clarity and consistency. The results of the bibliographic information and preliminary findings of this ongoing work are reported in the following section.

Preliminary Results. Initial descriptive patterns of our final sample are presented along with a preliminary summary and findings.

Overview of descriptive patterns. From Figure 2, the annual trend of publications is presented (from 2000 to February 2026). The sample shows a strong growth over time, with a significant increase after 2019, which is consistent with the sure of CE as a strategic and policy priority. Despite the sharp growth, the annual publication of CSCM-related studies stays below 30. The top 5 journals in which the articles were published included International Journal of Production Economics, International Journal of Logistics Management, International Journal of Production Research, Journal of Purchasing and Supply Management, and International Journal of Physical Distribution and Logistics Management.

Figure 2. Annual publications

Additionally, the main research methods applied in the articles were identified and grouped accordingly. The other category emerged from papers that used methods such as conceptual discussions with empirical illustrations, secondary use of the grey-DEMATEL technique. The findings are summarized in Table 2. Case studies account for 40.7% of the research methods used in our final sample and are the most dominant (especially qualitative case studies). This is followed by survey-based studies (often analyzed via SEM) and mixed-methods designs. Archival/secondary data studies (analyzing, for instance, national databases and sustainability reports) are also frequent in the final sample, accounting for 10.4%.

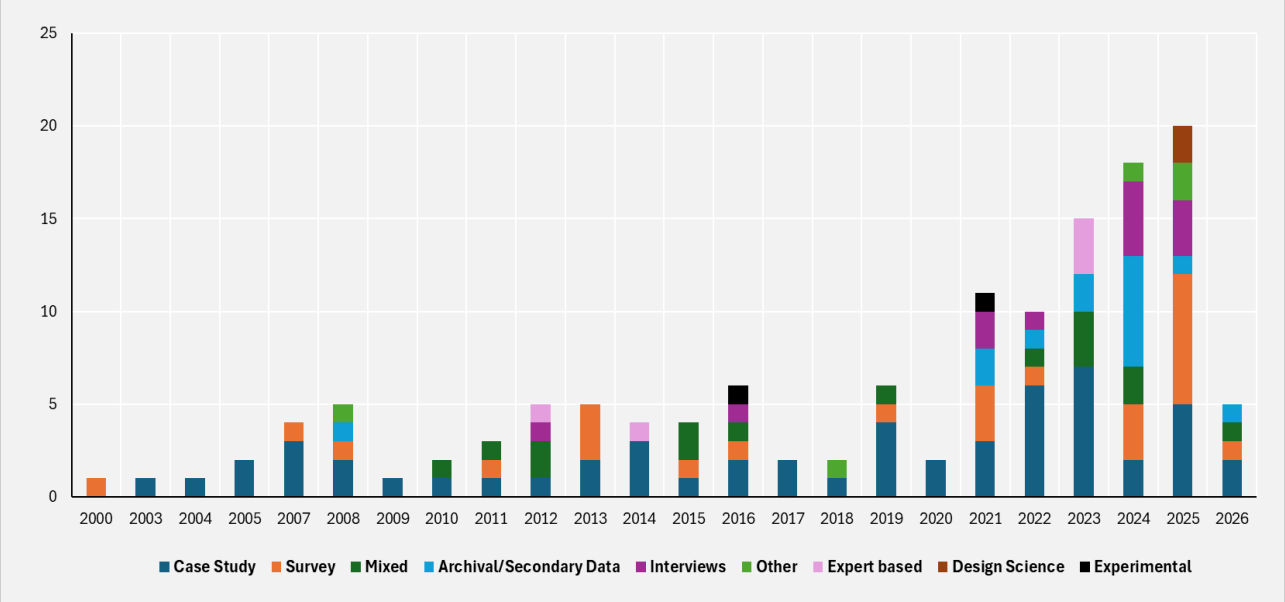


Table 2. Frequency of research methods applied

Methods	Frequency	%
Case Study	55	40.7
Survey	25	18.5
Mixed	15	11.1
Archival/Secondary Data	14	10.4
Interviews	12	8.9
Expert based	5	3.7
Other	5	3.7
Experimental	2	1.5
Design Science	2	1.5
Total	**135**	**100**

Figure 3 below provides insights into trends in the research methods used over the years, from 2000 to 2026. Case studies have remained the dominant research method, especially before 2011 with limited evidence of surveys and other

methods, and this reflects the exploratory nature of early CSCM research. After 2010, publications increased modestly and the research methods also began to widen. We observe that mixed methods and secondary data approaches started to appear more frequently, and a notable transition occurred after 2019, where there were sharp increases in annual publications and a more balanced portfolio of research methods. Although case studies remained the backbone, surveys have expanded significantly and archival/secondary data studies become more visible, especially from 2023 onwards. In addition, most of the research methods, such as interview focused studies and expert based research methods, that were largely absent in earlier years have become more noticeable in the most recent years (from 2012). Experimental and design science methods appear only from 2016 and sporadically. The chart indicates that although case studies (especially qualitative case research) continue to dominate, CSCM field is progressing toward more methodological pluralism with surveys and archival studies gaining momentum. Furthermore, newer approaches, such as design science and experimental, are beginning to enter the mainstream.

Figure 3. Research methods used over the years

Theoretical lenses. The theory use is uneven in the sample. A total of 34 theories were found, with a total frequency count of 76. Table 3 presents the top 10 theories that were used across our final sample. Among the papers that explicitly stated a theoretical lens, the frequently used theories include the resource-based view (RBV)/natural resource-based view (NRBV), which together account for 11.3%, followed by the dynamic capabilities theory, institutional theory, and the contingency theory. Additionally, some papers applied two or more theories in their studies.

Table 3. Top 10 theories used

Theory	Frequency	Percentage
Dynamic capabilities theory	8	10.7
Institutional theory	8	10.7
Contingency theory	7	9.3
Resource dependence theory	5	6.7
Resource-based view	5	6.7
Stakeholder theory	5	6.7
Natural resource-based view	4	5.3
Theory of planned behavior	4	5.3
Relational view theory	2	2.7
Signaling theory	2	2.7
Total (top 10)	**50**	**66.7**

Preliminary findings on the three-dimensional perspective. Preliminary coding shows that closing loops dominates the CSCM research, which is consistent with the historical trajectory of CLSC research (Guide & Van Wassenhove, 2009). Studies have investigated return flows, acquisition and sorting challenges, and relationship structures for collecting cores (e.g., Insanic & Gadde, 2014; Östlin et al., 2008). On the other hand, there is less research on slowing loops as phenomena such as repair and refurbishment appear less frequently and are often studied as standalone phenomena, and this suggests

an emerging but fragmented stream in CSCM (Gatenholm et al., 2021; Golinska-Dawson et al., 2025; Nilsson & Hazen, 2025). Another visible loop is narrowing loops, but studies on it tend to be concentrated in very specific contexts, such as materials packaging redesign, material efficiency, and integration of recycled content (e.g., Cozzolino & De Giovanni, 2023; Danvers et al., 2026).

Also, most upstream and downstream processes mapped by Hazen et al. (2021) are less consistently examined as circularity measures. And when these upstream and downstream processes, such as customer service management and customer supplier relationship management, do appear, they are mostly treated as supporting elements (such as collaboration, information sharing and standards) rather than as the main object of analysis, although recent papers have begun to address them explicitly (e.g., Elnourani et al., 2026; Laukkanen et al., 2026). Additionally, there is a domination of focal firms and dyadic perspectives, with multi-actor configurations being less systematically theorized. Intermediaries and platforms are slowly emerging as actors that play a role in CSCM (e.g., Do & Stevenson, 2025; Ratsimandresey & Miemczyk, 2024; Shi & Zhu, 2024). Public actors appear in many papers as regulatory pressures or infrastructural constraints, but very few studies examine the micro-mechanisms through which they co-design circular systems (e.g., Atasu & VanWassenhove, 2012; Rahman & Subramanian, 2012). These perspectives will be further coded and synthesized and will result in a final framework.

Preliminary thematic clusters. A set of thematic clusters are expected to emerge from the ongoing synthesis. From a preliminary reading of the existing research, we expect that there will be clusters which include intersection among closed-loop with returns management practices and partners such as collectors/remanufacturers/recovery partners. Another expected cluster may capture slowing loops with customer service processes and different actors involved, such as retailers and consumers. Additionally, an expected cluster may focus on narrowing loops. Additionally, an expected cluster may focus on narrowing loops with product development/redesign and procurement processes, and actors such as suppliers of recycled packaging and regulatory agencies to ensure compliance.
The clusters that would emerge after the full coding and synthesis will allow us to systematically compare where CSCM research is concentrated across the different loops, SCM processes, and actor configurations. Lastly, they will pinpoint the most underexplored clusters and combinations to inform a framework and a future research agenda.

Research limitations. This paper is a work-in-progress and thus presents preliminary findings. The corpus has been finalized through screening; however, the comprehensive coding of all texts is ongoing. The distribution and cluster boundaries will be further refined. Additionally, restricting the sample to a core journal list strengthens disciplinary coherence, nonetheless, it may underrepresent related circularity research within engineering and environmental domains. The exclusion of studies focused solely on algorithms or optimization aligns with our intended syntheses, though this may omit operational insights that are relevant for specific recovery and remanufacturing challenges. Lastly, the classification of theories is limited to what the authors explicitly state, and we acknowledge that some papers may implicitly employ theoretical assumptions without explicitly labelling them.

Managerial implications. For practitioners, our proposed three-dimensional perspective (loops*process*actors) helps avoid a narrow approach to circularity. Managers can use the synthesizing framework we expect to propose to make explicit which loop strategy is prioritized, to align the SCM processes that must change, and to anticipate which actors must be engaged and governed (for instance, platforms, intermediaries, and consumers). The implications underscore that circularity is a supply chain design and governance challenge, and that it requires decisions about which loops to enable, which processes need to be reconfigured, and which actors must be mobilized in order to make these changes happen and be durable.

Originality of the paper. This ongoing research contributes a process-oriented and actor-aware framing for CSCM, which to our best knowledge remains scarce. While prior studies synthesize practices or sectors, our approach explicitly maps the literature across circular loop types, core SCM processes, and actor configurations. The full review will provide a consolidated coding scheme usable by researchers in the field, an evidence-based identification of underexplored loop-process-actor combinations. Lastly, it will provide a research agenda oriented towards theory building and empirically testable propositions that can inform both scholarship and circular transition practice.

A conceptual framework for assessing HSE culture within the client-contractor relationship

EMILIA FILIPPI[1], DUCCIO TOSI[2], NICCOLÒ MARIA TODARO[3], FRANCESCO TESTA[4]

Abstract. *In recent decades, contracting arrangements have become increasingly widespread across industries, yet their growing use has also introduced significant health, safety, and environmental (HSE) challenges due to the complexity of managing risks across organizational boundaries. In such settings, the role of the client organization extends beyond formal monitoring and contractual control, encompassing the need to actively shape relationships with contractors and to influence the development of a shared HSE culture. However, despite the recognized importance of HSE culture in improving safety performance, previous research has provided limited insight into the specific dimensions through which HSE culture is formed, enacted, and systematically assessed within client-contractor relationships. To address this gap, this study develops a conceptual framework for assessing HSE culture in client-contractor settings. The framework is developed through an action research approach within the HSE Lab, a collaborative initiative between industry and academia aimed at co-designing and testing innovative tools to strengthen HSE management capabilities. The development process integrates a systematic review of academic and grey literature with iterative consultations involving HSE experts and practitioners from participating companies. The resulting framework conceptualizes HSE culture as a multidimensional construct composed of six interrelated dimensions (i.e., coordination and control; communication and engagement; HSE management system; anomaly management; work pressure; training and competence). It further embeds a processual perspective, capturing how HSE culture evolves across the different phases of the client-contractor relationship (i.e., before, during, and after service execution). In addition, the framework emphasizes HSE culture as a shared responsibility between the client organization and contractors. Although the framework has not yet been empirically validated in operational contexts, it provides a structured foundation for the development of practical assessment tools. By enabling a systematic understanding of HSE culture across organizational boundaries, the study contributes to both theory and practice, supporting more effective, process-oriented, and culturally informed contractor management.*

Keywords: *Client organization; Contractors; HSE culture; Framework*

Framing of the research. *In recent decades, the use of contracting arrangements, i.e., defined as situations in which an organization outsources specific activities or services to external companies through formal contractual agreements, has expanded significantly across many industries (Nunes 2012). This trend is driven by several factors, including organizations' focus on core business activities, the need to access specialized expertise and equipment, the flexibility required to address temporary operational needs and market fluctuations, cost efficiency considerations, the externalization of less profitable or more hazardous activities, and the opportunity to leverage local knowledge when operating in specific geographical contexts (Alary 2006; Manu et al. 2009).*

However, while contracting arrangements can provide important organizational and economic advantages, they also introduce some managerial and operational challenges. The involvement of multiple contractors within the same operational environment increases the complexity of coordination and oversight (Alary 2006; Dale et al. 2020). Contractors often bring their own operational practices, processes, and risk profiles, which interact with those of the client organization and other contractors operating on the same site (Bahn 2012). Managing such complex arrangements is further complicated by the structure of contracting networks: contractors may not be clearly identified, sometimes they provide services intermittently, and operate with limited visibility (Alary 2006). This fragmentation can make it difficult for client organizations to maintain a comprehensive overview of contractor activities and may lead to duplication of monitoring efforts in order to ensure adequate service quality and compliance with organizational requirements (Alary 2006).

These challenges become particularly critical when considering health, safety, and environmental (HSE) issues (Lingard and Oswald 2020; Todaro et al., 2023), due to several reasons. Contractual arrangements often rely on payment systems linked to the completion of specific tasks rather than the time spent performing them (Manu et al. 2009). As a result, contractors may face strong incentives to complete work as quickly as possible, sometimes leading to excessive working hours or the reduction of safety precautions when these are perceived as slowing down production (Manu et al.

2009; Lingard and Oswald 2020). Contractors' employees usually work in unfamiliar situations and may be exposed to unknown hazards (Nunes 2012). The involvement of smaller firms within subcontracting chains can create resource constraints, limiting the ability of some contractors to invest in adequate HSE management systems (Dale et al. 2020; Dale et al. 2021). Moreover, complex contracting arrangements may generate ambiguity regarding roles and responsibilities for HSE management, particularly when multiple organizations operate simultaneously on the same site (Manu et al. 2009; Nunes 2012). Fragmented communication, limited collaboration among contractors, and differences in safety culture between the client organization and contractors can further complicate the effective management of HSE risks (Manu et al. 2009).

As the entity that finances and commissions the project, the client organization occupies a strategic position that enables it to influence the commitment of contractors toward HSE (Lingard et al. 2020). By defining key project requirements (e.g., schedule, budget, and performance expectations), the client organization establishes operational constraints that can directly affect both occupational HSE conditions and the occurrence of safety incidents (Smallwood 2017; Harvey et al. 2018). For this reason, the client organization should assume greater responsibility for HSE in the projects it procures (Winkler 2006; Smallwood 2017). Indeed, a careless or indifferent attitude by the client organization can negatively influence safety standards across all organizations involved in the project (Lingard et al. 2020). Conversely, active client involvement is associated with improved HSE performance: when the client organization demonstrates genuine interest and concern for HSE issues, contractors are more likely to maintain high standards, even if only to meet client expectations (Wu et al., 2015; Lingard et al. 2020).

The client organization's influence can manifest across multiple phases of the relationship with contractors. In the early stages, such as prequalification and contractor selection, the client organization can contribute to risk prevention by selecting contractors with strong safety records, verifying technical competence, and ensuring adequate resources for safety management (Nunes 2012; Abdul Razak et al., 2021; Umeokafor, 2017). Contractor evaluation may combine lagging indicators, which measure outcomes of past events (e.g., injuries or fatalities), and leading indicators, which capture proactive elements of safety management that can signal potential weaknesses before accidents occur (Liang et al., 2018). The client organization may also include service-specific HSE annexes in contractual agreements to clearly define requirements and expectations (Alary, 2006). Finally, the client organization can conduct analyses of contractors' capabilities or plan activities in advance (Karakhan et al. 2018). During later phases of the relationship, the client organization can classify contracted services according to risk level, prioritize control measures, and implement standardized audits to monitor contractors' compliance and performance (Alary, 2006). In addition, the client organization may require specific HSE procedures, define safety objectives, provide guidelines, and promote the integration of HSE considerations throughout operational activities (Umeokafor, 2017). In these activities, both output and process controls can be used. Output controls involve defining performance targets, such as injury or incident frequency rates, and monitoring contractors' achievement of these targets (Lingard et al. 2020). Instead, process controls involve direct intervention in organizational practices by specifying the procedures and management systems contractors must adopt to achieve project objectives (Eriksson and Laan, 2007).

However, the effectiveness of control mechanisms is limited if they are not complemented by activities that promote trust, collaboration, and a shared commitment to HSE (Lingard et al. 2020; Umeokafor 2017). The client organization seeking to influence HSE performance must operate across organizational boundaries, foster collaborative relationships with contractors, and influence their employees' safety-related behaviors (Lingard and Oswald 2020; Lingard et al. 2020; Ajayi et al. 2022). To this end, the client organization can engage in relationship-building activities (Lingard et al. 2020; Umeokafor 2017) and support the development of contractors' HSE management systems (Dale et al. 2021). In addition, the client organization can intervene at the level of HSE culture, defined as the shared perceptions of workers regarding safety policies, procedures, and practices within an organization at a given point in time (Zohar 2003; Casey et al. 2017). Previous research highlights the role of HSE culture in improving both HSE management and performance in contractor-based projects (Wu et al. 2012; Zhang and Chen 2015; Dale et al. 2020). In particular, the client organization's HSE culture has been found to have an indirect positive effect on overall project HSE performance, mediated through the HSE performance of contractors (Musonda et al. 2012).

Overall, the literature suggests that the client organization's role extends beyond formal oversight; it is central not only to shaping a positive HSE culture within the client-contractor relationship but also to actively promoting and sustaining it. By collaborating closely with contractors, the client organization can cultivate an HSE culture that permeates all levels of contractor operations while simultaneously strengthening HSE practices within both the contractors and the client organization itself.

Purpose of the paper. *Managing HSE in contractor-based and multi-actor settings remains a critical challenge, as recurring and interrelated issues (e.g., fragmented responsibilities, heterogeneous practices, and coordination difficulties) increase the likelihood of ambiguity, unsafe behaviors, and inadequate risk control. These challenges are particularly relevant because contractors' HSE practices directly affect not only project-level safety outcomes but also the overall performance and risk exposure of the client organization. In response, prior research has emphasized the need to move beyond compliance-based approaches toward more integrated and proactive forms of HSE management, highlighting the importance of interactions, coordination, and alignment of behaviors across organizational boundaries. Within this perspective, HSE culture has been increasingly recognized as a key lever for improving HSE performance in contractor-based projects (Wu et al., 2012; Zhang and Chen, 2015; Dale et al., 2020).*

However, despite this growing recognition, existing research has paid limited attention to how HSE culture can be systematically understood, assessed, and managed within the client-contractor relationship. In particular, there is still a lack of conceptual and operational frameworks that identify the key dimensions through which HSE culture manifests across organizational boundaries and that support organizations in actively strengthening it. This represents both a research gap and a managerial gap, as client organizations currently lack structured tools to evaluate and improve their ability to influence HSE culture beyond their own organizational boundaries.

Against this background, the purpose of this study is to advance the understanding of HSE culture in client-contractor settings by identifying its key dimensions and developing a structured framework to support its assessment and management. The resulting framework is designed to capture both the perceptions of the client organization and those of contractors, enabling a comprehensive evaluation of how HSE culture is promoted, perceived, and enacted across organizational boundaries. In doing so, the study provides a foundation for the development of practical tools aimed at strengthening HSE practices throughout the project supply chain.

Methodology. *This study adopts an action research approach, as it is particularly suitable for investigating complex, practice-based phenomena that unfold across organizational boundaries and require close interaction between researchers and practitioners. In the present study, the aim is not only to conceptualize HSE culture in the client-contractor relationship but also to ground this conceptualization in real organizational practices and challenges. Action research is therefore appropriate as it enables the co-development of context-sensitive knowledge while simultaneously addressing a relevant managerial problem, namely, how to understand and strengthen HSE culture across organizational boundaries (Bradbury, 2015; Brydon-Miller & Coghlan, 2014).*

To ensure methodological rigor, the study was designed in line with the four key elements of action research identified by Shani and Pasmore (2016):

1. *Context is critical because action research generates localized theory through localized action. Understanding the context in which action takes place (e.g., external business and social environment, internal organizational setting) is therefore essential;*
2. *Quality of relationships represents a fundamental condition for effective action research. Productive collaboration between researchers and practitioners depends on various factors, such as the development of trust, open dialogue, and a shared language;*
3. *Quality of the action research process concerns the integration of action and inquiry. The research process should be both rigorous and reflective, enabling participants to engage in systematic analysis while simultaneously addressing practical organizational challenges. This process supports the development of deeper understanding and meaning around the issues under investigation;*
4. *Outcomes represent a defining feature of action research, which includes improved organizational practices, the development of capabilities, and the generation of new knowledge.*

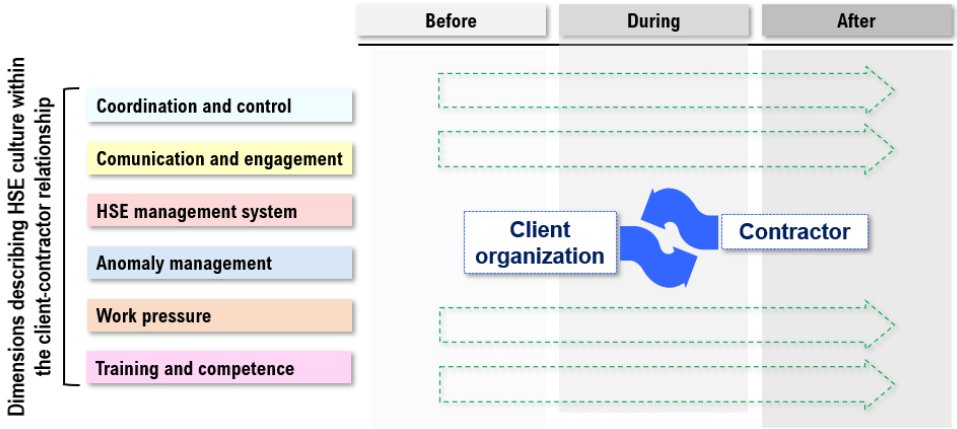
These four key elements of action research were explicitly operationalized in this research setting.

First, context was addressed by embedding the study within the Health, Safety and Environment Laboratory (HSE Lab), a collaborative initiative between companies and academia aimed at co-designing, developing, and testing innovative approaches and tools to strengthen organizations' managerial and organizational capabilities in addressing HSE challenges. The HSE Lab involves 37 HSE practitioners, mainly middle- and senior-level managers, from 16 large Italian companies operating across different economic sectors and frequently relying on contractors in their operational activities. This setting provided access to diverse organizational contexts characterized by complex contractor networks, allowing the framework to capture challenges and practices that are common across industries while remaining grounded in real-world conditions.

Second, the quality of relationships was actively fostered through sustained interaction between researchers and practitioners over time. Rather than assuming trust as a given, the research design relied on repeated engagement through formal workshops, joint discussions, and iterative feedback sessions. The long-term participation of several companies (some involved since the establishment in 2017) facilitated the progressive development of trust, a shared language around HSE issues, and openness in discussing critical practices and challenges. This relational continuity enabled participants to provide candid insights and contributed to the depth and reliability of the data collected.

Third, the quality of the action research process was ensured through a structured and iterative combination of data collection and analysis activities. The study followed three main steps.

- *(i) A literature review was conducted using the Web of Science database with keywords such as "HSE", "safety culture", "safety climate", "supply chain", and "contractors". This search resulted in 18 relevant academic contributions, which were complemented by eight documents from the grey literature, including reports and guidelines produced by governmental organizations, consulting bodies, and industrial associations (e.g., the European Agency for Safety and Health at Work, Health and Safety Executive). These sources were used to identify initial themes and dimensions related to HSE culture in multi-actor settings.*
- *(ii) To integrate and contextualize these insights, five HSE experts (i.e., HSE consultants and specialists from companies participating in the HSE Lab) were interviewed for a total of 2.5 hours. The interviews were semi-structured and focused on identifying critical factors influencing HSE culture in client-contractor relationships, as well as practical challenges in managing such relationships.*



(iii) The collected materials (literature and interview transcripts) were analyzed to identify recurring themes and clustering them into conceptual dimensions. This process led to the identification of 12 preliminary dimensions, i.e., evaluation and control, coordination and cooperation, communication, engagement, awareness, HSE management system, documentation system, complexity management, anomaly management, work pressure, training and competence, and work stability and continuity.

These dimensions were then refined through a validation phase involving a second consultation with seven HSE experts and further discussions within the HSE Lab. During this phase, participants were asked to assess the relevance, clarity, and completeness of each dimension, as well as to identify potential overlaps. Based on this feedback, some dimensions were merged and redefined.

Finally, outcomes were ensured by producing both theoretical and practical contributions. The main outcome of the research is a conceptual framework that integrates multiple dimensions of HSE culture within the relationship between client organizations and contractors, and considers their evolution across different phases of the client-contractor relationship. At the same time, the framework provides the basis for the development of operational tools to support organizations in assessing and improving HSE culture in practice. The resulting framework is presented in the Results section.

Results. *The preliminary framework for assessing HSE culture within the client-contractor relationship is presented in Fig 1.*

Fig 1. Framework describing the relationship between client organizations and contractors

Source: Our elaboration

The framework is characterized by three main elements.

First, the HSE culture within the client-contractor relationship is conceptualized as a multidimensional construct. This approach acknowledges the inherent complexity of managing HSE across organizational boundaries and recognizes that multiple dimensions interact to collectively influence HSE performance. For this reason, six dimensions are identified to capture the various manifestations of a positive HSE culture in the client-contractor relationship (Table 1). These dimensions regard coordination and control mechanisms, communication and engagement processes, the effectiveness of HSE management systems, the management of anomalies, work pressure, and the development of training and competencies.

Second, the framework highlights the temporal dimension of the client-contractor relationship, suggesting that a positive HSE culture develops throughout the entire lifecycle of the relationship. In particular, three main phases are identified. The "before" phase includes activities and practices that characterize the preliminary relationship between the client organization and the contractor prior to the start of the work, such as supplier qualification processes, the definition of tender criteria, the inclusion of HSE clauses and technical specifications in contracts, and preliminary controls. The "during" phase refers to the manifestations of HSE culture during the execution of the service, including monitoring activities, training initiatives, awareness-raising actions, and coordination among the different actors involved in the operational process. The "after" phase concerns the manifestations of a positive HSE culture following the completion of the service and the conclusion of the contractual relationship, such as post-project feedback, final evaluation reports, recognition of good performance, and the development of long-term partnerships.

Finally, the framework emphasizes that HSE culture should be understood as a shared responsibility between the client organization and contractors. In contractor-based settings, HSE outcomes are not determined solely by the actions of a single organization *but emerge from the interactions, coordination mechanisms, and shared practices established between the parties. For this reason, both the client organization and contractors are expected to actively cooperate in promoting safe and environmentally responsible practices, each contributing according to their respective roles,*

responsibilities, and competencies. Through continuous collaboration, both parties can strengthen HSE culture across organizational boundaries and contribute to improving overall HSE performance.

Tab 1. Dimensions *describing HSE culture* within the client-contractor relationship

Dimension	Description
Coordination and control	This dimension assesses the quality and effectiveness of the evaluation, control, and monitoring activities carried out toward contractors, as well as the coordination and cooperation initiatives established between the parties. These initiatives aim to clarify the objectives of the relationship, expected outcomes, operational procedures, timelines, and tools, thereby reducing risks associated with uncertainty, misunderstandings, operational interferences, and limited knowledge of site-specific activities.
Communication and engagement	This dimension captures the quality and effectiveness of communication processes and initiatives aimed at engaging and raising awareness among contractor personnel on HSE issues. It concerns the exchange of information between client organizations and contractors, including openness to communication, the ease of transmitting and receiving information, and the potential presence of barriers such as linguistic, cultural, or organizational differences.
HSE management system	This dimension examines the quality and effectiveness of the systems adopted by both client organizations and contractors in ensuring positive HSE performance. In particular, it considers the ability of these systems to address interference risks, emergencies, unexpected events, and organizational changes, as well as the quality, completeness, clarity, and accessibility of the relevant HSE documentation.
Anomaly management	This dimension evaluates the quality, effectiveness, and timeliness of HSE safeguard actions implemented in response to regulatory or contractual non-compliance, as well as accidents or near-miss events. This dimension includes the processes of identifying and analyzing non-conformities or incidents, defining corrective actions, implementing them, and assessing their effectiveness through follow-up activities.
Work pressure	This dimension captures the pressure exerted on contractors' HSE performance by additional operational requirements linked to production objectives, such as cost containment, tight deadlines, and demanding work rhythms in the presence of complex tasks.
Training and competence	This dimension evaluates the presence of the technical and soft skills required to improve HSE performance, as well as the quality and effectiveness of training initiatives beyond mandatory requirements aimed at developing the competencies needed to raise awareness of HSE issues among contractor personnel.

Research limitations. *While the proposed framework for assessing HSE culture within the client-contractor relationship has been rigorously developed and preliminarily validated through consultations with HSE experts, some limitations should be acknowledged. First, the framework has not yet been empirically tested in real-world operational settings. Therefore, its practical applicability and reliability in capturing the quality of HSE culture within the client-contractor relationship remain to be assessed. Moreover, although the framework was developed based on academic literature, grey literature, and expert input, it remains possible that additional dimensions of HSE culture relevant to the client-contractor relationship have not yet been captured. To address these limitations, three complementary instruments are currently being developed within the HSE Lab: (i) a questionnaire to be administered to a sample of workers from both client organizations and contractors, (ii) a checklist to support the assessment of HSE culture during audits, and (iii) an interview protocol designed to guide discussions between client organizations and key contractor personnel (e.g., employee safety delegates). The application of these instruments in real contexts will enable the empirical validation of the framework. In particular, it will allow the assessment of its applicability, reliability, and robustness, while also providing the opportunity to address current limitations and, if necessary, further refine the model based on evidence emerging from real-world practices.*

Managerial implications. *The proposed framework provides a conceptual map of the key dimensions through which HSE culture is shaped within client-contractor relationships. It enables organizations to better understand, monitor, and enhance HSE culture in contractor management, offering a lens to identify strengths and weaknesses in how HSE is promoted across organizational boundaries.*

When combined with the operational tools currently under development (i.e., a questionnaire, an audit checklist, and an interview protocol), the framework enables organizations to systematically evaluate the practices, actions, and initiatives implemented within the client-contractor relationship and to identify which dimensions of HSE culture require further strengthening. In this way, the framework can support organizations in promoting HSE culture beyond their own organizational boundaries and across the contractor network, offering guidance for continuous improvement and more informed strategic decision-making in contractor management. Once developed, the operational tools will facilitate the practical application of the framework and enable more structured and evidence-based assessments.

When combined with the operational tools currently under development (i.e., a questionnaire, an audit checklist, and an interview protocol), the framework enables organizations to systematically evaluate the practices, actions, and initiatives implemented within the client-contractor relationship and to identify which dimensions of HSE culture require further strengthening. In this way, the framework can support organizations in promoting HSE culture beyond their own organizational boundaries and across the contractor network, offering guidance for continuous improvement and more

informed strategic decision-making in contractor management. Once developed, the operational tools will facilitate the practical application of the framework and enable more structured and evidence-based assessments.

The framework and the operational tools are designed to be complementary to existing normative, managerial, and organizational instruments used for contractor selection, management, and oversight. By integrating them into routine management practices, the client organization can move beyond compliance-focused interventions toward a more proactive and culture-oriented approach that promotes shared responsibility for HSE performance within the client-contractor relationship. In particular, the framework and its tools can support auditing processes by complementing existing monitoring and control mechanisms.

Moreover, the framework and the operational tools enable both vertical and horizontal assessment approaches of HSE culture. A vertical approach allows managers to conduct in-depth diagnostics of HSE culture within a specific site, operational area, or business unit by engaging a representative sample of contractor personnel. This approach helps reveal local practices, potential bottlenecks, and areas for improvement that may not emerge from aggregated performance indicators. Conversely, a horizontal approach provides a broader overview of HSE culture across multiple sites or business areas, typically by surveying a limited set of respondents or key informants (e.g., HSE officers or employee safety representatives). This perspective is particularly useful for identifying systemic patterns and benchmarking HSE culture across different organizational contexts. The possibility of applying the framework through these two complementary assessment approaches enhances its usefulness as a tool for both detailed diagnostics and strategic oversight, enabling a more comprehensive understanding of HSE culture across the client-contractor relationship.

Originality of the paper. *This study develops a conceptual framework for assessing HSE culture within client-contractor relationships, addressing a relevant but still underdeveloped area in the literature. While previous research has widely recognized the importance of HSE culture in improving safety performance in contractor-based and multi-actor projects (Wu et al., 2012; Zhang and Chen, 2015; Dale et al., 2020), it has largely focused on its general relevance, without sufficiently unpacking how such culture is actually structured, operationalized, and enacted across organizational boundaries. As a result, there is still limited understanding of the specific dimensions through which HSE culture emerges in inter-organizational settings and of how it can be systematically assessed within supply chain relationships.*

The framework proposed in this study addresses this gap by conceptualizing HSE culture as a multidimensional and relational construct embedded in client-contractor interactions. By identifying six interrelated dimensions, it offers a structured analytical lens to capture how HSE culture is shaped. In doing so, the framework moves beyond a monolithic view of HSE culture and provides a more granular understanding of its multiple manifestations in contractor-based environments.

In addition, the framework introduces a processual perspective by explicitly considering the temporal development of HSE culture across the lifecycle of the client-contractor relationship. This allows for a more dynamic interpretation of how cultural influences are established before work execution, enacted during operations, and consolidated (or weakened) after project completion.

Finally, the framework advances a relational and supply chain-oriented view of HSE culture, emphasizing that safety performance does not originate within a single organization but emerges from interdependencies between clients and contractors. In this sense, it reframes HSE culture as a cross-boundary phenomenon shaped through ongoing interaction, rather than an internal organizational attribute.

Although the framework has not yet been empirically validated in operational contexts and further dimensions may emerge through future applications, it provides a necessary conceptual foundation for moving from general claims about the importance of HSE culture to its structured assessment in real client-contractor systems. By doing so, it offers both a research agenda for future empirical work and a practical basis for developing tools aimed at improving HSE management across supply chains.

A demand and supply analysis of environmental externalities and firms' zero debt policy

ANTONIO RENZI*, PAOLO SAONA HOFFMANN** AND GIANLUCA VAGNANI***

Abstract. *Zero-leverage firms remain a puzzle in business studies. Traditional views focus on demand factors like financial flexibility or credit constraints, often conflating these elements (Strebulaev & Yang, 2013; Morais, Serrasqueiro & Ramalho, 2020). This research presents a supply-side mechanism linking environmental externalities to access to debt. Based on the 'brown premium' in equity markets (Bolton & Kacperczyk, 2021), creditors favor firms with high negative externalities because of strong cash flows, whereas they discount sustainable firms with high initial costs. This creates a supply constraint that precludes leverage for environmentally friendly firms. Using a bivariate probit model on 1,022 firms across 54 countries from 2011-2022, the results show that environmental impacts significantly reduce debt availability, especially for firms with low externalities. The study highlights the importance of joint demand-supply estimation to mitigate bias (Saona, San Martín & Vallelado, 2024), suggesting that capital markets may penalize green firms through debt rationing.*

Keywords: *Environmental externalities; zero-leverage firms; panel data; bivariate probit model; brown premium*

Framing of the research. The persistent and economically significant presence of firms with zero debt on their balance sheets—the so-called "zero-leverage puzzle"—remains a challenging anomaly in business research. Traditional theories of capital structure have difficulty explaining why many publicly traded companies forgo the tax benefits of debt (Strebulaev & Yang, 2013). Research offers explanations based on a dual-perspective framework that includes both firm-demand perspectives (such as managerial conservatism or high profitability) and creditor-supply reasons (including information asymmetry or a lack of collateral) (Morais, Serrasqueiro & Ramalho, 2020; Ebrahimi, Gupta & Ozkan, 2020). In these studies, the zero-debt scenario is a corner solution representing the joint equilibrium of a firm's desire to borrow and the financial system's willingness to lend.

Building on this dual-perspective framework, we introduce a novel supply-side mechanism centered on environmental externalities. Evidence of a "brown premium" shows that firms with significant negative externalities exhibit stronger short-term performance (Bolton & Kacperczyk, 2021). We argue this creates a temporal mismatch in credit risk assessment. For creditors with short-term horizons, "brown" firms appear appealing due to robust current cash flows, which signal high debt-servicing capacity—even if their activities entail higher future transition risks. Conversely, sustainable firms incur high upfront costs that depress short-term profitability, making them seem riskier under conventional assessment, despite lower long-term vulnerability. Consequently, a firm's environmental profile may act as a powerful filter, reducing debt supply for sustainable firms and pushing them toward zero leverage.

This mechanism creates a counterintuitive supply-side incentive: activities that increase future transition risks—such as exposure to carbon pricing, regulatory tightening, and asset stranding—can enhance short-term creditworthiness and, simultaneously, raise the potential profitability of lending. By contrast, firms that invest in sustainable practices typically incur high upfront costs, which depress short-term profitability and make them appear riskier under conventional credit assessments, even though they are less vulnerable in the long run. We therefore hypothesize that firms with lower environmental impacts are substantially less likely to obtain debt, increasing their probability of operating with zero leverage.

It is important to distinguish our approach from existing literature on ESG and debt financing. Recent studies find that higher ESG performance increases debt supply, concluding that creditors view high ESG scores favorably as signals of lower risk and better management (Morais, Ferreira, Marques & Ramalho, 2025). This presents a puzzle when contrasted with the evidence of a "brown premium" in equity markets (Bolton & Kacperczyk, 2021). We argue this apparent contradiction stems from a fundamental measurement disconnect: ESG scores measure corporate sustainability ratings, disclosure efforts, and policies, whereas our study relies on the concept of monetized environmental externalities, which quantifies the actual negative societal cost of a firm's operations (Freiberg, Park, Serafeim & Zochowski, 2021; Saona, Renzi, Vagnani & Taragoni, 2025). A firm can have a high ESG score while still generating significant negative environmental externalities, and conversely, a "green" firm might have a lower ESG score due to poor disclosure but create minimal actual damage. Our study tests the debt market's response to actual environmental impact, not sustainability signaling.

Purpose of the paper. This study investigates the zero-leverage puzzle through the lens of environmental externalities, employing a theoretical model and, empirically, a bivariate probit model to disentangle debt demand from supply. Our

objective is to test whether environmental impact acts as a supply-side constraint that pushes sustainable firms toward zero leverage.

Testing this supply-side hypothesis requires a methodology that disentangles latent demand and supply decisions, which are conflated in the observed zero-leverage outcome (Meng & Schmidt, 1985). Moving beyond single-equation approaches that risk conflation (Saona, San Martín & Vallelado, 2024), we employ a bivariate probit model with partial observability (Poirier, 1980). This method is critical: as our results demonstrate, the environmental impact variable is statistically insignificant in a standard univariate probit model but emerges as a strong negative determinant of debt supply in the bivariate framework.

We test our hypotheses using a global sample of 1,022 non-financial firms from 54 countries over the period 2011-2022, comprising 4,471 firm-year observations. Our analysis reveals three key findings that resolve the empirical conflation problem. First, environmental externalities exert a strong, statistically significant negative effect on debt supply—a result that is masked by conventional univariate probit models. Firms with lower environmental impact (higher sustainability) are substantially less likely to obtain debt, directly increasing their probability of zero leverage. Second, this supply-side constraint is moderated by firm maturity: the negative effect of environmental sustainability on credit access is significantly more pronounced for younger, growth-oriented firms (Lefebvre, 2021; Lundberg & Lotfaliei, 2020). Third, we disentangle conflicting forces in the leverage decision, showing that while high market valuation (Tobin's Q) reduces a firm's demand for debt (consistent with financial flexibility), it simultaneously increases creditors' supply of debt.

Our contribution is twofold: methodologically, we enhance the capital structure literature by employing a model that directly addresses identification issues associated with corner solutions (Morais, Serrasqueiro & Ramalho, 2020). The bivariate probit model allows us to explicitly distinguish between the determinants of the firm's decision associated with the demand for debt and those that restrict access to debt (Saona, San Martín & Vallelado, 2024). Theoretically, we advance a more nuanced understanding of the zero-leverage policy by disentangling the debt decision into demand- and supply-side considerations. Specifically, we propose and test a supply-side mechanism that links environmental transition risks to core financing results, with important implications for understanding how capital markets can both support and impede the shift to a sustainable economy.

Methodology. Our empirical approach employs a bivariate probit model with partial observability, as developed by Poirier (1980). This method is particularly appropriate for addressing the issue of partial observability, which arises because the observed debt outcome reflects the joint decision made by both fund suppliers and firms seeking external financing (Morais, Serrasqueiro & Ramalho, 2020). Unlike a standard univariate probit model, which cannot disentangle whether the observed debt outcome results from demand-side or supply-side factors, the bivariate probit model captures both decision processes.

We define two binary outcomes: y1 = 1 if the firm seeks debt and 0 otherwise; y2 = 1 if the creditor grants credit and 0 otherwise. The probability that a firm carries debt is Pr[y = 1] = Pr[y1* > 0, y2* > 0]. The model is estimated via maximum likelihood, and identification requires that at least one variable in the demand equation is excluded from the supply equation, or vice versa (Poirier, 1980).

The dependent variable, NZL, is a dummy that equals one if the firm carries debt and zero if it is completely unleveraged, consistent with Ramalho, Rita and da Silva (2018) and Strebulaev and Yang (2013). As a robustness check, we also define an alternative dummy variable, NZL5, for firms with debt levels below 5% (Huang, Li & Gao, 2017).

Environmental impact is measured as the monetized value of corporate environmental externalities from the Impact-Weighted Accounts dataset (Harvard Business School), scaled by total assets (EI1) (Freiberg, Park, Serafeim & Zochowski, 2021; Serafeim, Zochowski & Downing, 2019). As alternative specifications, we compute environmental impact relative to sales (EI2) and to operating income (EI3) (Saona, Renzi, Vagnani & Taragoni, 2025). These variables when positive (negative) imply positive (negative) environmental impact.

Firm value is proxied by Tobin's Q (FV), calculated as the sum of market capitalization and total liabilities divided by total assets according to Chung and Pruitt (1994). The firm's life-cycle stage is constructed following Anthony and Ramesh (1992) and Saona, San Martín and Vallelado (2024) as LifeCycle = (1 + Div)*(1 + SalesGrowth)*(1 + CAPEX), where lower values indicate mature firms and higher values characterize growth-oriented firms.

Firm size (Size) is measured as the natural logarithm of total assets. Asset tangibility (Tang) is net property, plant, and equipment divided by total assets. Profitability (ROA) is net income over total assets. Default risk is captured using the Altman Z-Score (Altman, 1968). The non-debt tax shield (NDTS) is measured as annual depreciation over total assets (Graham, 2000). Financial reporting quality is proxied by the StarMine earnings quality score (Transp) (Cline, Williamson & Xiong, 2021; Saona, Muro & López-Quesada, 2025). Liquidity (Liquid) is measured using the current ratio. External governance and information environment quality are proxied by the number of sell-side analysts covering the firm's stock (Analysts), following He, Ren and Taffler (2020).

For model identification, we include PrivateCreditGDP—a country-level measure of financial development—only in the supply equation (Morais, Serrasqueiro & Ramalho, 2020; Saona, San Martín & Vallelado, 2024). This exclusion restriction is theoretically grounded: while national credit market depth affects lenders' willingness to lend, it does not directly influence an individual firm's desire for debt once other firm-level characteristics are controlled for.

The sample consists of 1,022 non-financial firms from 54 countries over the period 2011-2022, resulting in 4,471 firm-year observations. A minimum of four consecutive annual observations per firm is required, with an average of 4.37

observations per firm (Arellano & Bond, 1991; Baltagi, 2013). Financial institutions are excluded because of their regulatory status and divergent financial reporting standards. Financial and accounting data are sourced from the LSEG Workspace database, and environmental impact valuation metrics are drawn from the Impact-Weighted Accounts Project.

Results. The descriptive statistics reveal that approximately 9% of firms in the sample operate with zero debt. The average value of environmental impact scaled by total assets (EI1) corresponds to a monetized externality equivalent to 7.25% of total assets, with negative values reflecting adverse environmental externalities. The average Tobin's Q is 1.50, indicating generally positive market valuation. Firms exhibit comfortable liquidity positions, with current assets exceeding current liabilities by approximately 48% on average. Tangible assets account for nearly 32% of total assets, while average profitability is 5.20%. Mean-difference tests show that unlevered firms tend to exhibit lower environmental impact, higher market valuation, greater liquidity and profitability, lower default risk, and higher earnings quality than levered firms. They are also younger on average, consistent with Lefebvre (2021) and Lundberg and Lotfaliei (2020).

The bivariate probit model reveals a positive and statistically significant estimated correlation coefficient ($\rho = 0.696$, $p < 0.01$) between the error terms of the demand and supply equations, confirming the presence of correlated unobserved factors and justifying the joint estimation framework (Poirier, 1980). The estimated intra-class correlation coefficient in the standard univariate probit results ($\rho = 0.794$) suggests that nearly 80% of the total variance in the latent propensity to maintain zero leverage is attributable to firm-specific unobserved heterogeneity.

The comparison between the two approaches reveals substantial differences. In the bivariate probit model, firms with higher environmental impact (EI1) are significantly less likely to be zero-leverage from the supply side, with a coefficient of -7.112 ($p < 0.01$). This finding is consistent with the "brown premium" documented in equity markets (Bolton & Kacperczyk, 2021): firms that generate higher negative externalities tend to exhibit stronger short-term cash flows, making them more attractive to creditors. In contrast, firms investing in sustainability face higher upfront costs, which depress short-term profitability and reduce their appeal under conventional credit assessments (Chava, 2014). Importantly, this effect is not detected in the conventional univariate probit model, where EI1 is statistically insignificant, illustrating the limitations of standard models and confirming the importance of the bivariate approach (Meng & Schmidt, 1985).

The marginal effects analysis shows that a one-standard-deviation increase in EI1 (0.148) is associated with a statistically significant decrease of 0.894 percentage points in the probability of obtaining debt when sought. Firms with lower environmental externalities face a 6.04 percentage point higher probability of being credit-constrained (Pr(y1=1, y2=0)), while the probability of successful debt financing (Pr(y1=1, y2=1)) decreases by a corresponding 6.04 percentage points.

The firm life cycle exhibits consistent effects across both modeling approaches. Younger and early-stage firms are more likely to remain debt-free, reflecting limited reputation, weaker collateral, and greater reliance on internal financing (Berger & Udell, 1998; Diamond, 1989). The marginal effects indicate that a one-standard-deviation increase in LifeCycle (0.337) reduces the probability of having debt by 0.452 percentage points.

Firm value exhibits asymmetric effects. From the demand side, firms with higher market valuation are less likely to shift from a debt-free to a debt-financed structure (coefficient -0.511, $p < 0.01$), consistent with financial flexibility motives. From the supply side, however, creditors are more willing to extend credit to high-valuation firms (coefficient 1.339, $p < 0.01$). The marginal effects show that high-valuation firms are 0.69 percentage points more likely to obtain debt when sought, yet simultaneously 1.18 percentage points less likely to demand it. This dual effect is not observable in univariate models and supports the financial flexibility hypothesis (Morais et al., 2021).

Firm size positively affects the likelihood of holding debt (coefficient 0.341, $p < 0.01$), driven primarily by supply-side factors, consistent with the greater ease with which larger firms access credit markets (Gregory, Rutherford, Oswald & Gardiner, 2005). Capital expenditure, treated as a demand-side variable, positively affects leverage with a coefficient of 20.264 ($p < 0.01$), indicating that expanding firms are more likely to use external financing. Default risk also plays a significant role: as firms become safer (higher Z-scores), the likelihood of remaining debt-free increases (coefficient -0.081, $p < 0.01$), suggesting a substitution of equity for debt. Non-debt tax shields influence debt demand rather than credit supply (coefficient 22.031, $p < 0.01$), with firms having higher depreciation reducing their reliance on debt tax shields, consistent with Graham (2000). The proxy for credit rationing, PrivateCreditGDP, enters positively and significantly on the supply side (coefficient 0.011, $p < 0.01$), indicating that firms in more developed credit markets face fewer financing constraints (Faulkender & Petersen, 2006).

Robustness checks using alternative environmental impact measures confirm these findings. When environmental impact is scaled by sales (EI2), the supply-side coefficient is -26.033 ($p < 0.01$), and when scaled by operating income (EI3), it is -0.113 ($p < 0.05$). Interaction analyses reveal that the effect of environmental externalities is heterogeneous by firm maturity (Brambor, Clark & Golder, 2006). The positive coefficient on EI2 × LifeCycle (8.381, $p < 0.01$) indicates that the negative effect of environmental impact on debt supply is attenuated for younger firms. For early-stage companies, strong cash flows associated with higher environmental impact may partially offset the "liability of newness," making them relatively more attractive to short-term oriented creditors (Diamond, 1989).

When using ESG environmental scores instead of monetized externalities, firms with stronger environmental disclosure are more likely to obtain financing from the supply side (coefficient 0.890, $p < 0.05$), consistent with creditors offering more favorable conditions to firms with better ESG Environmental performance (Morais, Ferreira, Marques & Ramalho, 2025). This result seems to contrast with our main findings. However, ESG environmental scores capture

disclosure and management quality rather than actual environmental impact, providing complementary insights. Thus, while creditors are more prone to give money to firms with high ESG scores, they are less prone to do so for firms that invest in sustainable activities, but such investments do not necessarily are not reflected in higher ratings scores.

Industry heterogeneity analysis following Patten (2002) and Bansal and Clelland (2004) shows that the brown premium is stronger in environmentally sensitive industries (basic materials, energy, industrials, utilities). The interaction term EI1 × High (for high-impact industries) has a coefficient of -4.935 ($p < 0.05$), and the combined marginal effect for these firms is -0.083, compared to -0.036 for non-sensitive industries (Sanches Garcia, Mendes-Da-Silva & Orsato, 2017). This suggests a clear preference in credit markets for financing firms in environmentally intensive sectors.

Institutional environment also matters. The interaction between environmental impact and environmental policy stringency (EI2 × EPS) is negative and statistically significant (coefficient -31.664, $p < 0.05$), indicating that the association between lower environmental impact and lower probability of debt is amplified in stricter regulatory environments. The marginal effect of this interaction is -0.325 ($p < 0.05$), suggesting that regulatory stringency significantly conditions how environmental performance translates into credit market outcomes.

Research Limitations. The sample excludes private firms and smaller enterprises (Berger & Udell, 1998). Impact-Weighted Accounts data may not capture all environmental dimensions. Identification relies on exclusion restriction that PrivateCreditGDP affects only supply (Morais, Serrasqueiro & Ramalho, 2020). The bivariate model cannot distinguish all zero-leverage cases (Meng & Schmidt, 1985). Environmental measures may not capture temporal dynamics. The study period includes economic events potentially affecting results. We cannot directly observe creditor decision processes (Stiglitz & Weiss, 1981).

Managerial implications. Our findings carry important implications for managers, particularly those leading sustainable or transitioning firms. First and foremost, managers should recognize that zero-leverage policies may often be imposed constraints rather than voluntary choices (Devos et al., 2012). The evidence suggests that sustainable firms face systematic barriers in debt markets, with creditors favoring "brown" firms that generate stronger short-term cash flows (Bolton & Kacperczyk, 2021). This implies that managers of green firms need to proactively address creditor perceptions by developing alternative financing strategies.

For managers of sustainable firms, our results indicate a need to cultivate relationships with creditors who have longer-term horizons or specialized expertise in sustainability finance. Green banks, impact investors, and development finance institutions may have different risk assessments that better align with the long-term value proposition of sustainable business models. Additionally, managers should strengthen communication of long-term risk profiles to traditional creditors, emphasizing how sustainability investments reduce vulnerability to transition risks such as carbon pricing, regulatory tightening, and reputational damage (Chava, 2014).

The heterogeneous effects by firm life cycle suggest that younger sustainable firms face particularly acute financing constraints (Lefebvre, 2021; Lundberg & Lotfaliei, 2020). Managers of early-stage green companies should prioritize building track records and collateral that can signal creditworthiness to traditional lenders (Berger & Udell, 1998; Diamond, 1989). Alternative financing sources such as venture capital, private equity, or green bonds may be more accessible during early growth stages before conventional bank financing becomes available.

For managers of firms in environmentally sensitive industries, our findings suggest that current credit market conditions remain favorable, but this may change as transition risks materialize and environmental regulations tighten (Patten, 2002; Bansal & Clelland, 2004). These managers should consider whether current access to debt based on short-term cash flows adequately accounts for mounting long-term transition risks. Proactive environmental investments could help maintain credit access as regulatory frameworks evolve and creditor preferences shift.

At the strategic level, our results highlight the importance of considering financing implications in environmental strategy formulation. The finding that environmental disclosure (ESG scores) and actual environmental impact have opposite effects on credit access suggests that managers cannot rely solely on sustainability reporting to overcome financing constraints (Morais, Ferreira, Marques & Ramalho, 2025). Creditors respond to tangible short-term financial implications of environmental externalities, not just disclosure quality. This calls for integrated strategy that simultaneously addresses actual environmental performance and communication of long-term value.

For financial managers, the conflicting effects of firm value on debt demand and supply underscore the importance of sophisticated capital structure planning (Strebulaev & Yang, 2013). High market valuation reduces the desire for debt while increasing its availability, creating opportunities for strategic financing decisions that balance financial flexibility with optimal capital structure (Graham, 2000).

Finally, the moderating role of environmental policy stringency suggests that managers operating in countries with strong environmental regulations face amplified credit market responses to environmental performance. This institutional context should inform both environmental strategy and financing plans, with particular attention to regulatory trends that may reshape creditor assessments over time.

Originality of the paper. This study makes several original contributions to the corporate finance and sustainability literature. First, we introduce a novel supply-side mechanism linking environmental externalities to debt access, extending the "brown premium" documented in equity markets (Bolton & Kacperczyk, 2021) to credit markets. While previous research has examined how ESG performance affects financing (Morais, Ferreira, Marques & Ramalho, 2025), we are

the first to distinguish between sustainability disclosure (ESG scores) and actual monetized environmental externalities (Freiberg et al., 2021), showing that these have opposing effects on debt supply.

Methodologically, we advance the capital structure literature by employing a bivariate probit model with partial observability (Poirier, 1980) that explicitly disentangles demand-side financial flexibility from supply-side financial constraints (Morais, Serrasqueiro & Ramalho, 2020). Our demonstration that the environmental impact variable is insignificant in conventional univariate probit but highly significant in the bivariate framework provides compelling evidence of the importance of this methodological approach. This contributes to resolving identification issues associated with corner solutions in corporate finance (Meng & Schmidt, 1985; Saona, San Martín & Vallelado, 2024).

We also provide a theoretical foundation for our empirical findings by extending Tirole's (2010) continuous-investment model to incorporate environmental externalities. The model demonstrates formally that debt capacity decreases as positive environmental externalities increase, with a threshold effect producing zero leverage when collateral value is fully eroded. This theoretical contribution bridges corporate finance theory and environmental economics.

Fourth, our analysis of heterogeneity across firm life cycles (Lefebvre, 2021; Lundberg & Lotfaliei, 2020), industry sectors (Patten, 2002; Sanches Garcia, Mendes-Da-Silva & Orsato, 2017), and institutional environments provides a deeper understanding of how environmental considerations shape capital structure decisions. The finding that the environmental impact effect is more pronounced for younger firms and in environmentally sensitive industries, and amplified by regulatory stringency, offers a more complete picture than previous studies.

By using monetized environmental externalities from the Impact-Weighted Accounts dataset (Serafeim, Zochowski & Downing, 2019) rather than self-reported ESG scores, we provide a more objective measure of actual environmental impact. This allows us to test creditor responses to tangible environmental damage rather than sustainability signaling, revealing a potentially problematic misalignment between short-term creditor incentives and long-term societal climate goals.

Our global sample of 1,022 firms across 54 countries further provides broad external validity and enables analysis of how institutional context moderates the relationship between environmental impact and debt access. This international perspective is particularly valuable given cross-country variation in environmental regulations and financial market development (El Ghoul et al., 2018; Bessler et al., 2013).

Finally, our findings have important policy implications by highlighting a critical friction in the transition to a sustainable economy: capital markets may inadvertently penalize sustainability front-runners while continuing to fund environmentally damaging activities. This suggests that policy interventions addressing creditor time horizons or internalizing environmental externalities in credit assessments could help align financial markets with sustainability objectives.

A Review of Sustainable Business Models for Earth Observation-based Climate Services

FABIO IANNONE*, ALESSIO NOVI, TIBERIO DADDI, MARCO FREY, FRANCESCA CECCHI[1]

Abstract. *The rapid expansion of downstream space activities in the New Space era is reshaping how economic, environmental and social value is created from space infrastructures. Commercial applications of Earth observation (EO), satellite navigation and communication increasingly drive sectoral growth and redefine value chains (Bousedra, 2023; Baber & Ojala, 2024). Concurrently, downstream data-intensive services – particularly EO based climate monitoring and environmental applications – face growing expectations to contribute to sustainable and responsible business practice, integrating environmental stewardship, social justice and economic resilience.*

However, despite the acknowledged potential of satellite data to support climate adaptation, mitigation and sustainable development goals, we know relatively little about how sustainable business model innovation (SBMI) concepts and frameworks are applied to downstream space value chains. The mechanisms through which downstream intermediaries, platforms and service providers configure their value propositions, creation & delivery architectures and value capture logics to deliver triple-bottom-line outcomes remain fragmented and under-synthesised.

This work-in-progress paper presents the protocol of a planned literature review that aims to systematically map and critically synthesise existing knowledge on SBMI as applied to the downstream space economy, focusing on EO based climate and environmental applications. Building on the triadic conceptualisation of SBMI as sustainable value proposition innovation (SVPI), sustainable value creation & delivery innovation (SVCDI), and sustainable value capture innovation (SVCI) (Shakeel et al., 2020; Bashir et al., 2022), the review will examine business model configurations that transform satellite data into value added services for public and private users engaged in climate mitigation, adaptation and territorial management.

Methodologically, this work-in-progress outlines an initial plan to conduct a systematic literature review following Xiao and Watson (2019), using Web of Science and Scopus as primary databases. Recognising the emergent nature of New Space and downstream literatures, the design explicitly acknowledges possible methodological adaptation: depending on volume, diversity and maturity of identified evidence, the protocol may be refined toward a scoping review (Peters et al., 2020; Tricco et al., 2016) or an integrative review (Toronto & Remington, 2020).

The paper concludes by articulating expected theoretical and practical contributions – including development of a taxonomy of sustainable business models for downstream EO services – and detailing how the review will be further developed prior to and following the SIMA 2026 conference.

Keywords: *sustainable business model; downstream space economy; earth observation; literature review*

Framing of the research. *Over the last decade, the global space sector has undergone profound transformation associated with New Space: the liberalisation of space activities, entry of private actors and investors, adoption of novel business models oriented toward profit generation, and reorientation of space agencies toward market-oriented policies (Bousedra, 2023; Parrella et al., 2022). This shift has coincided with the digital evolution of the economy, fostering convergence between space technologies and data-intensive industries such as ICT, finance, agriculture and environmental monitoring (Bousedra, 2023). The downstream segment – encompassing value-added goods and services derived from space infrastructures including satellite communication, navigation and Earth observation (EO) – has experienced particularly rapid expansion. Opposed to the upstream segment (rocket and satellite manufacturing), downstream is where most economic value and societal impact can still be generated, interfacing directly with end-users across diverse sectors (Bousedra, 2023; Valente et al., 2025).*

Recent work on space business model value chains highlights that New Space is characterised by complex, multi-actor ecosystems where firms co-create value through interconnected data, hardware and intellectual property chains (Baber & Ojala, 2024). Intermediaries and platforms play crucial orchestration roles, bridging abundant but technically complex satellite data with operational needs of non-specialist users. In parallel, Sustainable and Responsible Business scholarship underlines the urgency of business models that simultaneously tackle climate change, social inclusion and economic resilience, leveraging data infrastructures to support sustainability transitions.

Within this context, downstream EO based services for climate adaptation and mitigation – precision agriculture, flood early-warning, infrastructure monitoring, forest management – offer promising yet under theorised arenas for sustainable business model innovation (SBMI). How value is proposed, created, delivered and captured sustainably across diverse public and private users, remains an open question. This working paper therefore designs a literature review protocol bridging SBMI scholarship with emerging work on the downstream space economy.

SBMI sits at the intersection of business models (BM), business model innovation (BMI) and sustainable business models (SBM), emphasising joint creation of economic, environmental and social value for multiple stakeholders (Geissdoerfer et al., 2018; Shakeel et al., 2020). Geissdoerfer et al. (2018) define SBMI as the conceptualisation and implementation of sustainable business models, including creation of new models, diversification or transformation of existing ones to reduce negative impacts or generate positive ones. Shakeel et al. (2020) define SBMI as the transition from a conventional business model to a sustainable business model through modifications to its components to explicitly address sustainability issues and build durable competitive advantage, emphasising radical, systematic and holistic reconfiguration.

Shakeel et al. (2020) propose a triadic framework:

- *Sustainable Value Proposition Innovation (SVPI): redefining what value is offered, integrating economic, environmental and social benefits.*
- *Sustainable Value Creation and Delivery Innovation (SVCDI): reconfiguring how value is produced and distributed – resources, processes, partnerships, technologies – to minimise negative externalities.*
- *Sustainable Value Capture Innovation (SVCI): redesigning how value is monetised – pricing models, revenue streams – aligning financial sustainability with broader goals.*

Bashir et al. (2022) empirically validated this triadic structure, demonstrating that SBMI is a measurable organisational capability positively associated with economic performance and competitive advantage, even in high-uncertainty contexts. Complementary tools include sustainable business model archetypes (Bocken et al., 2014), the Triple-Layered Business Model Canvas (Joyce & Paquin, 2016), and a taxonomy of 45 SBM patterns (Lüdeke-Freund et al., 2018). Baldassarre et al. (2017) bridge SBMI and user-driven innovation through an iterative talking–thinking–testing process, particularly relevant for data-intensive services where user involvement in prototyping is essential.

The space economy spans upstream (launch, satellites) to downstream (applications/services) and enabling sectors. New Space represents a structural transformation: (1) entry of private firms and venture capital, (2) adoption of commercial business models, and (3) reorientation of space agencies toward market-enabling policies and public-private partnerships (Bousedra, 2023). A fundamental driver is convergence with the digital economy. Digital giants and start-ups now produce vast quantities of navigation, geolocation and imagery data in near-real-time. Downstream growth is driven by three domains: communications, Earth observation and satellite navigation (Bousedra, 2023). New actors – often not branding as "space companies" – provide space-based services across agriculture, transport, finance and other sectors. Baber and Ojala (2024) conceptualise emerging business model value chains in New Space, identifying distinct chains for data, hardware and intellectual property. The data value chain runs from satellite-based generation, through ground-station reception, to value-added processing and delivery to end-users. Intermediaries and platforms bridge the gap between technically complex satellite data and operational user needs.

Purpose of the paper. *Despite recognition that many downstream EO applications contribute to multiple Sustainable Development Goals (Valente et al., 2025), the SBMI and space economy literatures have remained separate. Valente et al. (2025) document substantial work linking space to sustainability outcomes but note that explicit engagement with SBMI frameworks is rare. Conversely, SBMI scholarship has proliferated across manufacturing, energy, mobility and food systems but has paid limited attention to data-intensive, multi-actor ecosystems characteristic of downstream space. Questions such as how sustainable value propositions are co-designed with public/private users, how usage-based pricing aligns value capture with accessibility, or how sustainable value creation is configured along complex data-hardware-IP chains remain largely unexplored. This constitutes a clear research gap: we lack consolidated understanding of (1) whether/how SBMI concepts apply to downstream space, (2) how SVPI–SVCDI–SVCI manifest in EO-based services, (3) which SBM archetypes/patterns are relevant, and (4) what sustainability outcomes are associated with different configurations. Addressing this gap is both theoretically and practically relevant. Theoretically, downstream space offers a novel empirical setting for SBMI research. Practically, insights could inform design of more effective, equitable business models for EO services, helping policymakers, agencies and platforms navigate the "paradox of abundance" – vast satellite data availability but limited utilisation due to accessibility, interpretability and affordability barriers.*

The overarching aim is to systematically map and critically synthesise existing scholarly knowledge on how SBMI and related SBM concepts have been applied to the downstream space economy, focusing on EO-based climate and environmental services. Hence, our Research questions are:

RQ1a: How has SBMI (and related SBM concepts) been applied to downstream space and EO-based service business models? RQ1b: How are SVPI, SVCDI and SVCI configured in business models transforming satellite data into value-added services for public/private end-users?

RQ2a: Which SBM archetypes, patterns or design tools are most used to design/analyse business models in downstream EO contexts? RQ2b: What sustainability outcomes – economic, environmental, social – are associated with different business model configurations in downstream space applications?

Methodology. *At this stage, the review is planned as a systematic literature review (SLR) following Xiao and Watson (2019), appropriate for assessing extent, patterns, quality and gaps in emerging knowledge transparently and rigorously. However, both New Space and SBMI literatures are characterised by disciplinary heterogeneity and rapid evolution, spanning management, policy, engineering, earth sciences and geography. The initial protocol starts with systematic*

search and screening but remains flexible in synthesis stages. Given this uncertainty, this work-in-progress explicitly acknowledges possible methodological adaptation:

- *If evidence is mature, homogeneous and amenable to quality appraisal, proceed as full systematic review.*
- *If evidence is fragmented, conceptually rich but empirically sparse, a scoping review may be more appropriate (Peters et al., 2020; Tricco et al., 2016).*
- *If substantial work exists across multiple paradigms, an integrative review could enable interpretive synthesis (Toronto & Remington, 2020).*

Table 1. Databases and search strategy

Core databases	*Web of Science and Scopus, chosen for comprehensive coverage across management, innovation, sustainability and applied sciences. Supplementary searches may include Google Scholar for grey literature*
Search strategies *(three pillars)*	*1. SBMI/SBM concepts: "sustainable business model*", "business model innovation", "sustainable value proposition", "sustainable value creation/capture", "triple bottom line", etc.* *2. Space/downstream terms: "space economy", "New Space", "downstream space", "Earth observation", "EO", "satellite data/service*", "geospatial service*", etc.* *3. Climate/sustainability domains: "climate service*", "climate adaptation/mitigation", "environmental monitoring", "precision agriculture", "water management", "disaster risk", "SDG*", etc.*
Example search *string (to be refined)*	*("sustainable business model*" OR "business model innovation" OR "sustainable value") AND ("space economy" OR "New Space" OR "Earth observation" OR "satellite data") AND ("climate" OR "environment*" OR "sustainab*")*

The review will follow a multi-stage screening process designed to ensure rigour and transparency. In the first stage, two reviewers will independently screen all retrieved records based on titles and abstracts, applying the predefined inclusion and exclusion criteria. Any disagreements between reviewers will be resolved through discussion or, if necessary, consultation with a third reviewer to reach consensus. Studies that pass the initial title and abstract screening will proceed to full-text screening, where they will be assessed in detail against the final inclusion criteria. At this stage, reasons for exclusion will be systematically documented to maintain a transparent audit trail and support future replication of the review. For studies meeting all inclusion criteria, data will be extracted using a structured form designed to capture key information including bibliographic details, type of downstream application (e.g., agriculture, water management, climate services), business model components discussed, SBMI frameworks or concepts employed, research methodology, reported sustainability outcomes, and principal findings. If the review proceeds as a full systematic literature review, quality appraisal will be conducted using adapted checklists appropriate for qualitative studies, case studies or conceptual papers. The synthesis phase will combine multiple approaches to maximise insight. A narrative synthesis will organize findings thematically according to the research questions, while a configurational synthesis will develop a taxonomy of sustainable business models for downstream EO services, mapping relationships among value proposition, creation, delivery and capture mechanisms. Additionally, descriptive statistics will be generated to identify publication trends over time, geographic distribution of research, and methodological approaches employed across the corpus.

Table 2. Inclusion and exclusion criteria

Inclusion	• *Peer-reviewed articles, conference papers, book chapters in English.* • *Studies discussing/analysing business models in downstream space economy, particularly EO services.* • *Studies engaging with sustainability, SBMI, SBM or related frameworks.* • *Climate-related or environmental applications.*
Exclusion	• *Exclusively upstream space (launch, manufacturing) without downstream perspective.* • *Space exploration/astronomy without business model focus.* • *Purely technical studies without business model/sustainability discussion.* • *Non-English publications.*

Results. *This research is a work-in-progress, hence we theorize expected contribution rather than results. First, our first expected contribution is to provide the first systematic map of SBMI/SBM use in downstream space and EO-based services. Organising findings along SVPI–SVCDI–SVCI will clarify which aspects have received attention and where blind spots remain. Second, we are willing to contribute to conceptual integration between SBMI scholarship and New Space/downstream space literature. Juxtaposing SBMI categories with space value chains (Baber & Ojala, 2024) will advance understanding of sustainable value creation in complex, multi-actor, data-intensive ecosystems. Third, lay groundwork for a theoretically grounded taxonomy of sustainable business models for downstream EO services, organising configurations by:*

- *Target user segments (public/private; large/small).*
- *Value proposition focus (monitoring, analytics, decision-support, predictive).*
- *Value creation mechanisms (in-house/platform; open-source/proprietary; cloud/on-premise).*
- *Value capture models (subscription, pay-per-use, freemium, outcome-based).*

- *Sustainability levers (SDG alignment, environmental impact, social inclusion, governance).*

Research limitations. *As a work-in-progress, this paper will undergo substantial development before and after the Sinergie-SIMA 2026 conference. In the pre-conference phase (March–May 2026), the research team will finalise the review protocol and search strategy, conduct systematic searches in Web of Science and Scopus, and complete initial screening by two independent reviewers with inter-rater reliability checks. Based on preliminary findings, the review type will be confirmed or adapted toward scoping or integrative approaches. A structured coding framework aligned with the SVPI–SVCDI–SVCI triad will be developed and piloted, enabling preliminary mapping of studies by year, geography, application domain and methodology, as well as identification of early thematic patterns and archetypes.*

Conference presentation will provide opportunities to share the protocol and preliminary findings, receive critical feedback on conceptual boundaries and coding choices, and refine the emerging taxonomy through discussion with the Sinergie-SIMA community. Post-conference, the team will complete full data extraction and in-depth synthesis, develop a final taxonomy integrating SBMI dimensions with space value chains, and prepare a journal manuscript targeting innovation and sustainability outlets. The taxonomy will subsequently serve as conceptual foundation for empirical research on the Italian EO ecosystem (IRIDE, ASI, e-GEOS/CLEOS), involving qualitative case studies and interviews with public and private users, ultimately contributing to both scholarship and practice in sustainable space business.

Managerial implications. *We expect the following practical implications:*

- *For policymakers and space agencies (ESA, ASI, Copernicus, IRIDE), offer evidence-based insights into which configurations support successful uptake and sustainability outcomes, informing procurement, subsidies, capacity-building and partnerships.*
- *For downstream intermediaries and platforms (e-GEOS/CLEOS, Planet Labs, ICEYE), provide structured overview of sustainable value proposition/capture strategies, helping navigate trade-offs between accessibility and economic viability.*
- *For end-user sectors (agriculture, water, civil protection, urban planning), clarify available/emerging sustainable business models and their benefits/risks.*
- *For impact investors and venture capital, provide conceptual roadmap of SBM archetypes supporting due diligence and portfolio strategy.*

Finally, In the EO context – and many other settings – a paradox of abundance exists: vast high-quality satellite data (For EU/Italy: Copernicus, COSMO-SkyMed, IRIDE) but limited utilisation due to awareness, technical complexity, costs and capacity gaps. By reviewing SBMI frameworks for downstream EO, this work will contribute to understanding how intermediaries and platforms can bridge the gap between data abundance and effective use, designing business models that democratise access, lower barriers, provide user-friendly analytics and align incentives.

Originality of the paper. *To the best of our knowledge, no reviews are currently available on the topic of Sustainable Business Models for Earth Observation-based Climate Services. Therefore, this paper offers an original contribution by addressing this gap and providing new evidence from the literature, useful both for academia, policymakers and practictioners.*

AI & Sustainability: analysis of the dual relationship, possible risks and focus on the Italian context

MAXIMILIAN BROGLIO[1]

Abstract. *In a severely degraded global context, where the crossing of planetary boundaries, climate change, environmental contamination, and the indiscriminate use of resources are no longer news, the concept of sustainability is becoming increasingly central and important, even at the corporate level. It is vital for companies to imbue their strategic lines with sustainability so they can account for (and therefore mitigate) their environmental, economic, social, and governance impacts. At the same time, another topic that is assuming strategic importance is the adoption and exploitation of artificial intelligence: this new tool represents a new paradigm capable of transforming companies, allowing them to increase their productivity, efficiency, and therefore competitiveness.*

These two themes intersect in a synergistic and dual relationship that deserves careful analysis: it is interesting to both evaluate how artificial intelligence can serve sustainability through various applications (for example, in the field of environmental or technical sustainability) and the distinctive features of sustainable AI, for example in the fields of ethics and privacy, without neglecting considerations related to risks and negative impacts.

It is also interesting to analyse these issues within the Italian context, to understand the rate of AI adoption within the Italian corporate fabric, its level of maturity, and how internal sustainability professionals are involved, thus providing useful insights regarding the need for funding and training, for example.

It is essential to conduct research in this field to provide policymakers with a strong information base that allows them to correctly direct political and regulatory strategies, enabling a correct and equitable integration between sustainability and AI for effective, optimized, and sustainable business development.
Keywords: *AI; sustainability; sustainable AI; AI ethics; sustainability professionals; green AI*

Framing of the research. *In terms of research framing, this ongoing work is clearly connected to two main research streams: sustainability, which, as confirmed by the significant growth in the number of specific publications, represents a hot, widely explored, and well-researched topic and artificial intelligence, which, despite being relatively new, is monopolizing interest even in the corporate sphere as a truly game-changing topic.*

The specific theme of this research project therefore takes shape through their combination, seeking to analyse the specifics and characteristics of this dual and synergistic relationship, attempting to fill the gap in the literature: indeed, it is recognized that analysing the applications of AI for corporate sustainability, as well as the characteristics of sustainable AI (along with the associated risks and impacts), is essential to better understand its characteristics and provide useful information at the corporate level (and thus to policymakers); it is also considered essential to limit the analysis to the Italian context to provide specific and detailed guidance and to assess the role and level of involvement of internal sustainability professionals.

The research, like all sustainability-related research, is part of the equally well-known ESG framework (which in turn is connected to global socio-environmental issues and is inextricably linked to recent European and national regulatory provisions requiring companies to pay greater attention to the impacts associated with their activities), a factor capable of influencing aspects such as reputation, competitiveness, financing possibilities, and business continuity.

The ongoing work ultimately aims to explore the connection between AI and sustainability, with a specific focus on the Italian business context to unravel the skein within a heterogeneous and poorly harmonized research landscape, seeking to offer interesting insights, especially of a practical nature.

Purpose of the paper. *The paper, after a brief introduction that separately contextualizes the concepts of AI and sustainability to dispel any doubts, primarily aims to investigate the relationship between artificial intelligence and sustainability within the corporate context and specifically to evaluate two aspects: how artificial intelligence can work for sustainability in terms of possible concrete applications (for example, in the field of social sustainability by improving inclusiveness, in the field of environmental sustainability by increasing energy efficiency, in the field of economic sustainability by optimizing the supply chain, in the field of technical sustainability by incentivizing automation and innovation) and what the characteristics of sustainable AI are in terms of ethics, transparency, responsibility, and privacy.*

The research also aims to assess the risks and potential negative impacts of AI in the ESG context, seeking to move beyond an overly simplistic, positive narrative; specifically, the aim is to assess its potential ecological risks (AI footprint), socioeconomic and ethical risks, as well as those related to data and algorithms, while also considering how these risks can often be intertwined, simultaneously affecting multiple spheres.

The possible mitigations that companies can implement to reduce the potential negative impacts associated with unsustainable use of AI are also assessed.

[1] Universitas Mercatorum – Roma, e-mail: maximilian.broglio@studenti.unimercatorum.it

The final section, through meticulous analysis of statistical surveys at the Italian company level, will investigate in more detail the level of AI adoption and the degree of involvement of sustainability departments, precisely analysing the most frequent barriers and obstacles that lurk behind full and committed implementation (e.g., lack of skills, inadequate financial resources).

All these considerations are intended to provide an interesting source of information for assessing the current state of the relationship between AI and sustainability and its level of maturity in the Italian business context. This will provide a clear and comprehensive framework that can serve as a source of information for policymakers and regulatory bodies: it is hoped that this will shape a broader framework for fully exploiting the great potential this tool has to offer, while always keeping sustainability in mind.

This work is ongoing, so further developments or insights may be considered later in the research process.

Methodology. *Methodologically, this ongoing work is characterized by a qualitative approach. A review of the scientific literature and detailed reports from institutions working on these topics has been exploited to analyse in detail the connection between AI and sustainability, assessing how artificial intelligence can contribute to sustainability through specific applications and the distinctive characteristics of sustainable AI. Issues such as risks and potential negative impacts in this context were not overlooked, thus evaluating potential mitigation measures. Statistical surveys in the Italian business context were also evaluated to assess the state of the art, level of maturity, and adoption rate, and thus draw valuable insights (for policymakers and regulatory bodies).*

In terms of temporal context, the analysis is inevitably tied to the most recent findings, given that the topic is constantly and rapidly evolving (analysing older data would obviously undermine the reliability and usefulness of the research). Regarding the geographical context, aside from the more general considerations that have a more universal value, it has been decided to focus the analysis on the Italian context to better define the results and thus provide specific and useful insights.

It would then be interesting to expand the analysis with a quantitative phase, again within the Italian context, to better analyse and update the actual connection between AI and sustainability within the Italian business context.

Results. *In order to initially dispel any doubts, the ongoing analysis began with an analysis of the actual meaning of the concepts of sustainability and artificial intelligence to fully understand their characteristics and nuances while analysing their interconnected relationship.*

The concept of sustainability is a multidimensional concept whose meaning has evolved and continues to evolve over time. To find a starting point, one can refer to the definition dated 1987 achievable from the report of the World Commission on Environment and Development titled Our Common Future (known as the Brundtland Commission) which refers to the «development that meets the needs of the present without compromising the ability of future generations to meet their own needs» that inevitably takes into account a strong intragenerational and intergenerational balance that transcends environmental impacts integrating economic and social dimensions: indeed, it is these three pillars (environmental, social, and economic) that have paved the way for all sustainable strategies, representing the compass to follow to ensure a truly sustainable approach. Specifically, respecting the considerations associated with the three pillars, which must be considered in conjunction with one another and not separately, ensures equitable development aligned with global needs and planetary health. The environmental sphere refers to issues such as resource conservation, ecosystem integrity, safeguarding biodiversity protection, and reducing the climate-altering impacts of anthropogenic gases and environmental contamination; the social sphere refers to equity, inclusion, social justice, education, ensuring equal access to resources and strengthening community cohesion; the economic sphere refers to the vision of a long-term economic prosperity that is resilient and inclusive and it has to be underlined that, the United Nations (UN), in order to operationalize these concepts, adopted the 2030 Agenda for Sustainable Development in September 2015, which includes 17 Sustainable Development Goals (SDGs).

The concept of artificial intelligence has gained particular traction in recent years, but it is a well-established concept considering that already in 1950, Alan Turing introduced the concept in his article titled "Computing Machinery and Intelligence"[2]; simply put, artificial intelligence (AI) today is a multidisciplinary field of computer science characterized by a set of technologies that allows a machine to emulate human capabilities through algorithms that learn from information available and/or collected directly by the machine to improve their performance over time.

There are different types of AI: the first one is Machine Learning (ML) that represents the fundamental branch of AI characterized by algorithms capable of automatically learning from existing data (that must be structured and labelled) and making predictions about future data; then there is the Deep Learning (DL) that exploits deep artificial neural networks[3] (that have hidden layers between the input and output) allowing them to learn complex representations from data (complex and unstructured as images, text, audio, or video, without manual preprocessing); another type can be represented by Generative AI in which, algorithms, trained on large amounts of data (structured or unstructured), can generate new outputs similar to the original data; finally there is Agentic AI, mainly deployed since the second half of

[2] Turing questioned whether machines could emulate human thinking and proposed the famous "Turing Test", in which a human interrogator attempts to distinguish the textual responses provided by a computer from those of a human.

[3] For example, can be considered Convolutional Neural Networks (CNNs) that are effective for analysing satellite imagery to monitor land changes and Recurrent Neural Networks (RNNs) that are instead used for tasks involving time-series data like weather forecasting.

2024, designed to pursue specific goals autonomously within a specific context with capabilities to make decisions, take actions, and adapt strategies based on environmental feedback and increasingly used in software and computer engineering or interfaces, in robotics and autonomous vehicles, or in decision-support systems (Casper et al., 2025). These AI technologies offer fundamental opportunities for addressing sustainability challenges with a precision unattainable through old methods allowing the transition from a reactive to a predictive and proactive approach in environmental and resource management.

Once the two different definitions have been clarified, it is useful to move on to the analysis of the dual relationship between sustainability and AI: artificial intelligence can represent a boost for all those activities that are linked to achieving sustainability in various business fields but at the same time it must itself take on sustainable connotations in order to be implemented without contraindications so it is important to consider how AI can contribute to sustainability in terms of possible applications and which are the main characteristics of a sustainable AI. Starting from the first aspect the AI can contribute to four types of sustainability: environmental sustainability[4], social sustainability[5], economic sustainability[6], technical sustainability[7] and individual sustainability[8] thus representing a truly key factor in the sustainable transition path for companies; as regards the characteristics of a sustainable AI, it can be stated that there are four main areas to focus on: ethics and fairness[9], accountability and responsibility[10], data privacy and security[11], transparency and explainability[12]; all these issues have to be taken into account to avoid the risk of an unsustainable AI.

These considerations related to the possible AI's unsustainability are clearly linked to the risks and the negative impacts associated to AI; starting from the assumption that, for Vinuesa et al. (2020)[13], AI has the potential to have both positive and negative impacts on corporate sustainability (AI could support the achievement of 134 of the 169 SDG targets but also notes that 59 of the 169 SDG targets could be negatively impacted), it has to be remarked that three types of risks can be considered: ecological risks (AI footprint)[14], socio-economic and ethical risks[15], data and algorithm-related risks[16] (which can also intersect with each other). In this context of analysis, the concept of "AI green paradox" comes into play, that is, that the benefits of ecological solutions implemented by AI are outweighed by the environmental costs[17] that arise from the use of AI itself: this aspect must be addressed through a clear, careful, proactive and strategic direction aimed at adopting a "green AI" taking into account the above mentioned risks; to achieve this, governance frameworks and international cooperation, funding and incentive policies (for green AI), international collaboration, open-source platforms and training programs are also needed.

An interesting insight into these issues in the Italian context can be deduced from the recent study dated 2025 by Sustainability Makers[18] where state of art, risks, barriers, and involvement of sustainability professionals are evaluated; in particular, in this work, what can be deduced is that AI is permeating companies (45.4% of companies are using AI, of which 30.9% with an extensive use, mainly exploited to improve operational efficiency (97.2%) and only partially for product and/or service innovation (50.2%)), 85% of large companies and 50% of SMEs have established units dedicated to AI implementation, the main obstacles are lack of skills[19], resistance to change (37% of companies during the implementation), lack of financial resources (23% of SMEs), difficulty in finding profitable areas of application. A critical

[4] For example, in terms of energy efficiency, waste management, climate modelling, resource management and disaster management.
[5] For example, in terms of cultural diversity, inclusion and poverty alleviation.
[6] For example, in terms of supply chain optimization, business operations, financial services and labour market.
[7] For example, in terms of process optimization, automation, research and innovation.
[8] For example, in terms of work efficiency, career development and knowledge accessibility.
[9] For example, in terms of bias mitigation, equity and responsible data use.
[10] For example, in terms of traceability and auditing.
[11] For example, in terms of privacy preserving algorithms and data anonymization techniques.
[12] For example, in terms of stakeholder engagement and explanations for IA decisions.
[13] VINUESA ET AL. (2020), *The role of artificial intelligence in achieving the Sustainable Development Goals*. Nature communications, 11(1), 1-10.
[14] For example, in terms of energy consumption (training AI models, especially large ones like deep learning models, requires a significant amount of energy), water consumption (some data centers use water cooling systems, which can consume significant amounts of fresh water), e-waste management (the rapid obsolescence of hardware technologies used for AI contributes to the growing amount of e-waste). All these factors can be summarized in the concept of digital pollution.
[15] For example, in terms of potential job losses (AI-powered automation can replace human jobs, especially in some sectors), technology dependence (the increased use of AI in various areas of daily life can lead to an overdependence on technology), security (AI can be used for malicious purposes), unequal access to technology (risk that AI will become the privilege of a few, accentuating inequalities).
[16] For example, in terms of 'black box' responsibility, erosion of digital trust, systemic digital bias (AI algorithms can reflect and amplify biases present in the data they are trained on thus leading to discriminatory decisions).
[17] In terms of energy consumption (and so carbon footprint), water consumption, e-waste. The concept of "green debt" refers exactly to the risk that the short-term AI benefits toward sustainability are outweighed by the long-term ecological of its development, resulting in overall net ecological deficit.
[18] Italian association that brings together professionals dedicated to defining and implementing sustainability strategies and projects in businesses and other organizations. The study is titled "Intelligenza artificiale al servizio della sostenibilità" and it is based on technical literature review and online survey administered to a sample of Italian companies (large, medium and small manufacturing and service companies).
[19] Companies experience a lack of skills during the phase of project initiation (36.1%) and project implementation (39.7%).

point in the Italian context is that social and environmental risks[20] related to AI are not properly under control (only 50% of companies have trained employees on these risks, and 64.1% of companies are not actively managing these risks); finally regarding the link with sustainability departments, the study reveals that sustainability managers are only occasionally involved in implementation processes (54.4% of large companies and 75.0% of small companies) and primarily in defining objectives (59.5%), the majority of sustainability departments have adopted AI initiatives (56.8%), AI adoption initiatives in the sustainability field are primarily focused on data analysis (85.0%) and reporting (63.0%), sustainability units feel the need to further develop skills and do not perceive themselves as prepared (62.2%).

The analysis conducted so far within this ongoing work has obtained interesting results in the evaluation of the dual relationship between AI and sustainability especially within the Italian business context, which will need to be increased with further developments in the continuation of the research to further explore these issues.

Research limitations. *The main limitations concern the data, methods, and theoretical framework used to analyse the relationship between AI and sustainability.*

Starting from the data, it is noted that the limited availability and transparency of data (often non-public or incomplete) on energy consumption, emissions, water use, and hardware throughout the entire life cycle of AI systems (training, inference, infrastructure, supply chain), along with the inevitable difficulty in defining standard and comparable metrics for the environmental and social impact of AI, undoubtedly pose challenges to the reliability of studies in this area. Regarding methodological issues, it should be clarified that the AI ecosystem is inevitably highly heterogeneous (different models, data centers, cloud providers, national energy mixes), making it difficult to properly isolate the specific contribution of AI from other digital factors. Furthermore, indirect effects such as the "rebound effect", in which AI-generated efficiencies stimulate new demand and consumption, are complex to quantify and generalize (it is difficult to generalize results from individual models, companies, or data centers to the entire AI ecosystem beyond specific sector studies). Furthermore, forecasting models with many assumptions (on energy scenarios, AI adoption, future regulation) introduce uncertainty and potential biases.

Conceptually, it is important to pay attention to the chosen scope of sustainability: many studies are characterized by a reductionist vision, focusing primarily on environmental aspects (CO_2, water resources, e-waste) with a view to optimization, dangerously neglecting potential social (inequality, job losses) and ethical (governance, green rights) dimensions. It has also to be highlighted that large AI companies control key technical data and can limit access to it for competitive or security reasons, generating information asymmetry; furthermore, it has to be remarked that, currently, there is a sort of positive narrative surrounding AI that can, however, distort research and funding agendas, pushing people to overemphasize benefits and underestimate sustainability impacts and risks.

Managerial implications. *An in-depth analysis of the delicate relationship between two such timely and important topics as AI and sustainability inevitably has managerial implications. First and foremost, evaluating the potential applications of AI in the service of sustainability, as well as the specific characteristics of sustainable AI, allows companies, and particularly internal professionals responsible for optimization, innovation, and sustainability, to find interesting insights to apply within their corporate contexts, ensuring competitiveness and innovation through this essential dual and synergistic relationship. This work also allows companies to become aware (if they have not already done so) of all the risks and potential negative impacts associated with AI, enabling them to immediately address them by adopting mitigation strategies and reconfiguring operations and strategic decisions.*

These insights can thus serve as a compass within a tremendously evolving and decisive context, one in which it is difficult to keep pace, both in terms of skills and resources. This work should act as a driving force for companies, within the limits of their operating margins, to invest in this direction to ensure business continuity, regulatory compliance, improved reputation, and mitigation of socio-environmental impacts.

Finally, the analysis of the Italian context aims to shed light on the current maturity of the Italian business landscape, highlighting the increasingly urgent need for investment, training and well-calibrated political and regulatory decisions.

Originality of the paper. *This work represents an interesting opportunity to investigate the relationship between AI and sustainability (focusing specifically on the Italian business context) in its dual conception, analysing both how AI can impact sustainability and what constitutes AI's sustainability. This analysis is increasingly crucial in the current business environment, characterized by the hypertrophic and disruptive growth of the use of artificial intelligence and where sustainability is an imperative that cannot be overlooked if resilience, competitiveness, and growth are to be ensured within an ecosystem shaken by well-known socioeconomic and environmental challenges (global warming, conflicts, environmental contamination, social tensions).*

The originality lies in the desire to analyse all the characteristics of this relationship between sustainability and AI without overlooking the negative aspects associated with the risks and negative impacts that may arise and which clearly must be adequately managed.

The goal is to provide a comprehensive overview that allows for accurate and adequate information while recognizing the complexity of the issue and the potentially significant impact it could have on corporate strategic decisions (and thus, on business continuity). The focus on the Italian context, which needs to be strengthened in the future, also serves as a

[20] Mainly identified as privacy, technology dependency and energy consumption.

magnifying glass for a deeper understanding of the level of maturity and awareness surrounding these issues, thus enabling to correctly guide future national political and regulatory decisions.

Authenticity, Skepticism, and Trust Formation in Corporate Social Responsibility actions

FABRIZIO ERBETTA[•], VALERIA FARALLA[*]

Abstract. *Corporate social responsibility (CSR) initiatives are attracting growing attention from stakeholders, making perceived authenticity a critical determinant of their effectiveness. This study investigates how CSR perceived authenticity shapes two distinct dimensions of consumer trust — cognitive and affective — both directly and indirectly through the mediating role of situational skepticism. Using a between-subjects experimental design administered via the Prolific platform and PLS-SEM estimation, we exposed participants to either high- or low-authenticity CSR scenarios and measured their perceptions, skepticism, and trust responses. Results indicate that CSR perceived authenticity directly and positively influences both cognitive trust and, to a greater extent, affective trust. Moreover, authenticity significantly reduces situational skepticism, which in turn partially mediates the relationship between authenticity and cognitive trust, but not affective trust. Dispositional skepticism, included as a control variable, does not significantly affect either form of trust or situational skepticism. These findings suggest that cognitive and affective trust operate through partially distinct psychological mechanisms: cognitive trust is shaped by a skepticism-filtered process, while affective trust may respond more directly to emotional and relational cues in firms' authentic CSR practices. Theoretical and managerial implications are discussed.*
Key words: *CSR; authenticity; skepticism; cognitive trust; affective trust; mediation*

Framing of the research. *It is well-established that corporate social responsibility (CSR) initiatives have become increasingly prominent in companies' agendas. However, the motivations behind these initiatives can be traced back either to a public-oriented rationale or to a more self-serving one (Mantovani et al., 2017). While the former reflects a genuine concern for social welfare, the latter is more closely associated with internal motives, such as the pursuit of private benefits. Suspicions of rent-seeking may lead stakeholders to view CSR initiatives with skepticism a priori (Wagner et al., 2009). This may dampen positive responses or even trigger negative reactions. Stakeholder responses may therefore depend on the impression these initiatives create, particularly in relation to perceptions of the firm's genuine commitment to the supported cause (Joo et al., 2019).*

In this respect, the extent to which stakeholders perceive CSR efforts as authentic becomes particularly important. Prior research, indeed, suggests that value-driven motives underlying CSR initiatives tend to reduce skepticism, whereas selfish, strategic, or stakeholder-driven motives are more likely to trigger skeptical reactions (Skarmeas and Leonidou, 2013).

Despite the relevance of the relationship between perceived authenticity and skepticism, and its potential implications for stakeholder-related outcomes, empirical research on this topic remains limited. A notable exception is the study by Virkus and Klein (2026), who examine the role of the authenticity perceived in brand activism in shaping skepticism and several important consumer-based responses.

Purpose of the paper. *Given the relevance of perceived authenticity, some studies, such as those by Alhouti et al. (2016) and Joo et al. (2019), have developed and validated scales to measure CSR perceived authenticity. The adoption of such scales is then used by Alhouti et al. (2016) to investigate several antecedents of CSR authenticity, and by Joo et al. (2019) to conceptualize the construct of authenticity as comprising multiple dimensions. Furthermore, subsequent studies have suggested that higher levels of perceived authenticity may mitigate stakeholders' skepticism toward firms' social initiatives (Schmidt et al., 2021).*

In this regard, prior literature has distinguished between different forms of consumer skepticism. Forehand and Grier (2003) and Skarmeas and Leonidou (2013) differentiate between dispositional and situational skepticism. Dispositional skepticism refers to a relatively stable personality trait that predisposes individuals to doubt firms' motives and is therefore largely beyond firms' control. Situational skepticism, by contrast, emerges in response to specific corporate initiatives – such as CSR campaigns or brand activism – and may be shaped by how these initiatives are perceived by stakeholders. In this sense, perceptions of authenticity may play a key role in either fuelling or attenuating situational skepticism.

Beyond its role in shaping skepticism, perceived CSR authenticity has also been associated with a range of relevant stakeholder-related outcomes. For instance, Alhouti et al. (2016) show that perceived authenticity can positively influence outcomes such as customer loyalty and purchase intentions, while Virkus and Klein (2026) identify purchase intention and willingness to engage in word-of-mouth as key consequences in the context of brand activism. Among the possible outcomes of authenticity perceptions, trust may represent a particularly relevant construct. Johnson and Grayson (2005) distinguish between cognitive trust, which is grounded in rational evaluations of a firm's competence and reliability, and

[•] Associate Professor in *Management* – University of Piemonte Orientale, e-mail: fabrizio.erbetta@uniupo.it
[*] Researcher Tenure Track in *Management* – University of Piemonte Orientale, e-mail: valeria.faralla@uniupo.it

affective trust, which reflects emotional bonds and feelings of care or concern. This distinction may provide useful insights into whether the effect of perceived authenticity – through its influence on situational skepticism – primarily operates through a cognitive mechanism or through a more affective pathway.

Accordingly, this study investigates whether the construct of CSR perceived authenticity fosters cognitive trust differently from affective trust, both directly and indirectly through situational skepticism. By distinguishing between cognitive and affective trust – an approach that has not yet been explored in the CSR context – this study contributes to the literature by examining whether the expected reduction in situational skepticism resulting from higher CSR perceived authenticity operates primarily within a cognitive or an affective sphere.

In particular, using PLS-SEM we test the following set of hypotheses:

H1a: CSR perceived authenticity impacts positively and directly on stakeholders' cognitive trust

H1b: CSR perceived authenticity impacts positively and directly on stakeholders' affective trust

H2a: CSR perceived authenticity impacts positively and indirectly on cognitive trust, mediated by decreasing stakeholders' situational skepticism

H2b: CSR perceived authenticity impacts positively and indirectly on affective trust, mediated by decreasing stakeholders' situational skepticism

Methodology. *This study employs a between-subjects experimental design with two conditions: high-authenticity versus low-authenticity corporate social responsibility. Participants will be randomly assigned to one of the two conditions via an automated randomisation procedure embedded in the survey platform. The survey will be administered via LimeSurvey and consists of several sections described below. All respondents will be asked to provide informed consent prior to participation.*

Participants will be recruited via the Prolific online research platform, aiming to obtain at least 300 completed responses from a nationally representative sample in the United Kingdom. After providing consent and entering their Prolific ID, participants will complete the survey sequentially. Three attention-check items will be embedded throughout the survey to ensure data quality; responses from participants who fail the attention checks will be excluded from the final analysis.

Prior to the experimental manipulation, participants will complete a 6-item measure of general consumer skepticism (e.g., "Most people will tell a lie if they can gain by it"; "Most people are not really honest by nature"). Items are rated on a 4-point scale ranging from 1 (low agreement) to 4 (high agreement). This scale was included as a pre-manipulation covariate to control for individual differences in dispositional skepticism and was taken from Mohr et al. (1998).

At this point, participants will be provided with standardised definitions of CSR and CSR authenticity — operationalised as the perceived genuineness, sincerity, and transparency of CSR actions. They will be then assigned to either the high-authenticity or the low-authenticity condition. In both conditions, participants will be presented with a list of six CSR practice categories (donations to charities, environmental sustainability programs, workplace inclusion and diversity, ethical supply chain policies, employee volunteering, and eco-friendly products/packaging) plus an open "Other" option. Critically, the behavioural examples illustrating each practice differ systematically across conditions: high-authenticity examples depict substantive, ongoing, and transparent commitments, whereas low-authenticity examples represent superficial, performative, or misleading implementations (i.e., greenwashing or social washing) (e.g., "A company consistently donates a fixed percentage of its annual profits to social or environmental charities that align with its mission, ensuring ongoing support for initiatives that reflect its contribution to meaningful community development" versus "A company makes a one-time, highly publicised donation after a scandal but does not maintain an ongoing commitment or report on the outcomes of the donation").

Participants will be required to select the CSR practice category most consistent with their own experience and will then be asked to identify a real company engaging in that practice at the assigned level of authenticity. If no real company can be recalled, participants may proceed with a hypothetical one. At the end of the survey, participants will indicate whether the company they had in mind was real or hypothetical; this information will be used as a robustness check in analyses.

Upon completing the manipulation, participants will respond to a series of self-report measures designed to capture their perceptions of, and reactions to, the target company's CSR practices and the company more broadly. Each instrument is described in turn below.

CSR Practice Perceptions: Participants' perceptions of authenticity of the identified company's CSR practice and of the company more broadly are assessed across multiple dimensions using an established scale developed by Joo et al. (2019). All items are measured on a 7-point Likert scale ranging from 1 (Strongly Disagree) to 7 (Strongly Agree).

CSR Skepticism (situational): CSR-specific skepticism is assessed using four bipolar items rated on a 7-point scale. Each item presented two opposing anchors (e.g., 1 = "It is doubtless that the CSR practice is socially responsible" vs. 7 = "It is doubtful that the CSR practice is socially responsible"). Items were reverse-coded where applicable so that higher scores reflect greater skepticism. This scale was developed by Skarmeas and Leonidou (2013).

Willingness to Pay: A single item assesses participants' willingness to pay more for a product from a company known for genuinely practicing CSR, compared to a competitor engaging in CSR for marketing purposes only. Response options were: "Not willing to pay more", "Up to 5% more", "6–10% more", "11–20% more", "More than 20% more".

Consumer Trust: Trust in the identified company was measured using seven items (e.g., "I have no reservations about acting on the company's advertising"; "If I share my concerns with the company, I feel it would respond caringly") rated

on a scale from 1 (not at all) to 7 (very much). The scale was adapted from Johnson and Grayson (2005) and captures both the affective and cognitive dimensions of trust.

Consumer Satisfaction: Satisfaction with the product or service received from the identified company was assessed using three semantic differential items (Sad/Happy; Contented/Disgusted; Dissatisfied/Satisfied), each rated on a 7-point scale. Given that satisfaction presupposes direct consumption experience, this measure was administered only to participants who identified a real — rather than a hypothetical — company.

Individual Importance of Social and Environmental Issues: A single item assessed the personal salience of social and environmental issues to participants in their daily lives, rated on a 10-point scale ranging from 1 (not at all important) to 10 (extremely important).

A pilot experiment has already been conducted via Prolific to test the survey instrument, the effectiveness of the manipulation, and procedural clarity. Based on pilot results, item wording was refined, instructions were clarified, and the option to proceed with a hypothetical company was introduced, as several pilot participants found it challenging to identify a real company. Pilot participants will not be included in the final sample.

Results. *We estimated our conceptual model using PLS-SEM approach (in particular the estimates were carried out through the software SmartPLS version 4 (Ringle et al., 2024)). The CSR perceived authenticity (which serves as our exogenous latent construct) and situational skepticism, cognitive trust and affective trust (which serve as our endogenous latent constructs) were all measured using a reflective approach, considering as indicators and scales those presented in the previous (Methodology) section. Our mediating construct is situational skepticism, which reflects stakeholders' skepticism toward specific CSR initiatives characterized by high (or low) authenticity. However, we also included dispositional skepticism in the model as a control variable. In our conceptual framework, dispositional skepticism influences the endogenous mediating latent construct (i.e. situational skepticism) as well as the two outcome variables, cognitive trust and affective trust. This reason is that skepticism as a personality trait may carry over to situational skepticism and, also, negatively affect both forms of trust.*

We first checked for reliability and validity of the constructs in our model (using Cronbach's alfa, Composite Reliability (CR) indices, Average Variance Extracted (AVE) and Heterotrait-Monotrait (HTMT) statistics). The indicators of CSR perceived authenticity appear to exhibit some degree of redundancy (CR > 0.95). Nevertheless, the Average Variance Extracted (AVE) exceeds the recommended threshold of 0.5, suggesting that the construct retains adequate convergent validity. Furthermore, the indicator loadings on the respective latent constructs are almost entirely above the recommended threshold of 0.7. This suggests that the indicators exhibit satisfactory indicator reliability, as they share a substantial proportion of variance with their underlying constructs (see Hair et al. (2012) and Hair et al. (2017) for details on PLS-SEM).

Subsequently, we turned to the main focus of the analysis, namely the estimation of the structural model's path coefficients, using 5,000 bootstrap replications. As the results in Table 1 indicate, the CSR perceived authenticity improves cognitive trust (0.523, $p < 0.01$) and, to a larger extent, the affective trust (0.786, $p < 0.01$), thus confirming hypotheses H1a and b. The evidence of a stronger direct effect of CSR perceived authenticity on affective trust highlights its ability to foster an emotional connection between firms and stakeholders scrutinizing CSR practices. However, CSR perceived authenticity contributes to a reduction in situational skepticism (−0.721, $p < 0.01$), which represents the part of individuals' skepticism that can adapt based on observation of CSR actions. This reduction, in turn, contributes to an increase in cognitive trust, as indicated by the negative coefficient (−0.250, $p < 0.01$), whereas its impact on affective trust is not significant. This gives rise to the consideration that a mediation (indirect) effect of situational skepticism in the relationship between CSR perceived authenticity and cognitive trust occurs. As outlined in Table 2, this relationship is partially mediated (adopting the description of the mediation effect provided by Zhao et al., 2010) thus conforming hypothesis H2a. However, no mediation appears in the relationship between CSR perceived authenticity and affective trust. Therefore, hypothesis H2b does not find support.

Overall, these results suggest that (1) stakeholders' perception of authenticity in the scrutiny of firms' CSR practices directly fosters the development of affective trust, and (2) situational skepticism introduces a mediating pathway that operates exclusively within the cognitive domain. The main insight is that while cognitive trust tends to develop more cautiously in a direct way, it benefits from the mitigation of the skepticism filter. This filter appears to operate primarily at the deliberative level of the trust-formation process toward the firm. In other words, when individuals harbour skepticism, the development of cognitive trust is hindered, whereas reducing such skepticism facilitates the attribution of trust.

Interestingly, persistent skepticism does not significantly influence situational skepticism nor the two forms of trust. This finding suggests that stakeholders' evaluations of CSR initiatives are primarily shaped by situational cues rather than by stable individual predispositions toward skepticism. In particular, the perception of authenticity in firms' CSR practices appears to play a more central role in shaping stakeholders' reactions than general skeptical tendencies. This finding highlights the importance of authenticity cues in shaping stakeholders' trust judgments, as such cues may attenuate the influence of pre-existing skeptical orientations.

Research limitations. *Despite its contributions, this study is subject to limitations that should be acknowledged and addressed in future research. Firstly, the sample is drawn exclusively from the United Kingdom via the Prolific platform. While Prolific panels tend to provide nationally representative samples along key socio-demographic dimensions, the findings may not generalise to other cultural or institutional contexts where norms around CSR, corporate transparency, and consumer trust differ substantially. Cross-cultural replications would strengthen the external validity of the results. Secondly, the study relies entirely on self-reported measures collected at a single point in time. This cross-sectional approach precludes any causal inference about the temporal dynamics of trust formation. Longitudinal designs could shed light on how authenticity perceptions and trust evolve as stakeholders accumulate experience with a company's CSR behaviour over time. Moreover, the study focuses on stakeholders as consumers, considering them the primary audience of CSR communication. The mechanisms identified here — particularly the differential pathways to cognitive versus affective trust — may operate differently among other stakeholder groups, such as employees, investors, or community members, whose relationships with the firm are governed by distinct motivational and relational logics. Finally, although the present model focuses on situational skepticism— given the key role it may play in shaping stakeholder responses to CSR initiatives —the trust-formation process is likely shaped by additional variables not captured in the present framework, such as brand familiarity, prior CSR associations, or issue involvement. Incorporating these factors in future models could enrich our understanding of the boundary conditions under which authenticity perceptions translate into stakeholder trust. At the same time, beyond the mechanisms explored here, other psychological processes may also shape stakeholders' reactions to CSR initiatives. Future research could explore additional mediating variables (e.g., moral evaluation or identification with the firm) in order to deepen our understanding of the processes through which CSR authenticity influences stakeholder attitudes and behaviors.*

Managerial implications. *From a theoretical standpoint, this study makes several contributions to the CSR literature. First, by adopting a multidimensional conceptualisation of trust, it demonstrates that cognitive and affective trust are not interchangeable outcomes. While cognitive trust develops through a deliberative, skepticism-filtered process, affective trust appears to be more directly activated by authenticity perceptions, suggesting that emotional and rational pathways to trust formation operate differently in the CSR context. Second, the finding that situational skepticism mediates only the cognitive pathway contributes to a more refined understanding of the role of skepticism in CSR research, clarifying that it acts as a barrier to trust. Third, the non-significant role of dispositional skepticism suggests that stable individual predispositions may be overridden by contextual authenticity cues. These theoretical insights also carry meaningful practical implications for managers.*

The finding that the mediation mechanism operates only through the cognitive pathway, via the reduction of situational skepticism, while affective trust is influenced solely through a direct effect, suggests that different dimensions of trust are activated through distinct psychological mechanisms. This provides several meaningful managerial implications. First, cognitive trust appears to emerge from evaluative and rational processes in which individuals assess the credibility and reliability of the information they receive. In this context, situational skepticism functions as a critical filter that shapes whether individuals accept or question organizational messages or practices. Consequently, reducing skepticism becomes a key managerial goal for fostering cognitive trust. Secondly, affective trust appears to be generated more directly through relational and emotional cues, such as shared values and empathy. This implies that managers

seeking to cultivate affective trust should complement informational transparency with communication approaches that emphasize value alignment and empathy.

Taken together, these findings highlight the importance of adopting a dual strategy in trust-building initiatives. On the one hand, organizations should actively reduce situational skepticism by providing credible and substantiated information in order to support the development of cognitive trust. On the other hand, they should simultaneously invest in communication practices that foster emotional connection and identification, which can directly strengthen affective trust. By recognizing that cognitive and affective trust rely on partially distinct mechanisms, managers can design more nuanced communication strategies that address both the rational and emotional dimensions of stakeholder trust.

Furthermore, the results highlight a lack of significance in the dispositional skepticism on situational skepticism and on the two forms of trust. One possible interpretation is that persistent skepticism reflects a broad dispositional orientation, whereas situational skepticism is activated through the evaluation of specific organizational actions. When stakeholders observe concrete CSR practices, their judgments may rely more heavily on contextual signals, such as perceived authenticity, than on generalized attitudes. In this sense, situational skepticism appears to function as a context-sensitive response rather than as a simple extension of dispositional skepticism and CSR authenticity signals may therefore override stakeholders' dispositional skepticism.

Originality of the paper. *The main contribution of this paper lies in adopting a multidimensional perspective on trust as an outcome associated with stakeholders who closely monitor corporate social responsibility (CSR) initiatives. Trust can be conceptualized as comprising both cognitive and affective dimensions, allowing for a more nuanced investigation of the mechanisms through which it is formed. By distinguishing between these two facets, the study explores whether different psychological processes underlie the development of cognitive versus affective trust. Adopting this multidimensional lens thus provides deeper insight into how stakeholders (such as, in particular, consumers) interpret and respond to CSR actions, highlighting that distinct mediating mechanisms may influence the formation of trust along its cognitive and affective dimensions.*

Crossing the borders: How Digital Transformation enables Social Value Co-Creation

MATTEO DOMINIDIATO[1], ELISA MARTINA MARTINELLI[2]

Abstract. *This preliminary study explores the critical intersection of digital transformation, social sustainability, and business relationships—a nexus currently under-represented in literature, which predominantly emphasizes environmental and economic dimensions. The research aims to investigate how firms embedded within specific networks can leverage advanced technologies to pursue social sustainability objectives. Adopting a qualitative methodology based on a single case study, the paper analyzes the evolution of corporate social commitment from traditional philanthropy toward an integrated digital strategy. The findings reveal that the application of Industry 4.0 technologies enables the co-creation of relational value with stakeholders. The study highlights that social sustainability is not merely an internal output but a collaborative result of network expansion and technological convergence that bridges competence gaps and generates systemic benefits for the extended community composed by several actors.*
Keywords: *social sustainability; innovation; strategic marketing; business relationships; digital transformation.*

Framing of the research. *Sustainability has emerged as a paramount objective for companies and society at large. Greenland (1997) characterizes sustainability as a strategic approach to optimizing current resource allocation to meet future demands. A seminal shift occurred with Elkington's (1998) "Triple Bottom Line" (TBL) framework, which requires organizations to balance economic, environmental, and social dimensions. These pillars remain central to modern corporate sustainability discourse (Khan et al., 2023; Elkington, 2013). The literature underscores sustainability's importance for contemporary business models, with these three pillars being integral to financial decisions and corporate investments (Gregory, 2024). Moreover, the United Nations 2030 Agenda, through its 17 Sustainable Development Goals (SDGs), has provided clear guidelines for addressing global challenges, highlighting the importance of balancing economic growth with social and environmental concerns. Consequently, sustainability is now regarded not merely as an ethical choice, but as an essential condition for long-term success and competitiveness across many industries.*

Research tends to interpret sustainability broadly, with an emphasis on reducing environmental impact and optimizing economic performance, while frequently underexploring the social dimension of business operations (Girdhar and Punia, 2026). Social sustainability is defined by Sanders and Wood (2024) as a holistic approach aimed at environmental protection, enhancing quality of life, and preserving social capital. Although the social dimension of sustainability is receiving increasing scholarly attention, it still lacks a unique, coherent, and strategic understanding (Khan et al., 2026). This theoretical gap hinders the provision of adequate tools for managers and entrepreneurs to fully comprehend the discipline. As a consequence, firm-led initiatives often appear limited, episodic, and poorly structured, leaving the field fragmented (Girdhar and Punia, 2026; Hogrefe and Bohnet-Joschko, 2023; Öberg, 2012). Furthermore, this issue can be linked to the widespread application of Corporate Social Responsibility (CSR) practices which, while extensively examined at the firm level, often lack a broader perspective (Girdhar and Punia, 2026).

Parallel to this necessity, digital transformation (DT) is fundamentally restructuring industrial paradigms. DT has garnered increasing attention as a significant external force impacting both businesses and society (Matt et al., 2023), encompassing all changes brought about by the deployment of digital technologies (Majchrzak et al., 2016). To successfully navigate this transition, firms must adopt comprehensive digital strategies that enhance operational performance and organizational agility (Hess et al., 2016). Furthermore, DT serves as a catalyst for business model innovation, enabling firms to redefine how value is created, delivered, and captured (Teece, 2010; Zott and Amit, 2008). By leveraging core competencies through technological adoption (Liu et al., 2011), organizations can implement new business logics to secure a competitive advantage (Casadesus-Masanell & Ricart, 2010).

The convergence of digitalization and sustainability—often discussed within the context of Industry 4.0—presents fertile ground for innovation (Rahman et al., 2023; Upadhyay et al., 2021). However, while the economic and environmental ramifications of Industry 4.0 are well-documented, the social dimension remains under-researched. This scholarly gap is particularly evident regarding the impact of Industry 4.0 on social sustainability. As stakeholders increasingly demand demonstrable social engagement, there is a critical need for empirical research—especially within B2B contexts—to explore how technologically-mediated relationships enhance a firm's social commitment (Rahman et al., 2023).

Business markets are based on networks of actors that interact and exchange resources: these exchange systems (Shashi et al., 2025) are interconnected, as interactions within a specific relationship impact all other interactions (Håkansson and Snehota, 1995). These mutual influences form the foundation of a value-added chain, where value is co-created by all actors involved in the network (Re and Magnani, 2026; Lacoste, 2016). Value creation is a dynamic process

[1] Università Cattolica del Sacro Cuore, Milano, matteo.dominidiato@unicatt.it
[2] Università Cattolica del Sacro Cuore, Milano, elisamartina.martinelli@unicatt.it

embedded in specific contexts where conditions continuously evolve in time and space (Dziubaniuk and Aarikka-Stenroos, 2025; Grönroos and Voima, 2013). Möller (2013) describe the network as a relational system of interconnections among entities. Due to its inherent dynamism, the network undergoes a dual evolution: key interdependencies become institutionalized and difficult to alter, yet the network remains fluid through the entry or exit of members. Consequently, business networks exhibit a dualism between stability and change (Håkansson and Snehota, 1995) directed toward a common aim: the co-creation of value. This concept is based on the premise that network actors establish relationships not only for the value of exchanged goods but for mutual value creation (Lindgreen and Wynstra, 2005). The idea that network actors collaborate to produce higher value than providers can deliver alone is fundamental to B2B marketing (Lacoste, 2016). Therefore, understanding the network context is crucial. Investigating how actors react to their surrounding networks—impacted by forces such as social sustainability and DT—is essential (Re and Magnani, 2026).

To structure the empirical investigation, this study adopts the Activities–Resources–Actors (ARA) model (Håkansson and Snehota, 1995) as its conceptual lens, complemented by recent contributions on sustainable value co-creation in business networks (Lacoste, 2016; Re and Magnani, 2026). The ARA framework allows social sustainability to be analyzed as the joint outcome of three interdependent layers: the activity layer (how firms organize and connect social, technological, and operational practices); the resource layer (which tangible and intangible assets—including digital infrastructures—are mobilized and combined with those of partners); and the actor layer (which heterogeneous parties are progressively included in the network and how their bonds evolve). This framing positions digital transformation not as an external variable, but as an enabling infrastructure that reshapes activity links, resource ties, and actor bonds within the network, providing the conceptual scaffold for the analytical dimensions developed in the Results section.

Purpose of the paper. *The present research is designed to address the aforementioned gaps by investigating the intersection of DT, social sustainability, and business relationships. By positioning this study at the nexus of these three domains, we aim to explore how companies embedded in specific networks can pursue social sustainability goals by leveraging advanced technologies.*

Methodology. *This research is currently positioned at the initial, exploratory stage of a larger, ongoing research project. The investigation was primarily executed using a qualitative approach, grounded in a single case study design. This methodological choice was predicated on three core rationales—exploratory suitability, the uncovering of complex dynamics, and theoretical depth—directly addressing the novelty and complexity of the research objective. Firstly, qualitative methodologies are optimally suited for initial exploratory inquiries, particularly within specialized and dynamic industry contexts like the smart building ecosystem (Yin, 2013; Ellram, 1996). Secondly, a deep qualitative analysis focused on a single successful case is essential for uncovering intricate, underlying organizational and collaborative dynamics that may remain inaccessible through structured, quantitative instruments (Yin, 2009). This methodology is also highly appropriate for contexts defined by multi-subject relationships and interactions, which represent a core theme of digital platform collaboration (Mantere and Ketokivi, 2013). Lastly, the case study approach is employed here to provide theoretical depth by examining a contemporary phenomenon within its native, real-world context, particularly where the boundaries between the technological phenomenon and the organizational system are ambiguous (Yin, 2013).*

The selected case study is Florim, a company founded in 1962 in the Sassuolo district (Italy), which is a leader in the ceramic industry and engages in the production of ceramics for various purposes, from household furnishings to industrial applications. Florim was chosen for this research due to its notable commitment to sustainability principles. Indeed, the company has received the prestigious B Corp certification, demonstrating its tangible dedication to having a positive impact on both the environment and society.

Florim is treated here as a revelatory case (Yin, 2009) rather than a merely illustrative one. Three features support this status. First, the firm operates in a traditional, asset-heavy manufacturing sector—ceramics—where social sustainability is rarely problematized at network level, making the observation of a structured social-digital strategy theoretically informative beyond the single firm. Second, Florim hosts the first medical training centre embedded within a private Italian company to be certified by the American Heart Association, an empirical configuration that allows the observation of dynamics—the convergence of digital infrastructure, social purpose, and inter-organizational competence integration—that are typically inaccessible or fragmented in more conventional settings. Third, the firm's status as a B Corp combined with a long-standing investment in Industry 4.0 makes visible the joint unfolding of digital and social transformation processes that, in most companies, occur in separate organizational silos. Following the logic of theoretical sampling (Eisenhardt and Graebner, 2007), the case is therefore selected for its capacity to extend rather than test theory, providing analytical generalization (Yin, 2013) toward a more systemic understanding of social value co-creation in business networks.

Data collection involved a triangulation of primary and secondary sources to ensure the robustness of the findings. Secondary data encompassed a comprehensive review of publicly available documents, including market analyses, corporate reports, company presentations, official websites, and conference materials, which were used to establish the context and define the firm's strategic positioning and platform capabilities (Dubé and Paré, 2003; Eisenhardt, 1989; Miles and Huberman, 1984). Primary data were gathered via 5 semi-structured interviews conducted with key organizational figures, ensuring their credibility as reliable sources capable of providing valuable insights for this research (Alvesson and Ashcraft, 2012). A semi-structured interview guide was employed to afford participants the

flexibility to introduce other relevant topics they considered important. The interviews were conducted either face-to-face or via Microsoft Teams in Italian between September 2023 and November 2025. These sessions lasted approximately one hour and a half, were recorded, and subsequently transcribed for analysis. It should be noted that data collection is currently ongoing, with further interviews already scheduled with the company to deepen the empirical evidence. The iterative nature of data collection is consistent with the systematic combining logic adopted in this study, in which fieldwork and theoretical framing co-evolve. The empirical base presented here, however, is already considered sufficiently saturated with respect to the three analytical dimensions discussed in the Results section, as the most recent interviews produced no new first- or second-order themes. Additional interviews will serve to extend the network perspective beyond the focal firm rather than to consolidate the within-case interpretation.

Data analysis followed an abductive logic consistent with the systematic combining approach (Dubois and Gadde, 2002), which is particularly suited to qualitative inquiry within the IMP tradition, where empirical material and theoretical framework are progressively refined in parallel. Interview transcripts and secondary sources were analyzed through coding activity. Open coding was applied to the full corpus, generating first-order concepts that remained close to the language of the informants (e.g., "giving back to the territory", "training healthcare professionals", "step outside our network"). This helped identifying three aggregate analytical dimensions presented in the Results section (network-embedded social sustainability; digital technologies as relational enablers; network expansion as a precondition for social value creation), explicitly mapped onto the Activities–Resources–Actors (ARA) model (Håkansson and Snehota, 1995) to ensure consistency with the broader theoretical conversation.

Data triangulation was implemented across primary interviews, corporate sustainability reports, B Corp documentation, and public communications, allowing convergent evidence on the same phenomenon to be cross-checked. Moreover, a member checking was conducted by sharing preliminary findings with the firm's Sustainability Manager, who confirmed the plausibility of the analytical interpretation and provided clarifications on contested points.

Results. *Florim distinguishes itself from its peers through an advanced perspective on social sustainability that transcends traditional corporate philanthropy. This preliminary single case study analysis highlights three emerging analytical dimensions that link DT, network dynamics, and social value creation: (1) network-embedded social sustainability, (2) digital technologies as relational enablers, and (3) network expansion as a precondition for social value creation.*

First, the findings suggest that social sustainability evolves from an internal, firm-centric activity into a network-embedded process of value co-creation. Beyond standard environmental practices, the company has adopted a strategic social approach that extends well beyond employee training. Florim is committed to giving back to its local territory by leveraging the resources and human capital generated within its production processes, prioritizing the well-being of its workforce, their families, and the wider community. This shift indicates that social sustainability outcomes are not produced in isolation, but emerge through continuous interaction with multiple stakeholder groups, supporting a relational interpretation of the social pillar of sustainability.

The first key stakeholder group is Florim's workforce. With 1,432 employees worldwide, the company invests heavily in professional development, delivering over 13,000 hours of training in 2024. This includes the launch of Florim Learning, a digital platform that contributed 3,000 hours of specialized education. Programs focusing on leadership, cybersecurity, and the internal Master's degree demonstrate a commitment to lifelong learning. Furthermore, workplace safety remains a central pillar; in 2024, accidents decreased by 38% compared to the previous year, supported by prevention programs and free medical screenings in partnership with Sassuolo Hospital. These initiatives exemplify how internal stakeholders are integrated into a broader system of social value creation, where digital tools (e.g., learning platforms) facilitate continuous capability development and relational engagement.

The second stakeholder is the local community. Florim promotes public health through vaccination campaigns and blood donation drives, alongside welfare initiatives such as childcare support and flexible work arrangements. This engagement is formalized through the Ing. Giovanni Lucchese Foundation—named after the founder of Floor Gres and current Florim patriarch—which was officially registered in the National Third Sector Register in 2024. The Foundation provides scholarships, supports local hospitals, and funds social projects, including Red Cross initiatives and autism support programs, thereby strengthening the social fabric of the ceramic district. From an analytical perspective, these activities highlight how firms can act as orchestrators of local network, reinforcing the idea that social sustainability is co-produced at the territorial level rather than delivered unilaterally.

The third stakeholder group comprises voluntary associations. On a global scale, Florim contributes to the Water is Life project in collaboration with Rock No War. This voluntary organization has been active for many years in international solidarity, aiming to provide concrete aid and relief in regions where conflict or underdevelopment have caused significant hardship. To date, the Water is Life project has completed 88 interventions across 29 countries, delivering clean water to marginalized populations. This evidence further supports the interpretation of social sustainability as a multi-scalar phenomenon, extending beyond local boundaries and enabled by network linkages that connect geographically dispersed actors.

The fourth stakeholder category is represented by cultural entities. Through initiatives such as the Florim Gallery, partnerships with the Peggy Guggenheim Collection, and the Art to Share project, the company pursues a holistic vision that integrates innovation, culture, and solidarity to generate a positive global impact. These collaborations illustrate

how non-traditional partners contribute to the co-creation of social value, expanding the conceptualization of relevant actors within business networks.

Second, the findings show that DT acts as a relational infrastructure that enables and amplifies social value co-creation. The final and most critical stakeholder group consists of healthcare institutions. This dimension represents the core of the present research, as it provides a clear empirical illustration of how a company can address social sustainability gaps by operating at the nexus of DT and strategic business relationships. In 2014, Florim launched the "Florim Health & Training Center" at its Fiorano headquarters, a project that transcends traditional corporate philanthropy by integrating advanced technology into the company's social value proposition. By allocating over 600 square meters of its industrial facility to medical training, research, and advanced simulation, Florim established the first center within a private Italian company to be certified by the American Heart Association. This initiative is not merely a social project but a sophisticated application of DT to the public welfare sector. The center is equipped with high-fidelity medical humanoids capable of replicating complex human physiological functions. These humanoids are managed via a state-of-the-art control room, utilizing Internet of Things (IoT) and digital monitoring systems to provide real-time feedback during medical simulations. This technological infrastructure allows healthcare professionals—not only from the local district but from across Italy—to refine their life-saving skills in a risk-free, technologically advanced environment. Analytically, this case demonstrates that digital technologies function as boundary-spanning mechanisms that connect heterogeneous actors and enable the creation of shared value even outside the traditional core business environment. Rather than being limited to efficiency improvements, digital tools become central elements in structuring and sustaining inter-organizational relationships oriented toward social outcomes.

Third, the findings highlight that pursuing social sustainability requires the intentional expansion and reconfiguration of business networks. The development of this project highlights the critical role of inter-organizational relationships in navigating unfamiliar strategic domains. As the Sustainability Manager emphasized, the realization of the Health & Training Center required Florim to step outside its established industrial network. The company faced a significant competence gap, as the resources required for medical simulation were entirely foreign to its core business of ceramic production. To bridge this gap, Florim had to cultivate a new network of experts, medical equipment providers, and healthcare institutions. This process of network expansion demonstrates that social sustainability is often a collaborative outcome: the company leveraged its physical facilities and financial strength, while its new partners provided the specialized knowledge and technological standards required for medical certification. This finding suggests that value co-creation in the context of social sustainability is not only a matter of interaction among existing actors within the same core business environment, but also of actively incorporating new ones, thereby extending current network boundaries and redefining the locus of value creation.

Furthermore, this case underscores how technologically-mediated relationships can act as a catalyst for social performance. Florim did not simply apply Industry 4.0 logic to its manufacturing lines (e.g., its automated factory); it extended this digital mindset to its social initiatives. The center functions as an automated hub of excellence where the convergence of digital tools and professional networks creates a unique form of relational value that benefits the entire network of actors involved. Overall, the findings move beyond a purely descriptive account by demonstrating how DT, network reconfiguration, and social sustainability are jointly intertwined, offering a basis for theoretical generalization toward a more systemic and relational understanding of social value co-creation.

Read through the ARA lens, the three analytical dimensions can be synthesized into an emerging interpretive proposition: social sustainability in B2B networks is co-produced through digitally mediated activity links that mobilize heterogeneous resource ties and progressively reconfigure actor bonds beyond the focal firm's industrial network. Three theoretical implications follow from this proposition. First, the locus of social value creation shifts from the firm to the network: social outcomes are not delivered, but emerge from interaction patterns that the firm orchestrates but does not own. Second, digital technologies operate as boundary-spanning resources, whose function is not primarily efficiency-related but relational, enabling activity links between actors that would otherwise lack a shared technical language (e.g., a ceramic manufacturer and healthcare institutions). Third, social sustainability appears to require an intentional asymmetry in network structure: the focal firm contributes physical and financial resources, while non-traditional partners contribute legitimacy and specialized competence, generating a form of relational value that none of the actors could produce in isolation. These insights move the discussion beyond the descriptive account of the case toward a more general theoretical contribution to the IMP tradition and to the literature on digital-enabled sustainability.

Research limitations. *This study represents the preliminary, exploratory phase of a broader, ongoing research project aimed at mapping the complex synergies between digital innovation and social sustainability in business networks. Consequently, the findings presented must be interpreted within the context of several inherent limitations that provide fertile ground for future scholarly inquiry.*

A primary constraint lies in the research's current reliance on a single case study within the Italian ceramic district. While this approach offers exceptional depth, it limits the broader generalizability of the results across different industrial sectors or geographical regions with diverse institutional frameworks. To address this, future research should adopt a multiple-case study design or cross-sectoral analysis.

Furthermore, the exploratory nature of this initial phase focuses heavily on strategic intent and the qualitative description of technological integration. There is currently a lack of longitudinal quantitative data to measure the long-term impact of these digital social initiatives. Future investigations could therefore employ longitudinal methodologies

providing a more robust empirical basis for the exploration of the synergy between digital maturity and social performance.

Lastly, as data collection is still in progress, the current evidence is primarily reflective of the focal firm's internal perspective. While this provides a clear view of corporate vision, it may overlook the nuances of how external partners perceive and extract value from these technologically-mediated relationships. To resolve this limitation, future research directions should include a multi-actor perspective, gathering primary data from the wider network, such as healthcare institutions. This panoramic approach would allow for a more comprehensive understanding of how value is truly co-created at the nexus of DT and social sustainability, ensuring that the benefits are systemic rather than merely organizational.

Managerial implications. *The findings of this research offer several critical insights for practitioners and strategic leaders aiming to synchronize digital innovation with social responsibility. In addition to their practical relevance, these implications are grounded in the empirical evidence and directly connected to the theoretical dimensions emerging from the analysis (i.e., network embeddedness of social sustainability, digital technologies as relational enablers, and network reconfiguration).*

Primarily, the study suggests that managers must evolve their perspective from traditional, episodic corporate philanthropy toward a Social Sustainability 4.0 model. In this framework, DT is not merely an internal tool for optimizing manufacturing efficiency but a core component of the firm's social value proposition. By integrating advanced technologies—such as IoT-driven medical simulation or dedicated digital learning platforms—into social initiatives, managers can transition from being passive donors to becoming active architects of high-value social networks. This shift requires a digital mindset that views technological assets as versatile instruments capable of generating measurable impacts far beyond the factory borders.

Furthermore, the research underscores the necessity for managers to proactively navigate and bridge competence gaps when pursuing ambitious social objectives. The case of the Florim Health & Training Center demonstrates that radical social innovation often necessitates stepping outside established industrial networks. For management, this implies a need for high relational agility: the ability to identify, cultivate, and orchestrate partnerships with non-conventional actors, such as healthcare institutions, medical equipment providers, and scientific experts. Successful social performance, therefore, becomes a collaborative outcome of network expansion, where the focal firm leverages its financial and physical resources while its partners provide the specialized knowledge and certifications required for credibility. Empirical findings indicate that this process is not spontaneous but requires intentional network reconfiguration, reinforcing the managerial need to develop capabilities in partner selection, coordination, and long-term relationship management across domains.

Finally, the study highlights that investments in digital infrastructure for social purposes can serve as a powerful relational catalyst. By providing shared technological assets that benefit the broader community—such as national healthcare systems or local educational districts—firms can significantly enhance their legitimacy and territorial embeddedness. Managers should recognize that these technologically-mediated relationships create a unique form of relational value that transcends financial returns, ultimately strengthening the firm's competitive positioning by aligning corporate success with systemic social progress. This suggests that social sustainability initiatives, when digitally enabled, should be strategically designed as open and participatory platforms rather than closed, firm-centric programs related to the traditional core business of the company.

Originality of the paper. *The originality of this research lies in its integrated positioning at the nexus DT, social sustainability, and B2B relationship, addressing some gaps in current literature. The paper articulates three specific theoretical contributions, which advance the conversation on social sustainability, digital transformation, and business networks beyond a restatement of existing positions.*

While research has traditionally focused primarily the attention on environmental and economic sustainability, leaving the social dimension underexplored and strategically fragmented (Girdhar and Punia, 2026; Khan et al., 2026), this study addresses this specific gap by providing a coherent and strategic exploration of social sustainability. Specifically, the research does not simply reaffirm this gap, but critically problematizes it by highlighting the lack of a network-oriented and technology-enabled understanding of social sustainability. The paper argues that prior literature has treated the social pillar either as an internal firm outcome or as a CSR extension, overlooking its relational and systemic nature. By analyzing how Florim integrates its social commitment into its core operational logic, this study conceptualizes social sustainability as a network-embedded and co-created process, moving beyond the episodic and poorly structured initiatives (Hogrefe and Bohnet-Joschko, 2023; Öberg, 2012).

Furthermore, while the ramifications of Industry 4.0 are well-documented in manufacturing, their implications on social sustainability have been only marginally theorized, particularly within B2B contexts (Rahman et al., 2023). This research extends existing knowledge by showing how DT acts not only as an operational enabler but as a relational infrastructure that supports new forms of social value co-creation. The study highlights the use of high-fidelity humanoids and IoT-driven monitoring not as mere industrial tools, but as mechanisms through which heterogeneous actors (firms, healthcare institutions, and communities) interact and jointly generate social outcomes. In doing so, it responds to the call for research into how technologically-mediated relationships enhance a firm's social commitment (Rahman et al.,

2023), providing an empirically grounded interpretation of digital technologies as boundary-spanning devices in social sustainability processes.

Finally, the paper contributes to network theory by refining the concept of value co-creation in light of social sustainability objectives. While literature suggests that value is co-created by all actors in a network (Lacoste, 2016; Lindgreen and Wynstra, 2005) and that businesses must recognize objectives beyond financial interests (Re and Magnani, 2026), this research advances this perspective by demonstrating that the pursuit of social sustainability requires intentional network reconfiguration and expansion beyond traditional industry boundaries. It shows that the convergence of digital tools and professional networks generates a distinct form of relational value—social-systemic value—that is not fully captured by existing co-creation frameworks. This is particularly evident when firms enter unfamiliar domains and mobilize new competencies through digitally enabled collaborations, thereby extending current theory on value co-creation toward a more systemic and socially oriented interpretation.

The study introduces the notion of social-systemic value as a distinct outcome of digitally mediated network reconfiguration: a form of relational value that (i) is socially oriented in its purpose, (ii) is systemic in its scope, as it accrues to the network and the surrounding community rather than to dyadic exchange, and (iii) is digitally enabled in its mode of production, since high-fidelity digital infrastructures are constitutive—not merely supportive—of the relational ties that generate it. This construct is offered as a preliminary theoretical contribution to be tested and refined in subsequent stages of the research project.

CSR Behaviour and Perceived Relevance in Micro and Small Family Businesses: Evidence from the Italian Context

VICTORIA GIANNETTI[1], GIANPAOLO BASILE[2], MARIA PALAZZO[3], ALESSANDRA MICOZZI[4]

Abstract. This paper adopts an inductive approach based on empirical research conducted in Italy by Universitas Mercatorum and Federterziario within the LAMP Observatory activities. The study examines 139 micro and small firms to analyse the level of knowledge and implementation of sustainability practices, CSR and ESG behaviours, and their perceived relevance, while exploring the latent influence of the temporal dimension. On this premise, the empirical context is characterised by micro and small enterprises, predominantly family-owned and managed.

To address this issue, the study draws on the literature on sustainability and ESG issues in micro and small family businesses. Furthermore, it analyses sustainability orientation using a Perceived Relevance–Implementation matrix that captures the relationship between perceived relevance and CSR/ESG behaviours.

The matrix enables an integrated interpretation of the degree of consistency or misalignment between the cognitive and operational dimensions of sustainability. The findings reveal heterogeneous patterns across firms and suggest that the temporal dimension may play a relevant role in explaining the evolution of sustainability practices.

The study contributes to the literature on CSR and ESG in micro and small family firms by providing exploratory empirical evidence and proposing an interpretative framework for analysing the alignment between perceived relevance and organisational implementation.

Keywords: sustainability; ESG; micro and small firms; family business; CSR practices; perceived relevance – implementation matrix.

Framing of the research. The rapid growth of socially responsible investment (SRI) and the publication of international standards for CSR reporting, such as the GRI guidelines, have laid the foundation for reporting to play a significant role in the disclosure of corporate performance (Cho, 2013).

Therefore, since CSR information is not directly reflected in traditional financial statements, in recent years, many stakeholders increasingly seek information on firms' CSR and ESG performance in order to evaluate corporate behaviour and sustainability commitments (Cohen et al., 2011; Esposito De Falco et al., 2021). This matter is a relevant fact for investors, stakeholders, and market decision-making (Sehrish et al., 2024), thereby improving the firm's reputation (An et al., 2011) and reducing uncertainty about the firm's value (Izadi et al. 2025).

In this vein, voluntary disclosure regarding CSR aspects reduces the problems of asymmetric information between different stakeholders and market agents, which is especially important in economic contexts, such as those populated by micro and small firms, that are characterised by a strong focus and commitment to stakeholders (Ferrero et al., 2015).

Regarding CSR applications, Dahlsrud (2008) and Mariani et al. (2023) argued that behaviours and strategies might vary across organisational settings, and that business families characterise the global economy. Therefore, many researchers, such as Chrisman et al. (2012) and De Massis et al. (2014), have sought to define this type of firm. Drawing on existing research, this study defines a family business as any firm characterized by transgenerational intent, a distinct family identity, and unique social and human capital, where the founder retains ownership and holds a seat on the board of directors (Chrisman et al., 2012; Habbershon et al., 2003; Miller et al., 2011; Gjergji et al., 2021).

In this context, the specific characteristics of family businesses, such as simpler management structures, limited financial and human resources, and stronger social relations influenced by the desire to preserve the socioemotional wealth (SEW), may affect the effectiveness of CSR disclosure (Berrone et al., 2012; Dey et al., 2022).

Regarding that, a lot of researchers such as Kolk & Perego (2010) argue that family business firms act according to the community's component status in the society in which they operate, for this reason they are considered stakeholder-oriented and expected to fulfil certain social responsibilities and observable behaviours, such as waste management, welfare, gender equity, that produce their impacts in short terms and in communitarian tangible manner (Banerjee, 2002; Schuler and Cording, 2006).

Factors such as business size, increasing market competition, globalisation, and the temporal dimension are interrelated. Therefore, firms, predominantly large companies, with financial resources, develop more ethical procedures and/or substantial investments to achieve long-term goals. Rather than micro and small businesses, which are prevalently involved in overcoming local competitive challenges, are local stakeholder-oriented, have limited financial resources and focus their responsible efforts on the sustainable short-term objective.

Regarding this, family members feel a strong sense of identification with the company, which is seen as an extension of it, and through which it also develops social ties with a wide range of stakeholders, such as employees, suppliers, customers, lenders, and the community at large (Fuetsch, 2022).

According to the signaling theory this condition shows how a given pattern of action might signal particular hidden attributes, provide benefits to both signaler and observers, and meet the conditions for observable CSR behaviours that contribute to Institutional theory objectives.

According to Ericson and Laibson (2019), agents are more likely in the present to choose an action that generates immediate experienced utility. Because many ESG investments are long-term oriented and pay off far into the future, they may be perceived as having less financial, social, or emotional utility than projects with more immediate benefits. To reinforce this trend, psychologists, sociologists, and economists have argued that people favour generosity towards those with whom they are socially close rather than mere acquaintances or strangers. This approach allows firms to evaluate immediate effects while reducing perceived investment risks (Van Boven et al., 2010).

Despite the growing literature on CSR and ESG disclosure, existing studies have mainly focused on large corporations and listed firms (Esposito De Falco et al. 2024; Martins et al., 2022). Much less is known about how sustainability is perceived and operationalized within micro and small family businesses. Notably, the relationship between the perceived relevance of sustainability and the effective implementation of CSR practices remains largely unexplored, especially in light of firms' temporal orientation (Cantele & Zardini, 2020). This paper aims to address this gap by analysing the alignment between perceived relevance and CSR behaviour in Italian micro and small family firms.

Purpose of the paper. This paper aims to analyze the implementation and perceived relevance of CSR and ESG practices, while considering the temporal dimension as a latent variable that may influence these factors.

This study is theoretically grounded in a scientific framework that highlights two key and interconnected dimensions, drawing on Institutional and Signaling theories.

Regarding that, the research questions is:
What is the relationship between the perceived relevance of sustainability and the implementation of CSR behaviours in micro and small family firms?

Methodology. *3.1 Research design.* This study adopts an exploratory, inductive research design to investigate whether and how a specific temporal orientation influences CSR behaviours and Perceived relevance in micro and small family firms. Given the limited availability of structured, comparable data on sustainability practices among Italian micro and small enterprises, a survey-based methodology was considered the most appropriate for capturing both the cognitive and operational dimensions of sustainability.

The research follows a cross-sectional design and focuses on the biennium 2023–2024, thereby enabling a homogeneous temporal reference for evaluating firms' sustainability practices. The aim is not to test causal relationships through advanced econometric modelling, but rather to identify patterns of coherence or misalignment between what firms declare about sustainability and what they actually implement.

3.2 Data collection and sample characteristics. Data were collected through a structured questionnaire administered online to firms affiliated with FederTerziario, a national Italian employers' association representing micro, small and medium-sized enterprises. The survey was conducted exclusively within the FederTerziario network. This bounded organizational context is relevant to the interpretation of the findings, as the firms surveyed are embedded in a shared representative system that may shape informational flows, normative orientations and managerial awareness, particularly regarding sustainability-related issues.

The sampling strategy follows a non-probabilistic approach, consistent with the exploratory purpose of the research and with the association-based access to respondents. While the sampling strategy does not allow statistical generalization, it is appropriate for exploratory research aimed at identifying emerging patterns within a specific organizational context. Out of an initial sample of 139 firms, 136 valid questionnaires were collected and included in the final analysis.

The sample is predominantly composed of micro and small enterprises, reflecting the typical composition of the FederTerziario network. A significant proportion of firms employ fewer than five employees and report annual revenues below €500,000. From a governance perspective, more than 70% of the firms declare family ownership or management, and over half are directly managed by the entrepreneur or principal shareholder. The vast majority have not experienced a generational transition in the last decade, suggesting relatively stable ownership and control structures. Overall, the profile of respondents is coherent with the structural characteristics of the Italian productive system, in which micro and small family firms represent a dominant organizational form.

3.3 Structure of the questionnaire. The questionnaire was designed to align with a coherent analytical architecture that links firm structural characteristics to sustainability orientation and behavioural outcomes. Rather than being a purely descriptive tool, the instrument reflects the theoretical framework underpinning the study, particularly the relationship among governance configuration, stakeholder embeddedness, and CSR behaviours.

The survey included multiple sections covering firm profile, ownership and governance, human resource management, territorial embeddedness and sustainability practices. Sections A and B focus on structural and governance characteristics, which are particularly relevant in the context of micro and small family firms, where ownership concentration and

managerial centralization may influence strategic orientation and temporal horizon. Section C explores human resource policies and organizational practices, capturing internal relational dynamics and investment orientation. Section D investigates the firm's embeddedness within its territorial and institutional environment. Section E concentrates on sustainability and ESG issues and constitutes the empirical core of the present contribution.

The overall structure of the questionnaire is summarized in Table 1.

Table 1 – Conceptual structure of the questionnaire

Section	Analytical Dimension	Theoretical Relevance	N° of Questions
A–B	Structural and governance configuration	Ownership concentration, managerial centralization, generational continuity	12
C	Organizational and relational dynamics	Human capital investment, internal stakeholder orientation	13
D	Territorial and institutional embeddedness	Origins and Interactions among Firms, Territory, and Institutions	10
E	Sustainability and ESG orientation	Perception, implementation and formalization of CSR practices	12

3.4 Construction of the Perceived Relevance–Implementation Matrix. To interpret the configuration of sustainability within the sampled firms, a materiality-inspired matrix was developed. The matrix conceptually maps the selected ESG themes across two analytical dimensions, perceived relevance to the firm (horizontal axis) and CSR behaviour (vertical axis), thereby providing a structured framework for their interpretation. The ESG themes in the matrix were derived from questionnaire items on environmental practices, human capital management, occupational safety, and governance mechanisms. The positioning of themes within the matrix is based on the relative distribution of the perception and implementation indices rather than on predefined thresholds.

The aim of this analytical framework is not to assess materiality in a normative reporting sense, but to examine the level of internal coherence between the cognitive framing of sustainability and its effective organizational embedding. The perceived relevance dimension reflects the managerial perception expressed by the respondents, primarily entrepreneurs or owner-managers, regarding the importance attributed to specific ESG themes. The CSR behaviour dimension captures the extent to which CSR practices and formal governance mechanisms are effectively adopted.

The horizontal axis integrates evidence from three survey items: spontaneous associations with sustainability (E1), perceived benefits linked to sustainable behaviour (E2), and the extent to which sustainability is considered a guiding value (E3). For each theme *t*, a Perception Index (PI_t) was constructed as the arithmetic mean of the relevant percentage values:

$$PI_t = \frac{\sum_{i=1}^{m_t} P_{it}}{m_t}$$

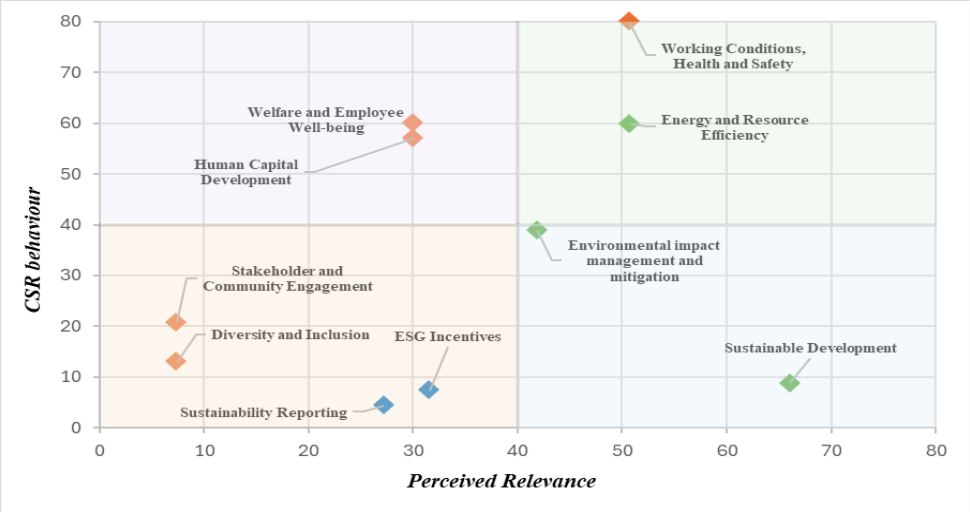
where P_{it} represents the perception proxies associated with theme *t*, and m_t denotes the number of perception variables considered.

The vertical axis synthesizes environmental and social practices (E4–E5), disclosure tools (E6), and ESG-linked remuneration systems (E8). For each theme, an Implementation Index (II_t) was calculated as:

$$II_t = \frac{\sum_{i=1}^{n_t} I_{it}}{n_t}$$

where I_{it} denotes the implementation proxies associated with theme *t*, and n_t represents their number.

Given the exploratory nature of the study, the indices were constructed as simple arithmetic means of selected proxies, without applying weighting or standardization procedures. The objective is interpretative rather than predictive. In this study, the temporal dimension is not directly operationalized through specific survey items. Instead, it is used as an interpretive analytical lens to explain the patterns of alignment and misalignment observed between perceived relevance and CSR behaviour. The matrix therefore, provides a structured reading of patterns of coherence and misalignment between perceived relevance and organizational embedding, rather than a statistically generalizable measurement.



Results. The empirical findings are presented through the Perceived Relevance–Implementation matrix, which operationalizes the relationship between CSR behaviours and firms'orientation. By comparing declared importance and actual implementation of ESG themes, the analysis identifies patterns of coherence and misalignment that help explain how sustainability is embedded within micro and small family firms. Table 2 reports the values of the and the Implementation Index (II) for the ESG themes considered in the analysis, providing the empirical basis for their positioning within the matrix. The positioning of ESG themes according to the Perception Index and the Implementation Index is illustrated in Figure 1.

Table 2 - Perception and Implementation Indices by ESG Theme

ESG Themes	*Perception Index (PI)*	*Implementation Index (II)*
Environmental impact management and mitigation	41,9	39
Energy and Resource Efficiency	50,7	60
Sustainable Development	66	8,9
Working Conditions, Health and Safety	50,7	80
Human Capital Development	30	57
Welfare and Employee Well-being	30	60
Diversity and Inclusion	7,4	13
Stakeholder and Community Engagement	7,4	20,8
Sustainability Reporting	27,2	4,4
ESG Incentives	31,6	7,4

Figure 1. Perceived Relevance – CSR behaviour matrix

Source: Authors' elaboration based on survey data (2023–2024)

The matrix provides an integrated representation of sustainability within the sampled firms, highlighting the degree of alignment, or misalignment, between the cognitive and operational dimensions of ESG themes. The intersection between perceived relevance and CSR behaviour reveals differentiated patterns across environmental, social and governance domains, suggesting an evolutionary trajectory that remains incomplete.

Environmental dimension: operational convergence under normative pressure. Environmental protection emerges as the most pivotal theme at a perceptual level. In response to E1, 60.3% of respondents spontaneously associate sustainability with environmental protection. In E2, 50.7% identify cost savings from energy efficiency as a key benefit, while 23.5% cite climate risk reduction. At the operational level, environmental practices are relatively widespread. Approximately 70% of firms report waste separation practices, 68% declare the use of recycled or low-impact materials, and around 60% monitor energy consumption. However, more advanced practices show significantly lower diffusion: only about 10% monitor greenhouse gas emissions and approximately 15% have adopted a structured environmental management system. This configuration places environmental issues in the quadrant characterized by relatively high perceived relevance and moderate implementation. Nonetheless, implementation remains concentrated in basic and efficiency-oriented practices rather than in systematic impact measurement and structured environmental governance. These issues require structural investments and changes in organizational culture that could produce reputational and economic effects in the long term.

Occupational health and safety: strong alignment. Decent and safe working conditions are cited by 50.7% of respondents as a core aspect of sustainability. At the implementation level, approximately 80% of firms report adopting a health and safety management system. This represents the strongest alignment between perception and implementation within the matrix. The coherence observed in this area reflects the presence of well-established regulatory frameworks that make

the adoption of such practices almost mandatory and produce immediate impacts on reputation, considering that employees could be community components.

Human capital and welfare: implementation exceeding explicit ESG framing. Training and human capital development display a distinct configuration. Around 30% of respondents associate sustainability with employee-related aspects at the perceptual level, while implementation rates for structured training plans reach approximately 55–60%. Welfare initiatives show similar levels of adoption, around 60%. In this case, operational practices exceed explicit ESG framing. Firms invest in internal social initiatives for organizational and relational reasons, employee retention, skill development and workplace climate, yet these initiatives are not always conceptualized as part of a formal sustainability strategy. This pattern reflects an inward-looking sustainability embedded in daily management rather than in an articulated ESG paradigm, producing, in the temporal dimension view, the same effects described before.

Governance and formalization: structural weakness. Governance-related themes occupy the quadrant characterized by both low perceived relevance and low implementation. Although 27.2% of respondents associate sustainability with transparency in management, only 4.4% of firms have produced a sustainability report in the 2023–2024 biennium. Likewise, only 7.4% have introduced remuneration systems linked to ESG objectives, and the adoption of recognized standards such as GRI or SDGs remains marginal. The broader theme of sustainable development reveals a particularly pronounced gap. While 66% of respondents place sustainability in the upper levels of the Likert scale when asked whether it represents a guiding value, structured implementation tools remain extremely limited: reporting at 4.4%, ESG incentives at 7.4%, and environmental management systems at approximately 15%.

Differentiated Signaling Mechanisms Across ESG Domains. Beyond the alignment between perceived relevance and CSR behaviour, the matrix also reveals differentiated signaling patterns across ESG domains. Practices that are directly observable by internal and local stakeholders, such as occupational health and safety or basic environmental initiatives, display relatively high levels of implementation, as visible CSR initiatives can influence stakeholder perceptions and behaviours and reinforce the credibility of sustainability commitments (Wu et al., 2025). These behaviours are visible within the community and can function as relational signals of responsibility and reliability, consistent with recent interpretations of signaling processes in sustainability contexts (Connelly et al., 2011). Conversely, formal disclosure mechanisms, such as sustainability reporting (4.4%) or ESG-linked remuneration systems (7.4%), remain marginal. These instruments are typically directed toward more distant stakeholders, including financial actors and institutional investors, and require higher organizational and informational investments. Recent European evidence supports the view that structured sustainability and ESG disclosure help reduce information asymmetries and strengthen credibility in capital markets. For instance, sustainability reporting has been shown to be negatively associated with information asymmetry in UK-listed firms, although the relationship is moderated by family control (Al Natour et al., 2022). Complementary evidence on European SMEs indicates that ESG disclosure is associated with a lower cost of capital, with family business status influencing this relationship (Gjergji et al., 2021).
These findings reinforce the interpretation that formal ESG disclosure mechanisms operate not only as transparency instruments but also as strategic devices aimed at enhancing credibility and mitigating uncertainty in capital markets and within communities where the firms operate. Therefore, the limited adoption of such mechanisms among the sampled firms suggests that their communication strategies are not primarily oriented toward distant financial stakeholders. Instead, sustainability practices function predominantly as relationally embedded forms of accountability, rooted in proximity-based stakeholder interactions rather than in structured disclosure systems designed to address broader market-level information asymmetries. The matrix highlights a sustainability configuration characterised by selective operational consolidation and limited formalisation of governance, indicating structural gaps in the strategic integration of ESG practices.

Discussion. The Perceived Relevance–Implementation matrix provides a theoretically grounded interpretation of sustainability within micro and small family firms. The findings reveal an uneven integration of sustainability across ESG domains, with stronger consolidation in regulated and operational areas and weaker formalization in governance mechanisms.

From an Institutional Theory perspective, firms operate within environments shaped by regulatory frameworks and normative expectations that influence organizational behaviour (Campbell, 2007). The strong alignment observed in occupational health and safety and basic environmental practices can therefore be interpreted as the result of coercive and normative pressures that encourage the adoption of practices that ensure compliance and social legitimacy. Conversely, governance-related mechanisms such as sustainability reporting, ESG-linked remuneration systems and standardized disclosure frameworks remain weakly institutionalized within micro and small enterprises. Their limited diffusion suggests that formal ESG disclosure has not yet become a consolidated expectation for this segment (Setyaningsih et al., 2024). As a result, sustainability practices tend to develop primarily in areas with stronger regulatory pressure (Tyler et al., 2024) and where benefits are more immediate and observable, such as cost savings or improved resource efficiency (Mohammadi et al., 2026). In family firms, sustainability may also serve as a symbolic resource, through which organisations signal conformity with socially desirable norms and values (Rehman & Hamdan, 2023). The high

proportion of respondents who declare sustainability as a guiding value indicates strong symbolic endorsement, consistent with the reputational and socioemotional considerations that often characterise family-controlled firms (Mariani et al., 2023). However, the gap between this symbolic commitment and the limited adoption of governance mechanisms suggests that legitimacy is often pursued through visible operational practices rather than through formal accountability systems (Esposito De Falco & Cucari, 2025). The findings can also be interpreted through the lens of temporal orientation. Practices associated with immediate economic benefits or regulatory compliance are widely implemented, whereas mechanisms requiring medium- to long-term investments, such as sustainability reporting systems or certified environmental management frameworks, remain marginal. The temporal dimension therefore helps explain why micro and small family firms tend to prioritize CSR practices characterized by immediate, observable benefits over long-term governance investments. In organizational contexts characterized by centralized decision-making and limited managerial specialization, such investments may be perceived as disproportionate to the firm's scale (Spence, L. J. 2016). Consequently, firms appear more inclined to adopt sustainability practices that produce visible outcomes within local stakeholder networks, such as employees, customers and community members, while governance tools directed toward more distant stakeholders remain less frequently adopted (Ernst et al., 2022).

Overall, sustainability in the analysed firms appears socially legitimized but organizationally only partially institutionalized. It is widely recognized at the symbolic level and operationally embedded in selected domains, yet only partially institutionalized within governance structures. The matrix, therefore, suggests that sustainability in micro and small family firms is situated in a transitional stage, where cognitive awareness precedes full systemic integration and where temporal orientation shapes the translation of sustainability values into structured governance practices.

Research limitations. Despite the theoretical and empirical contributions of this study, several limitations should be acknowledged. First, the research uses a cross-sectional survey design, which captures sustainability perceptions and practices at a single point in time. This approach constrains the ability to infer causal relationships and to fully assess the dynamic evolution of sustainability integration within micro and small family firms. Given the relevance of temporal orientation and evolutionary trajectories highlighted in the analysis, longitudinal studies would be particularly valuable in capturing how CSR behaviours and governance mechanisms develop over time and in response to changing institutional pressures.

Second, the empirical evidence relies on self-reported data collected through questionnaires. While this method enables access to a broad sample of firms, it may introduce response bias, particularly regarding socially desirable constructs such as sustainability and CSR. The strong symbolic endorsement of sustainability values observed in the findings may partly reflect normative expectations rather than actual operational commitment. Consequently, future research could integrate qualitative methods, such as in-depth interviews or case studies, and objective performance indicators to triangulate responses and strengthen construct validity. Third, the sample is geographically and institutionally bounded to the Italian context and is further shaped by Federterziario's role as the distributing body. While this setting allows for a focused investigation of micro and small family firms operating within a specific macro-institutional environment, it limits the generalizability of the results. Institutional pressures, regulatory frameworks, and cultural norms differ substantially across countries, potentially leading to divergent sustainability trajectories. Comparative cross-country studies would therefore be useful for assessing the robustness of the proposed interpretations and exploring the contextual embeddedness of CSR behaviours.

Managerial implications. The findings of this study underscore the inherent limitations of generalizing the ESG practices of micro and small family firms. (Le Breton-Miller & Miller, 2024). Nevertheless, this work offers several salient managerial implications for such enterprises, as well as for professional advisors, external consultants, trade associations, and policymakers supporting sustainability transitions in this peculiar business segment.

The Perceived Relevance–Implementation matrix highlights a configuration characterized by selective operational consolidation and limited formal governance, suggesting that sustainability remains largely embedded in daily practices rather than strategically integrated into organizational systems. First, the results indicate that environmental sustainability is primarily interpreted through the lens of efficiency and regulatory compliance. While basic practices such as waste separation, energy monitoring, and the use of recycled materials are relatively widespread, more advanced tools, such as greenhouse gas accounting and structured environmental management systems, remain marginal. Managers should therefore consider shifting from a cost-saving and compliance-driven logic toward a more strategic environmental orientation. Introducing simplified environmental performance measurement systems and progressive monitoring tools can enable firms to better understand their environmental impact, support continuous improvement, and prepare for increasingly stringent regulatory and market requirements. Tailored advisory services and scalable environmental management frameworks could facilitate this transition without imposing excessive organizational burdens. Second, the strong alignment observed in occupational health and safety reflects the effectiveness of regulatory enforcement in shaping managerial behaviour. This suggests that regulatory clarity and institutional support play a crucial role in fostering the adoption of sustainability practices among micro and small enterprises. Managers can leverage this alignment by extending compliance-based approaches to other ESG domains, progressively embedding sustainability routines into formal procedures. In this perspective, regulatory compliance can serve as a gateway toward more comprehensive ESG integration rather than remaining an isolated operational requirement. Third, the results on human capital and employee welfare indicate that many socially oriented practices are already in place but are not explicitly framed as part of a

sustainability strategy. Managers may benefit from reinterpreting training, welfare, and employee engagement initiatives within an integrated ESG framework, thus enhancing internal coherence and external communication. By formalizing these practices, firms can improve organizational learning, strengthen employer branding, and reinforce relational trust with employees and local stakeholders, while also increasing awareness of sustainability as a strategic driver rather than merely an operational necessity.

Originality of the paper. This paper offers contributions to the literature on sustainability, ESG, and family business by advancing both conceptual understanding and empirical evidence on micro and small family enterprises, a segment that remains significantly underexplored in sustainability research. The study provides novel empirical evidence on the cognitive–operational gap in sustainability and ESG practices within micro and small family firms. By systematically contrasting perceived relevance and actual implementation, the research uncovers a structural misalignment across ESG domains, revealing that sustainability is recognized as a guiding value yet only partially institutionalized in governance mechanisms. This nuanced perspective advances existing scholarship, which has predominantly focused either on large corporations or on observable CSR practices, by explicitly addressing the interpretative and behavioural dimensions of sustainability at the micro-enterprise level.

Moreover, the introduction and application of the Perceived Relevance–Implementation matrix represent a methodological innovation. The matrix enables an integrated, theory-informed assessment of sustainability maturity, allowing the identification of differentiated ESG trajectories and the detection of evolutionary patterns. This analytical framework provides a scalable, adaptable tool for future empirical studies to examine sustainability integration in heterogeneous organizational contexts, particularly where formal governance structures are weak or underdeveloped.

Besides, the paper advances theoretical understanding by linking Institutional Theory with the concept of temporal bias to explain selective ESG adoption. While prior research has emphasized regulatory and normative pressures as drivers of CSR behaviour, this study demonstrates that short-term temporal orientation interacts with institutional forces, leading firms to prioritise low-risk, immediately beneficial practices over long-term strategic investments. This combined perspective provides a more dynamic explanation of sustainability behaviour in resource-constrained family firms and extends existing models of CSR adoption by incorporating intertemporal decision-making logic. Finally, the focus on micro and small family enterprises operating in the Italian institutional context constitutes a significant contextual contribution. By examining firms characterized by concentrated ownership, centralized decision-making, and limited managerial specialization, the study sheds light on how family logic, proximity-based stakeholder relationships, and informal governance structures shape sustainability pathways. This contributes to the family business literature by moving beyond large and listed family firms and addressing the dominant yet understudied population of micro and small family businesses.

Customer satisfaction and repurchase intention in the Italian and Swedish e-mobility markets

ALESSANDRO AUGURIO[1], LAURA CASTALDI[1], IDA CAMMINATIELLO[1], CLELIA MAZZONI[1]

Abstract. *Despite strong governments' support, the EV adoption rate in many European countries remains slow to meet the EU targets. The transition to e-mobility requires not only increasing adoption rates but also ensuring positive user experiences that encourage continued use. While prior research has largely focused on the purchase intention of potential adopters, less attention has been given to post-purchase behavior, including user satisfaction and repurchase intention. This study aims to investigate factors affecting customer satisfaction and repurchase intention among EV users in Italy and Sweden. Data were collected through an online survey administered to Italian and Swedish users and analyzed using Partial Least Squares (PLS) regression models. The analysis investigates the impact of EV attributes, contextual factors, usage patterns, use motivations and individual characteristics on customer satisfaction and repurchase intention for the entire sample, as well as for subsamples stratified by country and by engine type (BEV and PHEV). Furthermore, the relationship between satisfaction and repurchase intention was also explored. Results highlight that specific EV attributes, such as battery life and brand reputation, the availability of charging points, the individuals' openness to changes and their propensity to renewable energy, the opportunity to save charging costs and the EV suitability for the users' typical route exert a cross-cutting influence on satisfaction regardless of the country and the type of engine. Some differences emerging across national contexts and between BEV and PHEV users suggest that consumption patterns can vary according to the country and the specific type of engine. Furthermore, results indicate that neither customer satisfaction nor other analyzed factors significantly influence the repurchase intention. Beyond focusing on those factors that drive cross-cutting satisfaction, manufacturers and policymakers should implement tailored actions according to the type of engine and the country to ensure the user retention.*
Keywords: *e-mobility; electric vehicles; satisfaction; repurchase intention; regression analysis; multicollinearity.*

Framing of the research. *Electric vehicles (EVs) are identified as successors to internal combustion engine vehicles (ICEVs), as they are expected to contribute to the reduction of greenhouse gas emissions (Lee et al., 2026). Despite strong government support, the EV adoption rate in many countries remains too slow to meet the EU targets (ACEA, 2026). Scholars have extensively examined the EV purchase intention of potential consumers, identifying several factors influencing the switch from ICEVs to e-mobility. While literature has primarily focused on potential consumers and the introduction of EVs focusing on drivers and barriers, usage and post evaluation have received considerably less attention (Ivanova & Moreira, 2023; Lee et al., 2026). Addressing this gap is important as the analysis of the post purchase stage, which includes the usage, the user satisfaction and the repurchase, can provide useful findings to address the EV uptake. The issue of EV repurchase is particularly relevant considering that a significant share of EV users would consider returning to gasoline or diesel cars (McKinsey, 2024)[2]. Nonetheless, the understanding of user satisfaction is also crucial for the EV uptake as satisfied adopters are more likely to repurchase the product and influence the public through their opinions (Rogers, 2013). Finally, available studies indicate that users tend to adapt to EVs and develop new behaviors, suggesting that the EV experience can change favorably the overall perception of e-mobility making users more willing to replace their current EV with another electric one (Bühler et al., 2014; Labeye et al., 2016).*

Although the literature on satisfaction and repurchase intention concerning EVs remains relatively limited, there has been a slight increase in the number of publications in recent years, particularly concerning satisfaction.

Studies examined both satisfaction with specific aspects and overall user satisfaction. The range of the vehicle and the adequacy of charging networks affect positively user satisfaction with driving range and charging infrastructure, respectively (Hardman and Tal, 2021; Song et al., 2022). It is worth noting that range satisfaction tends to increase over time as users adapt to EVs and develop new usage behaviors, leading to a reduction in perceived barriers after adoption (Franke et al., 2017). Regarding overall satisfaction, factors affecting it can be grouped in the following categories: attributes, contextual factors and individual factors. Among the EV attributes, concerns about life battery and high purchase costs were proved to decrease overall satisfaction (Chu et al., 2019; Kwon et al., 2020; Hamed et al., 2021; Song et al., 2022; Rehman et al., 2024) whereas the environmental performance of vehicles, its innovativeness, and the driving pleasure were found to affect positively the overall satisfaction (Okada et al., 2019; Song et al., 2022). Likewise, the EV equipment such as safety devices and in-vehicle information systems—which diminish range anxiety—were found to increase the overall user satisfaction (Franke et al., 2017; Hamed et al., 2021). Scholars largely evidenced that contextual factors such as the adequateness of charging infrastructures and the presence of governmental support to e-mobility—tax benefits, exemption from traffic restriction– positively affect the overall satisfaction (Sun et al., 2017; Chu

[1] Department of Economics, University of Campania Luigi Vanvitelli, Corso Gran Priorato di Malta, 81043, Capua, Italy
[2] https://www.mckinsey.com/features/mckinsey-center-for-future-mobility/our-insights/new-twists-in-the-electric-vehicle-transition-a-consumer-perspective

et al., 2019; Okada et al., 2019; Kwon et al., 2020; Song et al., 2022; Cruz-Jesus et al., 2023). Finally, individual factors—such as environmental concern and usage patterns—emerge as further drivers of overall satisfaction, although less explored (Hamed et al., 2021; Cruz-Jesus et al., 2023).

Research on factors influencing the repurchase intention of EV users is even more limited. According to Kim et al. (2024) and Feng et al. (2025) the more the consumers are satisfied with aspects such as operating costs, charging infrastructure, range, and driving experience, the more they are likely to purchase another EV. However, Hasan (2021) found no evidence of a direct impact of overall satisfaction on repurchase intention, also observing that EV attributes—such as driving range, cost, and environmental performance—do not directly influence repurchase intention but instead affect it indirectly through user satisfaction or attitudes toward EVs.

Regarding individual aspects, environmental concern was found as a strong motivator to the repurchase (Lee et al., 2026). Some demographics such as age, number of electric vehicles owned, and household income (monthly) had a significant positive effect on repurchase intention in the study by Kim et al. (2024).

Purpose of the paper. *The scarcity of literature on EV post-purchase behavior led us to conduct an analysis of the factors affecting satisfaction and repurchase intention among a sample of Italian and Swedish EV users.*

The existing literature suggests that attributes, contextual factors, usage variables, and individual characteristics should be considered when analyzing customer satisfaction and repurchase intention.

We chose to conduct the investigation through a cross-country analysis. The cross-country approach is an emerging methodology in e-mobility research and allows scholars to explore how country-specific factors influence EV adoption and usage (Chu et al., 2019; Song et al., 2022). Previous studies suggest that national context, policies, and infrastructure conditions may significantly shape user satisfaction and usage patterns (Chu et al., 2019; Song et al., 2022; Augurio et al., 2025).

In this study, we perform a comparative analysis of the Swedish and Italian e-mobility markets, which are currently at different stages of development in the EV adoption. In Sweden, the e-mobility market has been steadily growing for several years. In 2025, EV sales accounted for 63.2% of all passenger cars sold[3], and the total EV stock represented 13.5% of all circulating vehicles (ACEA, 2026). In contrast, EVs still struggle to gain traction in Italy, where they represent only 7% of the circulating car fleet (ACEA, 2026). In 2025, EV sales accounted for just 12.6% of all passenger cars sold[4].

In addition, we decided to conduct the analysis by powertrain type (BEV and PHEV), as the literature provides no evidence on whether different EV technologies influence the post-purchase stage.

Methodology. *The research was performed by administering an online questionnaire to Italian and Swedish users of EVs who were at least 18 years old and who reported currently driving a BEV or PHEV. Given the low prevalence of EV users within the panel (estimated at approximately 2–5%), traditional quota-based stratification by sociodemographic variables was not feasible; therefore, a best-effort recruitment strategy was adopted. The random extraction of the respondents' selection and the dissemination of the online survey link were carried out by a qualified research service of the Toluna corporation, which uses an online platform for this purpose. Prior to data collection, the questionnaire was pilot tested on a subsample of 20 respondents to assess item clarity and survey flow. The results led to some minor amendments to the questionnaire. Data were collected in June 2023 via CAWI (Computer-Assisted Web Interviewing), with each session lasting approximately 25 minutes. The final achieved sample consisted of 320 complete responses, of which 164 were from Italy and 156 from Sweden. With regard to the type of EVs, 155 users reported to use a BEV whereas 165 a PHEV.*

In line with the empirical nature of the research, literature served as a source of inspiration for the formulation of the items. Items belong to 7 conceptual dimensions, identified based on extant literature: EV attributes, contextual factors, usage patterns, use motivations, individual characteristics (sociodemographics and psychographics), satisfaction and repurchase intention.

***EV attributes**—concerning price, technological features, equipment, and performance—were operationalized by asking respondents to rate the importance of each EV attribute on a scale ranging from 1 (lowest importance) to 9 (highest importance). **Contextual factors** were about the characteristics and adequateness of the charging infrastructure and the presence of governmental measures. Respondents were asked to rate the importance of each item on a scale ranging from 1 (lowest importance) to 9 (highest importance). As to **usage patterns**, respondents were asked about the number and types of cars owned, the brand of their main current EV and the EV range, their drive time per day, the annual average of kilometers driven and long trips, and the charging modality. **Use motivations** were measured by asking respondents to rate their agreement with sentences on a scale ranging from 1 (lowest agreement) to 9 (highest agreement). Sentences are related to functional, symbolic, and hedonic motivations to use an EV. **Individual characteristics** include both sociodemographics and psychographics. Sociodemographic elements refer to users' characteristics such as age, gender, household composition, education, etc. Psychographics were measured by asking respondents to rate how a list of statements regarding environmental concern and consumer innovativeness conform to the individual's personal beliefs and opinions using a score from 1 to 9, with 1 means "not compliant at all", 9 on the other hand, indicates "totally*

[3] https://www.acea.auto/pc-registrations/new-car-registrations-1-8-in-2025-battery-electric-17-4-market-share/
[4] https://www.acea.auto/pc-registrations/new-car-registrations-1-8-in-2025-battery-electric-17-4-market-share/

*compliant." **Customer satisfaction** was operationalized looking at the overall satisfaction of the individual and the satisfaction related to specific features such as price, VFM (value for money), maintenance and charging costs, technological equipment, reliability, electric range, and design. Respondents were asked to rate their satisfaction on a scale from 1 to 9. Finally, respondents were asked to rate their **repurchase intention** on a range from 1 to 100.*

Overall, the analysis includes a number of 93 items.

This study was performed by applying several linear regression models. The analysis poses important methodological challenges due to the presence of multicollinearity. Multicollinearity occurs when some explanatory variables are linear combinations of others. In such cases, these variables do not contribute significant additional explanatory power to the model and may sometimes be removed. However, reducing the number of variables through selection is not always desirable. An alternative approach to addressing the negative effects of multicollinearity involves the use of biased estimators. By accepting a small degree of bias, it is possible to achieve a substantial reduction in the estimator's variance. This principle underlies a class of methods known as shrinkage estimators (Camminatiello et al., 2024). Some studies suggest that partial least squares (PLS) regression (Wold, 1985) outperforms other methods in many cases by providing simpler and more parsimonious models (Frank and Friedman,1993). Therefore, in this research we consider PLS, as it has been increasingly developed in recent years and has proven effective in preventing overfitting.

In the first step, PLS constructs uncorrelated latent variables, called components, which are linear combinations of the original regressors. The number of latent variables A to be retained in the model can be selected using different criteria, the most common being cross-validation. A least squares regression is then performed on the subset of extracted latent variables.

To evaluate the performance of the models, we focus on the coefficient of determination (R^2) and the predicted residual error sum of squares (PRESS) criterion. The first criterion measures the goodness of fit of the model, while the second evaluates its predictive ability.

Results. *The empirical strategy is based on the construction of several linear regression models.*

Determinants of Customer Satisfaction. EV attributes, contextual factors, usage patterns, use motivations and individual characteristics were analyzed in relation to customer satisfaction for the entire sample, as well as for subsamples stratified by country (Italy and Sweden) and by engine type (BEV and PHEV). PLS regression was implemented using the R functions developed by J. F. Durand[5].

Overall, the goodness of fit and predictive ability is moderate and relatively similar across the five models (entire sample, 2 subsamples stratified by country—Italy and Sweden—and by engine type—BEV and PHEV).

In particular, the optimal dimension of the model carried out on the entire sample is A=2 components, which explain 45% of the variability in the dependent variables (R2). The predictive ability of the model is moderate with a PRESS=5.15. The optimal dimension of the model estimated:

- *on the Italian sample is A=1 component which explains the 40% of variability in the responses (R2), with PRESS=5.47;*
- *on the Swedish sample is A=2 component which explains the 50% of variability in the responses (R2), with PRESS=4.86;*
- *on the BEV engine sample is A=1 component which explains the 44% of variability in the responses (R2), with PRESS=5.08;*
- *on the PHEV engine sample is A=1 component which explains the 42% of variability in the responses (R2), with PRESS=5.28.*

The most influential variables are identified based on the magnitude and sign of the estimated coefficients. A higher absolute value of β indicates a stronger influence of the variable on the dependent variable. A positive coefficient indicates a direct relationship, meaning that an increase in the independent variable leads to an increase in customer satisfaction. Conversely, a negative coefficient indicates an inverse relationship, where an increase in the independent variable leads to a decrease in customer satisfaction.

Customer Satisfaction and Repurchase Intention. The relationship between customer satisfaction and repurchase intention was analyzed for the entire sample and for subsamples stratified by country (Italy and Sweden) and by engine type (BEV and PHEV). Across all five models, the goodness of fit and predictive ability appears to be relatively low, suggesting that customer satisfaction alone may not be sufficient to explain repurchase intention.

Determinants of Repurchase Intention. EV attributes, contextual factors, usage patterns, use motivations and individual characteristics were also examined in relation to repurchase intention, considering the entire sample as well as the subsamples stratified by country and engine type. The results indicate that the goodness of fit and predictive performance remain low and relatively similar across the five models, suggesting that additional variables or alternative modeling approaches may be necessary to better explain repurchase intention.

[5] https://jf-durand-pls.com/

In the remainder of this work, we focus exclusively on customer satisfaction, as the goodness of fit and predictive ability of all five models are discrete. Therefore, we avoid an in-depth analysis of the relationship between customer satisfaction and repurchase intention, as well as the determinants of repurchase intention, whose predictive ability is only acceptable and whose goodness of fit is poor.

Tables 1, 2, 3, 4, and 5 illustrate the most influential variables affecting customer satisfaction for each one of the 5 models, i.e., for the entire sample, 2 subsamples stratified by country (Italy and Sweden) and 2 subsamples stratified by engine type (BEV and PHEV).

In line with previous studies, our work shows that both satisfaction with specific EV aspects and overall user satisfaction are part of the post-adoption experience.

EV attributes, contextual factors, use motivations and individual characteristics have an impact on satisfaction in all 5 models. Usage patterns do not appear to be strongly relevant except for model 3, i.e., Swedish EV users, where the long trip frequency and the usage of public charging both have a negative impact on VFM satisfaction, while home charging positively affects it.

The 5 models have some differences but also common points. The most influential variables in model 1 are also influential in almost all the other models: brand reputation, battery life, the availability of charging points, fit between the EV's characteristics and the route requirements, saving charging cost, seeking reliable products, belief in the need for renewable energy sources, openness to radical changes. However, they have an impact on different types of satisfaction and are joined by different variables in the 5 models, thus according to the different country and adopted EV engine type.

Few variables have a relevant impact on overall satisfaction.

Overall, it is possible to observe that in each of the 5 models there are some main impacted types of satisfaction:

- *in model 1 (entire sample), VFM and reliability satisfaction;*
- *in models 2 and 4 (Italian and BEV users), technology and performance satisfaction;*
- *in model 3 (Swedish users), VFM and technology satisfaction;*
- *in model 5 (PHEV users), technology, performance and range satisfaction.*

When we stratify the sample by country (models 2-Italy and 3-Sweden), it is possible to observe some differences between Italian and Swedish users.

The regression coefficients of the model estimated for Sweden are generally higher than those for Italy. As the variables are standardized, this may indicate a stronger impact of the explanatory variables on customer satisfaction in the Swedish sample. This supports what already observed in literature, namely that satisfaction might increase over time as users become accustomed to EVs and adapt their usage behaviors accordingly (Franke et al., 2017).

Moreover, in model 3 (Sweden) two demographic variables are relevant, i.e., age and insecure income, where the first exerts a positive and the second a negative impact on VFM satisfaction.

Technical attributes (model, accessories, quietness, acceleration and onboard instrumentation), innovation elements, and governmental benefits—such as for example tax advantages and free parking—are more relevant for Italian users.

Overall, the comparison between Italian and Swedish users, in line with previous studies, supports that national context, policies, and infrastructure conditions contribute to shape user satisfaction (Chu et al., 2019; Song et al., 2022; Augurio et al., 2025).

When distinguishing by engine type (models 4-BEV and 5-PHEV), both similarities and differences in the attributes can be observed, some of which are related to the specific characteristics of the engine (e.g., charging time for BEVs). The attributes design and model indicate greater attention to aesthetics among PHEV users, which is also accompanied by a stronger concern for driving range. For BEV users, charging time appears to be a central attribute. Furthermore, BEV users seem to display greater environmental sensitivity.

Research limitations. *To improve the performance of the models, several methodological extensions can be considered. First, future analyses could account for nonlinear relationships between explanatory variables and dependent variables. Second, it would be useful to apply regularization techniques, such as the Least Absolute Shrinkage and Selection Operator (LASSO) developed by Tibshirani (1996), as well as its extensions, including Elastic Net regularization. These methods perform both regularization and variable selection, allowing the model to penalize less informative predictors and potentially eliminate variables that do not contribute significantly to the response variable. This approach may lead to more parsimonious and interpretable models. Finally, it would be advisable to estimate separate models for each dependent variable, allowing a more precise identification of the determinants of customer satisfaction and repurchase intention.*

Managerial implications. *The findings of the study provide several insights for managers and practitioners in the EV industry. First, customer satisfaction is influenced by a combination of EV attributes, contextual factors, usage patterns, use motivations and individual characteristics across different countries and engine types. This suggests that a holistic approach to product development and marketing is essential, addressing not only the technical specifications of the vehicle but also the contextual and motivational factors that drive satisfaction.*

For Italian users, technical attributes—such as model, accessories, quietness, acceleration and onboard instrumentation—along with innovation elements and governmental benefits (e.g., tax advantages and free parking) play a particularly relevant role. This implies that manufacturers targeting the Italian market should emphasize technological innovation, the quality and variety of features, and incentive programs to enhance perceived value.

Swedish users demonstrate a high sensitivity to environmental factors, with age and income insecurity also influencing satisfaction. Importantly, usage patterns are particularly relevant for this group. Managers should therefore consider how charging infrastructure, trip planning support, and incentives for home charging can improve user satisfaction in the Swedish market. Communication strategies should also highlight the environmental benefits of EV adoption, which are especially valued by Swedish users.

When considering engine type, both similarities and differences emerge. PHEV users tend to prioritize aesthetics and driving range, suggesting that design and range optimization should be key considerations for this segment. BEV users, however, place central importance on charging time and display higher environmental awareness. Thus, infrastructure improvements and strategies to reduce charging time are likely to enhance satisfaction among BEV users.

Across all markets and engine types, certain attributes consistently drive satisfaction, including brand reputation, battery life, availability of charging points, alignment between vehicle characteristics and route requirements, cost savings in charging, reliability of products, belief in the need for renewable energy, and openness to radical changes. Managers should consider these core factors as foundational elements in product development, customer experience, and communications strategies.

Finally, the results indicate that customer satisfaction alone does not fully explain repurchase intention, suggesting that additional factors—such as long-term cost considerations, and evolving personal motivations—should be investigated to better predict loyalty. Practitioners should adopt a comprehensive approach that integrates both product-related and contextual variables to foster not only satisfaction but also long-term customer retention.

Originality of the paper. *This study contributes to advancing the existing knowledge on e-mobility by focusing on the post-purchase stage, which has received limited attention from scholars. Furthermore, the study performs an exploratory analysis of factors affecting customer satisfaction and repurchase intention among EV users, adopting a cross-country comparative perspective between Italy and Sweden, two e-mobility markets characterized by different levels of EV diffusion. Moreover, the analysis distinguishes between BEV and PHEV users, highlighting that consumption dynamics in the post-adoption experience are also related to the type of engine. More specifically, the analysis by powertrain type (BEV and PHEV) contributes to existing literature by showing that different EV technologies can influence user satisfaction. By integrating EV attributes, contextual factors, usage patterns, motivations, and individual characteristics, the paper provides an extensive overview of elements that shape EV consumption providing valuable insights to manufacturers and policymakers to ensure the e-mobility uptake.*

Digital Nudging and Online Second-Hand Consumption: An Experimental Comparison of Green, Social and Fair Price Nudges

VALENTINA CASCIO[1], DILETTA MORELLI[2], CECILIA GRIECO[3]

Abstract. This study investigates the effectiveness of digital nudges in promoting purchase intentions towards second-hand products in online marketplaces. Drawing on behavioural economics and digital nudging theory, a between-subjects experimental design was employed with 206 participants randomly assigned to one of four conditions: a green nudge (environmental benefits), a social nudge (descriptive norm), a fair price nudge (economic savings), or a control condition (no nudge). Results from a one-way ANOVA revealed that all three nudge types significantly increased purchase intention compared to the control condition ($F(3,202) = 19.80$, $p < .001$, $\eta^2 = .23$), with no significant differences among the three nudge types. Hierarchical multiple regression further demonstrated that environmental motivations, economic savings, and platform trust were the strongest predictors of purchase intention, while perceived barriers (hygiene concerns and social stigma) showed no significant association. Age significantly moderated purchase intentions ($F(3,190) = 6.34$, $p < .001$), with younger consumers (18–39) expressing greater willingness to buy second-hand goods. Gender differences were in the expected direction but did not reach statistical significance. These findings contribute to the emerging literature on digital nudging applied to sustainable consumption, offering both theoretical insights and practical implications for e-commerce platforms seeking to promote circular economy behaviours.

Keywords: *digital nudging; second-hand consumption; sustainable consumption; behavioural economics; choice architecture; purchase intention*

Framing of the research. The growing diffusion of second-hand consumption represents one of the most significant transformations in contemporary consumer behaviour. Platforms such as Vinted, Depop, and Wallapop have fundamentally reshaped the marketplace for used goods, contributing to the consolidation of what scholars describe as the sharing economy, a socio-economic paradigm centred on access, redistribution, and peer-to-peer exchange rather than ownership (Grieco, 2024). Within this framework, second-hand consumption is understood not merely as an economic alternative to new purchases, but as a practice embedded in values of sustainability, authenticity, and community belonging (Fors et al., 2023). Global resale markets have expanded dramatically, with second-hand apparel alone projected to grow at a rate eleven times faster than the traditional retail sector (Hristova, 2019), driven by digitalisation, environmental awareness, and generational shifts in consumption norms.

The motivations underpinning second-hand purchase behaviour are multidimensional. Roux and Guiot (2008, 2009) identified a structured set of drivers including economic motivations (price fairness, bargain hunting, budget optimisation), hedonic and recreational motivations (treasure hunting, originality, nostalgia, social contact), symbolic and identity-related motivations (self-expression, anti-ostentation, authenticity-seeking), and ethical motivations (environmental concern, reduction of waste, support for circular economy principles). More recent syntheses confirm the continued relevance of these dimensions while extending them to include emerging drivers such as resale value awareness, self-care through responsible consumption, and competence demonstration, particularly among younger generations (Frahm et al., 2025a, 2025b).

Despite this positive trend, the adoption of second-hand consumption remains constrained by a set of persistent barriers. These include hygiene concerns and contamination fears, particularly salient for products in close bodily contact such as clothing (Koay et al., 2023), functional and quality risk perceptions, social stigma associated with used goods, and a deficit of trust in peer-to-peer digital platforms (Jang & Kim, 2023; Moriuchi & Takahashi, 2022). Theoretical frameworks such as perceived risk theory (Bauer, 1960, as cited in Koay et al., 2023) and the Extended Self Theory (Belk, 1988, as cited in Frahm et al., 2025a) help explain why second-hand objects may provoke avoidance responses rooted in symbolic contamination, identity threat, or social disapproval. Generational and gender differences further modulate these dynamics: older consumers tend to express greater hygiene sensitivity and functional risk concerns, while younger consumers, particularly Generation Z and Millennials, show greater openness to second-hand practices, integrating them into a sustainable identity (Dua, 2025; Harantová & Mazanec, 2025; Koay & Cheah, 2025).

These findings point to a well-documented gap between pro-environmental attitudes and actual purchasing behaviour, what the literature terms the attitude-behaviour gap (Prashar & Kaushal, 2025). Bridging this gap requires interventions that operate at the level of the decision-making process itself, rather than relying solely on attitude change or information provision.

This is precisely the contribution of behavioural economics and, more specifically, of nudge theory as developed by Thaler and Sunstein (2008, 2021). Building on evidence of bounded rationality (Simon, 1955), dual-process cognition (Evans & Stanovich, 2013), and systematic cognitive biases documented in Prospect Theory (Kahneman & Tversky, 1979), nudge theory proposes that behaviour can be predictably steered towards more desirable outcomes through carefully designed choice architectures, modifications to the decision environment that preserve individual freedom of choice while facilitating more rational or prosocial decisions. A nudge is defined as "any aspect of the choice architecture that alters people's behaviour in a predictable way without forbidding any options or significantly changing their economic incentives" (Thaler & Sunstein, 2021). This approach operates primarily on System 1, the fast, automatic, and heuristic-driven mode of cognition, reducing the cognitive load associated with sustainable choices and making preferred options more salient, accessible, and socially legitimate (Kahneman, 2011).

The application of nudging to digital environments, digital nudging, has emerged as a distinct and rapidly growing field (Weinmann et al., 2016). Digital nudges leverage interface design elements such as default settings, visual salience, framing, and social proof messages to orient user behaviour within online platforms, apps, and e-commerce sites (Mirsch et al., 2017). Empirical evidence supports the effectiveness of digital nudges across multiple domains of sustainable consumption, from energy saving (Beermann et al., 2022) to sustainable fashion (Prashar & Kaushal, 2025; Schürmann et al., 2023). Notably, Prashar and Kaushal (2025) found that combined verbal and visual nudges increased purchase intention for sustainable fashion items by 27.8% compared to control conditions.

Three specific nudge typologies are of particular relevance to the present research. Green nudges operate by making the environmental benefits of a choice more salient, activating pro-environmental values and fostering a sense of personal efficacy in contributing to sustainability (Amiri et al., 2024; Beermann et al., 2022). Social nudges leverage descriptive social norms, communicating what the majority of similar others do, to induce conformity and reduce the perceived social risk of non-conventional choices such as buying second-hand (Cialdini, 2003; Goldstein et al., 2008; Schultz et al., 2018). Fair price nudges act on the economic dimension of perceived value, rendering the cost advantages of second-hand purchases more cognitively accessible, thereby activating perceptions of fairness and rational utility maximisation (Cai, 2020; Mertens et al., 2022).

The literature further suggests that the effectiveness of these nudge types may vary as a function of individual differences, particularly gender and age. Women have been found to be more responsive to environmental and social norm appeals (Amiri et al., 2024; Demarque et al., 2015), while younger consumers show greater receptivity to digital nudges in general (Mirsch et al., 2017; Söderström et al., 2019). However, systematic comparative evidence on the differential effectiveness of green, social, and fair price nudges within the specific context of online second-hand consumption remains scarce (Gottselig et al., 2023). The present study addresses this gap directly.

Purpose of the paper. Despite the growing body of research on digital nudging and sustainable consumption, the specific application of nudge interventions to online second-hand marketplaces remains largely underexplored (Gottselig et al., 2023). Existing studies have examined nudging in contexts such as energy conservation (Beermann et al., 2022), financial decision-making (Cai, 2020; Mertens et al., 2022), and sustainable fashion retail (Prashar & Kaushal, 2025; Schürmann et al., 2023), yet no study to date has systematically compared the effectiveness of three distinct nudge typologies, environmental, social, and economic, within a single experimental framework applied to second-hand e-commerce.

The primary purpose of this paper is to examine whether and to what extent digital nudges increase consumers' intention to purchase second-hand products online, and whether different nudge types, green, social, and fair price, differ in their relative effectiveness. A secondary purpose is to explore how individual-level characteristics, specifically gender and age, and psychological variables, namely motivations, perceived barriers, and platform trust, interact with nudge exposure to shape purchase intentions.

To these ends, the following research hypotheses were formulated:

H1: The presence of a nudge (green, social, or fair price) increases purchase intention for second-hand products compared to a no-nudge control condition.

This hypothesis is grounded in the core tenet of nudge theory, according to which even minimal modifications to the choice architecture can reduce decision inertia and facilitate behaviours aligned with individuals' underlying values and goals (Thaler & Sunstein, 2021). In the context of second-hand consumption, where purchase decisions are often inhibited by uncertainty and perceived risk (Koay et al., 2023), an informational nudge is expected to provide a cognitive anchor that simplifies the decision and renders the sustainable option more salient and justifiable.

H2a: Female participants will show higher purchase intention for second-hand products than male participants.

This hypothesis draws on consistent evidence that women tend to exhibit stronger pro-environmental attitudes and greater sensitivity to ethical consumption appeals (Amiri et al., 2024; Zelezny, Chua, & Aldrich, 2000), and are reported to engage more frequently with second-hand platforms (Harantová & Mazanec, 2025).

H2b: Younger participants will show higher purchase intention for second-hand products than older participants.

This hypothesis is supported by research indicating that Generation Z and Millennials are the primary drivers of second-hand market growth, displaying greater familiarity with peer-to-peer digital platforms, stronger identification with sustainability values, and reduced sensitivity to the stigma traditionally associated with used goods (Dua, 2025; Koay & Cheah, 2025; Mazanec & Harantová, 2024).

H3a: Environmental, economic, and uniqueness-seeking motivations are positively associated with purchase intention for second-hand products.

This hypothesis follows from the motivational framework established by Roux and Guiot (2008, 2009) and subsequently confirmed in more recent literature (Frahm et al., 2025a, 2025b), which identifies environmental concern, economic savings, and the search for original or distinctive items as the principal drivers of second-hand purchase behaviour.

H3b: Perceived barriers, specifically hygiene concerns and social stigma, are negatively associated with purchase intention for second-hand products.

This hypothesis is grounded in perceived risk theory (Bauer, 1960, as cited in Koay et al., 2023) and empirical evidence documenting the inhibitory role of contamination fears and social disapproval on second-hand consumption (Koay et al., 2023; Mobarak et al., 2025).

H3c: Trust in second-hand platforms is positively associated with purchase intention for second-hand products.

In digital peer-to-peer marketplaces, trust functions as a prerequisite for purchase behaviour by reducing perceived transactional risk and increasing perceived platform reliability (Gammoudi & Saied Ben Rached, 2025; Jang & Kim, 2023). This hypothesis is therefore expected to receive strong empirical support.

Taken together, these hypotheses aim to provide an integrated account of the psychological, demographic, and situational determinants of second-hand purchase intention, with particular attention to the role of digital nudging as a low-cost, ethically grounded tool for promoting sustainable consumption behaviours.

Methodology. The present study adopted a between-subjects experimental design, in which each participant was randomly assigned to one of four conditions: a green nudge condition, a social nudge condition, a fair price nudge condition, or a no-nudge control condition. This design was chosen to prevent contamination effects that could arise from repeated exposure to similar stimuli, which might induce social desirability biases or demand characteristics in subsequent responses (Shadish, Cook, & Campbell, 2002).

Participants and procedure. A total of 206 participants completed an online questionnaire distributed through digital channels including social networks, university mailing lists, and broadcast messaging groups. Participation was voluntary and anonymous, and the survey required approximately 8–10 minutes to complete. The sample comprised 120 women (58.3%) and 86 men (41.7%), distributed across four age groups: 18–24 years (n = 62, 30.1%), 25–39 years (n = 46, 22.3%), 40–54 years (n = 49, 23.8%), and 55–73 years (n = 49, 23.8%). A chi-square test confirmed that gender distribution was homogeneous across age groups ($\chi^2(3) = 3.51$, $p = .319$). The vast majority of participants (92.7%) reported prior experience purchasing second-hand products, confirming the ecological relevance of the sample for the research objectives. Random assignment to the four experimental conditions yielded balanced group sizes: control (n = 54), fair price nudge (n = 48), social nudge (n = 53), and green nudge (n = 51).

Experimental Stimuli. The experimental stimuli consisted of a simulated e-commerce product page displaying a unisex white t-shirt available for purchase on a second-hand platform. The product description and visual presentation were held constant across all conditions; the only variation was the informational message, the nudge, displayed below the product description. The three nudge messages were developed on the basis of established frameworks in the digital nudging literature (Cialdini, 2003; Beermann et al., 2022; Cai, 2020):

- Green nudge: a message highlighting the positive environmental impact of purchasing a used item rather than a new one (e.g., reduction in CO_2 emissions and resource consumption);
- Social nudge: a descriptive norm message stating that "8 out of 10 people purchased this t-shirt second-hand rather than new," designed to activate social conformity mechanisms (Cialdini, 2003; Schultz et al., 2018);
- Fair price nudge: a message emphasising the economic savings associated with purchasing the used item compared to its new retail equivalent (Cai, 2020; Mertens et al., 2022);
- Control condition: no additional message beyond the standard product description.

Measures. All constructs were measured using validated scales adapted to the Italian context through a back-translation procedure (Brislin, 1970, as cited in Frahm et al., 2025a), and assessed on five-point Likert scales (1 = strongly disagree, 5 = strongly agree).

Environmental motivation was measured using the six-item Green Scale (Haws, Winterich, & Naylor, 2014; $\alpha = .921$), assessing the degree to which participants value environmental sustainability in their consumption choices.

Economic motivation (savings) and uniqueness motivation were each measured with two items drawn from the second-hand shoppers' motivation scale (Roux & Guiot, 2008; $\alpha = .887$ and $\alpha = .815$, respectively).

Perceived hygiene barriers and social stigma barriers were each assessed with four items adapted from Koay et al. (2023), originally developed by Kim et al. (2021) and Lang (2018) respectively ($\alpha = .872$ and $\alpha = .945$).

Platform trust was measured using an eleven-item scale articulated across three dimensions, credibility, integrity, and benevolence, adapted from Chouk and Perrien (2005) and validated in the second-hand online context by Gammoudi and Saied Ben Rached (2025; $\alpha = .925$).

Purchase intention was assessed with four items developed in accordance with the Theory of Planned Behavior (Ajzen, 1991, 2006), administered after exposure to the experimental stimulus. Internal consistency was high across all conditions (control: $\alpha = .866$; fair price: $\alpha = .899$; social: $\alpha = .917$; green: $\alpha = .945$).

A manipulation check item was included at the end of the questionnaire to verify that participants had correctly perceived the presence or absence of the informational box. A one-way ANOVA confirmed that the manipulation was successful: participants in the three nudge conditions reported significantly higher awareness of the informational message than those in the control condition ($F(3, 202) = 108.28$, $p < .001$), with no significant differences among the three nudge groups.

Analytical strategy. Data were analysed using IBM SPSS Statistics (Version 27). Following preliminary descriptive and reliability analyses, inferential analyses were conducted in three stages. First, a one-way ANOVA tested H1 by comparing mean purchase intention scores across the four experimental conditions, with Bonferroni post-hoc corrections applied for pairwise comparisons. Second, two factorial ANOVAs (2×4 and 4×4) were conducted to test H2a and H2b, examining the main effects of gender and age respectively, as well as their interactions with nudge type. Third, a three-step hierarchical multiple regression was conducted to test H3a, H3b, and H3c, entering sociodemographic variables in Block 1, psychological motivations and barriers in Block 2, and experimental condition dummies in Block 3. Effect sizes are reported as partial η^2 throughout. The significance threshold was set at $\alpha = .05$.

Results. Descriptive statistics and Pearson correlation analyses were conducted prior to hypothesis testing. Purchase intention was positively and significantly correlated with environmental motivations ($r = .35$, $p < .001$), platform trust ($r = .33$, $p < .001$), and economic savings motivations ($r = .31$, $p < .001$). A weak but significant positive association was observed with uniqueness motivation ($r = .15$, $p = .031$). By contrast, neither hygiene concerns ($r = -.09$, $p = .188$) nor social stigma ($r = .01$, $p = .942$) showed significant associations with purchase intention, a finding that diverges from conventional expectations in the second-hand literature and is discussed further below.

H1: Effectiveness of Nudges on Purchase Intention

A one-way ANOVA was conducted to test whether the presence of a nudge, regardless of type, increased purchase intention relative to the control condition. The analysis revealed a significant main effect of experimental condition on purchase intention, $F(3, 202) = 19.80$, $p < .001$, $\eta^2 = .23$, indicating that approximately 23% of the variance in purchase intention was explained by nudge exposure, a medium-to-large effect size according to Cohen's (1988) criteria.

As shown in Table 1, mean purchase intention scores were markedly higher in all three nudge conditions compared to the control. The control condition yielded the lowest mean ($M = 2.65$, $SD = 0.70$), while the fair price nudge ($M = 3.66$, $SD = 0.70$), social nudge ($M = 3.61$, $SD = 0.91$), and green nudge ($M = 3.70$, $SD = 0.91$) all produced substantially higher scores. Bonferroni post-hoc comparisons confirmed that each nudge condition differed significantly from the control (all $ps < .001$), while no significant differences emerged among the three nudge types (all $ps > .05$). H1 is therefore fully supported: the presence of a nudge, irrespective of its specific content, significantly increased second-hand purchase intention. This finding suggests that the mechanism of nudge effectiveness in this context resides primarily in the cognitive salience of the informational message rather than in the activation of any specific motivational pathway.

Table 1. Descriptive statistics of purchase intention by experimental condition

Condition	n	M	SD
Control	54	2.65	0.70
Fair price nudge	48	3.66	0.70
Social nudge	53	3.61	0.91
Green nudge	51	3.70	0.91

H2a: Gender Differences

A 2 (gender) × 4 (condition) factorial ANOVA revealed a significant main effect of experimental condition, $F(3, 198) = 16.18$, $p < .001$, $\eta^2 = .20$, consistent with the one-way ANOVA results. The main effect of gender did not reach statistical significance, $F(1, 198) = 2.49$, $p = .116$, $\eta^2 = .01$, indicating that male and female participants did not differ significantly in overall purchase intention. A marginally significant interaction trend between gender and nudge type was observed, $F(3, 198) = 2.32$, $p = .077$, $\eta^2 = .03$, suggesting that the effectiveness of specific nudge types may vary partially as a function of gender. Descriptively, women reported higher purchase intention than men across all nudge conditions, with the most pronounced differences observed in the green and fair price nudge conditions, a pattern consistent with evidence that women tend to respond more strongly to environmental and ethical consumption appeals (Amiri et al., 2024; Zelezny et al., 2000). H2a is not statistically confirmed, though the observed trend is theoretically coherent and warrants further investigation with larger and more balanced samples.

H2b: Age Differences

A 4 (condition) × 4 (age group) factorial ANOVA revealed a significant main effect of experimental condition, $F(3, 190) = 22.74$, $p < .001$, $\eta^2 = .26$, and a significant main effect of age, $F(3, 190) = 6.34$, $p < .001$, $\eta^2 = .09$. The interaction between age and nudge type was not significant, $F(9, 190) = 0.76$, $p = .654$, $\eta^2 = .04$, indicating that nudge effectiveness was broadly consistent across age groups. Mean purchase intention scores followed a clear decreasing pattern with age: participants aged 25–39 years reported the highest intentions ($M = 3.73$, $SD = 0.93$), followed by those aged 18–24 ($M = 3.56$, $SD = 0.97$), 55–73 ($M = 3.23$, $SD = 0.78$), and 40–54 ($M = 3.06$, $SD = 0.93$). Bonferroni pairwise comparisons confirmed significant differences between the 25–39 group and both the 40–54 ($p = .001$) and 55–73 groups ($p = .015$), and between the 18–24 group and the 40–54 group ($p = .007$). H2b is supported: younger participants expressed significantly higher second-hand purchase intentions than older participants, independently of nudge type.

H3: Motivations, Barriers, Trust, and Purchase Intention

A three-step hierarchical multiple regression was conducted to examine the joint predictive role of sociodemographic, psychological, and experimental variables on purchase intention.

Block 1 (sociodemographic variables: gender, age, second-hand experience, purchase frequency) was significant, $F(4, 201) = 12.02$, $p < .001$, $R^2 = .193$. Gender ($\beta = -.22$, $p < .001$) and purchase frequency ($\beta = .38$, $p < .001$) emerged as significant predictors, with women and more frequent buyers reporting higher purchase intentions.

Block 2 (motivations and barriers: environmental motivation, economic savings, uniqueness, platform trust, hygiene concerns, social stigma) produced a significant increment in explained variance, $\Delta R^2 = .098$, $p < .001$, bringing the total to $R^2 = .291$. Environmental motivation ($\beta = .22$, $p = .021$), economic savings motivation ($\beta = .22$, $p = .034$), and social stigma ($\beta = .22$, $p = .018$) emerged as significant predictors. Notably, social stigma showed a positive, rather than negative, association with purchase intention, a counterintuitive finding discussed in Section 6.

Block 3 (experimental condition dummies: fair price, social, green) produced a further significant increment, $\Delta R^2 = .201$, $p < .001$, yielding a final model explaining 49% of the total variance in purchase intention, $F(13, 192) = 14.32$, $p < .001$, $R^2 = .492$. All three nudge conditions were significant positive predictors: fair price ($\beta = .45$, $p < .001$), social ($\beta = .45$, $p < .001$), and green ($\beta = .50$, $p < .001$). Environmental motivation ($\beta = .32$, $p < .001$) and platform trust ($\beta = .11$, $p = .047$) retained independent predictive significance in the full model. H3a is partially supported: environmental and economic motivations significantly predicted purchase intention, while uniqueness motivation did not. H3b is not supported: perceived barriers showed no significant negative associations with purchase intention. H3c is fully supported: platform trust emerged as a consistent and significant positive predictor across model specifications.

Research limitations. Despite the relevant findings, this study presents several methodological and conceptual limitations that should be acknowledged. First, the sample, while numerically adequate, is not fully representative of the general population, with an overrepresentation of younger adults and female participants. Future studies should employ more heterogeneous and stratified samples across age, gender, and geographic provenance to enhance the generalisability of results.

Second, the study relied on hypothetical scenarios and self-reported purchase intention measures. Although the Theory of Planned Behavior (Ajzen, 1991) identifies intention as a reliable predictor of actual behaviour, the use of simulated stimuli reduces ecological validity. Future research would benefit from field experimental designs conducted directly within real second-hand e-commerce platforms, or from the analysis of actual behavioural data, to verify whether stated intentions translate into effective purchases.

Third, the cross-sectional design does not allow causal inferences regarding the directionality of relationships between psychological variables and purchase intention. Longitudinal or more complex experimental designs would be better suited to clarify the temporal dynamics through which motivations, barriers, and trust influence second-hand consumption behaviour over time.

A specific theoretical consideration concerns the counterintuitive finding regarding social stigma, which in the regression model showed a positive rather than negative association with purchase intention, contrary to H3b and prevailing literature (Koay et al., 2023). This result may reflect the progressive normalisation of second-hand consumption, particularly among younger consumers for whom stigma has ceased to represent a meaningful deterrent (Dua, 2025; Fors et al., 2023), or it may indicate that consumers more aware of stigma are simultaneously those most actively engaged in the second-hand market. This finding warrants cautious interpretation and further investigation in future research.

Finally, the study tested nudge effectiveness on a single product category — a unisex white t-shirt — which limits the generalisability of conclusions across different merchandise types. Replication across categories such as electronics or furniture would allow assessment of whether the observed effects hold across varying motivational profiles and perceived barriers (Frahm et al., 2025b).

Managerial implications. The findings of this study carry concrete and actionable implications for managers, marketers, and designers operating within the second-hand e-commerce ecosystem, as well as for policymakers interested in promoting sustainable consumption at scale.

For second-hand platform managers and e-commerce designers, the most immediate takeaway is that the simple inclusion of an informational nudge, regardless of its specific content, can increase consumers' purchase intention by a

meaningful and statistically robust margin. This represents a low-cost, scalable, and ethically grounded intervention: unlike discount-based incentives or advertising campaigns, nudges require no modification of prices, product assortment, or platform infrastructure. A brief message positioned below a product listing, whether emphasising environmental impact, social norms, or economic savings, is sufficient to shift the decision architecture in favour of the sustainable option. Platform designers should therefore treat informational nudge integration as a standard feature of product page design, rather than an optional or experimental add-on.

More specifically, the comparable effectiveness of green, social, and fair price nudges suggests that platforms need not commit to a single communication strategy. Instead, a dynamic or personalised nudge approach, in which the type of message displayed is adapted to the user's profile, browsing behaviour, or demographic segment, may maximise overall effectiveness. Given evidence that younger users respond well to social norm appeals and environmental framing (Mirsch et al., 2017), while older consumers tend to prefer transparency and economic clarity (Söderström et al., 2019), segmented nudge delivery represents a promising direction for personalisation strategies. Similarly, given the trend, observed in this study, though not statistically significant, for women to respond more strongly to green and fair price nudges, gender-responsive communication design may further enhance nudge impact.

For sustainable marketing practitioners, the results reinforce the strategic value of framing second-hand consumption as simultaneously environmentally responsible, socially normalised, and economically rational. The finding that all three nudge types produced equivalent effects suggests that the key mechanism is not the specific motivational lever activated, but rather the act of providing an explicit, salient justification for the purchase. Marketing communications should therefore prioritise clarity, immediacy, and relevance, making the benefit of buying second-hand immediately visible at the point of decision, without requiring consumers to engage in elaborate cognitive deliberation.

The central role of platform trust in predicting purchase intention, retained as a significant predictor even after controlling for nudge exposure and motivational variables, further indicates that trust-building is a prerequisite for nudge effectiveness. Platforms should invest in credibility signals such as verified seller ratings, transparent return policies, authenticity guarantees, and clear data protection standards. Without a foundation of perceived trustworthiness, even well-designed nudges may fail to convert browsing into purchasing, particularly among older or less digitally experienced consumers.

For policymakers and sustainability advocates, this study demonstrates that behavioural interventions grounded in nudge theory can meaningfully contribute to the promotion of circular economy behaviours without resorting to regulatory mandates or financial incentives. Digital nudges represent a form of soft policy, transparent, non-coercive, and scalable, that aligns with the libertarian paternalism framework advocated by Thaler and Sunstein (2021). Governments and public bodies collaborating with e-commerce platforms could mandate or incentivise the inclusion of environmental impact information at the point of sale, in line with emerging EU digital sustainability disclosure requirements. Such policies would not only promote second-hand consumption but also contribute to broader goals of waste reduction, resource efficiency, and carbon footprint minimisation across the fashion and consumer goods sectors.

Originality of the paper. This study makes several original contributions to the existing literature at the intersection of digital nudging, behavioural economics, and sustainable consumption.

First, and most centrally, this is among the first studies to systematically compare the effectiveness of three distinct digital nudge typologies, green, social, and fair price, within a single experimental framework applied specifically to online second-hand consumption. While prior research has examined individual nudge types in isolation, or has applied nudging to adjacent domains such as sustainable fashion retail (Prashar & Kaushal, 2025) or energy conservation (Beermann et al., 2022), no previous study has conducted a direct within-design comparison of environmental, normative, and economic nudges in the context of second-hand e-commerce. This comparative approach allows for a more nuanced understanding of the psychological mechanisms underlying nudge effectiveness, and provides practitioners with evidence-based guidance on communication strategy selection.

Second, the study contributes original empirical evidence on the equivalence of nudge types in this specific context. The finding that all three nudges produced statistically indistinguishable effects on purchase intention, despite operating through theoretically distinct motivational pathways, challenges assumptions of differential effectiveness that pervade the nudging literature (Congiu & Moscati, 2022) and suggests that, in the second-hand domain, the salience of the message itself may matter more than its specific content. This is a theoretically meaningful result that invites further investigation into the boundary conditions of nudge type specificity.

Third, the study integrates experimental manipulation with a rich battery of individual difference measures, motivations, perceived barriers, and platform trust, within a unified hierarchical regression framework. This design allows for the simultaneous assessment of situational nudge effects and stable psychological predictors, providing a more complete and ecologically valid account of second-hand purchase intention than experimental or correlational studies conducted in isolation. In particular, the finding that perceived barriers, hygiene concerns and social stigma, no longer predict purchase intention in this sample represents a novel empirical signal of cultural normalisation in second-hand consumption, particularly among younger consumers.

Fourth, the study extends the application of established scales, including the Green Scale (Haws et al., 2014), the second-hand motivation scale (Roux & Guiot, 2008), the perceived risk dimensions adapted from Koay et al. (2023), and the platform trust scale adapted from Gammoudi and Saied Ben Rached (2025), to an Italian-speaking sample,

contributing to the cross-cultural validation of these instruments in a European context that remains underrepresented in the international second-hand consumption literature.

Taken together, these contributions position this study as a foundational reference for future research on digital nudging in circular economy contexts, and offer a replicable experimental template that can be adapted across product categories, platforms, and cultural settings.

Embedding ESG in the Balanced Scorecard: A Work-in-Progress Framework for Strategic Translation, Innovation, and Long-Term Value Creation

FABRIZIO BALDASSARRE*, CLAUDIO ROSITO♦, VALERIO BUONO♣,
RAFFAELE CAMPO**, GENNARO DURANTE♠

Keywords: *Balanced Scorecard; ESG integration; strategic performance measurement; management control systems; dynamic capabilities; innovation*

Framing of the research. The increasing relevance of ESG issues has altered the strategic landscape within which firms define priorities, allocate resources, and justify long-term investments. However, in many organizations ESG remains only partially connected to the core architecture of strategic management. It is frequently visible in sustainability reports, investor communication, and compliance routines, yet much less embedded in the internal systems that actually structure strategic dialogue, managerial accountability, and day-to-day trade-offs. This disconnect creates an important managerial and scholarly problem: firms may publicly communicate sustainability commitments without substantially changing the organizational mechanisms through which strategic priorities are translated into action.

This paper starts from the assumption that the critical issue is not whether ESG indicators are present somewhere in the organization, but whether they are incorporated into the same system through which firms define strategic objectives, monitor progress, coordinate functions, and evaluate initiatives. From this perspective, the Balanced Scorecard is particularly relevant. Since its original formulation, the BSC has been more than a performance dashboard. Its importance lies in its ability to connect financial and non-financial objectives through a structured causal logic and to turn strategic intent into measurable priorities across organizational levels (Kaplan & Norton, 1992, 1996, 2001). In other words, the BSC can be understood as an architecture of strategic translation: it links vision, objectives, measures, targets, and initiatives, thereby shaping what managers discuss, how they interpret performance, and which actions are legitimized inside the organization.

This strategic architecture is especially important in contexts characterized by uncertainty, competing demands, and long time horizons. Research on strategic performance measurement systems has shown that these systems can influence alignment, organizational learning, role clarity, and managerial performance when they are designed and used in ways that connect measurement to strategy rather than merely to operational monitoring (Chenhall, 2005; Hall, 2008; Ittner et al., 2003). In this sense, the BSC is not just a tool for reporting outcomes; it is a mechanism for structuring managerial attention and organizational dialogue. That feature becomes crucial when organizations attempt to incorporate ESG goals that often cut across functions, combine short-term costs with long-term benefits, and involve tensions between efficiency, legitimacy, resilience, and innovation.

The sustainability literature has already recognized the potential compatibility between the BSC and sustainability objectives. The seminal contribution by Figge et al. (2002) showed that the Sustainability Balanced Scorecard can link sustainability management to business strategy by embedding environmental and social objectives into a scorecard logic. Later work has mapped different SBSC architectures and clarified that sustainability can be inserted into the BSC in multiple ways, for example by integrating sustainability objectives into existing perspectives, by adding a dedicated perspective, or by developing more hybrid configurations (Hansen & Schaltegger, 2016). These contributions are important because they demonstrate that sustainability is not conceptually foreign to strategic performance measurement.

Yet this stream of research also reveals an important limitation. Much of the SBSC literature has focused on architecture design, classification, and implementation options. Less attention has been devoted to the internal organizational effects of ESG-BSC integration: how it may alter managerial decision criteria, affect which initiatives receive resources, influence incentive schemes, or stabilize new patterns of cross-functional coordination and learning. In parallel, broader corporate sustainability research has shown that firms with deeper sustainability orientation tend to differ in organizational processes, long-term orientation, nonfinancial measurement, stakeholder engagement, and executive compensation (Eccles et al., 2014). This suggests that the internal strategic consequences of ESG integration may be

substantial, but it does not specify the role that the BSC, as a strategic translation infrastructure, may play in producing such consequences.

A second relevant stream concerns the relationship between sustainability and management control systems. Studies on sustainability control systems and CSR strategy have argued that control systems matter because they communicate priorities, delimit acceptable behaviour, support risk identification, and enable dialogue around strategic uncertainty (Gond et al., 2012; Arjaliès & Mundy, 2013; Beusch et al., 2022). This literature is highly relevant for the present study because it moves beyond the view of sustainability as disclosure and instead examines how it becomes operationalized inside firms. It also shows that the role of control is not limited to monitoring. Depending on their design and use, controls can either marginalize sustainability by treating it as an add-on, or integrate it into core strategic processes.

However, while this literature has developed rich insights into levers of control and system configurations, it has not fully clarified the specific role of the BSC as an integrated architecture of planning, strategic review, accountability, and initiative management. This is a significant omission, because the BSC can act as the organizational "carrier" through which ESG objectives become connected to the broader strategic system. Put differently, if ESG remains outside the BSC logic, it may remain symbolically important but strategically weak. If it is embedded inside the BSC logic, it may begin to influence how managers evaluate projects, how functions coordinate, which capabilities receive investment, and how long-term value is interpreted.

A third stream of research that matters for this paper is the literature on management control and innovation. Earlier research on product innovation, new product development, and ambidexterity has shown that formal controls are not necessarily enemies of innovation. On the contrary, when used interactively and in balanced ways, management control systems can support dialogue, prioritize uncertainty, and improve the organizational conditions under which innovation becomes productive rather than chaotic (Bisbe & Otley, 2004; Davila, 2000; Henri, 2006; Bedford, 2015; Chenhall et al., 2011). This insight is central for the present study because it suggests that the question is not whether ESG introduces more control and therefore less innovation, but rather whether ESG-related controls are designed and used in ways that stimulate learning, experimentation, and coordinated adaptation.

This issue becomes particularly salient when ESG is interpreted as a source of future growth, resilience, and innovation rather than as a constraint. If ESG targets are embedded in a scorecard only as compliance metrics, they may narrow managerial behaviour and encourage symbolic achievement. By contrast, if ESG priorities are linked to strategic objectives, investment initiatives, and interactive review routines, they may help managers identify new opportunities, justify capability-building investments, and reframe innovation agendas. In that case, the BSC does not simply record sustainability performance; it becomes a mechanism for exploring the strategic and innovative implications of sustainability commitments.

The final stream informing this paper is the dynamic capabilities and routine dynamics literature. Dynamic capabilities research has emphasized that firms create and sustain advantage in changing environments not only through static resources, but through the capacity to sense, seize, and reconfigure (Teece et al., 1997; Eisenhardt & Martin, 2000). Zollo and Winter (2002) further explain that such capabilities evolve through learning, articulation, and codification. In parallel, routine dynamics scholars have shown that routines are not merely sources of inertia, but can also be sources of flexibility and change when they organize repeated action while remaining open to reinterpretation and adaptation (Feldman & Pentland, 2003). These ideas are particularly useful for the present study because they provide a vocabulary for explaining why a strategically embedded ESG-BSC may matter over time. If the scorecard becomes a recurring site of strategic review, target negotiation, resource allocation, and cross-functional discussion, it may institutionalize the very routines through which dynamic capabilities are built.

Against this background, the paper addresses a gap at the intersection of BSC research, sustainability integration, management control, and innovation studies. Specifically, it seeks to explain how ESG objectives and metrics, when integrated into the BSC, can influence decision-making processes, investment priorities, incentives, and organizational routines in ways that support innovation-oriented dynamic capabilities and long-term value creation. The paper therefore reframes the BSC not as a neutral measurement device, nor as a reporting support, but as an internal strategic architecture whose design and use may materially affect how firms deal with sustainability-related opportunities and tensions.

Purpose of the paper. The purpose of this paper is to develop a conceptual framework that explains how the integration of ESG objectives and metrics into the Balanced Scorecard can affect strategic and organizational processes beyond disclosure and compliance. The paper is motivated by a simple but underexplored question: what changes inside the organization when ESG enters the scorecard that managers use to translate strategy into objectives, targets, initiatives, and reviews?

The paper adopts the view that the relevant unit of analysis is not "ESG performance" in general, but the strategic and organizational use of ESG within a BSC logic. This distinction is important. Many firms already disclose ESG data, monitor sustainability indicators, or publish integrated reports. Yet these practices do not necessarily imply that ESG affects internal choices. The present study therefore focuses on whether and how ESG becomes part of the strategic management architecture through which managers identify priorities, discuss trade-offs, review progress, and allocate attention and resources.

Conceptually, the paper defines an ESG-integrated Balanced Scorecard as a scorecard in which ESG objectives and metrics are embedded in at least five interrelated components:

(1) the strategic causal map linking objectives across perspectives;
(2) the portfolio of measures and targets;
(3) the cascading of objectives across units and functions;
(4) the prioritization of strategic initiatives and investments;
and (5) the accountability and incentive routines through which managers are evaluated and engaged.

From this perspective, ESG integration is not binary. It can vary in depth. At a superficial level, ESG may appear as an external reporting appendix or as a small set of isolated indicators, with minimal impact on strategic choices. At a more advanced level, it may be embedded in the causal logic of the scorecard, influence capital allocation, and become part of managerial review and incentive systems. The paper argues that these different degrees of integration are likely to be associated with different organizational consequences.

The proposed framework suggests that the effects of ESG-BSC integration are mediated by four processual mechanisms.

First, ESG integration may broaden managerial cognition and temporal orientation. By entering the scorecard's cause-and-effect chain, ESG metrics can make externalities, stakeholder expectations, capability gaps, and long-term risks more visible in strategic discussions. This can change the way managers interpret trade-offs between short-term financial performance and future resilience, legitimacy, or innovation potential.

It may also reshape resource allocation and the prioritization of investments. Once ESG objectives are linked to strategic initiatives rather than remaining isolated, capability-building projects that would otherwise appear discretionary may gain greater legitimacy. Investments in new processes, product redesign, data collection systems, supplier collaboration, employee training, or circular business models may move from the periphery to the strategic portfolio.

The third processual mechanism leads to a realignment between accountability and incentive systems. Research on sustainability-oriented firms suggests that sustainability becomes organizationally consequential when it is tied to governance and managerial evaluation, rather than being treated as a specialist concern (Eccles et al., 2014). If ESG targets are incorporated into the scorecard and cascaded across functions, they can encourage broader ownership and reduce the misalignment between finance, strategy, operations, and sustainability functions.

Finally, integrating ESG issues into the corporate BSC may stabilize new routines of coordination and continuous learning. Scorecards take shape through meetings, reviews, target negotiations, and exception handling. When ESG becomes part of these recurring routines, organizations may develop stronger sensing, seizing, and reconfiguring capabilities. This is especially likely when the scorecard is used interactively, that is, as a platform for dialogue, challenge, and strategic inquiry rather than as a narrow diagnostic system.

P1. The greater the extent to which ESG objectives and metrics are embedded within the BSC's cross-perspective causal logic, the more strategic decision-making will reflect broader value drivers and longer time horizons.

P2. The stronger the linkage between ESG objectives in the BSC and strategic initiatives, the more likely firms are to prioritize medium-term capability-building and innovation-oriented investments.

P3. The more ESG targets are cascaded through the BSC and connected to managerial accountability, the more likely firms are to develop cross-functional coordination and recurring organizational learning routines around sustainability-related priorities.

P4. The positive relationship between ESG-BSC integration and innovation orientation will be stronger when the BSC is used interactively rather than merely diagnostically.

Taken together, these propositions support the paper's core argument: ESG can become a driver of innovation and long-term value creation only when it is translated into the same organizational architecture that governs strategic priorities, discussions, targets, and resource commitments. The contribution is therefore not to propose yet another sustainability scorecard, but to explain how and why an ESG-integrated BSC may function as a strategic and innovation-enabling infrastructure.

Methodology. Because the paper is a work in progress, the methodology is presented in two connected stages: a current conceptual-development stage and a planned empirical stage.

The current stage is based on a focused conceptual review of the literature on five interconnected domains: Balanced Scorecard and strategic performance measurement; sustainability and ESG integration into strategy; management control systems and sustainability control systems; management control and innovation; and dynamic capabilities and organizational routines. The purpose of this first stage is not to produce an exhaustive systematic review, but to identify the core constructs, mechanisms, and theoretical tensions necessary to develop a coherent framework. The article set selected for this phase includes seminal and directly relevant contributions from strategic management, management accounting, sustainability, and innovation studies.

The second stage, planned but not yet completed, is designed as a qualitative multiple-case study. A qualitative design is appropriate because the paper is interested in internal mechanisms, processual effects, and organizational routines rather than in testing a narrow net-effect relationship between variables. More specifically, the aim is to investigate how ESG-BSC integration is enacted in practice and how different configurations of that integration relate to decision-making, investment choices, incentives, coordination, and innovation-related capability development.

The proposed empirical setting consists of medium-to-large firms that meet three criteria. First, they must use a formal strategic performance measurement system, ideally a Balanced Scorecard or a scorecard-like system that explicitly

translates strategy into measures and initiatives. Second, they must publicly or internally articulate ESG or sustainability objectives as relevant to business strategy rather than only to reporting. Third, they must operate in contexts where innovation and medium-term adaptation are meaningful, such as manufacturing, industrial services, consumer goods, infrastructure, or knowledge-intensive services.

The sample logic is purposeful and theory-driven. The intention is to select four to six cases varying along at least two dimensions: (1) the maturity of ESG integration into the scorecard; and (2) the innovation intensity or strategic renewal pressure of the business context.

This design should make it possible to compare firms where ESG is marginal, partially integrated, or deeply embedded, and to observe how these differences affect organizational processes.

Data collection is expected to rely on multiple sources. The first source will be semi-structured interviews with key organizational actors, including CFOs or controllers, chief sustainability officers or ESG managers, strategy managers, innovation managers, HR managers involved in incentives, and selected business-unit or operations managers. The second source will be internal or public documents, such as scorecards, strategy maps, planning templates, sustainability reports, incentive policies, investment committee guidelines, and presentations used in strategic reviews. The third source, where feasible, will be observational evidence from strategic review or planning meetings.

The interview protocol will focus on several themes: how ESG objectives enter the scorecard; how targets are chosen and cascaded; how strategic initiatives are selected and reviewed; whether ESG affects capital allocation and incentive systems; which functions own ESG measures; how review meetings are conducted; and whether managers perceive ESG metrics as compliance indicators, strategic drivers, or both.

The planned analysis strategy combines within-case process tracing with cross-case pattern matching. Within each case, the objective will be to reconstruct how ESG-BSC integration emerged and how it shapes decision episodes, investment discussions, and routine interactions. Across cases, the analysis will compare configurations and outcomes in order to refine the proposed propositions. A Gioia-style coding logic may be used in the early analytic stages to capture first-order practitioner concepts and second-order themes, especially around decision criteria, review routines, organizational learning, and capability development.

The main constructs to be explored include:

- degree of ESG-BSC integration;
- strategic use of ESG metrics;
- influence on resource allocation and initiative prioritization;
- link to incentives and accountability;
- cross-functional coordination;
- organizational learning routines;
- innovation orientation;
- indications of dynamic capability development.

This method fits the research question for three reasons. First, the paper investigates how a system operates, which makes a qualitative, mechanism-focused design appropriate. Second, the unit of analysis is organizational and processual rather than purely individual or financial. Third, the present literature suggests that the difference between symbolic and substantive sustainability integration may depend on use, interaction, and organizational context, which are difficult to capture through decontextualized measurement alone.

At the present stage, therefore, the methodological contribution of the paper is to provide a credible empirical pathway for testing the framework. The manuscript does not report final empirical findings; rather, it clarifies how the conceptual model can be examined in future research.

Results. As this short paper reports work in progress, the current “results” are conceptual rather than final empirical findings. More specifically, the paper generates two preliminary outputs: a mechanism-based framework and an emerging typology of ESG-BSC integration patterns.

The first output is the conceptual framework developed above. Its central result is the argument that the organizational consequences of ESG integration depend on whether ESG metrics are positioned outside or inside the BSC’s strategic causal architecture. When ESG measures remain peripheral, they are likely to be used mainly for reporting and legitimacy. In this configuration, their influence on decision-making, investment prioritization, and innovation routines is expected to remain weak. By contrast, when ESG is embedded in the causal structure of the scorecard and connected to targets, initiatives, review routines, and incentives, the system is expected to become more consequential for internal strategic behaviour.

The second output is an emerging typology of three possible integration patterns that will guide the empirical phase.

The first pattern can be described as peripheral integration. In this case, ESG indicators exist but are decoupled from the main scorecard logic. They are monitored separately, owned by specialists, and weakly linked to mainstream planning, capital budgeting, or incentives. The expected consequence is a compliance-oriented use of ESG with limited effects on innovation or capability development.

The second pattern is embedded integration. Here ESG objectives are incorporated into one or more BSC perspectives and linked to selected initiatives and review processes. This configuration is expected to improve coordination and make some medium-term investment priorities more visible, but without fully transforming managerial accountability or organizational routines.

The third pattern is generative integration. In this configuration, ESG is embedded not only in metrics but also in the causal map, target setting, initiative selection, resource allocation logic, and managerial review/incentive routines. The expected analytical implication is that ESG becomes a source of strategic inquiry and organizational learning, thereby supporting sensing, seizing, and reconfiguration processes linked to innovation and long-term value creation.

These patterns are not presented as empirical findings already verified. They are analytical expectations to be examined in the next stage of the research. Nevertheless, they already provide a useful way to sharpen the paper's contribution. They suggest that the debate should move away from the simple question of whether firms "use sustainability indicators" toward the more demanding question of how deeply sustainability is integrated into the organizational architecture of strategy execution.

A further expected analytical insight is that interactive use is likely to be a decisive condition. Even a technically well-designed ESG-BSC may have limited impact if it is used only diagnostically, that is, as a tool for variance reporting and target checking. The positive effects should be stronger when managers use the system interactively to challenge assumptions, discuss strategic uncertainties, coordinate functions, and revise initiative portfolios.

Overall, the present results indicate that an ESG-integrated BSC may become a strategic and innovation-enabling infrastructure when it influences not only what the organization measures, but how it discusses priorities, legitimizes investments, and reproduces learning routines over time.

Research limitations. The main limitation of the present paper is that it remains at a conceptual and design stage. The analytical propositions and integration typology have not yet been tested through fieldwork. A second limitation is that the argument is likely to be more applicable to firms with relatively formalized strategy and control systems; organizations relying on more emergent or informal strategic processes may require a different analytical lens. A third limitation concerns construct operationalization. Concepts such as long-term value creation, dynamic capabilities, or strategic use of ESG metrics are theoretically rich but empirically demanding, and their refinement will be an important task in the next stage of the project. Finally, industry and institutional differences may shape how ESG enters control systems, which means that findings from one context may not be automatically transferable to others.

Managerial implications. The paper suggests several managerial implications. First, managers should avoid treating ESG as a parallel dashboard detached from mainstream strategy execution. If the goal is to make ESG consequential, it must be translated into the same architecture that guides objectives, initiatives, reviews, and accountability. Second, firms should embed ESG into the BSC's causal logic, not merely into isolated KPI lists. This means clarifying how ESG-related objectives affect customer value, internal processes, learning needs, risk profiles, and financial outcomes over time.
Third, ESG-related priorities should influence initiative portfolios and investment reviews. When ESG metrics remain disconnected from resource allocation, organizations risk signalling ambition without changing what they actually fund.
Fourth, ownership matters. ESG integration should not remain confined to sustainability departments. Finance, strategy, operations, HR, and innovation functions need shared accountability if the scorecard is to shape routines and decisions.
Finally, the paper suggests that review routines are critical. Managers should use ESG-BSC systems interactively, as occasions for dialogue about trade-offs, emerging risks, capability gaps, and innovation opportunities. In this way, the scorecard can become a platform for coordinated learning and long-term strategic renewal rather than a static reporting mechanism.

Originality of the paper. The contribution of this paper lies in framing the Balanced Scorecard as a possible architecture through which ESG considerations can be translated into strategy, organizational learning, and capability development. Prior studies have shown that sustainability dimensions can be incorporated into scorecards and that sustainability-related issues can be addressed through management control systems. However, the literature has been less specific in explaining how ESG metrics, when integrated into the logic of the BSC, may influence decision criteria, investment priorities, incentive structures, and recurring organizational routines.

In this respect, the paper connects insights from BSC research, sustainability control systems, innovation-oriented management control, and the dynamic capabilities perspective. Its central argument is that ESG becomes strategically relevant not only through disclosure, but through its integration into the organizational infrastructure that links strategy to execution. From this perspective, the paper is situated less in the field of compliance or reporting, and more in that of strategic management, focusing on how ESG can become part of a planning, execution, and learning architecture that supports medium-term innovation and long-term value creation.

Emerging frames of tourism in small island destinations: The case of San Pietro Island

CHIARA DE BERNARDI[1], DANIEL ARENAS VIVES[2], CECILIA PASQUINELLI[3]

Abstract. *Tourism development on small islands requires balancing economic growth with the protection of environmental and cultural assets. This study focuses on San Pietro Island to explore how local stakeholders construct the meaning of tourism rather than merely report its impacts. Using framing theory, the research highlights the interpretive lenses through which stakeholders view tourism and community identity. Qualitative analysis (ongoing) reveals that tourism is framed in narratives emphasizing environmental stewardship, the preservation of local identity, and authenticity. By centering the study on these interpretive frames, rather than solely on stakeholder interests or impacts, this research illuminates how perceptions may shape tourism strategies, offering a fresh perspective on sustainable development in small island contexts.*
Keywords: *tourism management; small-island tourism; stakeholders; framing theory*

Framing of the research. *Small island destinations represent some of the most sensitive and complex contexts in tourism management (McLeod, 2025). Characterized by ecological fragility, strong social cohesion, and the constraints imposed by planetary boundaries, tourism is often a structural force that shapes everyday life and community identity (Graci and Maher, 2020; McLeod et al., 2021). In such contexts, even moderate variations in tourism flows can generate visible environmental pressures, social tensions, and transformations in local economic structures.*

For this reason, governance and stakeholder engagement are particularly central in small island tourism. Destination development cannot rely solely on market dynamics or centralized planning but depends on the interaction among residents, entrepreneurs, institutional actors, and other local stakeholders whose interests are closely intertwined (Bramwell and Lane, 2011; Hall, 2011). Drawing on Freeman's (1984) foundational work, stakeholder theory conceptualizes destinations as networks of interdependent actors whose collaboration is essential for sustainable outcomes. Accordingly, tourism planning research highlights the importance of involving a broad range of stakeholders (Cerdá-Mansilla et al., 2024; Huang et al., 2023), particularly local communities (Khazaei et al., 2015). This is especially relevant in island contexts, where dense social networks and limited resources make the alignment – or misalignment – of stakeholder perspectives particularly influential for development trajectories. A substantial body of tourism – and sustainable tourism – research has therefore examined stakeholder perceptions and engagement in destination development (Bornhorst et al., 2010; Burbano et al., 2022; Pasquinelli and Kavaratzis, 2025), with particular attention to residents' support for tourism. Studies grounded in social exchange theory show that such support largely depends on perceived economic benefits, environmental costs, trust in institutions, and distributive fairness (Nunkoo and So, 2016; Rasoolimanesh et al., 2015; Stylidis et al., 2022).

However, even within small island research, stakeholder perspectives are frequently operationalized through standardized attitudinal constructs. Empirical studies examining residents' support for tourism in island and peripheral destinations typically rely on models derived from social exchange theory, where tourism is conceptualized as a set of economic, social, and environmental impacts to be evaluated by local actors (e.g., Nunkoo and So, 2016; Rasoolimanesh et al., 2015; Stylidis, 2022). For instance, while the study of Butler (2019) shows how the increasing number of visitors to a remote island destination may have a positive impact on resident well-being and benefits, Thompson (2026) suggests that positive impacts can occur even with limited stakeholder collaboration

In these approaches, tourism tends to be treated as a relatively stable and predefined phenomenon – an economic activity producing measurable benefits and costs to which stakeholders respond. The analytical focus is therefore placed on identifying predictors of support or opposition, rather than on examining how tourism itself is interpreted and constructed within the local context.

Yet in small island destinations, tourism is often not a neutral or uncontested object (McLeod, 2025). It may be simultaneously experienced as an economic lifeline, a cultural threat, an opportunity for community continuity, or a risk of overexploitation. Conflicts may thus arise not only from uneven distributions of costs and benefits, but from fundamentally different interpretations of what tourism represents for the island and what its future should look like. As Hall (2011) and McLeod (2025) note, policy debates or frameworks in tourism frequently involve competing problem definitions rather than simple disagreements over resource allocation. In island contexts, where identity, heritage, and environmental stewardship are particularly salient, these divergences in interpretation may be especially pronounced.

To address this dimension, the present study complements stakeholder theory with framing theory. Originally developed by Goffman (1974) and further elaborated in social movement research (Benford and Snow, 2000), framing

analysis examines how actors construct meanings, define problems, attribute responsibilities, and articulate legitimate courses of action. Applying a framing perspective to small island tourism shifts the analytical focus from measuring support for tourism to examining how tourism itself is defined and narrated by local actors. Rather than assuming a shared understanding of tourism development, this approach investigates the interpretive frames through which stakeholders make sense of its role in the island's economy, identity, and future. Framing theory emphasizes that actors actively construct meanings around contested issues, defining what is at stake and what courses of action are legitimate. In tourism contexts, this implies that development is not simply evaluated but discursively constituted. The emergent frames shape not only individual attitudes, but also governance preferences, perceptions of policy legitimacy, and strategic priorities (Bramwell and Lane, 2011; Cornelissen and Werner, 2014).

In small islands, where social cohesion, spatial proximity, and place identity play a particularly central role, understanding these interpretive frames becomes even more important (Graci and Maher, 2020; McLeod et al., 2021). Tourism debates in such contexts frequently extend beyond economic performance to questions of heritage preservation, environmental limits, and intergenerational responsibility. Development strategies that align with one interpretive frame – such as growth-oriented competitiveness – may generate resistance from actors operating within preservation-oriented frames, even when overall levels of attitudinal support appear similar. As governance research suggests, conflicts often emerge from divergent problem definitions rather than solely from distributive disagreements (Bramwell and Lane, 2011; Hall, 2011). By uncovering how tourism is socially constructed through stakeholders' own narratives, a framing approach offers a deeper understanding of governance dynamics in island destinations.

Against this background, this study adopts an inductive framing-based perspective to explore how local stakeholders in a small island destination interpret tourism and articulate their visions for its development. By moving beyond attitudinal measures commonly used in stakeholder research (Nunkoo and So, 2016; Stylidis et al., 2022) and examining stakeholders' meaning-making processes, the research contributes to tourism management literature by integrating stakeholder theory with framing theory. In doing so, it offers a more nuanced account of how island tourism futures are negotiated, legitimized, and socially constructed.

Purpose of the paper. *Building on the theoretical considerations outlined above, this paper seeks to advance the understanding of stakeholder dynamics in small island tourism by shifting the analytical focus from attitudinal support to interpretive meaning-making. While existing research has provided substantial insights into residents' support for tourism (Khazaei et al., 2015) and its determinants, much of this literature conceptualizes tourism as a relatively stable object of evaluation. In fact, stakeholders are typically asked to assess perceived impacts and benefits, often within frameworks derived from social exchange theory (Rasoolimanesh et al., 2015). Although these approaches have significantly contributed to tourism governance research, they offer limited insight into how tourism itself is defined, problematized, and normatively positioned within local communities.*

In small island contexts, this limitation becomes particularly salient. Tourism is rarely experienced as a discrete economic sector; rather, it is deeply intertwined with identity, environmental limits (McLeod, 2025), heritage, and intergenerational continuity (Graci and Maher, 2020; McLeod et al., 2021). As governance scholarship suggests, conflicts in tourism development may stem not only from distributive disagreements but from divergent problem definitions and normative orientations (Bramwell and Lane, 2011; Hall, 2011). Understanding these divergences, therefore, requires analytical tools capable of capturing how stakeholders actively construct meaning around tourism and its future.

To address this gap, the present study adopts a framing perspective (Benford and Snow, 2000; Cornelissen and Werner, 2014; Goffman, 1974), which conceptualizes stakeholders not merely as evaluators of tourism outcomes but as active interpreters who structure their understandings through distinct interpretive frames. Framing theory, rooted in Goffman's (1974) seminal work Frame Analysis, has increasingly been applied to tourism research to understand how social situations are interpreted and codified by individuals with varying cultural backgrounds (Apchain and MacCannell, 2022). In tourist contexts, frames help both visitors and hosts make sense of interactions, often in simplified ways due to limited shared knowledge of social norms. Recent studies extend this perspective by examining how destinations strategically employ framing to influence tourist perceptions and behaviors. For instance, Hajarrahmah et al. (2026) demonstrate that diagnostic, prognostic, and motivational framing strategies, coupled with frame resonance, can significantly shape tourists' engagement in regenerative tourism across multiple countries. Similarly, other scholars have explored how framing informs tourists' discourse of transformation (Soulard and McGehee, 2023), public support for social movements (Bonilla and Tillery Jr, 2020), and climate change communication (Smith, 2015). Despite these advances, little is known about how framing operates from the perspective of local stakeholders, particularly in island contexts where the interaction between destination narratives and residents' perceptions can create tensions or misalignments. Addressing this gap, the present study applies framing theory to explore how tourism is discursively constituted and how these constructions shape visions of legitimate development. Accordingly, the study is guided by the following research question: What interpretive frames structure local stakeholders' understandings of tourism in a small island destination, and how do these frames shape their visions of development?

Theoretically, this research contributes to tourism management literature in two main ways. First, it extends stakeholder theory (Freeman, 1984) by integrating it with framing theory (Goffman, 1974), thereby moving beyond models that treat stakeholders primarily as respondents to predefined development scenarios. Second, it contributes to

small island tourism research by suggesting that local development futures are shaped not only by formal policies but also by how different perspectives and interpretations of tourism are constructed and negotiated.

From a managerial perspective, the findings suggest that effective destination governance in island contexts cannot rely solely on measuring levels of stakeholder support. Instead, it requires a nuanced understanding of the interpretive frames that underpin local debates, as these frames shape policy legitimacy, conflict dynamics, and long-term strategic alignment.

By repositioning stakeholders as meaning-makers rather than evaluators, combining stakeholder theory and framing theory, this study offers both a more nuanced account of how island tourism futures are negotiated, contested, and collectively imagined, and a more reflexive and governance-oriented account of how island tourism futures are collectively imagined and contested.

Methodology *To address our research question, we adopt a qualitative research design, appropriate for investigating "how" questions and for exploring socially constructed meanings in context (Barratt et al., 2011). The study follows an inductive approach inspired by Gioia et al.'s (2013) methodology, which is particularly suitable for early-stage theory development (Gehman et al., 2018) or when processes are complex.*

3.1 Research setting. The empirical setting of this study is the island municipality of Carloforte[4], located on San Pietro Island, off the southwestern coast of Sardinia (Italy). Carloforte represents a particularly appropriate context for three reasons.

First, small island destinations are characterized by ecological fragility, limited spatial and infrastructural capacity, and strong place-based identities, making them especially sensitive to tourism-related transformations (Graci and Maher, 2020; McLeod et al., 2021). In such settings, tourism is deeply intertwined with everyday life, local social relations, and collective identity, and even moderate increases in visitor flows may have visible economic, social, and environmental consequences (Bramwell and Lane, 2011).

Second, Carloforte is marked by a distinctive historical and cultural identity rooted in its Ligurian origins and long-standing maritime traditions. The island's economy historically revolved around tuna fishing (the "tonnara"), which remains a powerful symbolic and cultural reference in local narratives and continues to shape the island's gastronomic and identity discourse. This strong heritage dimension makes the case particularly suitable for exploring how tourism intersects with concepts like authenticity, tradition, and local future-making.

Third, tourism has gained increasing economic relevance in recent years. Local reports indicate that summer arrivals have reached significant levels, with approximately 33,000 non-resident arrivals in June 2025, 38,000 in July, and 56,000 in August[5]. Comparative data suggest that arrivals have grown by over 30% between 2022 and 2024, alongside an expansion in private accommodation and shorter average stays. These trends point to a progressive intensification and transformation of tourism dynamics on the island.

3.2 Data collection. Data are being collected through semi-structured interviews conducted in Italian. Interviews explore participants' perceptions of tourism's role in the local economy and society, observed changes over time, perceived opportunities and challenges, and expectations for the island's future. Interviews explored stakeholders' perceptions of tourism through open-ended questions, following an inductive approach (Gioia et al., 2013). Interviews are audio-recorded and transcribed verbatim. The research design follows an iterative logic in which data collection and analysis proceed in parallel, enabling progressive refinement of emerging insights (Langley and Abdallah, 2011). Given that the project is ongoing, the findings presented in this paper should be considered preliminary and part of a broader multi-stage research process.

We employ a purposive and theoretically informed sampling strategy (Eisenhardt and Graebner, 2007; Glaser and Strauss, 1967). Informants are selected based on theoretical appropriateness and their potential to provide information-rich accounts of tourism-related dynamics on the island, rather than on representativeness. The intended sample comprises approximately 30–35 interviewees representing different local stakeholder categories, including tourism operators, entrepreneurs, long-term residents, newer inhabitants, small business owners, public officials – but not tourists – and other actors involved in or affected by tourism governance and development. At the time of writing, four initial exploratory interviews have been conducted with informants. Data collection will continue in the coming months until theoretical saturation is reached (Corley and Gioia, 2004).

3.3 Data analysis. Data is analyzed inductively, following Gioia et al.'s (2013) methodology. The process involves iterative coding and constant comparison between empirical material and emerging interpretations (Glaser and Strauss, 1967; Suddaby, 2006). Following Gioia et al. (2013), we identify first-order concepts (expressed in the informants' own terms), second-order themes, and aggregate dimensions in an iterative process. Given the ongoing nature of data collection, these dimensions remain provisional and will be further refined as additional interviews are conducted and theoretical saturation is approached (Corley and Gioia, 2004)

To enhance analytical rigor and minimize personal bias, the analysis consists of a back-and-forth process, with each author independently engaging in open coding, remaining close to the informants' language. We then engage in multiple

[4] Carloforte is the only municipality on San Pietro Island.
[5] Osservatorio del Turismo, Artigianato e Commercio. Sardegna Turismo.

rounds of discussion to compare coding structures, interrogate divergent readings of the data, and achieve convergence on emerging interpretations.

Results. *At the time of writing, four exploratory interviews have been conducted in this initial stage. These preliminary informants include a long-term foreign resident originally from Germany, a local police officer, and two long-term Sardinian residents living on the island. The findings presented here should be considered preliminary and indicative of emerging interpretive patterns rather than definitive conclusions.*

Evidence reveals that tourism is interpreted through distinct lenses reflecting different priorities for identity, development trajectory, and long-term sustainability. Aligned with the methodology (Gioia et al., 2013; Strauss and Corbin, 1998), Table 1 (data structure) illustrates the preliminary process of investigation, presenting the first-order concepts (open coding) that lead to the second-order themes and, ultimately, to the aggregate dimensions that emerged from the analysis (axial coding).

Two aggregate dimensions currently structure these narratives: tourism as the preservation of authenticity and tourism as the custodianship of place. While analytically distinct, these frames coexist in stakeholders' accounts and together shape how tourism is interpreted and evaluated within the local context.

Table 1. Data structure (initial draft)

First-order concepts	Second-order themes	Aggregate dimensions
Carloforte is a small jewel	Perceived authenticity of the island	Tourism as preservation of authenticity
This place has strong traditions and a very unique culture		
Things happen here that could only happen in Carloforte	Uniqueness of local atmosphere and experiences	
People come here because it feels different from other places		
People come here for the sea, the nature, and the landscape	Value of natural environment and landscape	
The island is still very natural and wild in many places		
Tourism has brought growth and opportunities to the island	Tourism as a driver of local development	Tourism as custodianship of place
Tourism must be regulated to protect the island	Need for regulation and balance in tourism flows	

Tourism as preservation of authenticity. The first interpretive frame emerging from the data conceptualizes tourism primarily as a way to experience and preserve the island's authenticity (Croes et al., 2013). Within this perspective, the value of tourism lies not only in its economic contribution but also in its ability to attract visitors interested in the island's distinctive cultural, social, and natural environment. Several informants described Carloforte as a place characterized by a strong sense of authenticity, rooted both in its cultural traditions and in its relatively unspoiled natural landscape. The island was frequently portrayed as "different" from other Sardinian destinations, particularly because it has maintained a strong local identity and a close relationship with the surrounding natural environment. For example, the German resident described the island as a place whose appeal derives precisely from its authenticity and natural character:

"Carloforte is a small jewel. It is not like the rest of Sardinia. There is something very authentic here – the traditions, the people, but also the nature. The island is still wild in many places, and that's part of its beauty."

Similarly, informants highlighted the importance of preserving the island's natural resources, including its coastal landscapes, marine environment, and relatively untouched areas. These natural features were described as fundamental elements of the island's attractiveness and identity:

"People come here for the sea, for the nature, for the landscape. Carloforte is still a very natural island. If we lose that, we lose the real value of this place."

In these narratives, tourism is perceived positively when it allows visitors to experience this combination of cultural authenticity and natural beauty without transforming it. Tourism should therefore remain compatible with the island's existing rhythms, landscapes, and ways of life. Two second-order themes underpin this interpretive frame. The first concerns the perceived authenticity of the island, which informants associate with local traditions, social life, and historical identity. The second relates to the value of the natural environment, including the island's landscapes, coastal ecosystems, and sense of environmental integrity. These narratives resonate with the tourism literature on authenticity (De Bernardi and Arenas, 2022; Nguyen and Cheung, 2016; Park et al., 2019), which highlights how destinations derive value from the preservation of distinctive cultural and environmental characteristics (Rickly, 2022; Rickly-Boyd, 2013; Wang, 1999). In island contexts in particular, authenticity is often closely linked to the perceived integrity of natural environments and landscapes, which play a central role in shaping visitors' experiences and local identity (Graci and Maher, 2020).

Tourism as custodianship of place. Alongside authenticity-oriented narratives, a second interpretive frame emerges from the interviews, emphasizing the responsibility of local actors to manage tourism in ways that protect the island's long-term sustainability. Within this frame, tourism is simultaneously recognized as economically valuable and potentially problematic if left unmanaged. Several informants acknowledged the important role tourism has played in the island's economic development. Long-term residents highlighted how tourism has positively contributed to local growth and expanded economic opportunities over time. However, these narratives were often accompanied by concerns about specific forms of tourism perceived as unsustainable or poorly integrated into the local context. In particular, informants expressed criticism toward large volumes of short-term visitors arriving for day trips. A local police officer, for example, described the impact of daily ferry visitors during peak summer periods:

"The problem is not tourism itself. The problem is when there is no selection. Uncontrolled day-trip tourism can create social and infrastructural pressures".

These concerns were not limited to social or infrastructural impacts but also extended to environmental pressures. Informants frequently emphasized the need to protect the island's landscapes and marine environment from overuse. In this sense, tourism was often framed as a phenomenon that requires careful governance and collective responsibility. Even informants who recognized its economic benefits emphasized the need to regulate tourism flows and maintain a balance between development and preservation:

"Tourism is important for the island, of course. But it must be regulated. We cannot lose what makes this place special."

These themes reflect a broader understanding of tourism as something that must be actively managed to safeguard both the community and the natural environment. This perspective aligns with the concept of custodianship (Dacin et al., 2019; Haugh et al., 2026) in tourism and sustainability literature, which emphasizes the role of local actors as guardians of destination resources and identity and responsible for protecting the long-term integrity of destinations (Boley et al., 2018; Moscardo, 2021). In this sense, tourism development is not only an economic issue but also a matter of environmental stewardship and intergenerational responsibility.

Research limitations. *This study focuses on the perspectives of local stakeholders, capturing how actors embedded in the destination interpret tourism development and the preservation of environmental and cultural resources. While this approach provides important insights into locally grounded visions of tourism, it does not include the perspectives of tourists, whose expectations and perceptions may differ from those of residents and institutional actors. Future research could therefore explore how visitors perceive the island's identity, natural environment, and tourism offer, and whether these perceptions align with local narratives (Bramwell and Lane, 2011).*

Furthermore, additional research could examine whether the interpretive frames identified in this study are translated into actual policies, governance practices, and tourism management strategies over time. Longitudinal or policy-oriented studies could explore how stakeholder framings influence decision-making processes and destination planning in practice (Hall, 2008).

Managerial implications. *The findings offer a useful starting point for tourism planning (Cerd´a-Mansilla et al., 2024; Huang et al., 2023) in destinations characterized by strong environmental and cultural identities. By identifying how local stakeholders frame tourism development – particularly in relation to the protection of natural resources and the island's relatively unspoiled character – this study provides insights that may support policymakers and destination managers in designing strategies that reflect local values and priorities.*

Importantly, tourism development cannot rely on standardized policy models, as effective strategies must be grounded in the specific social, environmental, and cultural context of each destination (Hall, 2008). Understanding the interpretive frames of local actors, therefore, becomes a key step in developing context-sensitive tourism policies and in assessing the degree of alignment between stakeholder visions and visitor expectations (Bramwell and Lane, 2011).

Originality of the paper. *This study contributes to tourism research by applying framing theory to the analysis of stakeholder perspectives in a small-island tourism context. Framing theory highlights how actors interpret issues and construct meanings that influence perceptions, priorities, and potential actions (Goffman, 1974). While stakeholder participation has been widely discussed in tourism studies, less attention has been given to the interpretive processes through which stakeholders frame tourism development and destination resources.*

By identifying the frames through which local actors interpret tourism and the preservation of natural and cultural assets, the study provides a theoretically informed perspective on how tourism development narratives are socially constructed within destination communities. In doing so, it contributes to expanding the application of framing theory within tourism research and offers a conceptual lens for understanding how local meanings and values shape tourism development in environmentally sensitive destinations (Benford and Snow, 2000).

Evolution of the role of the sustainability manager in the Italian context

MAXIMILIAN BROGLIO[1]

Abstract. *The corporate ecosystem has undergone significant changes in recent years, especially with regard to certain managerial positions that have developed and evolved to monitor and manage changes and contingencies occurring outside the company's perimeter. Indeed, the global context in which companies operate is marked by numerous critical issues, such as widespread degradation, the crossing of various planetary boundaries, climate change related to anthropogenic climate-altering emissions, pollution of various environmental matrices, the reckless and unsustainable use of resources, the loss of numerous species due to human activity, geopolitical and social crises, and conflicts gripping several countries. This general context has meant that companies can no longer afford not to account for and address these burdensome issues (also in light of the resulting regulatory interventions, especially at the European level). This has led to the emergence of highly specialized professionals capable of expertly and competently managing issues across the company. It is important to emphasize that these aspects must be viewed through a double materiality lens: aspects of the company that impact the external ecosystem from an "inside-out" perspective, and external aspects that impact business continuity from an "outside-in" perspective. The need to proactively manage the most crucial issues is proving to be a key factor in achieving a competitive advantage and ensuring survival in a context where ESG issues have become a cornerstone of every corporate strategic plan.*

In this context, the role of sustainability manager is increasingly playing a strategic role within the company, characterized by transversal skills. In recent years, it has evolved from a purely operational role, focused on the execution of environmental initiatives, to a strategic position that integrates sustainability into high-level corporate decisions.

The current work aims to trace its evolution within the Italian context, attempting to delineate its evolution in terms of skills, tasks, positioning, and training programs, and to assess its adoption rate by Italian companies (including by evaluating trends). The research also aims to outline a regulatory framework to fully understand the drivers behind their growth and then begin to evaluate their future perspectives.

Keywords: *Sustainability; Sustainability manager; ESG; corporate strategy; corporate management.*

Framing of the research. *In terms of framing the research, it is important to immediately recognize that the analytical study of the sustainability manager is intimately connected to two strands of research: sustainability, which has seen exponential growth in recent years, and corporate management, thus representing a sort of hybridization of the two. This research seeks to address the research gap related to the lack of precise, up-to-date public data on this professional figure in the Italian corporate context (as highlighted in the research limitations), recognizing that it is essential to provide a more detailed and in-depth picture of the skills, positioning, role, and adoption rate of these roles by Italian companies, the drivers behind growth, and future prospects.*

The research also fits perfectly within the equally well-known ESG framework, an increasingly crucial element in the corporate context as it can affect aspects such as reputation, competitiveness, financing possibilities, and business continuity. All these considerations are naturally linked both to the well-known transcendence of planetary boundaries, which inexorably forces companies to rethink their operations, shifting toward socio-environmentally sustainable practices, and to the proliferation of regulatory mandates (especially European ones, which are then naturally implemented within the national context) that require companies to pay greater attention to the impacts associated with their operations (emissions impacts related to the production site, impacts along the supply chain, impacts on local communities, etc.).

The ongoing work, in order to better explore the evolution of the role of the sustainability manager in Italy, therefore aims to analyse its specific features and numbers in order to provide interesting insights and to serve as a reminder of the strategic importance of this role within the corporate context.

Purpose of the paper. *The primary objective of this ongoing work is to provide a clear and comprehensive descriptive analysis of the sustainability manager role within the Italian corporate context.*

The analysis aims to provide an opportunity to update the specifics of this professional role within Italy in terms of skills, tasks, positioning within the corporate organization, and attitudes, while also addressing the motivations (such as the degraded global context and ESG factors, along with the resulting mandatory European regulatory requirements) behind the emergence of this role.

In addition to providing a snapshot of the current situation, it is essential to evaluate the evolution of this role over recent years, both in terms of the skills and tasks required and in terms of its positioning within the specific company

[1] Universitas Mercatorum – Roma, e-mail: maximilian.broglio@studenti.unimercatorum.it

context (for example, by evaluating the level of the position, the relationship with top management) to understand how it is evolving and to attempt to outline, in a perspective view, its future characteristics.

It is equally important to analyse the numerical evolution (is the trend growing, as easily predictable?) over recent years to understand how this role is growing in importance in the Italian corporate context (also making necessary distinctions, for example, in terms of the company's geographic location or gender).

A subsequent objective is to emphasize the importance of this role in contributing to the company's resilience, its ESG regulatory compliance, its business continuity, and its reduction of social and environmental impacts. This will enable the company, through scientifically considered strategic choices, to move toward a sustainable future that, in addition to being characterized by lower socio-environmental impact, allows the company to enhance its reputation, thus achieving a competitive advantage (in a market where sustainability is essential).

Precisely in relation to these advantages associated with the strategic adoption of sustainability managers, there is an indirect desire to motivate administrators to seize this opportunity even when there are no mere regulatory constraints obliging them; hence, during the ongoing research, surveys will be administered to various companies to assess the situation and obtain the opinion of top management.

The work is also intended to be a source of information for industry professionals who want to update their knowledge or for professionals who want to pursue this career but currently lack sufficient data and information to gain a complete picture of the situation.

Methodology. *From a methodological perspective, a qualitative research approach was chosen, through which a systematic review of the technical and scientific literature on the role of the sustainability manager was undertaken. This was accompanied by a review of various statistical surveys and reports that traced the evolution of this role in various fields. This allowed for assessment of aspects such as positioning, required skills, actual role, adoption rate within companies (with specifics on the type of company and its geographic location), drivers of growth, and the regulatory frameworks that govern it.*

In terms of temporal scoping, the analysis focused on the most recent findings to ensure adequate updating in a rapidly evolving context, both in terms of regulations and skills. Regarding the geographical boundaries of the research, Italy was chosen to provide a detailed and specific analysis in a context not so well delineated in the literature.

Considering this is a work in progress, the intention is to subsequently continue with a quantitative phase through the use of a statistical survey to be administered to a representative company sample. This will allow to further quantify the growth rate, positioning, skills, role, and actual impact of this figure within the Italian corporate strategic decision-making context.

Results. *Starting from the general technical framework, the professional profile of the sustainability manager in Italy, as anticipated, has evolved from an operational role, simply focused on managing environmental issues, to a strategic position that allows for integrating sustainability into high-level corporate decisions (the role is gradually moving towards high-level governance). In the last decade, in fact, the role has undergone significant professionalization following external pressures, such as regulatory mandates such as EU Directive no. 2022/2464, also known as the Corporate Sustainability Reporting Directive (CSRD), which aims to standardize and strengthen corporate sustainability reporting requirements (which came into force on January 5, 2023, replacing the previous Non-Financial Reporting Directive (NFRD)), growing pressure from investors and consumers, and the inexorable and ongoing deterioration of planetary health. The role was initially primarily tied to the execution of environmental and Corporate Social Responsibility (CSR) projects, but today it contributes to business model transformation, with cross-functional expertise in ESG governance. The increasingly centrality this role is assuming in the Italian context is leading it to engage[2] directly with the board of directors, becoming a key figure in Italian corporate organizational charts, growing in importance alongside the strategic importance of sustainability, very often with specialized oversight of non-financial reporting and ESG risks.*

In terms of skills, this role must have transversal yet advanced technical skills, having to navigate ESG and sustainability regulations (to ensure legal compliance), sustainability reporting, data analysis and KPI monitoring, supply chain knowledge and impact measurement (for example, through Life Cycle Assessment), without focusing solely on the pure environmental aspect (social impact, for example, is becoming increasingly important). Specifically, they must master regulations, standards, and reporting specifications such as the Corporate Sustainability Reporting Directive (CSRD)[3], the Sustainable Finance Disclosure Regulation (SFDR), the European Sustainability Reporting Standards (ESRS), the Corporate Sustainability Due Diligence Directive, the EU Taxonomy, reporting standards and initiatives such as the GRI (Global Reporting Initiative), SASB (Sustainability Accounting Standards Board), TCFD (Task Force on Climate-related Financial Disclosures), SBTi (Science-Based Targets Initiative), certification systems such as ISO 14001, SA8000, B Corp, and various other protocols, such as those for carbon footprinting. This knowledge must be combined with significant analytical skills to expertly and efficiently manage the large amounts of data, for example, with the help of digital tools such as IoT or AI. Skills must also go beyond this, addressing issues such as materiality analysis (double materiality according to the latest regulatory requirements), stakeholder engagement, preventing greenwashing and

[2] For example, as Chief Sustainability Officer.
[3] Implemented in Italy with Legislative Decree 125/2024.

reputational risks, internal management training, audit oversight, developing action plans for optimizing resources (including energy efficiency) and departments, and reducing waste and emissions, supporting leadership with risk and opportunity analyses (aligning sustainability with core business), promoting technological innovation, raising awareness of ethical governance, and the relationship between sustainability and finance.

The sustainability manager must therefore operate holistically, just as the vision of sustainability is holistic: it's not about focusing on one aspect rather than another, which is why skills must necessarily be cross-sectoral. Furthermore, being in a constantly evolving context, the sustainability manager must be proactive in managing change and innovation to continually address new challenges (even considering the more stringent and binding regulatory requirements resulting from the CSRD, despite the simplifications of the Omnibus package).

In Italy, when dealing with the role of the sustainability manager, reference must be made to the UNI/PdR 109 reference practice "Non-regulated professional activities: professional profiles in the field of sustainability" developed by UNI together with Intertek, Confassociazioni, and CSR Manager Network, which is divided into two parts: specifically, part 1 (UNI/PdR 109.1:2021) «defines the requirements relating to the professional activity of the Sustainability Manager and Sustainability Practitioner, i.e. the professional who carries out management activities at a managerial level of sustainability in the company and corporate social responsibility and the professional who develops and manages sustainability at an operational level», while part 2 (UNI/PdR 109.2:2021) «defines the requirements relating to the professional activity of the Sustainability & CSR Auditor, SDG Action Manager, SDG User, i.e. the professional who carries out audit activities in the field of sustainability and corporate social responsibility, management of SDG objectives in organizational structures, management aspects and daily activities of citizens related to the SDGs not related to specific professional activities». It should be clarified that the Sustainability Manager and Practitioner logically have different roles and responsibilities as the former requires advanced managerial skills with strategic decision-making autonomy and involves the development of ESG strategies, plan monitoring and risk and stakeholder management, while the latter focuses on operational support with a lesser mastery of the same knowledge (for example, support in reporting and projects without decision-making autonomy); both in any case require a secondary school diploma and 40 hours of specific training in the last 3 years[4].

In numerical terms, it's important to start from the assumption that in Italy there are no precise and up-to-date public data that can provide a basis for a detailed analysis[5]: for example, referring to the Accredia website, there are only 113 certified sustainability managers[6]. To address this, surveys conducted by private institutions such as Deloitte[7] were considered, which revealed that only 7% of Italian companies have a person dedicated exclusively to sustainability (a position that is also recent, meaning it has been in place for 2-5 years, for 52% of companies), a figure that rises to 37% for companies with more than 50 employees. The data therefore show that this role is relatively new for most companies (71% of these roles have been active for less than 5 years) and a 19% increase in requests has been observed since 2021, driven by ESG regulations and the demand for green skills. It can therefore be stated that this role[8], classified in 38% of cases as a manager[9], is following a growing trend (it is among the top 5 most sought-after), with projections of expansion in the next 5 years due to stakeholder and compliance issues[10], it is linked to the company's size, and it is also concentrated in Northern Italy (11% in the North West alone) [11]. It is also evident that among companies with a sustainability manager, 85% adopt sustainability plans and 80% actively communicate ESG objectives (against lower national averages).

[4] It should also be noted that a manager requires three years of full-time managerial experience in sustainability, while a Practitioner requires only proven operational experience and a different exam. Educational programs to become a sustainability manager in Italy may include master's degrees, executive courses of at least 40 hours, and professional certifications recognized by UNI and CEPAS. Sustainability Manager certification (which requires an update process to maintain certification) in Italy must be obtained from an accredited body that complies with UNI/PdR 109.1:2021 and ISO 17024 standards, with lists available in the Accredia database, such as Intertek Italia Spa.

[5] The registers are public but partial (certified only) and can be integrated with surveys, for example from the Osservatorio Bilancio Sostenibilità for aggregate estimates or, for a complete mapping, combined with LinkedIn or GRI company reports.

[6] Evidently, the data cannot be representative of the Italian total, which also includes non-certified individuals.

[7] "Il ruolo del sustainability manager", 2023

[8] Who in 31% of cases reports directly to the CEO and who in 43% manages teams of up to 2 people.

[9] In Italy, sustainability managers generally reach senior positions in the organizational charts of large companies, often as Chief Sustainability Officer or Group Sustainability Officer reporting directly to the CEO, integrating strategic committees and operational teams.

[10] For companies, the main driving force will come from stakeholder expectations, customers (37%) and suppliers (20%) rather than from shareholders (13%).

[11] The presence of this role is correlated with the concentration of large companies and multinationals, with an estimated greater prevalence in Northern Italy (Lombardia, Veneto, Emilia-Romagna), where 70-80% of companies with more than 50 employees and formal ESG plans are located. Growth in particular is driven by industrial hubs and PNRR incentives, with more consolidated roles in export-oriented contexts and ESG investors.

Finally, some interesting data emerges from the 2024 studies promoted by Sustainability Makers[12] in collaboration with EASP[13] and AIDP[14]; the first study highlights two interesting considerations: a strong female component among internal sustainability professionals and a significant increase in in-house professionals dedicated exclusively to sustainability; the second study shows that organizational sustainability units are beginning to appear not only in large companies (71.6%) but also in small companies (33.3%), and that the role of Sustainability Manager is beginning to be present not only in large companies (71.2%), but also in medium-sized (66.7%) and small companies (55.6%).

In conclusion, it can be stated that the role of sustainability manager within the Italian context is increasingly growing, driven by pressing socio-environmental issues, compliance, and commercial and reputational needs, albeit with diversification in terms of company size and geographical location.

This ongoing work aims to clarify and outline the characteristics, evolution, and prospects of this role within the Italian context, also analysing its numerical evolutionary trends, in the knowledge that this role will assume an increasingly strategic role within the Italian business context. It would be interesting for future research to focus even more on numerical analysis as well as on the drivers and obstacles that may influence its adoption.

Research limitations. *The research presents several limitations, primarily related to the availability of specific and geographically contextualized company data. Specifically, it is reiterated that in Italy, precise and up-to-date public data on the numerical and geographical distribution of sustainability managers do not exist (there are no official public datasets or centralized national registers to map sustainability managers in Italy, as the role is not regulated as a professional body, thus limiting sources to private surveys or accredited lists: these ones are, however, partial, as is the case with the national accreditation body Accredia's register, which lists professionals certified in sustainability through the databases for the UNI/PdR 109.1:2021 and UNI/PdR 109.2:2021 standards for Sustainability Managers and Practitioners, accessible online for searches by region or sector) and are available only analyses, such as the Deloitte 2023-2025 one, which, however, do not provide detailed regional or provincial breakdowns. To overcome these limitations, it is possible to turn to networks like Sustainability Makers, which publishes reports and profiles of professionals (over 500 members) with aggregated data from ESG governance surveys or consider surveys and observatories like the Osservatorio Bilancio Sostenibilità, which offers annual surveys with publicly available, non-named or georeferenced demographic data. It is possible also to consult ISPRA and MATES project[15] reports, which provide qualitative analyses of profiles, downloadable for indirect company correlations***.***

Managerial implications. *A detailed analysis of the specific technical characteristics of the sustainability manager role, ranging from role to positioning, skills to responsibilities, as well as an updated assessment of its adoption trends within Italian corporate contexts, certainly provides a wealth of interesting information both for professionals already employed in the role and, above all, for professionals who wish to approach the role by pursuing this type of career.*

This information can also be of great importance for companies, which can better understand the crucial importance this role has for the corporate ecosystem in terms of compliance with increasingly stringent regulations, reputation, creation of a competitive advantage, lower socio-environmental impact, and greater resilience - in short, ensuring the company's survival and flourishing.

This work can allow companies to fully understand the need to employ such a figure who is capable of managing issues across the ESG spheres, ensuring business continuity in this challenging external environment. The hope is also to act as a lever for less inclined administrators (where there are no regulatory obligations) so that, especially by outlining advantages and growing numbers, they are truly convinced of the great positive impact that can derive from it.

Originality of the paper. *This work represents an important opportunity to outline an updated and contextualized description of the role of the sustainability manager within the Italian context (where such precise and up-to-date public data does not exist). This role is increasingly crucial in the corporate world due to the delicate socioeconomic and environmental context in which companies operate (global warming, conflicts, environmental contamination, social tensions).*

The originality lies precisely in the precise and detailed analysis of all the facets of this managerial figure (from role to positioning, from skills to tasks), without neglecting issues such as the numerical evolution within the Italian corporate fabric (in connection with potential drivers such as commercial needs, regulatory requirements, etc.). The ultimate goal is to provide a detailed and up-to-date framework that can clarify and provide information on issues that are not always so well-defined. This numerical analysis allows to provide a snapshot demonstrating the evolution and ever-increasing importance of this professional figure (this could provide further impetus to senior figures who still today view the need for a figure like this in a company with suspicion).

Exploring the relationship between firm innovativeness and biodiversity: opportunity or liability?

COSTANZA BALDRIGHI[1], BERKE OKUR[2], MAURO CAPESTRO[3], STEFANO DENICOLAI[4]

Abstract. *Environmental sustainability, including biodiversity protection, is a central concern for many firms. However, preserving biodiversity is often considered a liability by companies, which frame it as a potential constraint to their profitable activities and view their relationship with biodiversity merely in terms of limiting negative impacts on it. Nevertheless, some scholars have started observing the relationship with biodiversity as a potential source of competitive advantage, investigating its role in influencing firm performance and risk mitigation capability. In this perspective, our exploratory research aims to explore whether the relationship with biodiversity can influence a company's level of innovativeness.*

We adopted a mixed-method approach, consisting of an original survey completed by 226 valid responses (Italian firms: 81,4%; international firms: 18,6%), followed by in-depth interviews with the CEO / managers of ten Italian firms. Quantitative results indicate that firms passively operating in a biodiverse environment without integrating it into their business model are less likely to be highly innovative; conversely, firms deliberately engaging with biodiversity tend to perform better in innovation-related measures, highlighting the crucial distinction between active and passive exposure in innovation processes. Qualitative results emphasize the relevance of both stakeholders and digital technologies for biodiversity practices and goals, and of biodiversity for firm innovativeness. Findings help advance the literature about the link between biodiversity and firm innovativeness and to define some managerial implications.

Keywords: *biodiversity; innovation management; firm innovativeness; stakeholder theory; digitalization; mixed-method.*

Framing of the research. *In recent years, sustainability has become an increasingly important concern for firms and policymakers. Among the various dimensions of environmental sustainability, the conservation of biodiversity, meant as "the variety of life, including variation among species and functional traits" (Cardinale et al., 2012, p. 60), has received growing attention due to its implications for ecosystems and economic systems. Firms are finding new ways to incorporate biodiversity into their sustainability practices in the process of understanding how it impacts the business environment. New frameworks and tools can help organizations tackle sustainability and biodiversity issues by reducing the impacts of their activities on the environment (Reale et al., 2019). As sustainability, including the pressing topic of biodiversity protection, is gaining popularity amongst researchers, policymakers, and businesses, this debate is now more relevant than ever before.*

While policymakers seek to protect the environment's interests, they introduce constraints and tensions that companies must consider when undertaking business activities. This pressure on firms is not only imposed by policymakers but also by consumers who favor products and services from companies that have sustainability practices. Although this pressure is generally viewed as having a negative impact on companies, it can encourage firms to define innovative management strategies to counteract the environmental impacts. This approach also contributes to their long-term stability and may help secure key resources for the firm (Ivanov, 2022). These tensions bring up important questions regarding the role of innovation in this context: thus, the link between biodiversity and innovation is far from being explained. With this research, we aim to contribute to filling the gaps in the literature regarding this relationship. Recent studies have been focusing more on the effects of biodiversity and adjacent topics. Research argues that biodiversity and ecosystem service management should be regarded as a core sustainability issue that can influence firm performance (Wagner, 2023). Katic and colleagues (2023) found that companies are adopting biodiversity impact measurement and management tools into their processes as a way to mitigate and understand how biodiversity affects them. Overall, the literature has a fragmented perspective on biodiversity, as on one side it could be regarded as a strategic issue for firms, and on the other side, it could be a potential driver for firm innovativeness and growth.

Contributing to this topic, a growing number of scholars and practitioners are recently looking at managing sustainability and biodiversity issues by considering the role played by stakeholders (Bronzetti et al., 2023), with respect to the activation of sustainable business solutions that could positively affect biodiversity practices (Henriques & Sharma, 2005). Specifically, for biodiversity practices, scholars refer to the activities that can help to tackle the loss of biodiversity (Salmi et al., 2023). Boiral and Heras-Saizarbitoria (2017) proposed a framework that differentiates biodiversity practices into: (i) internal practices that are implemented by the firm itself; and (ii) external practices implemented in association or collaboration with various stakeholders.

[4] University of Pavia, Italy, email: stefano.denicolai@unipv.it

Another important aspect in motivating operational practices to tackle biodiversity issues is linked to the diffusion of ecological knowledge. Specifically, ecological knowledge is vital in influencing biodiversity culture and shaping learning about biodiversity in the social context. Stakeholders are integrated into this learning process (Smith et al., 2020) because of their key role in value co-creation (Boiral and Heras-Saizarbitoria, 2017). According to stakeholder theory, in developing their overall strategies, companies and organizations must consider the interests and expectations of their various stakeholders, defined as "any identifiable group or individual who can affect the achievement of an organization's objectives, or who is affected by the achievement of an organization's objectives" (Freeman & Reed 1983, p. 91). Some studies have highlighted the importance of stakeholders' engagement and involvement in managing complex environmental issues and promoting proactive environmental strategies (e.g., Buysse & Verbeke, 2003; Cragg & Greenbaum, 2002).

In addition to stakeholders, digitalization also plays a key role in managing sustainable goals (Broccardo et al., 2023). Emerging digital technologies may lead to variations in how organizations involve stakeholders in sustainable practices. Moreover, in recent years, there has been growing attention on how digitalization can support organizations in the optimization of business processes, including environmental sustainability concerns (Piccarozzi et al., 2022, 2023). Digital technologies can serve as solutions for facing biodiversity issues in different ways, as they can be used to offer innovative regenerative solutions in agriculture (Cumming et al., 2020), but also to tackle biodiversity loss, playing a complementary role alongside existing technology, or supporting other innovation processes (Ziegler et al., 2022).

The connection between biodiversity and innovation emerges as a promising field of research as pursuing biodiversity goals could affect firm innovativeness, in terms of processes, products, services, and business models. These contributions suggest that biodiversity may represent not only a constraint, but also a potential strategic resource for firms. In the management literature, it has been found that diversity is considered a driver of innovation (Hewlett et al., 2013). Different forms of diversity, such as gender, culture, education, background, and cognitive (Mitchell, 2008; Østergaard et al., 2011), as well as the diversity of cooperation and relationships among companies and stakeholders (Vence & Trigo, 2009), have positive effects on firm innovativeness. In the context of sustainability (and biodiversity), companies have started to innovate their business models to include also environmental and social considerations (Feger & Mermet, 2022). These sustainable business models are designed to integrate sustainability into companies to create ecological and social values, and to adapt the firm to the changing external environment. This perspective will drive the next wave of innovation and growth in the global economy and will also contribute to reshaping businesses and the relationships with society (Porter & Kramer 2019).

Purpose of the paper. *Overall, existing research provides fragmented insights: on the one hand, biodiversity is increasingly recognized as a strategic issue for firms; on the other, the literature on sustainability and innovation suggests that innovation can support environmental objectives only under specific conditions and may otherwise entail trade-offs (Pichlak & Szromek, 2021). Despite an increasing interest in the implementation of biodiversity practices from a business viewpoint, we still lack a deeper understanding of the effects on innovation and firm innovativeness. The main purposes of the study concern assessing the relationship between biodiversity and firm innovativeness and the following deeper understanding of the factors, in terms of new theoretical patterns (Sabherwal & King, 1991), that can affect this relationship. In doing so, the study tries to answer the following research questions:*

RQ1: Does biodiversity affect firm innovativeness?

RQ2: What is the role of stakeholders in biodiversity practices?

RQ3: What is the role of digitalization in biodiversity practices?

The purpose of the study is to evaluate the management of biodiversity from a business perspective and assess the relationship with innovation and, specifically, with firm innovativeness. We attempt to answer the study's research questions through both a quantitative study assessing the relationship between biodiversity and firm innovativeness and a qualitative one to gain a deeper understanding of this relationship and the factors that can affect it, to develop a theoretical framework useful for future research.

Methodology. *The empirical analysis is based on data collected through a survey targeting executives responsible for innovation and sustainability within their organizations (e.g., Chief Innovation Officers – CInO, and Chief Sustainability Officers – CSO). CEOs were also included, as smaller companies may not have dedicated C-level executives responsible for innovation and/or sustainability. The survey captures data regarding firm innovativeness, organizational approach to sustainability practices, biodiversity-related activities, and other firms' characteristics. We collected a total of 226 responses. Table 1 summarizes the main characteristics of the sample.*

An ordered logit model is used to analyze the relationship between the firm's biodiversity-related activities and innovativeness in terms of performance. In our analysis, the firm's innovativeness (dependent variable) was measured using the share of revenue generated from innovative products and services in the last 3 years, using a 5-point scale ranging from 0% to over 25%. As regards biodiversity-related activities (independent variables), we measured five items capturing various aspects of the firm's relationship with biodiversity. The items are 1) operating in biodiversity-rich environments (oper_bio_rich), 2) innovation activities are carried out in biodiversity-rich ecosystems (act_bio_rich), 3) biodiversity preservation efforts (preserving_bio), 4) assessment of impact on biodiversity (impact_bio), and 5) the use of biodiversity as a source of competitive advantage (comp_adv_bio).

In the model, we control for country of origin (country), firm size (size), and industry sector (sector) to account for organizational and institutional factors that may affect both innovation performance and biodiversity-related activities. The country variable is modeled as a dummy variable since more than 80% of the responses were headquartered in Italy. In addition, the industry sector is introduced as a binary variable differentiating manufacturing firms from other industries, since manufacturing companies account for approximately two-thirds of the sample (64.6%).

For the qualitative study, we performed a multiple case study (Yin, 2014) using multiple material sources from in-depth interviews, to better understand the phenomenon, and secondary data extracted from companies' websites and companies' LinkedIn webpages. We have collected data about ten Italian firms, detailed in Table 2.

Tab. 2: Case studies

Company	***Founded***	***Size (employees)***	***Industry/Activity***	***Interviewed***
Company 1	*2017*	*Medium-sized*	*Technology / Technology provider*	*Marketing manager*
Company 2	*2019*	*Medium-sized*	*Food / Food delivery services; Education services*	*Co-founder*
Company 3	*2018*	*Medium-sized*	*Consulting / Innovation and technology consulting services*	*Marketing manager and Agronomist*
Company 4	*2022*	*Small-sized*	*Technology / Bio-technology solutions*	*Co-founder*
Company 5	*2019*	*Small-sized*	*Food / Health food production*	*Founder / Marketing manager*
Company 6	*2017*	*Small-sized*	*Technology / Technology provider for agriculture*	*Sustainability manager*
Company 7	*1974*	*Large-sized*	*Food / Production of canned fish*	*CEO*
Company 8	*1974*	*Small-sized*	*Food / Wine producer*	*CEO*
Company 9	*2016*	*Large-sized*	*Consulting / Sustainability and biodiversity-related services*	*Co-founder*
Company 10	*2022*	*Small-sized*	*Technology / Sustainable-related digital solutions*	*CEO*

Source: authors' own elaboration

In this case, we performed two steps of analysis: a preliminary desk analysis of companies' website and LinkedIn webpage and a content analysis of the interviews done to extract common concepts useful for our research goals. The interviews aimed at investigating the link between business and biodiversity, the firms' activities (practices) adopted for biodiversity goals, and the effect of these practices on innovation.

Results. *According to our quantitative results, we observed a heterogeneous relationship between company innovation performance and biodiversity-related activities. As shown in Table 3, considering companies that have active engagement with biodiversity (act_bio_rich), it is positively correlated with higher revenue from innovative products ($\beta = 0.38$, $p < .05$), while operating in a biodiverse environment shows a negative correlation ($\beta = -0.44$, $p < .01$). These results suggest that there are deeper mechanisms involved in biodiversity's impact on innovation performance, since the effect is not uniformly positive, which signifies a trade-off. Based on these results, we can mainly state that, on one side, companies that actively carry out innovation-related activities in biodiversity-rich environments tend to perform better in the overall*

level of innovation; instead, on the other side, simply operating in a biodiverse environment does not assure innovation performance.

Tab. 3: Regression results

The contrasting findings indicate that the distinction between positive and negative correlation might stem from external factors, such as environmental policies and regulations, and a deliberate and strategic inclusion of biodiversity in the business processes. Regarding the control variables, we found a significant negative effect of size, suggesting that larger companies tend to generate less revenue from innovative products, in line with evidence from the literature (Chandy & Tellis, 1998).

The evaluation of the ten firms involved in the qualitative study started with a desk analysis of the companies' websites and LinkedIn pages to mainly assess how biodiversity is part of the business (activities, products, services for biodiversity) and the collaborations and the digital technologies used to manage biodiversity. A summary of the main results of the desk analysis is reported in Table 4.

From this first step of qualitative analysis, emerged a clear positive role of both stakeholders and digitalization as two relevant factors that firms involved with biodiversity concerns have to take into consideration. Stakeholders can support and/or push a firm to implement biodiversity practices for different reasons. Digital technologies are essential to monitoring and managing biodiversity.

In addition to the desk analysis of companies' websites and LinkedIn pages, we analyzed the interviews done with managers and a co-founder of the ten companies considered in this study. The content analysis of the interviews allowed us to have some insights into our research goals. Firstly, all companies consider biodiversity a current issue that firms must tackle and thus consider in their own overall strategy.

As far as the relationship between biodiversity and innovation, we found (as the following quotes show) that biodiversity can positively affect a firm's innovativeness in very different ways, with positive effects on products, services, processes, and business models.

"When we noticed that people were interested in biodiversity issues, we basically modified our business model to involve individuals." (Company 1)

"Biodiversity allows us to satisfy different people's needs. In this way, we can innovate our business also promoting personalized nutrition." (Company 2)

"In our solutions, we offer the clients the opportunity to innovate the business models." (Company 3)

"Biotechnology can certainly be an extraordinary lever of innovation to face biodiversity issues." (Company 4)

"Offering bio-solutions is very innovative because probably these situations could have been addressed with chemical or other industrial solutions." (Company 5)

"We developed an innovative DSS (decision support systems) tool that uses sensors in the field, which are processed using agronomic models, to provide advice to farmers." (Company 6)

"To preserve product characteristics and assure a top-quality product, we innovated our salting process, which now takes place within 24 hours of the catch at the fishing grounds." (Company 7)

"We launched a project in 2008 to rediscover old historic grape varieties through mass selection." (Company 8)

"We use bees as bioindicators by measuring emissions in the environment covering a very large area." (Company 9)

"We use innovative algorithms to identify correlations and describe any trends about biodiversity." (Company 10)

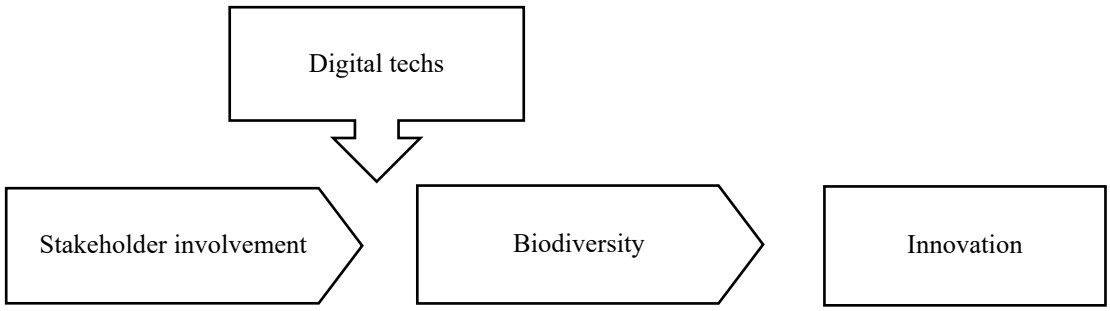
As far as the role of stakeholders for biodiversity issues is concerned, through the analysis of interviews emerged that the involvement of stakeholders is a key factor that helps firms to reach sustainable and biodiversity goals, because of the complexity of these topics.

Tab. 4: Main results of qualitative desk analysis

Company	***Products/Services***	***Collaboration strategies***	***Digital techs for biodiversity***
Company 1	▪ *Monitoring* ▪ *Regeneration* ▪ *Education* ▪ *Innovative biodiversity-related services for citizens*	▪ *Collaborations with their clients to control bees' lives* ▪ *Collaborations with other organizations (universities and research centers) to develop new solutions* ▪ *Involvement of the clients of their clients*	▪ *IoT* ▪ *Sensors* ▪ *Satellite imagery* ▪ *AI tools* ▪ *App*
Company 2	▪ *Food production (recipes) and delivery for individuals and organizations* ▪ *Personalized nutrition*	▪ *Collaborations with suppliers to assure ingredients variety* ▪ *Collaborations with other organizations (universities, research centers, and consultants) for technical aspects*	▪ *Digital platform,* ▪ *App (for service delivery, for personalized nutrition, for B2B relationship)*
Company 3	▪ *Nature-based solutions* ▪ *Local and industrial resource efficiency solutions services* ▪ *Biodiversity monitoring and innovative regeneration services* ▪ *Open Innovation*	▪ *Involvement of clients to favor biodiversity practices and promote them in the client's network.*	▪ *Sensors* ▪ *Satellite imagery* ▪ *Virtual collaboration tools*
Company 4	▪ *R&D and production of science-based and plant-derived active ingredients for the Personal Care and Health Care markets.*	▪ *Very important collaboration with research centers, universities, and other organizations (mainly consultants) for the development of innovative solutions*	▪ *Smart production technologies instrumental for the business based on biodiversity*
Company 5	▪ *Production of functional fibers and antioxidants for health food that are already present in nature.*	▪ *Collaborations with different organizations (from business partners to universities, research centers, and consultants) to develop innovative solutions*	▪ *Smart production technologies instrumental for business biodiversity-based* ▪ *Digital platform*
Company 6	▪ *Consulting services and technology provider for the digitalization of agriculture firms*	▪ *Several collaborations with the following organizations: supply-chain, food producers and distributors, other tech providers, and the agriculture association*	▪ *AI tools* ▪ *IoT* ▪ *Sensors* ▪ *Satellite imagery* ▪ *Digital platform for agriculture solutions for managing sustainability and biodiversity issues*
Company 7	▪ *Production of canned fish using sustainable packages and assuring 100% of residual CO_2 emissions are offset*	▪ *Main collaboration with supply-chain, universities, and research centers.*	▪ *Life Cycle Assessment tools* ▪ *Digital data-driven tools for monitoring the supply chain*
Company 8	▪ *Wine production follows sustainable processes that preserve biodiversity*	▪ *Collaboration with consulting firms for sustainability and biodiversity concerns* ▪ *Collaboration with other business partners*	▪ *Innovative technological solutions are used to preserve product characteristics.*
Company 9	▪ *Innovative biodiversity-related services for citizens*	▪ *Collaborations with different organizations (business partners, universities, research centers, and consultants)*	▪ *Innovative digital solutions and AI tools for monitoring biodiversity and environmental impacts*
Company 10	▪ *Digital and consulting services for the monitoring and evaluation of biodiversity and environmental impacts of business*	▪ *The field of Open Innovation has a main collaboration with a consulting company* ▪ *Collaboration with a technology developer* ▪ *Collaboration with agri- and food-related firms*	▪ *AI tools* ▪ *Machine learning tools* ▪ *Cloud solutions* ▪ *Digital tools for data-driven analysis*

Source: authors' own elaboration

"In addition to our clients, citizens are also directly involved in the business because of the relevance of biodiversity. Moreover, we collaborate with different research universities and other institutions." (Company 1)
"In our business, we need the involvement of other organizations and of clients." (Company 2)
"Biodiversity needs stakeholders' involvement. Biodiversity loss is a social issue that needs the participation of different actors." (Company 3)



"We have to involve stakeholders and institutions and share with them the culture of bio-solutions to reach sustainable goals." (Company 4)
"Everyone has to participate actively. For example, scholars are useful for doing outreach to affect the culture." (Company 5)
"Research centers and universities are potential and essential partners in the development of specific indicators." (Company 6)
"We try to advocate on behalf of the fishermen...in this way we lead to 46 fishing vessels being certified by Friend of the Sea." (Company 7)
"Smart people respond very well to our biodiversity policy: suppliers and consortia ask us to visit vineyards to take inspiration from us." (Company 8)
"It is rare and always very difficult to achieve such operational and functional goals on one's own." (Company 9)
"Small producers support us because they appreciate the value this creates for the environment" (Company 10)

Finally, in addition to stakeholders, from the content analysis of interviews emerged the relevance of technologies in pursuing biodiversity goals. Specifically, companies stressed the role of digital technologies that are essential to monitoring, preserving, and promoting biodiversity.

"To provide our services, we need technology and data to precisely meet need of beekeepers as well as of individuals that adopt a beehive…Technology is for us necessary to assure biodiversity." (Company 1)
"'The advent of artificial intelligence allowed for easier prediction and knowing what ingredients must be produced and used in specific diet programs." (Company 2)
"In promoting our Nature Based Solutions, we consider technologies necessary to reach efficient sustainable results. Moreover, technologies allow us to monitor biodiversity and act immediately." (Company 3)
"We are a circular economy model that relies on digital technologies to work." (Company 4)
"Culture is important. Understanding the relevance of biodiversity affects the social approach to the topic." (Company 5)
"Biodiversity needs to harness innovation and technological tools to be protected." (Company 6)
"Preserving biodiversity is essential, and to achieve this, we need technological tools." (Company 7)
"Technology is essential to us – things like weather stations and software that predicts the spread of pathogens, or the recovery sprayer that halves the number of treatments required." (Company 8)
"We use sensors inside the hive to monitor the bees' health... an artificial intelligence system." (Company 9)
"The main challenge was to try to gather data and identify which variables are more or less significant. You can only do this by using technology." (Company 10)

The results of desk and content analyses of the firms involved in the qualitative study allowed us to depict a possible conceptual framework (Figure 1) that summarizes how the different variables relate among them, highlighting the double face of biodiversity promotion or loss prevention, as output of innovative services and a driver for innovation. Stakeholders can be a driver for the management of biodiversity issues; instead, digital technologies are surely a support that allows for managing biodiversity effectively and linking it to firm innovativeness in terms of products, services, processes, and business models.

Fig. 1: Conceptual framework proposed

Source: authors' own elaboration

Research limitations. *It should be noted that this study is exploratory in nature, and the findings need careful interpretation. First of all, further investigation is strongly recommended, especially using a different method for estimating the innovativeness of firms, focusing on other innovativeness measures linked to all the different kinds of innovation. Secondly, an increase in dataset depth and breadth would highly benefit the robustness of the study's results, as our sample was geographically constrained, which reduces the generalizability of our results. Third, the biodiversity-*

related items that were created for the questionnaire would benefit from further refinement. Lastly, taking into consideration the qualitative investigation, a more comprehensive stream of research that considers a quantitative approach and other variables in addition to those reported in Figure 1, such as culture, is needed to better understand cause-effect relationships among the different variables and deeper asses the relationship between biodiversity and innovation.

Managerial implications. *Although exploratory in nature, our research offers significant managerial implications. We argue that both sustainability and innovation managers should adopt a new perspective on biodiversity: integrating it into the innovation strategy appears to be positively related to a firm's overall innovativeness. Conversely, treating biodiversity as a mere contextual factor limits its innovation potential. Therefore, a different managerial approach is required: one that involves a shift in the mainstream mindset to recognize the relationship with biodiversity as a potential source of advantage. Moreover, in dealing with biodiversity goals, firms must consider the involvement of stakeholders to foster the process of transition towards sustainable businesses that favor biodiversity and, as a consequence, business innovation (products, processes, and business model innovation). The involvement of stakeholders leads to an integrated strategy that accelerates the process of transition towards sustainable businesses that favor biodiversity (Leclère et al., 2020). Moreover, firms must use digital technologies (various kinds of technologies for various kinds of activities and purposes) to reach positive results in terms of biodiversity protection and promotion. Digital technologies allow for the development of an efficient ecosystem of services (preventing, monitoring, but also promoting) needed for biodiversity (Pimm et al., 2015). By reaching biodiversity goals, companies had to innovate their own business model, as well as products and services, to meet both business and individual needs.*

Originality of the paper. *Conceptually, the main originality of our contribution consists of reframing biodiversity as a potential source of advantage, showing that actively including it in the innovation process is related to higher levels of innovation revenue. Moreover, the study offers a deeper understanding of the relationship between biodiversity and innovation through the qualitative study by introducing a new conceptual framework that highlights the possible double role of biodiversity as output of innovative services mostly developed through the involvement of different stakeholders, and as a driver for business innovation. In this model, digital technologies play a key supporting role. In this sense, policymakers should support companies in adopting the digital technologies needed to handle biodiversity as well as foster activities to promote the biodiversity-based culture.*

Food as Well-Being in the Digital Age: Motivational Drivers of Fruit Consumption among GenZ

ANTONELLA BOZZI[1], MARIO D'ARCO[2], VITTORIA MARINO[3]

Abstract. *Fresh fruit consumption is increasingly recognized not only as a driver of physical health but also as a contributor to psychological well-being, supporting the "food as well-being" perspective. Despite public health initiatives, Generation Z (GenZ, born 1997–2012) exhibits lower fruit intake compared to older cohorts, raising concerns about long-term dietary patterns and well-being trajectories. This ongoing study investigates the motivational mechanisms underlying fruit consumption among GenZ and examines the interplay between motivations and digitally mediated social influences. Drawing on Self-Determination Theory, this ongoing research differentiates autonomous motivations (intrinsic, integrated, identified) from controlled motivations (introjected, external) and amotivation, exploring their effects on actual fruit consumption and well-being. Data were collected via an online survey (N = 164) and analyzed using Structural Equation Modeling. Results indicate that intrinsic motivation and integrated regulation significantly predict fruit consumption, while controlled motivations do not. Moreover, social media influence on the diet moderates the relationship between integrated regulation and actual fruit consumption, weakening the expression of identity-based motivations. Fruit consumption, in turn, positively predicts well-being, highlighting the psychological benefits of healthy eating for younger consumers. These findings suggest that interventions should foster personally meaningful, identity-consistent fruit consumption rather than rely on externally driven pressures or trend-based messaging. This research advances understanding of the drivers of fruit consumption among GenZ and offers insights for designing targeted communication strategies that promote both healthier eating and well-being in digitally mediated environments.*

Keywords: *Food as well-being; Generation Z; Fruit consumption; Self-Determination Theory; Motivation; Social media influence*

Framing of the research. *Fresh fruit consumption plays a crucial role in promoting both physical and psychological well-being. A body of research suggests that eating fruits and vegetables is associated not only with improved physical health but also with higher levels of life satisfaction, positive mood, and overall well-being (Blanchflower et al., 2013; Conner et al., 2017; Mujcic & Oswald, 2016; Rooney et al., 2013; Wahl et al., 2017). These findings support the "food as well-being" perspective, according to which healthy dietary behaviors may represent a long-term investment in individuals' present and future well-being. This perspective is particularly relevant for younger consumers, whose dietary habits are likely to shape long-term health trajectories. However, despite increasing public health efforts to promote healthy eating, fresh fruit consumption is experiencing stagnation or decline across several national contexts (Stewart et al., 2024). At the same time, generational analyses indicate that Generation Z (GenZ, born 1997–2012) reports lower fruit intake compared to older cohorts (Alqahtani et al., 2025), raising concerns about long-term dietary patterns among younger consumers. Encouraging healthier dietary choices among younger consumers represents an important societal objective, reflected in the United Nations Sustainable Development Goal (SDG) 3 (Good Health and Well-Being), as well as in SDG 12, which promotes more sustainable food consumption patterns (United Nations, 2015). These trends highlight the strategic importance for firms operating in the fresh produce sector, as well as public health organizations, to identify the motivational mechanisms shaping fruit consumption among GenZ, thereby enabling the development of targeted interventions and communication strategies aimed at enhancing dietary behaviors and promoting overall well-being.*

Prior research on healthy eating has largely focused on interventions aimed at encouraging healthier food choices. Over the years, governments, public health organizations, and other stakeholders have promoted a wide range of initiatives designed to foster healthier dietary behaviors among younger consumers. These interventions are typically classified into "hard" and "soft" approaches. Hard approaches mainly rely on regulatory and economic measures implemented by governments, such as taxes, subsidies, and restrictions aimed at modifying food environments and consumption patterns. In contrast, soft approaches generally involve educational campaigns, information-based policies, and voluntary agreements with the food industry intended to guide consumers toward healthier food choices (Swinburn et al., 2015). However, purely informational approaches have been found to be effective in raising awareness but less successful in translating such awareness into actual behavioral change. Indeed, despite the known benefits, GenZ still reports significantly lower fruit intake compared to older cohorts, necessitating targeted interventions to reshape their dietary trajectories (Pocol et al., 2021). Consequently, research has increasingly focused on interventions capable of shaping food choices by modifying the decision environment, such as nudging strategies (Vecchio & Cavallo, 2019).

[1] University of Sannio, a.bozzi2@studenti.unisannio.it
[2] University of Sannio, madarco@unisannio.it
[3] University of Sannio, vmarino@unisannio.it

However, nudging interventions may be short-lived, suggesting that external interventions alone may not be sufficient to produce lasting dietary changes.

While previous research has explored structural and informational interventions promoting healthy eating, less attention has been devoted to the motivational mechanisms underlying fruit consumption among younger consumers, particularly within digitally mediated food environments. Scholars have therefore highlighted the importance of understanding the underlying motivations that drive individuals to adopt healthy eating behaviors (e.g., Zwierczyk, 2022). While studies have identified taste, price, and health as primary drivers for GenZ (Halicka et al., 2025), the motivational mechanisms specifically underlying fruit consumption remain insufficiently understood. A critical point of debate in current literature concerns the influence of social media on food consumption, a landscape that remains evolving and is gaining significant momentum (Chhabra et al., 2026). Research suggests that social media trends and influencers play a relatively limited role in shaping core food choices (Halicka et al., 2025), whereas other perspectives suggest that the role of social media is complex and ambivalent (Rounsefell et al., 2020).

Despite these advances, important gaps remain in the literature. The motivations driving fruit consumption among GenZ, and the ways in which social media may interact with these motivations, remain underexplored. Beyond understanding these drivers, it is also essential to examine the potential outcomes of these behaviors. Although evidence suggests a positive link between fruit consumption and well-being (Blanchflower et al., 2013; Conner et al., 2017; Mujcic & Oswald, 2016; Wahl et al., 2017), limited research has explored whether GenZ consumers—whose dietary habits and digital environments differ significantly from previous generations—actually see fresh fruit consumption as an antecedent of their well-being. Investigating the relationship between fresh fruit consumption, underlying motivations, and well-being among GenZ represents a crucial step toward understanding how healthier eating can contribute to both individual flourishing and broader societal goals.

Purpose of the paper. *This ongoing research aims to investigate the motivational factors that influence fruit consumption among Generation Z. By examining how different forms of motivation shape dietary choices, this research aims to contribute to the literature on healthy food consumption and provide insights for both marketers and public health practitioners seeking to encourage healthier and more sustainable eating behaviors among younger consumers.*

To investigate the motivational drivers of fruit consumption among younger consumers, this research adopts Self-Determination Theory (SDT) as its primary theoretical framework. Developed by Deci and Ryan (2000), SDT posits that human behavior is driven by a continuum of motivations, ranging from autonomous to controlled. While autonomous motivations primarily shape long-term commitment to a behavior, controlled motivations may initiate an action but often fail to sustain it over time. Intrinsic motivation represents the most autonomous form of regulation. According to Carbonneau et al. (2021), individuals with high intrinsic motivation are more likely to maintain healthy eating patterns over time because the behavior is inherently self-rewarding. In the context of fresh fruit consumption, we assume individuals consume fruit for the inherent satisfaction, enjoyment, and sensory pleasure derived from the activity itself. Consequently, this study hypothesizes that:

H1. *Intrinsic motivation significantly influences actual fruit consumption.*

However, individuals also engage in specific behaviors for reasons beyond inherent enjoyment; these are classified as extrinsic motivations. According to Deci and Ryan (2000), extrinsic motivations range from more autonomous to more controlled ones. Specifically, integrated and identified regulations are considered autonomous, while introjected and external regulations are categorized as controlled. In this context, integrated regulation occurs when fruit consumption is fully assimilated into one's identity, whereas identified regulation involves a conscious valuing of the associated health benefits. Conversely, introjected regulation involves internal pressures, such as guilt or shame, and external regulation stems from perceived pressure from family or peers. Literature suggests that most health-related behaviors are driven by extrinsic factors (Teixeira et al., 2011; McSpadden et al., 2016). Therefore, this study hypothesizes that:

H2. *Extrinsic motivations significantly influence actual fruit consumption.*

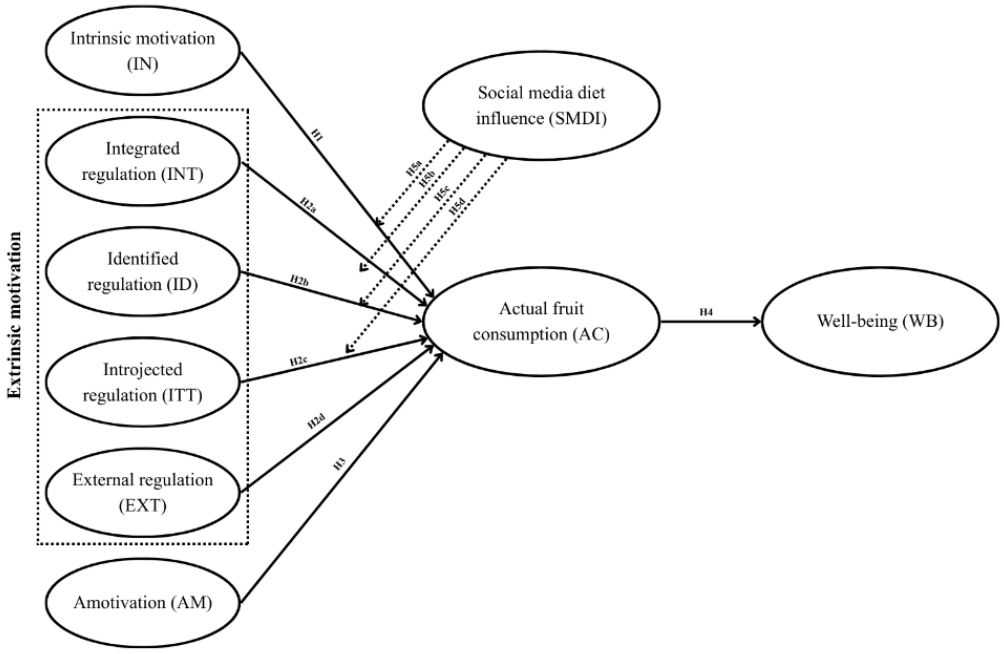
At the opposite end of the spectrum lies amotivation. Amotivated individuals typically lack interest in consuming fresh fruit and may perceive that increasing their intake would have no positive impact on their health. In this state, individuals fail to recognize the benefits of fruit consumption or feel incapable of modifying their current habits (Deci & Ryan, 2000). This leads to the following hypothesis:

H3. *Amotivation significantly influences AC.*

It has been well-documented that fuit intake increases health (Vecchia et al., 2004), contributing to both physical well-being and psychological well-being (Conner et al., 2017). The present research intends to better understand whteher the target audience sees fruit consumption as an antecedent of their overall well-being. Informational approaches have been largely employed to raise awareness about the positive consequences of engaging with healthy eating (Swinburn et al., 2015), but GenZ still reports significantly lower fruit intake compared to older cohorts (Pocol et al., 2021). The study assumes that GenZ actually consumes fresh fruit because they feel they can reach a higher state of well-being. Therefore, it is hypothesized that:

H4. *Actual fresh fruit consumption positively influences well-being.*

A critical variable in health-related behaviors is perceived social support, as it can significantly shape the relationship between an individual's motivations and their actions (McSpadden et al., 2016). Social support manifests in multiple forms and can influence behavior and well-being through various pathways (Feeney & Collins, 2015). Younger generations increasingly utilize social media platforms as a source of social support (Kim, 2014). Social media cues may



interact with motivations that involve some degree of internalization (i.e., intrinsic, integrated, identified, and introjected regulations), potentially reinforcing or interfering with the translation of these motivations into behavior. Given that the modern dietary landscape is increasingly influenced by digital environments—where notifications, food trends, and visual cues are pervasive (Patwardhan et al., 2024; Chhabra et al., 2026) —this study investigates the interaction between social media influence on diet and individual motivations with at least a partial degree of internalization (ranging from intrinsic to introjected regulations), leading to the following hypothesis:

H5. *Social media influence on diet moderates the relationship between intrinsic, integrated, identified and introjected regulations and actual fruit consumption.*

Finally,

Figure 1 illustrates the conceptual model under investigation.

Figure 1. Conceptual model

Source: authors' elaboration

Methodology.

Data collection and data analysis. *Data were collected via an online questionnaire administered through Google Form within the Italian context. Respondents indicated their level of agreement using a 7-point Likert scale, ranging from 1 ("strongly disagree") to 7 ("strongly agree"). Data analysis was conducted using IBM SPSS Statistics 25 and IBM SPSS AMOS 23. To evaluate the fit between the observed data and the hypothesized theoretical model, a Confirmatory Factor Analysis (CFA) was performed (Mueller & Hancock, 2015). Following the assessment of validity and reliability, Structural Equation Modeling (SEM) was employed to test the primary hypotheses. Finally, to examine the potential moderating effect of Social Media Diet Influence (SMDI), an interaction term method was utilized (Hair Jr. et al., 2021).*

Measurements. *All constructs were measured using validated scales. Actual Fresh Fruit consumption (AFC) was assessed with a self-reported frequency scale (0 = never/fewer than once per month to 7 = two or more times per day; Brug et al., 2006). Well-being was measured with items on satisfaction and quality of life (Mohanty & Kumar, 2025). Intrinsic and extrinsic motivation and amotivation were adapted from Appleton & Adams (2023) and Schulze & Janssen (2024). Social Media Diet Influence (SMDI) was adapted from Patwardhan et al. (2024).*

Results.

Sample profile. *Preliminary results are based on 164 valid responses. All participants were born between 1997 and 2012 (Gen Z), with the highest concentration born in 2003 (aged 23). The sample is predominantly female (58.5%) and mostly of them are students (67.7%). Regarding nutritional information, respondents identified physicians or nutritionists as their preferred source (31.1%), closely followed by TikTok (20.7%). The majority reported a preference for common fruits, such as bananas or apples (68.3%), typically consumed during breaks (45.7%) or during lunch (31.1%). Additionally, a significant portion of the sample reported regularly practicing sports (69.5%).*

Descriptive statistics, CFA, Reliability and Validity analysis. *Following Hair et al. (2010) and utilizing IBM SPSS Statistics 25, a descriptive analysis—including mean, standard deviation, skewness, and kurtosis for each item—was conducted. Skewness and kurtosis values for all items fell within the acceptable ranges of ±3 and ±10. respectively. Specifically, skewness values ranged from -1.651 to 2.958, while kurtosis values ranged from -1.175 to 9.383. The*

Confirmatory Factor Analysis (CFA) demonstrated a good model fit, with $\chi2(247) = 444.3$, $p < 0.001$, TLI = 0.927, CFI = 0.94, and RMSEA = 0.07. Factor loadings were predominantly above 0.7, with only one item yielding a loading of 0.6. Cronbach's alpha, composite reliability (CR), and average variance extracted (AVE) all exceeded the recommended thresholds of 0.7, 0.6, and 0.5, respectively. To assess discriminant validity, the Heterotrait-Monotrait (HTMT) ratio was employed due to its high sensitivity (Henseler et al., 2015). All calculated HTMT values remained consistently below the 0.85 threshold, thereby confirming the discriminant validity of the measurement scales used in this study.

Hypothesis testing. *SEM was performed using IBM SPSS AMOS 23. Intrinsic motivation (IN) and integrated regulation (INT) positively predicted actual fresh fruit consumption (AC), with standardized estimates of $\beta = 0.249$, $p = .041$ and $\beta = 0.619$, $p = .001$, respectively. Other motivational constructs—identified regulation (ID), introjected regulation (ITT), external regulation (EXT), amotivation (AM) —did not significantly predict AC (all $p > .05$). In turn, AC positively predicted well-being (WB; $\beta = 0.564$, $p < .001$). The interaction between SMDI and integrated regulation (interSMDIxINT) negatively predicted AC ($\beta = -0.211$, $p = .028$), all other interaction terms (SMDI × IN, SMDI × ID, SMDI × ITT) were not significant (all $p > .05$). Table 1 synthetises hypoteses testing.*

Discussion. *The findings of this study provide several insights into the motivational mechanisms underlying fresh fruit consumption among Generation Z. Consistent with the "food as well-being" perspective (Blanchflower et al., 2013; Conner et al., 2017; Mujcic & Oswald, 2016), the results confirm that actual fruit consumption positively predicts overall well-being, suggesting that younger consumers may indeed experience psychological benefits from engaging in healthier dietary behaviors. This result supports the argument that fruit consumption can contribute not only to physical health but also to broader dimensions of individual flourishing in younger cohorts as well. The results partially support the assumptions of Self-Determination Theory (Deci & Ryan, 2000). Intrinsic motivation and integrated regulation—both forms of autonomous motivation—were found to positively influence fruit consumption. This aligns with prior research indicating that self-determined motivations are more likely to sustain health-related behaviors over time because such behaviors are internally valued and self-endorsed (Carbonneau et al., 2021). In contrast, controlled forms of motivation, such as introjected and external regulation, did not significantly predict fruit consumption, suggesting that externally driven pressures may be insufficient to promote stable dietary behaviors among GenZ.*

Contrary to previous literature highlighting a moderatingrole of perceived social support on the association between controlled motivation and fruit and vegetable intake (McSapadden et al., 2016), results show a moderation effect of social media influence on diet on the association between integrated regulation (an autonomous form of motivation), and actual fruit consumption. Specifically, the interaction between SMDI and integrated regulation negatively predicted fruit consumption. This finding suggests that higher levels of social media influence weaken the positive association between integrated regulation and actual behavior. Integrated regulation reflects a deeply internalized form of motivation in which the behavior is aligned with personal values and becomes part of one's identity (Deci & Ryan, 2000). When dietary behaviors are strongly identity-based, individuals may rely primarily on internalized standards rather than external informational cues. In this context, individuals whose fruit consumption is strongly identity-based may be less responsive to social media stimuli, or such cues may even disrupt the consistency of their internally regulated eating habits. In particular, the "new food trends" promoted on social media may be perceived as superficial, temporary, or fashion-driven by individuals who instead experience fruit consumption as a deeply rooted and identity-relevant behavior. This discrepancy may generate a form of cognitive dissonance between a stable, value-based dietary identity and externally promoted, trend-based eating cues. When behaviors are strongly linked to personal identity, individuals may resist or disengage from external cues perceived as inconsistent with their self-concept (Oyserman, 2009; Deci & Ryan, 2000). As a consequence, rather than reinforcing fruit consumption, exposure to these social media trends may weaken the behavioral expression of internally regulated dietary habits, ultimately reducing the frequency of actual fruit consumption.

Source: authors' elaboration

Research limitations. *Despite providing valuable insights into the motivational mechanisms underlying fruit consumption among Generation Z, this study presents several limitations that should be acknowledged.*

First, the research presents an ongoing study, and the preliminary results rely on a relatively small sample size (N = 164) collected within the Italian context, which may limit the generalizability of the findings. Second, fruit consumption was measured using self-reported frequency data, which may be subject to recall bias or social desirability bias. Future research could employ more objective measures of dietary behavior, such as food diaries or digital tracking methods, to obtain more precise estimates of actual consumption patterns. Third, the study focuses specifically on the role of social media influence on diet as a contextual moderator. However, younger consumers operate within complex food environments that include multiple sources of social influence, such as family, peers, and institutional actors. Future research could explore how different forms of social influence interact with motivational processes in shaping healthy eating behaviors. Finally, although the present research examines fruit consumption as an antecedent of well-being, future studies could further investigate the broader psychological and lifestyle outcomes associated with healthy dietary behaviors among younger consumers, including mental health, life satisfaction, and subjective vitality.

Managerial implications. *The findings of this study offer several implications for practitioners operating in the fresh produce sector, as well as for public health organizations aiming to promote healthier dietary behaviors among younger consumers.*

First, the results suggest that strategies aimed at increasing fruit consumption among Generation Z should prioritize the activation of autonomous forms of motivation. In line with the principles of Self-Determination Theory, intrinsic motivation and integrated regulation were found to significantly predict fruit consumption, indicating that younger consumers are more likely to adopt healthier dietary behaviors when these behaviors are personally meaningful and aligned with their identity. For marketers and public health practitioners, this implies that communication strategies should move beyond purely informational messages emphasizing nutritional benefits and instead focus on fostering a positive and personally relevant relationship with fruit consumption. Campaigns could emphasize enjoyment, taste experiences, lifestyle integration, and the role of fruit consumption as part of a balanced and self-expressive way of living.

Second, the results indicate that externally driven pressures, such as social expectations or guilt-based messaging, may be less effective in promoting stable dietary habits among Gen Z. Traditional public health campaigns often rely on normative or prescriptive messages aimed at encouraging healthier food choices. However, the lack of significant effects for controlled forms of motivation suggests that such approaches may not generate lasting behavioral change among younger consumers. Instead, communication strategies may benefit from framing fruit consumption as a voluntary and self-endorsed choice rather than a socially imposed obligation.

Third, the moderating role of social media influence highlights the complexity of digital food environments. While social media platforms are often considered powerful tools for promoting healthy eating, the results suggest that their influence may not always reinforce healthy behaviors. In particular, exposure to food-related trends and visually appealing dietary content may weaken the behavioral impact of identity-based motivations for fruit consumption. For firms and public health organizations, this finding suggests that social media communication strategies should be carefully designed to avoid presenting healthy eating as a transient trend. Instead, digital campaigns may benefit from emphasizing authenticity, consistency, and long-term lifestyle integration rather than short-lived food trends.

Finally, the positive relationship between fruit consumption and overall well-being suggests that communication strategies may benefit from highlighting not only the physical health benefits of fruit intake but also its potential contribution to psychological well-being and quality of life. Framing fruit consumption as part of a broader well-being lifestyle may resonate particularly strongly with younger consumers, who often prioritize holistic well-being and personal development.

Originality of the paper. *Overall, this study contributes to the literature on healthy food consumption by showing that autonomous motivations play a central role in shaping fruit consumption among younger consumers, while digitally mediated social influences may not always reinforce healthy eating behaviors and may even weaken the behavioral expression of identity-based dietary motivations.*

Specifically, this ongoing research extends literature on fruit consumption by applying Self-Determination Theory to better understand the motivational mechanisms underlying dietary behaviors among Generation Z. While previous studies have primarily focused on structural interventions or informational campaigns aimed at promoting healthy eating, this research highlights the central role of autonomous motivations in shaping fruit consumption among younger consumers. The study contributes to the emerging literature on digital food environments by examining the moderating role of social media influence on the relationship between motivation and dietary behavior. The findings reveal that social media influence may not always reinforce healthy eating behaviors. Instead, exposure to social media food trends may weaken the behavioral expression of identity-based motivations, suggesting that digitally mediated environments can interact with motivational processes in complex and sometimes counterintuitive ways. Finally, this research integrates the study of dietary motivations with the broader "food as well-being" perspective by demonstrating that fruit consumption is positively associated with well-being among Generation Z consumers. By linking motivational drivers, dietary behavior, and well-being outcomes within a single conceptual framework, the study provides a more comprehensive understanding of how healthy eating behaviors contribute to individual flourishing.

Green Tech Startups: A bridge between science and sustainability

TINDARA ABBATE[*] RAFFAELLA COPPOLINO[•] ELVIRA TIZIANA LA ROCCA[♠]

Abstract. *Climate change has emphasized the need for innovative approaches that can link scientific knowledge and effective environmental action. Green tech startups are emerging as key actors and assume a relevant role in bridging this challenging gap by integrating environmental protection objectives with the development of advanced digital technological solutions. They leverage emerging technologies, such as artificial intelligence, to design and implement tools and platforms that enhance environmental monitoring, data-driven decision-making, and more sustainability practices.*

This research aims to explore how green tech startups seek to bridge scientific knowledge and the environment, and it focuses on two research questions: How do green tech startups link science and environmental goals? What could be the possible development trajectory of technology-based green innovation?

The study examines the case of Pachama to analyze its technology-based business model, development trajectory of green innovation, and the key challenges encountered during its growth. Particular attention is devoted to assessing the principal implications associated with the acquisition of the company by Carbon Direct. The results highlight that through the integration of technological innovation and environmental objectives green tech startups contribute to the development of scalable solutions to complex climate-related problems. Theoretical and managerial considerations are developed, including insights for future research directions.

Keywords: *green tech startups; innovation management; Artificial Intelligence; sustainability.*

Framing of the research. *The inevitable linkage between sustainability and Artificial Intelligence (AI) has increasingly been conceptualized in the management and innovation literature as a structural rather than merely occasional convergence (Nambisan et al., 2017). The pressing sustainability challenges, such as climate change, resource depletion, and biodiversity loss, are characterized by complexity, interdependence, uncertainty, and temporal asymmetry (Markard et al., 2012). Traditional reporting mechanisms and static performance indicators struggle to address these properties in a comprehensive manner. From this perspective, AI introduces a qualitatively different capability: it processes large-scale, heterogeneous datasets in real time, generates predictive insights, and supports adaptive decision-making under conditions of uncertainty and complexity (Raisch and Krakowski, 2021). In this sense, AI does not merely optimize existing sustainability practices; it enables the reconfiguration and translation of ecological phenomena into continuously monitored, algorithmically interpretable data streams. By doing so, it embeds digital intelligence within organizational sensing, learning, and decision-making architectures, thereby enhancing firms' capabilities to anticipate, adapt to, and shape evolving environmental conditions (Yoo et al., 2010; Teece et al., 1997).*

Through machine learning, IoT sensors, remote sensing technologies, cloud infrastructures, ecological activities and processes - carbon sequestration, deforestation patterns, energy consumption, and water usage - can be systematically translated into measurable indicators embedded within digital tools and platforms. In this way, AI reduces information asymmetries, enhances transparency, and lowers transaction costs in environmental markets (Haefner et al., 2023). Additionally, AI enables forms of predictive governance by identifying risk directions, simulating future environmental scenarios and defining sustainable business models, thereby shifting sustainability management from reactive compliance toward proactive resilience building.

In this evolving landscape, green tech startups play increasingly a pivotal role as entrepreneurial actors that operate and scale the convergence between AI and sustainability (Tian et al., 2023; Jorzik et al., 2024) by translating scientific knowledge and emerging technologies into scalable solutions capable of generating both environmental and economic value (Hockerts and Wüstenhagen, 2010). Considered at the intersection of technological experimentation and sustainable entrepreneurship, these organizations leverage AI capabilities to design tools and platforms that integrate environmental measurement, advanced analytics, and market interfaces (Gupta et al., 2023). Drawing on sustainable entrepreneurship literature (Schaltegger and Wagner, 2011), green tech startups embody hybrid value creation logics, simultaneously pursuing economic returns and measurable ecological and social impact (Jorzik et al., 2024). Their competitive advantage often derives from proprietary datasets, algorithmic learning models, and ecosystem orchestration capabilities that enable multi-sided interactions among corporations, investors, policymakers, and local communities. By embedding ecological intelligence into digital infrastructures, green tech startups contribute to the reconfiguration of environmental governance, from project-based interventions to continuously monitored, market-compatible systems. In doing so, they act not merely as technology providers but as architects of new socio-technical arrangements that harmonize sustainability objectives with digital innovation dynamics.

Purpose of the paper. *The growing overlap between digital technologies and sustainability transitions has stimulated increasing research interest in understanding the potential contribution of technology innovation to environmental governance and sustainable development. Although prior research has examined the contribution of digital innovation to organizations (Nambisan et al., 2017) and sustainability transitions (Markard et al., 2012), there has been relatively less research on the mechanisms that can be used by green tech startups to integrate scientific knowledge with environmental markets via data-driven infrastructures. In this regard, the growing application of artificial intelligence, and digital platforms to environmental processes has redefined the measurement, monitoring, and integration of ecological processes with economic systems. In this context, the technology innovation that can be used to quantify environmental processes such as carbon storage, biodiversity, and ecosystem regeneration. Against this background, there has been growing research interest in understanding the contribution of green tech startups to the integration of scientific knowledge with environmental markets. In this context, the application of digital technologies has enabled the design of platforms that can be used to integrate environmental measurement with environmental markets.*

Building on the framework of the 2030 Agenda for Sustainable Development, particularly SDG 12.2, and its interconnections with SDGs 7, 9, and 15, this research investigates the role of green tech startups in bridging scientific knowledge and environmental action. These firms increasingly operate at the intersection of scientific research, digital advanced technologies, and sustainability-oriented innovation, by defining and developing technology-based solutions aimed at improving resource efficiency, environmental monitoring, and the inevitable management of climate-related challenges (Fichter et al., 2025).

Within this context, the study aims to examine how green tech startups integrate scientific knowledge, advanced technologies, and environmental sustainability objectives into technological business models. It also explores how these firms transform research-based knowledge into innovation processes capable of generating environmental and economic value. Accordingly, the research addresses two main questions: 1) How do green tech startups link scientific knowledge with environmental goals? 2) What development trajectories may characterize technology-based green innovation?

These questions aim to shed light on the strategic, technological, and organizational dynamics that shape the evolution of green startups in the sustainability transition.

To answer these research questions, this research paper employs a qualitative single-case research design (Yin, 2009), focusing on the green tech startup company Pachama. The analysis explores the ways in which this startup company utilizes artificial intelligence and satellite monitoring technologies in measuring and verifying forest carbon storage in the voluntary carbon market. Additionally, this research paper explores the business model evolution of the startup company, as well as its technological capacity, after being acquired by Carbon Direct.

Methodology. *Green tech startups can be considered organizations that bridge functionally and efficiently the green and the blue theorized by Floridi (2020). Where green encompasses all environmental instances (urban, economic, political) and blue includes all digital technologies, ranging from big data to artificial intelligence.*

To encompass the widest possible range of issues that the construction of this bridge entails, we conducted an exploratory analysis using the snowball sampling technique (Biernacki and Waldorf, 1981) on primary and secondary data.

In the first phase, we attempted to identify the most active start-ups in the green-tech sector. Using the least restrictive search string possible, i.e., only the two key terms "green tech" and "companies", we identified and used as a reference the first ranking of green tech companies conducted by TIME and Statista, based on three pillars: positive environmental impact, drive for innovation, and financial strength (Time Staff, 2025), the list of the 25 Best Forestry Startups to Watch in 2026 and the 69 Best Climate Tech Green Tech Startups to Watch in 2026 (SeedTable, 2025).

Beyond the strong focus on decarbonization emerging from the analysis of the top companies on these lists we noted that one of the top startups, Pachama, in November 2025 was acquired by Carbon Direct.

Founded in 2018, Pachama supports environmentally responsible companies in offsetting their CO2 emissions with the purchase of carbon credits, by involving them with reliable reforestation and forest conservation projects, with the possibility of monitoring them through due diligence tools based on remote sensing and artificial intelligence. It guarantees a real-time measurement of the growth of forests and of the carbon stored inside them, becoming a promising startup as decarbonization moves from a "niche" to a globally recognized solution, essential to getting closer to zero impact. With the acquisition by Carbon Direct, Pachama does not lose its identity even better if both companies integrate their services. The carbon Direct engineering solutions, in fact, are improved and integrated by the Pachama platform and a satellite-based tool for monitoring, reporting, and evaluating their effectiveness.

So, we selected Pachama as a single case study (Yin, 2009) because it represents a prominent example of a green-tech venture that integrates scientific knowledge, digital advanced technologies, and environmental objectives to develop scalable climate solutions. Its rapid growth and subsequent acquisition by Carbon Direct provide a relevant setting for exploring and examining how green tech start-ups translate scientific knowledge and advanced digital technologies into scalable environmental solutions and viable business models.

In line with the aim and the initial phases of the research, to retrieve data about Pachama we adopted a broad, ethnographic approach to understand Pachama, aiming to better understand the dynamics of this startup.

In the exploratory phase, we collected data from multiple sources to analyze the phenomenon from various perspectives and identify the key players. Specifically, we conducted direct observation of the website and platform and

public interviews (to 2021 to 2025) with CEO Diego Saez Gil (now in the leadership team of Carbon Direct), analyzed key articles and web information about Pachama and its acquisition by Carbon Direct.

So, by collecting data from different websites, analyzing available online documents and interviews, we traced Pachama's development trajectory from its founding to its acquisition by Carbon Direct.

Results. *Operating in the voluntary carbon market (VCM), Pachama business concept is founded on the use of AI and satellite imagery to identify the extent of storage carbon in the forest ecosystems. Initially, in 2018, Pachama was involved in the development of its AI-based platform for carbon storage in forests. In the second stage of development, in 2019-2021, Pachama grew its business by establishing a digital marketplace for connecting forest conservation projects with corporate buyers of carbon credits. Then, in 2022-2024, Pachama made its business model more robust by participating in the development of reforestation projects. By the end of 2023, Pachama had raised approximately $88 million from major funds, such as Breakthrough Energy Ventures and the Amazon Climate Pledge Fund, as well as from well-known business angels, to finance several projects. However, in 2025, environmental uncertainty, including the lack of guarantees regarding additional federal funding for direct carbon capture (DAC), led to the abandonment of some of these projects, resulting in staff reductions. Pachama has returned to being the geospatial AI-based technology platform to help make informed investment decisions in nature-based climate solutions and sustainable land management (Giles, 2025). At the end of 2025, Pachama was acquired by Carbon Direct, a company specialized in carbon emission management, and its technology was integrated into a carbon management system of advisory, project development, and AI-based monitoring.*

In the initial phase, Pachama follows a platform-based intermediary model. It develops a platform integrating two types of players. On one side, Pachama deals with forest project developers of several reforestation and conservation projects all over the world. On the other side, Pachama deals with corporate buyers who want to access carbon credits from these projects. In this model, Pachama earns money from transaction fees for the sale of carbon credits that are traded on the platform. It acts as a middleman who removes information asymmetry for project developers and buyers. Pachama can be viewed as a technology market facilitator that helps in providing verification for voluntary carbon markets.

As the company grew, Pachama's activities evolves beyond the role of intermediary on the marketplace. Some challenges facing the voluntary carbon market are the lack of quality projects, the permanence and the measurement of the project. To overcome these challenges, Pachama becomes more involved in project development, the process of designing, implementing, and monitoring new projects in the forest. The company diversifies into project origination and initiatives directly involved in the reforestation projects. In this way, the startup improves the quality and credibility of the carbon credits developed through its system and it could create more value from the lifecycle of the carbon credits, rather than just the transaction fees. It unlocks additional value along the carbon credit value chain, decreases reliance on third-party project developers. Its business model evolves from a platform intermediary to a hybrid model incorporating both marketplace and asset activities, by developing specific capabilities (see Table 1) that permit the company to obtain positive results.

Table 1. Key capabilities of Pachama

Capability	***Description***	***Technology Role***	***Contribution to Environmental Markets***
Scientific capability	*Ability to measure and analyse ecological processes (forests' growth)*	*Satellite images, AI algorithms, use remote sensing techniques to analyse environmental data*	*Enables the measurement and verification of carbon storage*
Monitoring capability	*Monitoring of the conditions of the forests and environmental risks*	*AI-based monitoring systems to detect deforestation, rate of carbon absorption*	*Enhances the transparency and reliability of carbon credits in the market*
Platform capability	*Linking forest project developers with corporate buyers*	*Online marketplace for integrating environmental data and carbon credit trade*	*Supports coordination between environmental market supply and demand*
Project development capability	*implementation of reforestation or conservation projects*	*Integration of monitoring technology throughout the project*	*Ensures higher quality and integrity of carbon credit projects*
Strategic integration capability	*Integration with advisory and carbon management services with Carbon Direct*	*AI-based Measurement, Reporting, and Verification systems*	*Develops a full stack for carbon management*

Source: Author's own elaboration based on company reports and secondary data (Jha, 2022; Giles, J. (2025; https://www.ycombinator.com/companies/pachama; Carbon Direct, 2025).

In the last phase, up until its acquisition, Pachama addresses environmental uncertainty by reverting to a remote sensing platform that combines satellite imagery, drone and lidar technologies, and machine learning to expand forest protection and restoration while also enabling companies to offset their carbon emissions.

The Pachama case underscores a set of key capabilities that enable green tech startups to connect scientific knowledge with environmental sustainability. As indicated in Table 1, Pachama leverages its capabilities in scientific measurement, digital monitoring, platform coordination, and project development to deliver carbon market solutions that enable the firm to turn ecological data into credible environmental assets, facilitating transactional linkages between project developers and corporate buyers' key capabilities. In this way Pachama harmonizes science and environment.

Pachama's ability to use environmental intelligence in their technology platforms is contributing to the development of new forms of environmental governance in which ecological processes are continually validated and integrated into the economy.

Through the acquisition by Carbon Direct, Pachama's technology was integrated into its end-to-end carbon management model. Carbon Direct becomes a full stack carbon solutions company leveraging Pachama's AI-based Measurement, Reporting, and Verification (MRV) systems. Pachama gains financial security, access to more clients, and institutional credibility. This acquisition allows them to consolidate strategies in the carbon management sector, and it is in line with the sustainability transition theory (Geels, 2002).

Overall, Pachama case addresses our research questions as described in the following Table 2.

Table 2. How Pachama case addresses research questions of this study

RQ	***Evidence from case study***	***Mechanism***	***Implications***
How do green tech startups link science and environmental goals?	*Pachama uses AI, satellite imagery, and remote sensing technologies to monitor forest ecosystems. The Pachama platform connects forest conservation projects with corporations seeking carbon offsets*	*Scientific data are translated into digital datasets supporting carbon credit verification and environmental monitoring. AI system reduces information asymmetry and increases transparency in carbon markets*	*Green tech startups can bridge science and markets by integrating environmental measurement into digital platforms, enabling more credible environmental markets*
What could be the possible development trajectory of technology-based green innovation?	*Pachama evolved from a digital marketplace intermediary to a hybrid model including project origination. The acquisition by Carbon Direct integrated Pachama's AI monitoring systems with carbon management advisory services*	*Vertical integration allows greater control over the quality and supply of environmental assets. Integration of technological and advisory capabilities creates end-to-end carbon management solutions.*	*Green tech startups may expand upstream to strengthen environmental impact, sustainability and value creation. Future green tech ecosystems may combine technological platforms, environmental projects, and strategic advisory services*

Source: Author's own elaboration

The Pachama case demonstrates that the future of environmental sustainability could depend not just on conservation efforts but also on digital infrastructure for measuring and integrating ecological value into economic systems, in line with the literature (Chen et al., 2025; Fichter et al., 2025; Jorzik et al., 2024). It suggests broader trends in green tech startups' role as infrastructure providers (Jorzik et al., 2024; Pakura, 2020). The AI systems of verification may become incorporated into the carbon markets of compliance.

Research limitations. *The limitations of this study are that it is based on a single case study. Even though this single case study on Pachama gives a better understanding of AI in green innovation, it cannot be generalized to other sectors. In addition, this research is based on secondary data. There is a need to improve the understanding of the strategic processes of the organization through interviews with the stakeholders themselves (Creswell et al., 2011). Finally, the voluntary carbon market is observing major shifts in its regulations and institutions, which could have a major impact on the strategic position of organizations such as Pachama in the future.*

Future research could be based on comparative studies on different green tech startups to have a better understanding of the sustainability of the business model itself.

Managerial implications. *Green tech startups, such as Pachama, close the gap between science and the environment by converting the tools of scientific measurement into digital platforms. Managers could combine AI and remote sensing technology with the voluntary carbon markets. Pachama's business model illustrates the evolution from an intermediary to a vertically integrated developer. Its acquisition by Carbon Direct combines Pachama's technological strength with a carbon management system.*

As climate regulations become increasingly effective, the formation of AI-based systems can lead to biodiversity credits and natural capital markets, with green tech startups contributing to the environmental market.

Pachama does not just leverage technology to reach environmental goals, it is reframing environmental stewardship as a data-driven, monitored, and market-friendly system. The future of environmental protection and green innovation could depend on the development of digital infrastructures that can measure and validate environmental value in the economy and predict the potential damage to the environment in advance.

Originality of the paper. *The originality of this study is related to the focus on green tech startups as integrators that transform scientific measurement into digital infrastructures for environmental markets. We underline that this is a work in process. We want to shed new light on how AI-based platforms transform ecological processes into measurable datasets. In addition, this short paper also provides new evidence on how business model innovation and AI-based monitoring systems can enhance transparency in voluntary carbon markets, as illustrated by the Pachama startup case study.*

Information framing and plant-based food choices: An experiment on isolated and cumulative effects across dietary identities

ROBERTA IOVINO[1], FRANCESCO TESTA[1], MICOL BATELLI[1]

Abstract. *Reducing meat consumption is crucial for the transition toward more sustainable food systems. Informational and normative interventions are widely used to promote plant-based alternatives, yet empirical evidence regarding their effectiveness remains unclear. One possible explanation lies in the heterogeneity of consumers' dietary identities and in the psychological mechanisms that sustain meat consumption despite environmental and ethical awareness. This study investigates the isolated and cumulative effects of five informational cues - animal welfare information, health information, environmental impact disclosure, static social norms, and dynamic social norms - on consumers' choice between a meat-based and a plant-based dish in a restaurant context. The experiment was administered online in February 2025 by a professional survey provider to a sample of Italian consumers aged 18-70 (n = 2015). Participants were randomly assigned to one of seven experimental conditions. Logistic regression analyses show that environmental information and cumulative informational framing significantly increase the likelihood of selecting the plant-based option. The cumulative condition produces the strongest effect, particularly among meat-oriented consumers. Predicted probabilities indicate that plant-based choice rises from 3% to 24% among carnivores and from 17% to 32% among omnivores under cumulative framing. Cumulative informational framing may limit mechanisms of moral disengagement by constraining consumers' ability to rely on selective justificatory arguments. Additional analyses including socio-demographic and psychological variables confirm the robustness of the experimental results. Beyond the experimental manipulations, individual attitudes play a relevant role. In particular, attitudes toward meat reduction for health and environmental reasons, perceived pro-vegetarian social norms, and concern for animal welfare positively influence the likelihood of choosing the plant-based option. Conversely, hedonic attachment to meat consumption emerges as the strongest negative predictor of plant-based choice.*

Keywords: *plant-based choice; dietary identity; moral disengagement; cumulative informative framing; sustainable consumption*

1. Framing the research. The urgency of reducing meat consumption is widely recognized within sustainability discourse. Livestock production contributes significantly to greenhouse gas emissions, land degradation, water consumption, and biodiversity loss (Notarnicola et al., 2017). Also, an excessive intake of red and processed meat is associated with heightened risks of chronic and cardiovascular diseases (Wang et al., 2016; Neuenschwander et al., 2019). Simultaneously, the consumption of animal-based products has a huge impact on animal suffering (Graça, 2016; Nordquist et al., 2017). While awareness of these environmental, health and animal welfare implications has grown, consumer behavior remains resistant to change.

A wide range of behavioral interventions has therefore been developed to encourage plant-based consumption and reduce meat intake: these interventions typically rely on informational strategies -such as health claims and environmental labeling - as well as on normative cues signaling what others are doing (Lin et al., 2025; Wolfswinkel, 2025). However, empirical findings on their effectiveness are discouraging (Çoker et al., 2022; Pechey et al., 2022; Wolfswinkel et al., 2025) showing no or negligible effects on behavioral change.

A critical factor explaining this resistance can be dietary identity (Rosenfeld & Tomiyama, 2021) as food consumption is not merely functional but identity relevant. Individuals often define themselves through their dietary practices, and such identities can become integrated into the self-concept (Rosenfeld & Burrow, 2017). Identity-based motivation theory (Oyserman, 2009) posits that individuals are motivated to enact behaviors consistent with salient aspects of their identity. When a behavior aligns with identity, it feels authentic and self-congruent; when it conflicts, it generates psychological discomfort and defensive processing. Meat consumption, in particular, is often associated with masculinity, tradition, and social normality (Rothgerber, 2013; Piazza et al., 2015). Conversely, vegetarian and vegan identities tend to be moralized and linked to ethical commitments. The so-called "meat paradox" (Bastian & Loughnan, 2017) captures the tension between caring about animals and continuing to consume meat. To resolve this tension, individuals can engage in moral disengagement (Bandura, 2007; Graça et al., 2014). This means that individuals selectively interpret or dismiss information that threatens their identity or habitual behavior employing strategies such as denying animal mind, diffusing responsibility, or rationalizing meat consumption as natural, necessary, normal, and nice (Piazza et al., 2015). As a result, isolated informative cues and nudges may leave intact the justificatory structures sustaining meat consumption.

The present research builds on this theoretical background to propose that cumulative informational framing-integrating multiple informational arguments simultaneously - may reduce moral disengagement by constraining the availability of justificatory pathways. Framing effects suggest that individuals often respond differently to alternative

[1] Institute of Management, Sant'Anna School of Advanced Studies, Address: Sant'Anna School of Advanced Studies – Institute of Management, Piazza Martiri della Libertà 33, 56127 Pisa, Italy. Corresponding author's mail: roberta.iovino@santannapisa.it

descriptions of the same problem (Frisch, 1993). In the context of reducing meat consumption, this study posits that the key challenge may not lie solely in identifying the most effective information for promoting behavioral change, but rather in combining multiple informational cues in order to limit consumers' ability to disengage from a specific issue by relying on alternative justificatory considerations. When environmental, health, ethical, and social norm dimensions converge within a single message, selective dismissal becomes more difficult. This cumulative framing may therefore weaken defensive reasoning and reduce the likelihood that consumers "switch off" individual concerns. Such a mechanism is expected to be particularly relevant among omnivorous consumers, whose dietary identity is typically less rigidly anchored and therefore more open to influence from converging informational cues.

2. Purpose of the paper. The primary objective of this paper is to examine how different informational strategies influence consumers' choice between meat-based and plant-based dishes in a restaurant context, and how these effects vary across dietary identities and individual predispositions. In particular, our study investigates the isolated effects of different informational cues - including animal welfare information, health information, environmental impact disclosure, and social norms - as well as the impact of cumulative informational framing that combines multiple sustainability-related arguments within a single message. At the same time, the analysis explores whether the effectiveness of these interventions varies across dietary identities and whether plant-based choices are also shaped by underlying psychological factors, such as environmental concern, attitudes toward meat reduction, perceived social norms, concern for animal welfare, and hedonic attachment to meat consumption. By integrating experimental manipulation with the analysis of individual predispositions, the study aims to provide a more comprehensive understanding of how informational strategies interact with dietary identity and psychological drivers in shaping more sustainable food choices.

More specifically, the study addresses four research questions:

(RQ1) Do informational interventions influence consumers' choice between meat-based and plant-based dishes?

(RQ2) Do cumulative informational messages produce stronger behavioral effects than isolated informational cues?

(RQ3) To what extent does consumers' dietary identity shape their responsiveness to informational strategies?

(RQ4) To what extent do individual psychological predispositions - such as environmental concern, attitudes toward meat reduction, perceived social norms, concern for animal welfare, and hedonic attachment to meat consumption - affect plant-based food choices?

3. Methodology

Data Collection. The experiment was conducted online in February 2025. Data were collected through a professional survey provider (SWG), which administered the experiment using a Computer-Assisted Web Interviewing (CAWI) procedure to a large and representative sample of the Italian population aged between 18 and 70. A total of 2015 valid responses were obtained. Table 1 reports the sociodemographic characteristics of the sample.

Table 1: Sociodemographic characteristics

Demographics		**Frequencies (n=2015)**	**%**
Gender	Male	983	48.78
	Female	1032	51.22
Age class	18-24 years old	168	8.34
	25-34 years old	281	13.95
	35-44 years old	347	17.22
	45-54 years old	444	22.03
	55-70 years old	775	38.46
Education	Elementary and middle school	172	8.54
	High school	1323	65.66
	Bachelor degree	179	8.88
	Master's degree and postgraduate	341	16.92
Geographical area	North-west	538	26.7
	North-east	371	18.41
	Centre	390	19.35
	South	486	24.12
	Islands	230	11.41

Dietary identity of participants was measured by asking respondents to select the statement that best described their usual eating habits. Participants were presented with six mutually exclusive categories representing different positions along the meat consumption continuum: carnivore (meat is the predominant component of my meals), omnivore (I consume a varied diet including meat), reductionist (I eat meat but try to reduce my consumption), pescatarian (I avoid meat but consume fish and seafood), vegetarian (I do not eat meat or fish), and vegan (I avoid all animal-derived products, including eggs and dairy). This classification reflects a gradient of dietary identities ranging from meat-centered diets to strictly plant-based orientations. The distribution of respondents across these categories is reported in Table 2. The distribution of dietary identity reflects real Italian prevalence patterns, with omnivores constituting the majority of the sample.

Table 2: Dietary identities

Dietary identity	N = 2015	%
Carnivore	188	9.33
Omnivore	1176	58.36
Reductionist	513	25.46
Pescatarian	64	3.18
Vegetarian	58	2.88
Vegan	16	0.79

Experimental design. After indicating their dietary identity, participants were randomly assigned to one of seven experimental conditions. In each condition, respondents were presented with the same following task scenario:

"You are having dinner in a well-known and highly rated restaurant. You want to order a second course and the waiter points out two dishes of the day, masterfully prepared by the Chef. Which do you choose?".

The two alternatives presented were: (1) a meat-based stew (prepared with veal, lamb, or pork), and (2) a plant-based stew (prepared with legumes, tofu, or seitan).

The restaurant context was selected in order to isolate the decision from factors related to cooking skills, preparation time, or household food availability. The dishes were designed to be comparable in format and culinary style in order to minimize differences unrelated to the experimental manipulation.

The seven experimental conditions differed according to the informational cue accompanying the proposed dishes:

1. **Control condition:** no additional informational cue was provided.
2. **Animal welfare condition**: the plant-based dish was described as prepared without animal exploitation or suffering.
3. **Health condition**: the plant-based dish was presented as healthier than meat and beneficial for preventing chronic and cardiovascular diseases.
4. **Environmental impact condition:** environmental information was provided through the disclosure of CO_2 emissions associated with each dish, indicating a high climate impact for the meat-based option and a low climate impact for the plant-based option.
5. **Static social norm condition**: a message indicated that many customers - not only vegetarians and vegans - had chosen the plant-based dish and were satisfied with it.
6. **Dynamic social norm condition**: a message indicated that an increasing number of customers - not only vegetarians and vegans - were choosing the plant-based dish and were satisfied with it.
7. **Cumulative framing condition**: the plant-based dish was accompanied by the combination of all previously described informational cues, including environmental impact disclosure, animal welfare information, health benefits, and both static and dynamic social norm messages.

The complete description of the seven experimental conditions presented to participants is reported in **Appendix A.**

The number of participants per condition ranged from 287 to 289 respondents. This balanced allocation ensured comparable sample sizes across conditions and strengthened the internal validity of the experimental design.

To further verify the effectiveness of the random assignment procedure, we tested whether dietary identity differed across the seven experimental conditions. A one-way analysis of variance (ANOVA) revealed no significant differences in dietary identity across conditions ($F(6, 2008) = 0.58$, $p = 0.749$). This result indicates that respondents with different dietary identities were evenly distributed across experimental conditions, confirming the effectiveness of the randomization procedure and ensuring comparability between groups.

Measurement of other psychological dimensions. Other psychological variables were measured through the survey using multi-item Likert scales inspired or adapted from previous studies in the sustainable consumption and meat reduction literature. The scales captured general environmental concern (Trivedi et al., 2018), attitudes toward meat reduction for health and environmental reasons (Mai & Hoffmann, 2015), perceived pro-vegetarian social norms (De Groot et al., 2021), concern for animal welfare and hedonic attachment to meat consumption (Graça et al., 2015).

4. Results and discussion

Results description. We first explored the food choice across the seven experimental conditions (see Table 3).

Table 3: Distribution of food choices across experimental conditions

Experimental condition	Meat-based dish	Plant-based dish	Total	Plant-based (%)
1. Control	205	84	289	29.1
2. Animal welfare information	197	90	287	31.4
3. Health information	191	96	287	33.4
4. Environmental impact information	180	107	287	37.3
5. Static social norm	202	87	289	30.1
6. Dynamic social norm	199	89	288	30.9
7. Cumulative informational framing	169	119	288	41.3
Total	**1343**	**672**	**2015**	**33.4**

Logistic regression was employed to estimate the probability of choosing the plant-based option as a function of experimental conditions (Table 4). The control condition was used as the reference category.

Table 4: Logistic regression results

Plant-based choice	Odds ratio	Std. err.	z	P>z	[95% conf.	interval]
1 (control)						
2	1,11	0,20	0,60	0,549	0,78	1,59
3	1,23	0,22	1,13	0,257	0,86	1,75
4	**1,45**	0,26	2,09	0,037*	1,02	2,06
5	1,05	0,19	0,27	0,785	0,74	1,50
6	1,09	0,20	0,48	0,630	0,76	1,56
7	**1,72**	0,30	3,07	0,002**	1,22	2,43

The results indicate that most isolated informational frames do not significantly affect food choice relative to the control condition. In particular, the animal welfare, health, and social norm conditions do not produce statistically significant changes in the probability of selecting the plant-based dish. In contrast, the environmental impact condition shows a positive and statistically significant effect (OR = 1.45, p = 0.037), indicating that providing transparent information about the climate impact of food increases the likelihood that respondents choose the plant-based option compared with the control condition. The cumulative informational condition, which integrates environmental, health, animal welfare, and social norm messages, produces the strongest effect. In this condition, the probability of selecting the plant-based dish is significantly higher than in the control condition (OR = 1.72, p = 0.002).

Overall, these results suggest that isolated informational cues have no significant impact on consumers' food choices, with the exception of environmental information. However, combining multiple sustainability-related arguments appears to substantially increase the effectiveness of informational interventions aimed at promoting plant-based food choices.

To further explore whether these effects vary across consumer segments, we examined the role of dietary identity. Table 5 reports the predicted probabilities of choosing the plant-based dish across experimental conditions and dietary identities, derived from the logistic regression model including the interaction between experimental condition and dietary identity.

Table 5: Predicted probability of choosing the plant-based dish by experimental condition and dietary identity

Dietary identity	Control	Animal welfare	Health	Environmental impact	Static norm	Dynamic norm	Cumulative
Carnivore	0.03	0.14	0.04	0.18	0.07	0.15	0.24
Omnivore	0.17	0.20	0.27	0.28	0.18	0.19	0.32
Pescatarian	0.49	0.47	0.48	0.62	0.47	0.53	0.54
Reductionist	0.83	0.88	0.71	0.63	0.64	0.67	0.83
Vegetarian	—	0.86	0.89	0.86	0.92	0.83	0.90

The results highlight substantial differences across dietary groups. Informational framing produces the largest variation among carnivores and omnivores, while respondents with plant-oriented dietary identities (pescatarians, reductionists, and vegetarians) display consistently higher probabilities of selecting the plant-based option across conditions. Among omnivores, the probability of selecting the plant-based option increases from 17% in the control condition to 32% in the cumulative framing condition. A particularly strong relative change is observed among carnivores, whose probability of choosing the plant-based option rises from 3% in the control condition to 24% under cumulative framing. Vegan respondents are not reported in Table 5 because plant-based choice perfectly predicts the outcome in this subgroup.

Our findings suggest that effectiveness of information depends on consumers' dietary identity, with carnivores and omnivores representing the segments most responsive to informational interventions. Moreover, combining multiple informational cues appears to reduce selective dismissal and increases the likelihood of plant-based choice by limiting selective justification.

As a further robustness check, we estimated an additional logistic regression model including socio-demographic characteristics and several psychological/attitudinal factors (Table 6), such as environmental concern, attitudes toward meat reduction for health and environmental reasons, concern for animal welfare, perceived pro-vegetarian social norms, and hedonic attachment to meat consumption. The results remain consistent with the main analysis. In particular, the environmental impact condition ($\beta = 0.649$, $p = 0.002$) and the cumulative framing condition ($\beta = 0.809$, $p < 0.001$) significantly increase the likelihood of selecting the plant-based dish.

Psychological factors emerge as significant predictors of plant-based choice. These effects appear to operate across the sample independently of the experimental manipulations. Respondents who believe that reducing meat consumption benefits health ($\beta = 0.258$, $p < 0.001$) or the environment ($\beta = 0.130$, $p = 0.015$) are more likely to select the plant-based option. Similarly, perceived social norms favoring reduced meat consumption ($\beta = 0.191$, $p < 0.001$) and concern for animal welfare ($\beta = 0.196$, $p < 0.001$) positively influence plant-based choice. In contrast, hedonistic orientation toward meat shows a strong negative association with plant-based choice ($\beta = -0.543$, $p < 0.001$), suggesting that consumers who

prioritize sensory pleasure in meat consumption are less likely to choose plant-based options. Among socio-demographic variables, age displays a negative and significant effect, indicating that younger respondents are more inclined toward plant-based choices.

Table 6: Logistic regression results including control variables

Plant-based choice	Coefficient (β)	Std. Err.	z	p-value
Experimental conditions				
Animal welfare information	0.286	0.217	1.32	0.188
Health information	0.306	0.214	1.43	0.152
Environmental impact information	**0.649**	0.213	3.04	**0.002**
Static social norm	0.076	0.218	0.35	0.727
Dynamic social norm	0.217	0.217	1.00	0.317
Cumulative informational framing	**0.809**	0.214	3.79	**0.000**
Socio-demographic variables				
Age	-0.012	0.004	-2.90	0.004
Gender (Female)	0.128	0.115	1.12	0.262
University degree	-0.004	0.135	-0.03	0.974
Psychological factors				
Environmental concern	0.110	0.056	1.96	0.050
Attitude towards meat reduction for health reasons	0.258	0.057	4.55	0.000
Attitude towards meat reduction for environmental reasons	0.130	0.053	2.43	0.015
Perceived pro-vegetarian/vegan social norms	0.191	0.052	3.67	0.000
Hedonic attachment to meat consumption	**-0.543**	0.039	-13.78	**0.000**
Concern for animal welfare	0.196	0.038	5.16	0.000
Constant	-2.414	0.435	-5.55	0.000

5. Discussion. Our results show that not all informational cues are equally effective in influencing food choice. Among the isolated informational strategies tested, only environmental impact information significantly increased the likelihood of selecting the plant-based dish compared with the control condition. This finding is consistent with previous studies suggesting that environmental information may play a particularly relevant role in shaping sustainable food choices.

In contrast, the isolated informational cues related to health benefits, animal welfare, and social norms did not produce statistically significant changes in choice behavior. This result does not necessarily imply that these dimensions are irrelevant for consumers. Rather, it suggests that when presented individually within a short decision context, such as a restaurant menu, these messages may not be sufficiently salient to override existing preferences or habits. Previous research has highlighted that although consumers often express concern about health, animal welfare, or social norms, such concerns do not always translate into immediate behavioral change (Graça et al., 2019; Piazza et al., 2015).

Second, the cumulative informational condition produced the strongest effect among all experimental treatments. When environmental, health, ethical, and social norm information were presented simultaneously, the probability of selecting the plant-based dish increased significantly. This result supports the idea that combining multiple sustainability arguments may reduce consumers' ability to selectively dismiss individual concerns. When a single argument is emphasized, consumers may justify maintaining their existing behavior by focusing on alternative considerations. By contrast, cumulative informational framing constrains the availability of such justificatory pathways. This interpretation aligns with the concept of moral disengagement proposed by Bandura (2007). Consumers may cognitively disengage from the negative consequences of meat consumption by minimizing ethical, environmental, or health implications. However, when multiple dimensions are simultaneously highlighted, it becomes more difficult to deactivate each concern individually. The cumulative framing tested in this experiment may therefore reduce the opportunity for moral disengagement mechanisms to operate.

Third, the results reveal substantial heterogeneity across dietary identities. Consumers with plant-oriented dietary identities - such as pescatarians, reductionists, and vegetarians - already display high baseline probabilities of choosing the plant-based option. For these groups, informational framing produces only limited additional effects, as their dietary choices are largely consistent with their identity-based motivations. This finding is consistent with identity-based models of behavior suggesting that individuals tend to act in ways that are coherent with their self-concept and established habits.

By contrast, omnivorous and carnivorous consumers appear to be the most responsive segment to informational interventions. In this group, the probability of selecting the plant-based option increases substantially in cumulative informational condition compared with the control condition. This result suggests that informational strategies may be particularly effective among consumers whose dietary identity is less rigidly defined and therefore more open to influence.

Finally, the robustness analysis incorporating socio-demographic and psychological variables provides further insight into the drivers of plant-based choice. Several psychological factors emerge as significant predictors of behavior, including attitudes toward meat reduction for health and environmental reasons, concern for animal welfare, and perceived social norms favoring reduced meat consumption. These results confirm that individual predispositions play a central role in shaping dietary choices.

Among all predictors included in the model, hedonic attachment to meat consumption emerges as the strongest negative determinant of plant-based choice. Respondents who associate meat consumption with sensory pleasure are significantly less likely to select the plant-based dish. This finding supports previous research highlighting the central role

of taste expectations and hedonic motivations in sustaining meat consumption (Piazza et al., 2015; Graça et al., 2016). Even when consumers recognize environmental or ethical concerns, the perceived pleasure associated with meat consumption may facilitate forms of moral disengagement that justify maintaining existing dietary habits.

Overall, the findings suggest that informational strategies can influence food choices, but their effectiveness depends on both message design and consumer characteristics. In particular, environmental information and cumulative informational framing emerge as the most effective approaches for promoting plant-based choices, especially among consumers with meat-oriented dietary identities.

6. Research limitations. Despite its contributions, this study presents several limitations that should be considered when interpreting the results. First, the experiment relied on a hypothetical decision scenario rather than observing actual behavior. Although hypothetical choice experiments are widely used in consumer research to isolate causal mechanisms, real-world food choices may be influenced by additional contextual factors such as price, product availability, social context, or situational constraints. Future research could complement the present findings with field experiments conducted in real restaurant settings.

Second, the experiment was conducted within a specific consumption context, namely a restaurant menu choice. While this context was intentionally selected to minimize factors related to cooking skills, preparation time, and household food availability, consumer behavior may differ in other consumption settings, such as grocery shopping or home meal preparation.

Third, the study focuses on a national sample of Italian consumers aged between 18 and 70. Cultural norms, culinary traditions, and attitudes toward plant-based foods may vary across countries, potentially influencing the effectiveness of sustainability-related informational strategies. Future studies could replicate the experimental design in different cultural contexts to assess the generalizability of the results.

Fourth, dietary identity was measured through self-reported categories. Although this approach captures important differences in dietary orientation, individual eating habits may be more nuanced than categorical classifications suggest. Future research could explore more fine-grained measures of dietary behavior and food-related identities.

Fifth, our study does not directly measure moral disengagement, relying instead on theoretical inference.

Finally, while the present analysis incorporates several psychological variables, additional factors such as taste expectations, perceived product quality, or emotional responses to food could further contribute to explaining consumer choices. Integrating these dimensions into future experimental designs could provide a more comprehensive understanding of the mechanisms underlying sustainable food consumption.

7. Managerial implications. Our findings offer several implications for practitioners and policymakers interested in promoting more sustainable dietary choices.

First, the results suggest that communicating the environmental impact of food products can effectively encourage plant-based choices. Providing clear and concrete environmental information - such as carbon footprint indicators - may increase consumers' awareness of the ecological consequences of their dietary decisions. Restaurants, food service providers, and menu designers could incorporate environmental impact labels or sustainability indicators to support more informed choices.

Second, the effectiveness of cumulative informational framing indicates that sustainability communication may benefit from combining multiple arguments rather than focusing on a single dimension. Messages simultaneously highlighting environmental impact, health benefits, animal welfare considerations, and social norms may reinforce one another and reduce consumers' ability to selectively ignore individual concerns. Menu communication strategies could therefore integrate multiple sustainability cues within the same message to strengthen their overall impact.

Third, the heterogeneity observed across dietary identities suggests that communication strategies should be tailored to different consumer segments with omnivorous and carnivorous consumers appear to be the most responsive segment to informational interventions.

Finally, the strong negative effect of hedonic attachment to meat consumption highlights the importance of addressing taste perceptions in promoting plant-based diets. Informational messages alone may not be sufficient if consumers perceive plant-based dishes as less satisfying or less enjoyable than meat-based alternatives. Restaurants and food producers should therefore invest in improving the sensory quality, culinary appeal, and gastronomic positioning of plant-based dishes. Emphasizing taste, creativity, and culinary craftsmanship may help overcome hedonic barriers and increase the acceptance of plant-based options.

Taken together, these findings suggest that promoting more sustainable food choices requires a combination of complete informational strategies, increasing awareness champaigns as well as improvements in the sensory attractiveness of plant-based foods. By aligning sustainability communication with consumers' psychological motivations and taste expectations, practitioners may enhance the effectiveness of interventions aimed at reducing meat consumption.

8. Originality of the Paper. This study contributes to the literature on sustainable food consumption by advancing the understanding of how informational strategies influence consumers' dietary choices. While previous research has examined individual informational frames - such as environmental impact, health benefits or social norms - this study investigates both the isolated and cumulative effects of several informational cues within a controlled experimental setting.

First, the paper provides evidence that not all informational frames are equally effective in influencing food choices. Among the isolated messages tested, environmental impact information emerges as the only frame capable of significantly increasing the probability of selecting a plant-based option.

Second, the study empirically tests the concept of cumulative informational framing, showing that the simultaneous presentation of multiple arguments produces stronger behavioral effects than isolated messages. This result suggests that combining environmental, health, ethical, and social norm information may reduce consumers' ability to selectively dismiss individual concerns, thereby limiting mechanisms of moral disengagement.

Third, the study demonstrates that the effectiveness of informational framing depends on consumers' dietary identity. Informational interventions appear to be particularly effective among omnivorous and carnivorous consumers, whose dietary identity is less rigidly anchored to ethical considerations, while individuals with plant-oriented dietary identities already display high baseline probabilities of selecting plant-based options.

Finally, by integrating psychological drivers such as environmental concern, animal compassion, perceived social norms, and hedonic attachment to meat consumption, the study highlights the interplay between informational cues and underlying motivational factors in shaping sustainable food choices.

Appendix A: Experiment Design

Task scenario:
You are having dinner in a well-known and highly rated restaurant. You want to order a second course and the waiter points out on the menu two dishes of the day, masterfully prepared by the Chef. Which one do you choose?

Experimental conditions	Option 1	Option 2
1. Control	**Meat stew** (choice of veal, lamb, or pork) 	**Plant-based stew** (choice of legumes, tofu, or seitan) 
2. Animal welfare	**Meat stew** (choice of veal, lamb, or pork) 	**Plant-based stew** (choice of legumes, tofu, or seitan)  *Dish prepared without animal exploitation or suffering.*
3. Health	**Meat stew** (choice of veal, lamb, or pork) 	**Plant-based stew** (choice of legumes, tofu, or seitan)  *Healthier than meat, helping protect against chronic and cardiovascular diseases.*
4. Environmental impact	**Meat stew** (choice of veal, lamb, or pork)  *Climate change environmental impact: HIGH (4 kg of CO_2 per portion)*	**Plant-based stew** (choice of legumes, tofu, or seitan)  *Climate change environmental impact: LOW (0.12 kg of CO_2 per portion)*
5. Static social norms	**Meat stew** (choice of veal, lamb, or pork) 	**Plant-based stew** (choice of legumes, tofu, or seitan)  *Many customers, not only vegetarians and vegans, have chosen this dish and were satisfied!*
6. Dynamic social norms	**Meat stew** (choice of veal, lamb, or pork) 	**Plant-based stew** (choice of legumes, tofu, or seitan)  *More and more customers, not only vegetarians and vegans, are choosing this dish and are satisfied!*
7. Cumulative framing	**Meat stew** (choice of veal, lamb, or pork)  *Climate change environmental impact: HIGH (4 kg of CO_2 per portion)*	**Plant-based stew** (choice of legumes, tofu, or seitan)  *Climate change environmental impact: LOW (0.12 kg of CO_2 per portion)* *Dish prepared without animal exploitation or suffering.* *Healthier than meat, helping protect against chronic and cardiovascular diseases.* *Many (and increasingly more) customers, not only vegetarians and vegans, choose this dish and are satisfied!*

Is sustainable fashion cool? An exploration of ethical, slow and sustainable fashion hashtags on Instagram

DAVID D'ACUNTO[1], CECILIA PASQUINELLI[2], SANDRA MARIA CORREIA LOUREIRO[3], SERENA ROVAI[4]

Abstract. *This research aims to frame the concept of coolness in sustainable fashion discourse and reach insights into how coolness and sustainability are intertwined. It proposes an exploration of sustainable fashion discourse on Instagram, a digital setting where the social construction of coolness occurs. In this setting, the research questions that this study addresses are: How is coolness framed in the Instagram discourse on sustainable fashion? To respond to this broader question, this study explores i) the key dimensions of coolness in sustainable fashion; ii) what themes of sustainability emerge when referring to coolness; iii) the sentiment associated with coolness in sustainable fashion discourse and, iv) geographical differences among content creators. According to findings, sustainable fashion discourse incorporates coolness primarily as an aesthetic and symbolic attribute (Original, Attractive, and High Status), while deeper integration with sustainability narratives remains limited. Coolness is present and emotionally positive, but only weakly integrated with sustainability discourse within the analysed corpus. Authenticity functions as the strongest bridge between coolness and sustainability, particularly in relation to Human Rights. Higher coolness intensity weakens sustainability integration, suggesting a potential symbolic trade-off between the two overall concepts. Geographical differences are substantial, especially in emoji-based expression (Asia) and hashtag signalling (Africa and Europe).*
Keywords: Coolness, Sustainable fashion, Brand coolness, Instagram, Text analytics

Framing of the research. *Coolness is a subjective, socially constructed, and dynamic positive attribute of brands and, more generally, of cultural objects or individuals (Warren et al., 2019; Loureiro et al., 2024). It plays a special role in symbolic consumption where identity expression plays a central role (Stein et al. 2025). Coolness is not just a form of liking someone or something; rather, it is the result of an evaluation or judgement of distinctiveness, which is associated with various characteristics and dimensions emerged in the literature. Based on this definition, it is evident how coolness is embedded within a cultural and social context, evolving over time depending on the evolution of social groups (Warren et al., 2019). What is cool in a setting can be uncool in another; such setting for instance can be geographical, cultural and temporal. The social construction of coolness emphasises the importance to focus on the interactions between consumers, brands and cultural contexts to reach insights into what coolness is (Stein et al., 2025). In fact, coolness can be understood as a multifaceted and culturally embedded concept that has evolved from subcultural movements into a significant element of consumer culture (Loureiro and Lopes, 2012; Loureiro et al., 2024).*

Brand coolness corresponds to positive perceptions that consumers attribute to brands that appear as authentic, distinctive, and socially relevant (Stein et al., 2025). Ten main dimensions characterize cool brands: innovativeness (creativity and capacity to anticipate trends), emotional stimulation, exclusivity, positive emotions, preciousness, singularity, unconventionality, social conscience, youthfulness and vintage (Loureiro and Lopes, 2012). It was said to reflect perceptions of autonomy in relation to the independence from conventions, originality or nonconformity (Warren et al., 2019). Innovativeness, meaningfulness and capacity to stand out from the mainstream are discussed as key dimensions of a cool brand (Stein et al., 2025). According to Warren et al. (2019), a set of characteristics commonly associated to coolness are extraordinary, aesthetic appeal (design quality and visual attractiveness), energy, high-status, originality, authenticity (as perceptions of brands that are genuine and consistent with their own values), rebelliousness (linked to unconventionality contributing to the perceptions of differentiation from mainstream brands), sub-cultural appeal, iconicity and popularity. In the luxury fashion context, a distinction was made in conceptualising brand coolness, such as "mass cool" and "niche cool". Mass cool brands refer to the perceptions of coolness in the broader market, while niche cool brands are defined in relation to perceptions of coolness reached within specific and narrower subcultural groups (Loureiro et al., 2024). This distinction frames different concepts of coolness and may explain different consumer behaviours. This distinction mirrors the importance of understanding and conceptualising coolness within consumer segments and groups within them because interpretation and valuation of cool may vary.

Brand coolness was discussed in relation to the impact on consumer-brand relationships. Positive brand attitudes, emotional attachment and self–brand connections, brand credibility brand love, passionate desire, brand loyalty, increase of consumers' willingness to pay, word of mouth and brand equity have been discussed as a consequence of the perceived coolness (Loureiro and Lopes, 2012; Warren et al. 2019; Loureiro et al., 2020; Loureiro et al., 2024; Alanadoly and Salem, 2023; Stein et al., 2025).

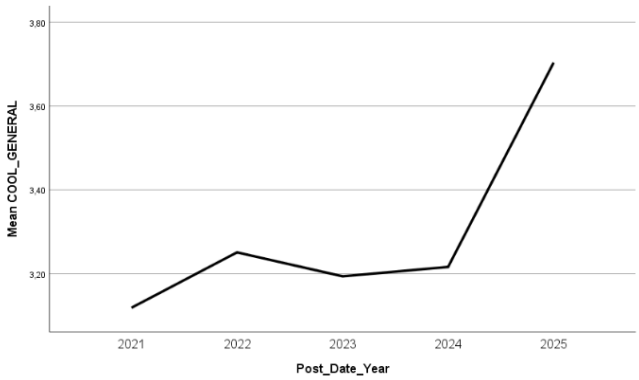
Attention has also been drawn to experiential modalities to construct perceived coolness. For instance, technology-enabled experiences such as virtual reality (VR) and gamification may play a significant role in shaping coolness perceptions (Stein et al., 2025). Immersive gaming may represent a modality to boost perceptions of coolness, particularly in relation to perceived enjoyment, although different segments may respond differently to the same experiential inputs (Alanadoly and Salem, 2023).

Purpose of the paper. *Considering the definition of coolness, there is a need to situate the study of the concept within specific settings, paying much attention to its constructed meanings in relation to given sectors, practices of consumption and groups of consumers. Research needs to acknowledge and focus on differences and nuances of coolness, as well as on the potentially different modalities to boost perceptions of coolness and its different outcomes. Besides, there is a need to gain insights not only into the positive impacts of perceived coolness but also into the negative responses that coolness might elicit depending on the analysed settings. These insights would complement the existing knowledge on coolness and its capacity to transfer meaning and value through consumer experiences. Accordingly, this study focuses on sustainable fashion as a field where the concept of coolness may enhance the knowledge of how sustainable fashion brands work and brand equity is built. On the other hand, attention needs to be driven to the controversial aspects that may characterise coolness in relation to brands and products that are supposed to appeal to a sense of responsibility for the planet, ethical consumption based on consciousness of ecological and social problems that are related to the fashion industry and global value chains. New social norms, as well as consumers, have tied together to drive fashion brands to engage in sustainability at different level, from fast-fashion to luxury (Karaosman et al., 2020), with the latter often negatively evaluated for their unresponsible practices (Wang et al., 2021) related to questionable raw materials, and social justice related issues (Bubicz et al., 2021; Gardetti, 2017; Henninger et al., 2017; McKinsey, 2026). Consequently, fashion brands have increasingly included sustainable product attributes, including green manufacturing (Karaosman et al., 2020), the dearth of expertise (Guercini and Ranfagni, 2013), product longevity (Kapferer, 2010), and commitment to eco-fashion besides environmental conservation (Godart and Seong, 2014). However, much of the literature often analyses sustainability without fully understanding its complex character (Nagendra et al., 2024; Alwani et al., 2025) in particular in fashion, with respect to its specificities regarding brand social sustainability interpretation as in sustainable fashion narrative.*

If coolness is socially constructed, does it emerge in sustainable fashion narrative? If so, what are the dimensions of coolness that assist the sustainable fashion discourse? Finally, what the impacts of coolness on sustainable fashion consumers? This enquiry has recently emerged in the sustainable fashion literature. Singh et al. (2024) focused on the relationship between sustainability, brand coolness, and brand romance in the context of sustainable fashion consumption. With a focus on Gen Z consumers, this study demonstrated that portraying sustainable fashion as "cool" can enhance its attractiveness and boost purchase intention, also by fostering emotional attachment. However, there is a need to investigate in depth the specific dimensions that constitute coolness in sustainable fashion, considering that the social and cultural setting where coolness is constructed and exerts its impacts highly influences how coolness takes shape. Research is needed to better understand how coolness is constructed within the fashion domain for then to understand how coolness and its underlying dimensions influence consumers' emotional responses toward sustainable fashion.

The purpose of this research is, therefore, to frame the concept of coolness in sustainable fashion discourse and reach insights into how coolness and sustainability are intertwined. This is pursued by exploring the sustainable fashion discourse on Instagram, which is a digital setting where users generate content and interact. Not only Instagram has been progressively and generally relevant among social media, but it has played an important role in fashion (Tia et al., 2024) and has been widely used to disseminate brand messages about sustainability by corporate brands and entrepreneur brands (Kwon & Lee, 2021; Milanesi et al., 2022; Pasquinelli et al., 2025). In Instagram discursive setting, the research questions that this study addresses are: How is coolness framed in Instagram discourse on sustainable fashion? To respond to this broader question, the following research questions have been addressed: RQ1: what are the key dimensions of coolness in sustainable fashion? RQ2: What themes of sustainability emerge when referring to coolness? RQ3: What sentiment is associated with coolness in sustainable fashion discourse? And finally: RQ4: is there any geographical difference among content creators in framing coolness in sustainable fashion?

Methodology. *This study adopts a quantitative, dictionary-based computational research design to examine how coolness is framed within sustainable fashion discourse on Instagram and how it relates to sustainability dimensions, sentiment, and geographical provenance. The research relies on large-scale social media analytics of digital trace data, enabling the observation of naturally occurring communication and reducing typical self-reporting biases (Tirunillai & Tellis, 2014). The unit of analysis is the individual Instagram post caption. Variables were operationalized at the post level using normalized frequency measures to control for caption length. To address the research questions, the study combines descriptive statistics, longitudinal trend analysis, Pearson correlation analysis, and one-way ANOVA tests. The dictionary-based approach ensures theoretical alignment and replicability (Humphreys & Wang, 2017). Robustness checks were conducted using a High-Coolness subsample to test whether higher coolness intensity corresponds to stronger sustainability integration.*



Data. *A total of 202,499 Instagram posts were collected by means of a specific data crawler through hashtag-based retrieval. The following hashtags were used: #ethicalfashionbrand, #slowfashionbrand, #slowfashionmovement,*

#sustainablefashionbrand. Posts collected span a five-year period (2021–2025). The dataset is evenly distributed across hashtags (≈25% each) and includes both brand-generated and user-generated content. For each post the following fields were retrieved: Post_Likes, Total_Comments, Followers, Followings, Total_Posts, Number_Photo, Word_Count_Post. Given the exploratory nature of this research, we focus on post captions only, excluding comments, in order to capture how coolness is framed in primary content production.

To examine the emotional and symbolic framing of coolness within sustainable fashion discourse, we conducted an automated textual analysis of Instagram post captions using Linguistic Inquiry and Word Count (LIWC 2022). LIWC is a validated computational linguistic tool that quantifies psychologically meaningful categories by matching textual input against an extensive dictionary of words, stems, and emojis (Boyd et al., 2022). The tool has been widely adopted in social media and influencer marketing research to capture emotional expressiveness in naturally occurring digital communication, including Instagram data (e.g. Garner & Myers, 2025; Son & Park, 2023; Holiday et al., 2023). The study combines different dictionaries. We employed two theory-driven dictionaries developed for this study: (1) a coolness dictionary (Warren et al., 2019), structured into nine dimensions (i.e. Extraordinary, Energetic, Attractive, Original, Authentic, Rebellious, High Status, Popular, Iconic) including relevant keywords and emoji for each category, and (2) a sustainability dictionary (Pencle & Mălăescu, 2016), capturing four thematic dimensions (i.e. Human Rights, Employees, Social & Community, Environment). In parallel, we operationalized textual emotional expression using LIWC's affective categories and specifically positive emotion (posemo), capturing words associated with positive affect (e.g., love, beautiful, amazing); and negative emotion (negemo), capturing language associated with negative affect (e.g., sad, angry, unfair). Emojis were analyzed alongside textual content and treated as paralinguistic emotional markers, consistent with research demonstrating their role in clarifying or amplifying emotional intent in social media environments (Prada et al., 2018; Holiday et al., 2023). Dictionary-based scores were computed as normalized frequency measures relative to caption length. Additionally, a High-Coolness subsample (i.e. Cool_General ≥ 5.00; N = 44,911) was constructed to assess whether the relationship between coolness and sustainability dimensions varies under conditions of higher discursive intensity. This robustness analysis allows us to examine whether stronger coolness framing enhances sustainability integration or, alternatively, leads to symbolic decoupling when coolness becomes dominant.

Results. *The marked rise of Cool_General in 2025 (figure 1) indicates that coolness becomes increasingly central in sustainable fashion discourse rather than remaining a marginal stylistic feature. To unpack this aggregate trend, we analyze the nine coolness dimensions composing the Cool_General index, identifying which specific symbolic components are the most relevant.*

Figure 1. Longitudinal evolution of Cool_General (2021–2025)

Key Dimensions of Coolness in Sustainable Fashion. *The mean value of Cool_General (M = 3.24; SD = 4.07) indicates that coolness is present in sustainable fashion discourse, although its distribution is highly dispersed, as reflected by the relatively large standard deviation. This suggests substantial heterogeneity in the intensity of coolness framing across posts.*

At the dimensional level, Original (M = 0.41; SD = 1.40) and Attractive (M = 0.30; SD = 1.01) emerge as the most salient components of coolness, followed by High Status (M = 0.19; SD = 0.85). These findings indicate that aesthetic differentiation and symbolic distinctiveness constitute the dominant expressions of coolness in sustainable fashion discourse. In contrast, dimensions such as Rebellious (M = 0.009), Energetic (M = 0.027), and Popular (M = 0.034) display very low mean values, suggesting that countercultural or overtly expressive forms of coolness are comparatively marginal. Authentic (M = 0.12) and Iconic (M = 0.11) occupy an intermediate position, indicating a moderate but non-dominant presence.

Overall, the descriptive results (table 1) suggest that coolness in sustainable fashion is primarily articulated through originality, aesthetic appeal, and status signaling rather than through rebellion or overt expressiveness.

Table 1. Descriptive statistics

Variable	*N*	*Min*	*Max*	*M*	*SD*
Cool_General	*202,357*	*0.00*	*89.47*	*3.24*	*4.07*
Extraordinary	*202,357*	*0.00*	*19.05*	*0.06*	*0.39*
Energetic	*202,357*	*0.00*	*25.00*	*0.03*	*0.27*
Attractive	*202,357*	*0.00*	*50.00*	*0.30*	*1.01*
Original	*202,357*	*0.00*	*50.00*	*0.41*	*1.40*
Authentic	*202,357*	*0.00*	*50.00*	*0.12*	*0.62*
Rebellious	*202,357*	*0.00*	*33.33*	*0.01*	*0.15*
High Status	*202,357*	*0.00*	*50.00*	*0.19*	*0.85*
Popular	*202,357*	*0.00*	*33.33*	*0.03*	*0.34*
Iconic	*202,357*	*0.00*	*50.00*	*0.11*	*0.68*

Note. Values represent normalized frequency measures at the Instagram post-caption level.
Cool_General reflects the aggregate coolness index computed from the nine underlying dimensions.

Coolness and Sustainability: Correlation Analysis. *We performed a Pearson Correlation analysis considering the full sample (N ≈ 202,357). The overall category of coolness (i.e. Cool_General) significantly correlates with all four sustainability dimensions (p < .01). Specifically, with Human Rights (r = .067), Employees (r = .020), Social & Community (r = −.042), and Environment (r = .031). The negative correlation with Social & Community suggests a potential discursive tension between coolness framing and community-oriented sustainability narratives.*

At the dimensional level, notable patterns emerge. Authentic is the only coolness dimension positively correlated with all sustainability dimensions (non-significant only for Employees). The correlation between Authentic and Human Rights is comparatively strong (r = .517, p < .01). Original is the only dimension negatively correlated with all sustainability dimensions (always statistically significant). Environmental sustainability appears more compatible with coolness framing than social dimensions, as fewer coolness dimensions are negatively associated with Environment.

We then performed a Pearson Correlation analysis considering only a High-Coolness Subsample (N = 44,911) (i.e. Cool_General ≥ 5). In this case, correlations between Cool_General and sustainability dimensions become even weaker, specifically Human Rights (r = .018, p < .01), Employees (r = .036, p < .01), Social & Community (r = −.050, p < .01), Environment (r = .011, p < .01). This suggests that stronger coolness intensity does not correspond to deeper integration of sustainability discourse. Rather, the association appears to weaken as coolness becomes more dominant. However, the relationship between Authentic and Human Rights strengthens further (r = .61, p < .01), reinforcing the idea that authenticity constitutes a key bridging construct between coolness and normative sustainability claims.

Conversely, Original remains negatively correlated with all sustainability dimensions, confirming its structurally antagonistic role.

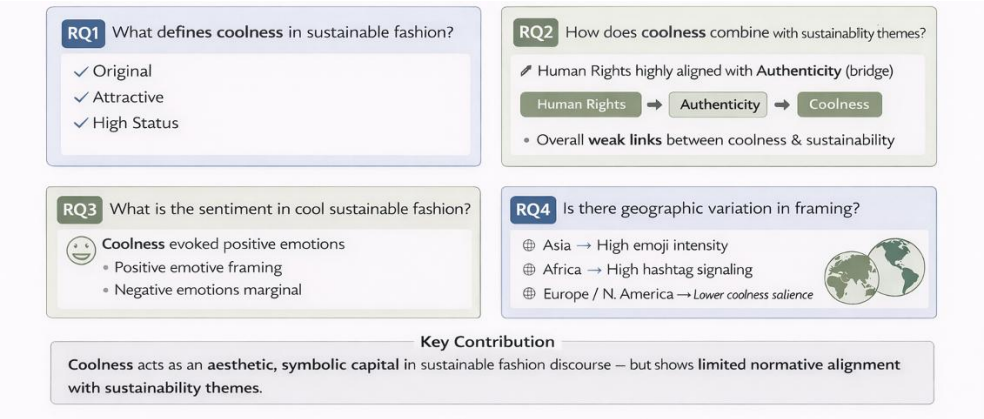
Coolness and Sentiment. *When considering the full sample (N≈ 202,357) Cool_General is more strongly correlated with positive sentiment (r = .139, p < .01) than with negative sentiment (r = .011, p < .01). Across dimensions Attractive shows the strongest positive correlation with positive sentiment (r = .257, p < .01), Iconic and Original show negligible or non-significant associations with positive sentiment, Negative sentiment correlations are generally weak and often non-significant. Overall, coolness framing is associated predominantly with a positive emotional tone. In the high-coolness subsample (N = 44,911) the strongest positive sentiment correlation concerns Attractive (r = .347, , p < .01), while Original and Iconic become negatively correlated with positive sentiment. This indicates that certain forms of coolness, when intensified, may decouple from positive affective framing.*

Geographical Differences in Coolness Framing. *Using a subsample of 146,578 posts with valid localization data, one-way ANOVA tests reveal statistically significant differences across continents for Cool_General (F = 44.705, p < .001), EmojiCool (F = 397.436, p < .001), HashtagsCool (F = 59.895, p < .001). Cool_General Mean levels are highest in Africa (M = 3.73) and Asia (M = 3.63), while Lowest in Europe (M = 3.23) and North America (M = 3.23). Post hoc tests confirm that Asia refers to coolness significantly more than Europe, North America, and Oceania. Africa exhibits consistently high levels, though not always significantly different from Asia. Asia shows substantially higher emoji-based coolness (Emoji_Cool) (M = .46) than all other regions, indicating a stronger reliance on symbolic-affective expression. Coolness hashtags (Hashtags_Cool) are most prevalent in Africa (M = .28) and Europe (M = .21), compared to other regions.*

Overall, results indicate that geographical provenance significantly shapes how coolness is expressed in sustainable fashion discourse, both lexically and symbolically.

Discussion. *This study aimed to investigate whether and how coolness emerges in sustainable fashion discourse in a digital setting, i.e. Instagram, examining the dimensions of coolness, its relationship with sustainability themes, the emerging emotional framing, and their geographical variation. Across the analysis, four core patterns emerged (figure 2). First, coolness is present and emotionally positive, but only weakly integrated with sustainability discourse within the analysed corpus. Second, Authenticity functions as the strongest bridge between coolness and sustainability, particularly in relation to Human Rights. Third, higher coolness intensity weakens sustainability integration, suggesting potential*

trade-off between the two overall concepts. Fourth, geographical differences are substantial, especially in emoji-based expression (Asia) and hashtag signalling (Africa and Europe).



These results indicate that coolness is indeed present in sustainable fashion narratives and has become increasingly salient over time, integrated into the sustainable fashion discourse. However, while used in the general discourse, when coming to discuss specific themes of sustainability, coolness role slightly decreases. This may support the argument that sustainability-oriented brands increasingly rely on coolness to enhance attractiveness and consumer engagement, particularly in visually driven social media environments such as Instagram, but at the same time coolness is less likely to be referred to when addressing directly and explicitly sustainability topics (such as social and ecological issues and challenges).

Coolness in sustainable fashion takes a specific shape. Being Original, Attractive, and High Status the most salient dimensions, coolness seems to be primarily expressed through aesthetic and creative differentiation and symbolic prestige, in contrast with general representations of coolness that also emphasize rebelliousness, subcultural positioning, or nonconformity (Warren et al., 2019). This is quite unexpected results, given the focus of this study, suggesting that coolness in sustainable fashion discourse do not integrate with the countercultural resistance that the sustainability discourse might embed.

Although coolness shows statistically significant correlations with sustainability themes, coefficients are small and, in some cases, negative. In particular, the negative correlation with the Social & Community dimension indicates a potential tension between coolness and community-oriented sustainability narratives. Authenticity, instead, emerged as a crucial bridging dimension. Authentic is the only coolness dimension positively associated with all sustainability themes and shows a particularly strong relationship with Human Rights. This result aligns with previous literature highlighting authenticity relevance in both sustainable consumption (Rovai and Jain, 2025) and perceptions of coolness (Warren et al., 2019; Loureiro et al., 2024), indicating the centrality of perceptions of genuineness and consistency with own values. Originality, instead, is in antithesis with sustainability discourse in fashion, as it is negatively correlated with all sustainability dimensions. When discourse emphasizes novelty, creativity and uniqueness, sustainability themes become extremely marginal.

The sentiment analysis indicates that when coolness is central to discourse there are primarily positive emotional expressions. This confirms the literature defining coolness as positive attribute (e.g., Loureiro and Lopes, 2012; Warren et al., 2019). Nevertheless, in high-coolness contexts some dimensions such as originality and iconicity show weaker or even negative associations with positive sentiment, suggesting that intense references to coolness might introduce more complex emotional dynamics, potentially leading to negative reactions. Finally, coolness is not constructed in the same way across geographical contexts, reinforcing the idea that coolness is culturally embedded and socially constructed (Warren et al., 2019), highlighting the importance of contextualizing coolness within specific cultural contexts and communication practices.

Figure 2. Emerging framework of coolness in sustainable fashion discourse

Research limitations. *The results are part of a first phase of a broader study, which aims to measure the impact of coolness on UGC in the sustainable fashion discourse on Instagram, focusing on the emotional responses to coolness-sustainability content. Before proceeding to this second phase of the research project, we will deepen insights into the collected data by adding a qualitative study aimed to further frame coolness, sustainability and their relationship. Particularly, we want to develop a qualitative content analysis of the text fragments where a negative sentiment has emerged. Although the adopted methodological approach ensures theoretical consistency and replicability, a limitation of the dictionary-based approach is its reduced ability to capture semantic nuance and contextual meaning. Developing qualitative insights in the phase two of this research will allow an integration of the findings with emerging meanings. These analysis focuses solely on post captions, excluding user comments and audience interactions. Including these elements (e.g. comments, likes, shares) in future research would allow a deeper understanding of how coolness and sustainability are co-constructed through engagement.*

Managerial implications. *Although these findings are preliminary, these insights suggest the need to think carefully about the relationship between coolness and sustainability in the sustainable fashion industry. Particularly, sustainable fashion brand managers may be cautious about the potential trade-offs between the two concepts: this implies reflecting on brand communication and how to leverage coolness for brand building. Which dimensions of coolness may be levered to frame sustainable fashion brands and, particularly, in relation to what sustainability dimensions. Even though this research needs further development, these preliminary findings encourage critical thinking about coolness in sustainable fashion, drawing attention to the chance that, in some settings and relatively to specific social groups, coolness may even activate negative sentiment and, generally, consumer response.*

Originality of the paper. *This research aims to frame the concept of coolness in sustainable fashion discourse and reach insights into how coolness and sustainability are intertwined. It proposes an exploration of sustainable fashion discourse on Instagram, understood as the digital context in which coolness is socially constructed. The explorative effort is carried out using an original dataset including brand-generated and user-generated content and a big data analysis.*

Market Segmentation along the Value-Chain and Sustainability Orientation: Evidence from Italian Fashion Firms

AMIR MAGHSSUDIPOUR[1], SILVIA RITA SEDITA AND THOMAS BASSETTI

Abstract. *Sustainability challenges are intrinsically value-chain specific: upstream production stages typically concentrate resource and pollution-intensive processes, while downstream stages are more exposed to consumer scrutiny and reputational pressures. This work examines whether market orientation (B2B versus B2C), used as a proxy for firms' position along the value chain, is associated with different patterns of environmental and social sustainability orientation. We study around 1000 Italian fashion firms by combining firm-level economic and governance data from the AIDA/Orbis database with original unstructured textual information extracted from corporate websites. Firms' sustainability orientation is measured through a lexicon-based Natural Language Processing approach. OLS estimates indicate that B2B firms communicate higher sustainability orientation than B2C firms on both the environmental and social dimension. The environmental sustainability orientation result supports the view that buyer requirements, certification regimes, and compliance incentives push upstream firms to adopt and signal greener practices. The social sustainability orientation result is more unexpected and suggests that social sustainability is increasingly governed through inter-firm relationships (audits, codes of conduct, and due diligence) rather than being driven primarily by consumer-facing reputation.*
Keywords: *value chain; B2B and B2C; sustainability orientation; environmental sustainability; social sustainability; fashion industry, natural language processing*

Framing of the research. Building on industrial marketing and sustainability research, we argue that market segmentation along the value-chain (B2B vs B2C) captures meaningful differences in firms' environmental and social sustainability orientation. B2B firms typically operate upstream or midstream, selling intermediate inputs, components, and manufacturing services to other firms. Their sustainability incentives are embedded in buyer-supplier relationships and in compliance with formal standards and certifications (Hoejmose et al., 2012; Huang et al., 2022). B2C firms are more likely to be downstream and consumer-facing; therefore, they are exposed to consumer activism, media attention, and brand legitimacy concerns (Johnson et al., 2018; Swani et al., 2014).

These differences matter because environmental and social sustainability may be governed through distinct channels. Environmental sustainability in supply chains is often monitored and incentivized via product specifications, certifications, and auditing routines (Sharma et al., 2010). Buyer pressure can be particularly effective when downstream actors internalize reputational risk and extend requirements upstream (Delmas & Montiel, 2009). In B2B contexts, sustainable brand positioning and the ability to meet clients' environmental expectations may directly shape relationship outcomes (Casidy & Lie, 2023) and create stakeholder value in climate-risk management (Khan et al., 2023).

Social sustainability, conversely, is often portrayed as more salient in consumer markets, where firms can leverage ethical sourcing, labor standards, and community engagement as differentiation signals. Consumer willingness to pay for ethical attributes and charity-linked products provides incentives for downstream communication (Elfenbein & McManus, 2010; Kimeldorf et al., 2006).

Overall, the literature lacks firm-level, comparative evidence on how sustainability orientation differs between B2B and B2C firms, and especially on how these differences play out across environmental versus social dimensions. This study addresses this gap with an empirical focus on Italian fashion firms, a context where both upstream production and downstream branding are prominent (Paulicelli, 2014; Tokatli, 2013).

Within this landscape, firms increasingly treat sustainability not only as operational change but also as strategic orientation: a set of priorities that shapes decisions, investments, partner selection, and communication. Communication is particularly relevant because sustainability claims affect reputation, consumer trust, and business relationships, yet standardized sustainability reporting remains uneven across firms, especially among SMEs (Dienes et al., 2016). This creates a measurement challenge: in many settings, the absence of structured disclosure prevents researchers from comparing sustainability commitments across firms and along value chains.

A related issue is that the availability of sustainability information is itself endogenous. Firms decide whether to publish a formal sustainability report, which topics to cover, and how to frame trade-offs. Systematic reviews of sustainability reporting identify multiple drivers - such as regulation, stakeholder pressure, and managerial attitudes - but also point to strong heterogeneity across sectors and firm sizes (Dienes et al., 2016; Lee, 2011; Roxas & Coetzer, 2012). Specifically, in industries populated by SMEs, reliance on formal reports would exclude large parts of the population and would over-represent highly visible firms. Website-based measures therefore complement reporting-based approaches by capturing sustainability narratives even when no report exists, albeit with the caveat that narratives may be selective.

A promising way to capture such commitments is to observe how firms publicly describe sustainability on their corporate websites. Websites represent a pervasive, low-cost channel used by both large and small firms to signal priorities to

[1] Dept. of Economics and Management, University of Padua, Padua, Italy

stakeholders, including customers, buyers, regulators, and employees. Text mining approaches have thus become an increasingly useful way to quantify otherwise hard-to-observe constructs such as sustainability orientation (e.g., Blasi et al., 2020). Website content is not a perfect proxy for performance, but it provides systematic evidence about what firms choose to emphasize and how they frame sustainability to external audiences.
Beyond differences in stakeholder exposure, B2B and B2C firms also differ in the channels and styles through which they communicate sustainability. Studies comparing communication in business versus consumer markets show systematic differences in the use of emotional versus functional appeals and in the content that firms post on social media (Swani et al., 2014; Swani et al., 2017). If such differences extend to corporate websites, then sustainability orientation should be understood as a strategically constructed signal tailored to the audience, rather than as a neutral reflection of underlying practices. This further motivates a measurement approach that can capture sustainability language at scale, while still allowing for careful interpretation of what "orientation" means in different markets.

Purpose of the paper. This work investigates how firms' position along the fashion value chain - operationalized through market orientation (B2B versus B2C) - relates to their sustainability orientation. The core objective is to understand whether upstream-oriented firms (B2B) and downstream-oriented firms (B2C) systematically differ in the emphasis they place on environmental and social sustainability when communicating to external stakeholders.
From a conceptual standpoint, we build on three complementary perspectives. First, institutional theory suggests that sustainability strategies respond to regulatory pressures, normative expectations, and stakeholder demands (Lee, 2011; Roxas & Coetzer, 2012). Second, market-based and relationship-based views highlight that sustainability can be a source of differentiation and relational value, particularly in buyer-seller relationships (Mariadoss et al., 2011; Talay et al., 2025). Third, a resource-based view emphasizes that sustainability orientation depends on capabilities, managerial attention, and the ability to mobilize resources for change (Tate & Bals, 2018).
These perspectives converge on the idea that B2B and B2C firms face different sustainability incentives. In B2B markets, sustainability is intertwined with procurement routines, certifications, and the need to comply with business clients' requirements. Sustainability-oriented collaborations can enhance trust and strategic alignment, supporting long-term relationships (Hoejmose et al., 2012; Sharma et al., 2010). Environmental considerations are particularly salient when clients seek to manage their own footprints and reputational risks by extending environmental standards upstream (Delmas & Montiel, 2009; Huang et al., 2022). Therefore, we expect B2B firms to communicate stronger environmental sustainability orientation than B2C firms.
Environmental sustainability is particularly likely to be shaped by industrial-market governance. Upstream firms often face requirements related to materials, chemical safety, traceability, and emissions. Compliance is monitored through audits and certifications, and environmental improvements can become a prerequisite for market access in buyer-driven chains. Because B2B firms depend on repeated transactions and reputation within professional networks, they may invest in environmental sustainability language as part of relational positioning (Casidy & Lie, 2023; Khan et al., 2023).
H1: The environmental sustainability orientation of B2B firms is higher than that of B2C firms.
In B2C markets, firms compete for end-consumers and are exposed to public scrutiny. Social sustainability messages - such as fair labor, inclusion, and community engagement - may be more effective as emotional and identity-based appeals in consumer branding (Swani et al., 2014; Iankova et al., 2019). Consumer willingness to reward ethical attributes can create incentives for downstream firms to emphasize social sustainability (Elfenbein & McManus, 2010; Kimeldorf et al., 2006). Consequently, a common expectation is that B2C firms would communicate stronger social sustainability orientation than B2B firms.
Social sustainability is often assumed to be more visible and thus more relevant for consumer-facing firms, because labor practices and community impacts are salient issues in public debates. Consumer sensitivity to ethical attributes can trigger reputational risks for brands and retailers, and can incentivize downstream firms to highlight social commitments in their marketing and corporate communication (Elfenbein & McManus, 2010; Kimeldorf et al., 2006).
H2: The social sustainability orientation of B2C firms is higher than that of B2B firms.
Beyond hypothesis testing, we also examine how firm characteristics related to size, financial structure, location, and governance are associated with sustainability orientation. This allows us to interpret whether differences across market orientation persist after accounting for firm resources and managerial capacity.

Methodology. We focus on Italian firms operating in the fashion sector, a context characterized by a dense ecosystem of upstream manufacturers and downstream brands competing in international markets (Paulicelli, 2014; Tokatli, 2013). The empirical sample includes 1,069 firms identified in the AIDA/Orbis Bureau van Dijk database. For each firm, we retrieved economic, geographical, and organizational indicators from AIDA/Orbis and linked them to the firm's corporate website. We capture sustainability orientation using a lexicon-based Natural Language Processing approach. The procedure follows three steps. First, we collected publicly available textual content from corporate websites (e.g., "about", "sustainability", "CSR", production and sourcing pages) and cleaned the corpus by removing HTML, boilerplate content, and stop words. Second, we built two sustainability lexicons - one environmental and one social - based on prior text mining research and qualitative refinement (Blasi et al., 2020). Both lexicons were originally constructed in Italian, reflecting the language of the corporate websites analysed. The environmental lexicon includes terms related to emissions, circular economy, sustainable materials, traceability, and environmental management (e.g., "carbon footprint", "recycled", "circular economy", "traceability"). The social lexicon includes terms related to labor standards, employee

wellbeing, diversity and inclusion, community engagement, and responsible sourcing (e.g., "fair wages", "working conditions", "community", "inclusion"). Third, for each firm we computed term frequency–inverse document frequency (TF-IDF) weights for lexicon terms and aggregated them to obtain two firm-level indices: environmental sustainability orientation and social sustainability orientation. Both indices are standardized (z-scores) to facilitate comparisons across models.

Operationally, TF-IDF assigns higher weight to terms that are frequent in a given firm's website but relatively rare across the full corpus. For each firm *i* and term *t* in the sustainability lexicon, we compute TF-IDF(*t,i*) = TF(*t,i*) * log(N/DF(*t*)), where TF is the term frequency in the firm-level corpus, DF is the number of firms whose websites contain the term, and N is the total number of firms. We then aggregate TF-IDF weights across all terms in the environmental lexicon to obtain the environmental index, and analogously for the social lexicon. This approach reduces the influence of generic words that appear across most websites and emphasizes distinctive sustainability language.

To assess face validity, we manually inspected a stratified subset of websites at different points of the score distribution and confirmed that high-scoring firms provide richer sustainability content (e.g., dedicated sustainability pages, detailed descriptions of materials and sourcing policies), while low-scoring firms provide little or no sustainability discussion. We also checked that the environmental and social indices are correlated but distinct, consistent with the idea that the two dimensions capture different sustainability emphases.

The key explanatory variable is a dummy identifying whether a firm primarily operates in B2B markets (B2B = 1) or in consumer markets (B2B = 0, i.e., B2C). Classification was conducted by combining structured information (business descriptions and activity fields) with website evidence regarding target customers and go-to-market channels. This operationalization captures whether the firm's core transactions occur mainly with other firms (intermediate markets) or with final consumers (consumer markets).

To isolate the association between market orientation and sustainability orientation, we include a set of controls which include Employees (firm size), Total Assets, Solvency Ratio, Share Capital, number of Executives and Managers, number of Advisors, number of Group Companies and Industrial Agglomeration (belonging to an industrial district). Continuous variables are standardized to make coefficient magnitudes comparable.

For the analysis, we estimate two linear regression models (OLS) with robust standard errors: one for environmental sustainability orientation and one for social sustainability orientation.

Results. Table 1 presents the descriptive statistics of the variables included in the analysis. It is worth noting that approximately 70% of firms are classified as B2B-oriented.

The two sustainability orientation indices are standardized around zero and display substantial dispersion, suggesting meaningful heterogeneity in how firms communicate sustainability on their websites.

Table 2 reports the OLS estimates linking firms' market positioning along the value-chain to environmental and social sustainability orientation. Consistent with H1, B2B firms exhibit significantly higher environmental sustainability orientation than B2C firms. Because the outcome is standardized, this corresponds to a difference of about 0.4 standard deviations between B2B and B2C firms, conditional on the set of controls.

Contrary to H2, B2B firms also exhibit significantly higher social sustainability orientation than B2C firms. This result suggests that social sustainability communication is not limited to consumer-facing firms. Instead, upstream-oriented firms appear to actively signal social practices and commitments, potentially reflecting the diffusion of social compliance requirements through buyer-supplier relationships and supply-chain governance.

Regarding controls, managerial capacity is consistently associated with stronger sustainability orientation in both dimensions: the coefficient on Managers is positive and statistically significant in both models. This pattern aligns with capability-based arguments that emphasize the role of managerial attention and internal governance in structuring sustainability priorities (Tate & Bals, 2018). For environmental orientation, the coefficient on Employees is negative and

significant, suggesting that larger workforces may face coordination challenges or may communicate environmental sustainability less intensively, once other financial controls are accounted for. In the social sustainability model, Total Assets and Group Companies are positively associated with social sustainability orientation, indicating that resource availability and group affiliation may facilitate the adoption or communication of social initiatives.

One plausible mechanism behind the stronger-than-expected social sustainability orientation among B2B firms is the increasing formalization of social compliance in supply chains. In buyer-driven chains, lead firms can shift monitoring costs upstream and require suppliers to document labor standards, training, and community-related initiatives. For suppliers, communicating such initiatives can signal reliability and reduce perceived risk in asymmetric buyer-seller relationships, thereby improving relationship satisfaction and stability (Talay et al., 2025). This interpretation also aligns with comparative evidence that stakeholder engagement practices differ between B2B and B2C firms (Johnson et al., 2018), suggesting that social sustainability in industrial markets may be less about mass persuasion and more about meeting the information needs of professional buyers and auditors.

The environmental sustainability result is consistent with the idea that B2B firms are embedded in governance structures where sustainability is codified via standards, certifications, and procurement requirements (Hoejmose et al., 2012; Huang et al., 2022). In these contexts, sustainability orientation supports relationship outcomes and competitive positioning (Casidy & Lie, 2023). The social sustainability result invites a reinterpretation of social sustainability along the value chain: rather than being predominantly consumer-driven, social sustainability communication may be increasingly shaped by private standards and due diligence practices that directly target suppliers. This interpretation is coherent with the growing role of upstream compliance and the relational nature of sustainability in industrial markets (Sharma et al., 2010; Talay et al., 2025).

Research limitations. First, our dependent variables capture sustainability orientation as communicated on websites, not necessarily sustainability performance. Website texts may reflect symbolic communication or greenwashing, even though they still provide valuable evidence on what firms choose to emphasize to stakeholders. Second, the B2B/B2C distinction is a simplified proxy for value-chain position. Many firms operate hybrid business models (mixed B2B and B2C channels), and classification necessarily captures the dominant market orientation rather than the full complexity of multi-channel strategies. Third, the analysis is cross-sectional, which limits causal interpretation. It is plausible that unobserved characteristics (e.g., leadership values, ownership structure, or client portfolio composition) influence both market segmentation along the value-chain and sustainability orientation. Fourth, the empirical setting is specific (Italian fashion

firms). Extending the approach to other countries and industries would help assess the generalizability of value-chain patterns in sustainability orientation. A further limitation is that corporate websites represent only one of the channels through which firms communicate sustainability. Future research could integrate multi-channel evidence to obtain a more comprehensive picture of how sustainability communication differs along the value chain.

Managerial implications. For managers in upstream and midstream (B2B) segments, the results underline that sustainability orientation is increasingly a competitive asset in inter-firm relationships. Investments in traceability, certifications, and credible social compliance programs can strengthen buyer trust and support long-term contracts. Importantly, communication should be aligned with verifiable practices to reduce greenwashing risks and to meet evolving due diligence requirements.
For managers in downstream (B2C) segments, the evidence suggests a potential communication gap, especially on social sustainability. Consumer-facing firms may need to move beyond generic claims and invest in transparent, comparable disclosures about labor standards, sourcing, and community impacts. Differentiation through sustainability requires credibility; therefore, downstream actors may benefit from third-party verification and stronger integration of supplier monitoring into brand narratives).
More broadly, the text-mining approach provides a practical benchmarking tool. Firms, industry associations, and policymakers can use similar analytics to monitor the evolution of sustainability narratives across value-chain positions, identify lagging areas (environmental versus social), and design targeted support initiatives.

Originality of the paper. The paper offers three main contributions. First, it provides firm-level evidence on how market segmentation along the value-chain (B2B versus B2C) - a proxy for value-chain position - correlates with sustainability orientation. Second, it distinguishes between firms' environmental and social sustainability orientation, showing that value-chain patterns differ across sustainability dimensions and that upstream firms may play a larger role in social sustainability signaling than commonly assumed. Third, it advances methodology by integrating structured firm data with unstructured website texts and by operationalizing sustainability orientation through a scalable lexicon-based TF-IDF approach, which is especially valuable for contexts where formal sustainability reporting is limited.

Promoting the energy transition: The influence of social norms on citizens' willingness to promote energy communities

ALICE ALOSI[1], GIULIA CASAMENTO[1], ELEONORA ANNUNZIATA[1], MARCO FREY[1]

Abstract. *To decarbonize the energy sector, there is a widespread consensus that the role of end-users in the energy system should change from passive consumption to active prosumption and engagement. This is of particular importance as an increasing number of technologies and business models focus on end users. These developments provide new opportunities for further technical and social innovation toward smarter, flexible, and integrated systems, such as Renewable Energy communities (RECs). Despite the high relevance, one of the critical challenges remains ensuring engagement and active citizen participation. The citizens' willingness to promote RECs is rather low compared to their willingness to participate, and there is limited knowledge on the citizens' willingness to promote, as well as the associated factors determining such willingness. Through a randomized survey-based experiment composed of three scenarios among citizens in Italy, this research investigates whether mimetic social norms (i.e., neighbourhood and authority figures) play a role in shaping individuals' willingness to promote RECs. The study is currently in the data collection phase.*

Keywords: *Social norms, energy communities, willingness to promote, citizens, experiment*

Framing of the research.

Energy Communities Business Models and citizens involvement. *Governance is the set of rules that the REC and all its stakeholders must follow, and the Energy Communities Business Model (ECBM), defined before the REC's implementation, embraces most of these rules (Moreno et al., 2022). How their members deploy the REC, how they interact with each other, and the decision-making power each has within the REC are highly dependent on the ECBMs adopted (Moreno et al., 2022; Reis et al., 2021). Reis et al. (2021) conducted a comprehensive review of the European literature on emerging ECBMs, identifying eight distinct archetypes. These include: collective self-consumption initiatives (European Commission, 2018; European Parliament, 2019) (i.e., Community collective generation), ECBMs dedicated mostly to SMEs (i.e., Community flexibility aggregation and Energy cooperatives), vehicle-to-grid and grid-to-vehicle solutions (i.e., E-mobility cooperatives), and four other ECBMs (i.e., Community prosumerism, Local energy markets, Third-party-sponsored communities, Community ESCO). In addition to categorising these models by function, Reis et al. (2021) classified them by investment and asset ownership structures, distinguishing between "customer-side" and "third-party-side" business models. However, this perspective may be overly narrow, particularly given the evolving role of citizens as central actors in RECs (Wahlund & Palm, 2022). Citizens are not only potential investors or consumers but can also play a key role in promoting, co-designing, implementing, and operating RECs—activities that significantly shape how value is created, addressed and distributed within the ECBM (Teece, 2010; Euchner & Ganguly, 2014).*

Despite this potential, evidence suggests that citizens' active involvement in governance remains limited. A study by Lennon et al. (2019) across five European countries found that most REC participants did not perceive themselves as having meaningful agency in decisions related to energy use, beyond their role as consumers. Similarly, Koirala et al. (2018) observed that while citizens are generally willing to participate in RECs, their willingness to promote and take initiative—what the authors refer to as "steering" local energy—is considerably lower. This gap highlights the need for further research into the factors that can positively influence citizen leadership and engagement in RECs.

Factors shaping citizens' acceptance and engagement in RECs. *Previous literature has largely focused on identifying the factors and dynamics that facilitate the implementation of RECs (Lode et al., 2022). For instance, the scarcity of clean energy in the local energy mix and the distance to central grid infrastructure were identified as driving factors for the development of local grids (Chan et al., 2017; Reis et al., 2021). In North-Western Europe, European countries are pioneers, and their long-standing tradition of renewable-based community projects (i.e., hydro, biomass, solar photovoltaic, and wind technologies) is driven by the need to address supply issues in rural and isolated areas (Huybrechts and Mertens, 2014; Bauwens et al., 2016). However, in contexts where energy supply is not a critical concern, citizens' acceptance becomes a prerequisite for fostering active motivation to join RECs (Lode et al., 2022), and engagement, defined in terms of the volume of financial investment made and the degree of participation in the governance of organisations (Bauwens et al., 2016). To address barriers related to citizens' acceptance (Doci et al., 2015), prior studies have highlighted the importance of enabling actors (e.g., utilities andmunicipalities) and the availability of accessible financial participation mechanisms as key facilitators of citizen mobilisation (Maleki-Dizaji et al., 2020; Sperling, 2017; Heaslip et al., 2016).*

In parallel, individual and community-level factors—such as cultural traditions, historical experiences, and psychological dimensions (e.g., social norms, values, cognitive traits and trust)—also play a crucial role in shaping willingness to participate and in building acceptance of RECs (Lode et al., 2022; Koirala et al., 2018; Doci et al., 2015).

[1] Institute of Management, Sant'Anna School of Advanced Studies (Pisa)

For instance, Bauwens et al. (2016) empirically examined the heterogeneity among members of community renewable energy projects, focusing on differences in motivations and levels of engagement. The study found that these motivational differences are reflected in the depth of involvement: norm-driven individuals tend to invest more financially and participate more actively in governance. Moreover, Bauwens et al. (2016) observed that self-interested motivations (e.g., financial incentives) and normative motivations (e.g., community identity and trust) appear to be somewhat mutually exclusive. Individuals driven by material incentives often show weaker identification with the community and a lower orientation toward environmental values.

The role of mimetic social norms in RECs engagement. *Personal choices are often influenced by others, and the role of mimetic social norms—such as those shaped by people we care about, neighbours, or authority figures— has gained increasing attention in the literature on renewable energy investments (Fischer et al., 2021). For instance, Mignon and Bergek (2016) found that some individuals choose to invest in renewable electricity production to align with peer behaviour and gain social acceptance or recognition. Similarly, other studies have highlighted how social interactions and peer effects can significantly influence the decision to adopt photovoltaic systems (Bollinger & Gillingham, 2012; McEachern & Hanson, 2008; Noll et al., 2014; Curtius et al., 2018).*

In the context of RECs, the activation of mimetic social norms has emerged as a promising mechanism for stimulating both engagement and investment decisions (Bauwens et al., 2016; Guetlein and Schleich, 2023). Mimetic social norms have been identified as the most influential factor in driving willingness to participate in community energy projects, surpassing even trust and environmental concern (Kalkbrenner and Roosen, 2016; Fischer et al., 2021). Guetlein and Schleich (2023) further confirmed the relevance of mimetic social norms, alongside place identity and trust, in shaping investment decisions regarding RECs. In addition, Conradie et al. (2021) applied the Theory of Planned Behaviour (TPB) to examine intentions to join a REC, finding that attitudes and subjective norms were the strongest predictors of such intentions. This underscores the importance of perceptions like "My friends would approve of participating in a local REC," suggesting that the opinions of family, friends, and neighbours are key levers for increasing REC adoption. However, previous studies have tended to treat "influencing actors" as a single, undifferentiated group, without isolating the specific effects of different referents. For example, while Kalkbrenner and Roosen (2016) focused specifically on peers such as neighbours or local community members, other studies (e.g., Fischer et al., 2021; Guetlein & Schleich, 2023; Conradie et al., 2021) considered the broader influence of social norms without distinguishing between referent categories like family, friends, or neighbours.

Mimetic social norms are shaped by factors such as personal proximity and the specific domain in question. People are generally more influenced by those who are physically or emotionally close to them, such as family, friends, and neighbours (Melnyk et al., 2019). The degree of influence also varies depending on the context. In the case of energy consumption, neighbours are often the strongest predictors of behavioural change, given their visibility in everyday life and the relevance of localised norms (Nolan et al., 2008; Griskevicius et al., 2012). At the same time, individuals also tend to emulate authority figures, especially when these figures are seen as knowledgeable or credible (Van Vugt et al. 2008). As such, government representatives, experts, or institutional actors can shape behaviour through formal or informal authority (Cialdini, 2001; Van Kleef et al., 2019). Both neighbourhood referents and authority figures could therefore play a critical role in shaping individual decision-making, particularly in collective action contexts (Griskevicius et al., 2012), such as REC engagement.

Purpose of the paper. *The global transition to a more sustainable and resilient energy system has been at the forefront of policy and scholarly discussions in recent years, particularly considering the ongoing energy crises and climate change concerns (IEA, 2023; Tomczyk & Łapniewska, 2025). Central to this transition is the decentralization of energy production and decision-making, a shift that seeks to reduce reliance on conventional, centralized energy companies by empowering consumers and local communities (Wahlund & Palm, 2022). In this context, RECs have emerged as a promising tool for fostering such decentralization, enabling citizens, small and medium enterprises (SMEs), and public authorities to take an active role in the generation, consumption, and management of energy. Therefore, RECs are not only seen as key players in the decarbonization of the energy system but also as sources of social, environmental, and economic benefits for their members (Lode et al., 2022; Moreno et al., 2022).*

Despite their potential, RECs face a critical challenge: ensuring meaningful and sustained citizen engagement (Lode et al., 2022). While willingness to participate in REC initiatives tends to be relatively high, willingness to take on more proactive roles—such as initiating or driving the development of a REC—remains significantly lower (Doci et al., 2015; Koirala et al., 2018). As highlighted by Koirala et al. (2018), citizens' willingness to steer local energy—that is, their readiness to take initiative as promoters and engage as active participants rather than passive consumers—is often limited. In this study, we focus on the concept of "promote" as an initial yet crucial form of proactive engagement in RECs. We define "promoting" as the act of publicly supporting and endorsing the idea of a REC, acting as a testimonial or informal ambassador. This includes mobilizing others, raising awareness, and encouraging participation—behaviors that often precede and potentially lead to deeper involvement in planning or governance activities. Understanding what drives this promotional role is key to unlocking the full transformative potential of RECs (Koirala et al., 2018). This study builds on the ECBM (Reis et al., 2021) as developed in the Italian context, where successful implementation could hinge on having motivated local promoters.

Through an experimental design, we examine how descriptive mimetic social norms—that is, individuals' perceptions of what others (e.g., peers, family or authority figures) typically do (Cialdini et al., 1990; Goldstein, Cialdini, &

Griskevicius, 2008)—shape their willingness to promote RECs. These norms reflect the influence of observed or assumed behaviors within one's social environment, suggesting that individuals may be more likely to promote RECs when they believe that others around them are doing the same. Prior literature has demonstrated the importance of mimetic social norms in fostering participation (Kalkbrenner & Roosen, 2016; Fischer et al., 2021; Guetlein & Schleich, 2023), to the best of our knowledge, no studies have disentangled the distinct influence of specific social referents in shaping individuals' willingness to promote RECs. Because the strength of social influence often depends on both personal proximity (e.g., close versus distant relationships) (Melnyk et al., 2019) and issue relevance (e.g., energy behaviors) (Griskevicius et al., 2012), this study focuses specifically on two influential referent groups: neighborhood peers and authority figures. We investigate not only whether these social norms affect individuals' willingness to promote RECs, but also which group exerts a greater influence.

With this aim, the study addresses the following research questions:

- *Do mimetic social norms (i.e., neighborhood and authority figures) influence individuals' willingness to promote RECs?*
- *Which of the two social referents—neighborhood peers or authority figures—has a stronger influence?*

Methodology. *We use a randomized survey-based experiment composed of three scenarios (hereafter referred to as scenarios 0, 1, and 2). This experiment is administered online by a commercial survey service provider. The reference target of the surveys is the Italian population aged 25 and over. We chose to focus on an Italian sample for two main reasons, in addition to the limited scientific literature available on the topic. Firstly, Italian legislation concerning RECs is relatively recent and still evolving (Italian Legislative Decree No. 199/2021, 2021), making the country a relevant case study where regulatory innovation actively shapes the development of RECs. Secondly, the adoption of RECs in Italy is not yet widespread, offering significant potential for growth and further development.*

The commercial agreement with the professional provider ensured that, for each survey, we would receive representative samples of the target population in terms of gender, age, and geographic area. A total of 2000 individuals will take part in the study. Each scenario is delivered through a short video (van Zelderen et al. 2024) composed of a common section, identical in all cases, and a distinct part—the stimulus—specific to each video. Scenario 0 represents the baseline case, with no stimulus applied. Scenario 1 and scenario 2 show respectively the neighborhood and authority figures' willingness to promote choices as a descriptive norm message (Goldstein et al., 2008). The respondents will be randomly assigned to one of the three scenarios and will be asked to complete a survey. Both the short scenario videos and the questions of the survey are presented in Italian to ensure clarity and accessibility for the Italian-speaking respondent pool. To measure our constructs, the study uses scales adapted from the literature, revised to better fit our aims. The samples' demographics and the control variables (i.e., neighborhood involvement; energy identity and motivation to lead) are in line with previous literature analyzing willingness to engage/participate/steer in RECs (e.g., Conradie et al. 2021; Koirala et al., 2018; Kalkbrenner and Roosen 2016).

The dependent variable, willingness to promote, is first measured as a behavior by asking respondents to leave a comment. Subsequently, we assess their intention, focusing on their level of interest in becoming promoters, drawing on the scales of Koirala et al. (2018) and Hoti et al. (2021). Respondents were required to select a single option from five mutually exclusive response categories. These categories were then aggregated into three dependent variables: non-participation (category 1), tokenism (categories 2 and 3), and citizen power (categories 4 and 5). For this second response phase, to ensure the quality of responses, we also consider participants' interest in joining a REC, using it as a benchmark for comparison with their willingness to promote it.

Results. *The study is currently in the data collection phase. Building on prior literature on social norms and pro-environmental behavior, we expect descriptive mimetic social norms to positively influence individuals' willingness to promote RECs. In particular, we anticipate that exposure to normative messages indicating that others are promoting RECs will increase respondents' willingness to act as promoters compared to the baseline scenario with no normative stimulus.*

Furthermore, we expect differences in the strength of influence depending on the type of social referent. On the one hand, neighborhood peers may exert a stronger influence due to their social proximity and everyday interaction, which can enhance identification and imitation dynamics. On the other hand, authority figures may also play a significant role, as they are often perceived as credible sources of information and guidance on complex issues such as energy transitions. The experiment will allow us to disentangle the relative effect of these two referent groups.

More broadly, the study is expected to contribute to the literature on citizen engagement in RECs by shedding light on the early-stage behavioral mechanisms that can stimulate proactive involvement, particularly in the form of promotion and advocacy. Understanding these dynamics is particularly relevant in contexts such as Italy, where the development of RECs is still emerging and relies strongly on local initiatives and social mobilization.

Research limitations. *This study presents several limitations that should be acknowledged. First, the research relies on a survey-based experimental design that measures individuals' willingness to promote RECs rather than observing actual behavior in real-world contexts. While experimental approaches allow for greater control over causal mechanisms and enable the identification of the effects of specific stimuli, responses collected in survey settings may not fully translate*

into real-life actions. As a result, the findings should be interpreted primarily as evidence of behavioral intentions rather than confirmed behavioral outcomes.

Second, the study focuses on descriptive mimetic social norms conveyed through short video scenarios. Although this design allows us to isolate the impact of different social referents, it inevitably simplifies the complexity of real-world social interactions and communication dynamics. In practice, individuals are exposed to multiple, sometimes conflicting, social signals from various sources, including the media, institutions, and personal networks. Future research could therefore explore more complex or combined normative messages, as well as the interaction between descriptive norms and other behavioral drivers such as perceived benefits, trust, or social identity.

Another limitation concerns the geographic scope of the study. The research focuses exclusively on an Italian sample, selected because of the relatively recent introduction of the regulatory framework for RECs and the still-emerging stage of their diffusion in the country. While this context offers a relevant case for analyzing early-stage engagement dynamics, the results may not be fully generalizable to countries where RECs are more established or where institutional and cultural conditions differ significantly.

Managerial implications. *The findings of this study are expected to generate several practical implications for policymakers, local authorities, and organizations involved in the development and promotion of RECs. One key implication concerns the role of communication strategies in fostering citizen engagement in REC initiatives. If descriptive mimetic social norms are shown to positively influence individuals' willingness to promote RECs, communication campaigns could benefit from highlighting examples of community members who actively support or endorse these initiatives. Presenting RECs as socially supported and locally endorsed initiatives may help reduce uncertainty and encourage broader participation.*

In particular, understanding which social referent exerts a stronger influence—whether neighborhood peers or authority figures—could help practitioners design more targeted engagement strategies. If neighborhood-based norms prove to be particularly influential, initiatives aimed at fostering local networks and peer-to-peer communication could be especially effective. For example, community meetings, neighborhood ambassadors, or local testimonials may help strengthen the perception that RECs are supported by people within one's immediate social environment.

Conversely, if authority figures play a more significant role, institutional endorsement from local governments, energy agencies, or recognized experts could be leveraged to legitimize and promote EC initiatives. Public statements, informational campaigns, and visible support from trusted institutions may help increase confidence and credibility, particularly among citizens who are less familiar with RECs.

More broadly, the results may help practitioners recognize the importance of citizens not only as participants or investors in RECs but also as informal promoters or ambassadors capable of mobilizing others. Encouraging this promotional role could be a valuable strategy for increasing awareness, strengthening community support, and accelerating the diffusion of RECs, particularly in contexts where these initiatives are still in the early stages of development.

Originality of the paper. *This paper contributes to the literature on RECs and citizen engagement by addressing an underexplored dimension of participation: the willingness to promote REC initiatives. While previous studies have primarily focused on individuals' willingness to join, invest in, or actively manage RECs, far less attention has been devoted to the role of citizens as promoters or advocates of these initiatives. By conceptualizing promotion as a form of proactive engagement that involves publicly supporting and encouraging participation in RECs, this study highlights an important behavioral mechanism that may precede and facilitate deeper forms of involvement.*

Another element of originality lies in the focus on descriptive mimetic social norms and their influence on individuals' willingness to promote RECs. Although the literature has extensively documented the role of social norms in shaping pro-environmental behaviors, limited research has examined how these norms influence engagement in community-based energy initiatives. Moreover, the study goes a step further by disentangling the influence of different social referents, comparing the effects of neighborhood peers and authority figures within an experimental framework.

By doing so, the research contributes to a more nuanced understanding of how different sources of social influence shape behavioral intentions related to the energy transition. The experimental design allows for the identification of causal relationships and offers empirical evidence on the relative strength of different normative signals.

Finally, the study provides new empirical insights in the Italian context, where the regulatory framework for RECs is relatively recent and their diffusion remains limited. Investigating the social mechanisms that may stimulate early engagement is therefore particularly relevant for understanding how RECs can develop and scale in emerging policy environments.

Stakeholder engagement, sostenibilità e co-creazione di valore nelle PMI: una revisione sistematica bibliometrica della letteratura

VINCENZO DELL'ANNO, MARTINA PERCUOCO, IRENE RICCIARDI, MAURO SCIARELLI

Abstract. *Le piccole e medie imprese (PMI) svolgono un ruolo cruciale nei sistemi economici globali, ma continuano ad affrontare difficoltà significative nell'implementazione di pratiche di sostenibilità e nel coinvolgimento efficace degli stakeholder. Sebbene il coinvolgimento degli stakeholder sia ampiamente studiato nel contesto delle grandi imprese, il suo ruolo nelle PMI rimane ancora poco esplorato e concettualmente frammentato. Per colmare questa lacuna, lo studio presenta una revisione bibliometrica sistematica di 195 articoli pubblicati tra il 2015 e il 2025 e indicizzati in Web of Science e Scopus, seguendo il protocollo PRISMA. I risultati mostrano un'evoluzione della produzione scientifica articolata in tre fasi, con una crescita particolarmente marcata negli ultimi anni. La ricerca risulta concentrata in pochi paesi europei ed è caratterizzata da una collaborazione internazionale ancora limitata. Inoltre, il campo è guidato da un principale canale di pubblicazione, mentre la comunità scientifica appare frammentata e priva di un nucleo stabile di autori dominanti. Le evidenze preliminari mostrano che il coinvolgimento degli stakeholder è sempre più interpretato come una leva strategica per promuovere la sostenibilità, integrare i criteri ESG e rafforzare il vantaggio competitivo. Tuttavia, la letteratura rimane prevalentemente descrittiva e mancano modelli teorici chiari che spieghino come i meccanismi di coinvolgimento possano attivare processi di co-creazione di valore. Alla luce di queste lacune, lo studio propone un programma di ricerca volto a sviluppare quadri teorici più integrati che colleghino il coinvolgimento degli stakeholder, la co-creazione e l'innovazione dei modelli di business sostenibili nelle PMI, offrendo anche indicazioni utili per manager e policy maker.*
Parole chiave: *stakeholder engagement; value co-creation; SMEs; sustainability; bibliometric analysis; ESG*

1. Inquadramento della ricerca. Le piccole e medie imprese (PMI) sono una componente fondamentale dei sistemi economici globali e contribuiscono in modo significativo all'innovazione, alla creazione di posti di lavoro e allo sviluppo socioeconomico (Fatoki, 2021; Muriithi, 2017). A livello globale, le PMI rappresentano circa il 90% di tutte le imprese e sono riconosciute come motori chiave della crescita economica sostenibile sia nelle economie avanzate che in quelle emergenti (Ligorio et al., 2025). Tuttavia, nonostante la loro importanza economica, le PMI continuano ad affrontare notevoli vincoli operativi, in particolare nell'attuazione di pratiche commerciali sostenibili e nel coinvolgimento efficace dei loro stakeholder (Chinaire, 2021). Questi vincoli sono in gran parte attribuibili alle risorse finanziarie limitate, al sostegno istituzionale inadeguato e alle più ampie pressioni strutturali all'interno del contesto operativo (Muriithi, 2017). Il coinvolgimento degli stakeholder, definito come "collaborazione basata sulla fiducia tra individui e/o istituzioni sociali con obiettivi diversi che possono essere raggiunti solo insieme" (Andriof & Waddock, 2017), è emerso come un meccanismo chiave attraverso il quale le PMI possono integrare la sostenibilità nelle loro attività, rafforzare la legittimità e promuovere l'innovazione. La letteratura mostra che il coinvolgimento degli stakeholder consente di identificare questioni di sostenibilità materialmente rilevanti, promuove la sensibilità organizzativa alle dimensioni ambientali, sociali e di governance (ESG) ed è uno strumento utile per sostenere la legittimità che le organizzazioni cercano quando comunicano le loro attività all'esterno (Campra et al., 2020). Tuttavia, sebbene il coinvolgimento degli stakeholder sia stato ampiamente studiato nelle grandi aziende, la sua applicazione nelle PMI rimane in gran parte inesplorata (Ligorio et al., 2025). Tuttavia, nonostante la loro importanza economica, le PMI continuano ad affrontare notevoli vincoli operativi, in particolare nell'attuazione di pratiche commerciali sostenibili e nel coinvolgimento efficace dei propri stakeholder (Muriithi, 2017). Questi vincoli sono in gran parte attribuibili a risorse finanziarie limitate, sostegno istituzionale inadeguato e pressioni strutturali più ampie all'interno dell'ambiente operativo (Chinaire, 2021). Allo stesso tempo, la co-creazione di valore, intesa come il processo attraverso il quale gli stakeholder partecipano attivamente alla creazione e alla fornitura di valore attraverso interazioni dirette (Yang & Leposky, 2022), ha acquisito sempre più importanza come meccanismo strategico per la competitività e la sostenibilità delle PMI. La co-creazione di valore facilita la condivisione di informazioni, la costruzione di fiducia e la collaborazione efficace con gli stakeholder, rafforzando al contempo la capacità delle PMI di generare valore significativo e ampliare la loro presenza sul mercato (Song et al., 2022; Mohamad et al., 2022). L'integrazione delle tecnologie digitali e delle pratiche di sostenibilità nei processi di co-creazione amplifica ulteriormente il suo potenziale, consentendo alle PMI di rispondere in modo dinamico alle mutevoli esigenze del mercato e alle aspettative degli stakeholder (Purnami et al., 2024). Tuttavia, rimane una lacuna critica nella letteratura riguardo al modo in cui i processi di coinvolgimento degli stakeholder contribuiscono specificamente alla co-creazione di valore nelle PMI (Ligorio et al., 2025). Sebbene diversi studi abbiano affrontato separatamente questioni quali la responsabilità sociale d'impresa (CSR), le catene di approvvigionamento "verdi" e il marketing digitale (Baumann et al., 2013), l'interconnessione tra i meccanismi di coinvolgimento degli stakeholder e i risultati della co-creazione di valore è

ancora frammentaria (Muridzi & Dhliwayo, 2025; Purnami et al., 2024). Inoltre, la ricerca accademica si è storicamente concentrata sulle aziende di grandi dimensioni, con una conseguente sottorappresentazione delle piccole e medie imprese nel dibattito accademico (Bartolacci et al., 2019; Cortes et al., 2021). Questa frammentazione è particolarmente evidente se si considerano questioni emergenti come la trasformazione digitale, l'integrazione della sostenibilità e il ruolo del coinvolgimento degli stakeholder nella gestione delle pressioni istituzionali, che sono aree cruciali per l'adattamento e la resilienza delle PMI (Ligorio et al., 2025; Purnami et al., 2024). Il crescente riconoscimento del ruolo centrale delle PMI nel raggiungimento degli Obiettivi di Sviluppo Sostenibile (SDG) delle Nazioni Unite (Muridzi & Dhliwayo, 2025; Matarazzo et al., 2024), insieme ai crescenti requisiti normativi relativi alla rendicontazione sulla sostenibilità e al coinvolgimento degli stakeholder (Giacomini et al., 2024), ha accentuato l'importanza di comprendere come questi processi interagiscono e generano valore reciproco. Tuttavia, mancano ancora mappature bibliometriche sistematiche che integrino il coinvolgimento degli stakeholder, la co-creazione di valore e la sostenibilità nel contesto delle PMI, in un campo di ricerca ancora recente, disperso tra riviste, paesi e prospettive teoriche e non sempre affrontato in modo congiunto (Purnami et al., 2024), lasciando la ricerca accademica, la politica e la pratica disallineate rispetto alle attuali trasformazioni del panorama imprenditoriale (Ligorio et al., 2025). Per colmare questa lacuna, il presente studio adotta una revisione bibliometrica sistematica della letteratura basata su pubblicazioni sottoposte a revisione paritaria, ritenuta particolarmente adatta a delimitare un campo ancora frammentato, individuare i nuclei emergenti del dibattito e far emergere i principali vuoti di ricerca. L'approccio bibliometrico è ampiamente utilizzato negli studi di gestione e contabilità, in quanto consente un esame approfondito e critico della letteratura su un argomento specifico (Marzi et al., 2024). In particolare, consente una valutazione critica delle ricerche pubblicate sfruttando gli indicatori bibliometrici e le relazioni di rete tra autori e contributi, al fine di mappare efficacemente il campo accademico e identificare le tendenze emergenti della ricerca (Paul & Criado, 2020; Van Raan, 2003). La selezione del campione è stata condotta attraverso una serie di passaggi successivi seguendo il protocollo PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses).

Il resto dell'articolo è strutturato come segue. La sezione 2 delinea lo scopo dello studio e le domande di ricerca. La sezione 3 descrive la metodologia, compreso il processo di selezione basato su PRISMA e le tecniche bibliometriche applicate. La sezione 4 riporta i principali risultati dell'analisi descrittiva. La sezione 5 discute i limiti dello studio. La sezione 6 presenta le implicazioni manageriali e politiche. Infine, la sezione 7 conclude con l'originalità.

2. Scopo. Lo scopo di questo studio è condurre un'analisi bibliometrica della letteratura accademica sul coinvolgimento degli stakeholder nelle PMI. Tale focus risulta particolarmente rilevante nel contesto delle piccole e medie imprese, che, pur essendo caratterizzate da significativi vincoli finanziari e organizzativi, sono chiamate a innovare e ad adattarsi rapidamente alle crescenti pressioni normative e alle aspettative del mercato in materia di sostenibilità. Lo studio cerca di identificare temi emergenti, nuove prospettive teoriche e lacune chiave nella ricerca all'intersezione tra coinvolgimento degli stakeholder, co-creazione di valore e sostenibilità, considerando anche il ruolo della trasformazione digitale e delle pressioni istituzionali, nonché le differenze contestuali tra le PMI.

Sulla base di queste premesse, vengono affrontate le seguenti domande di ricerca:

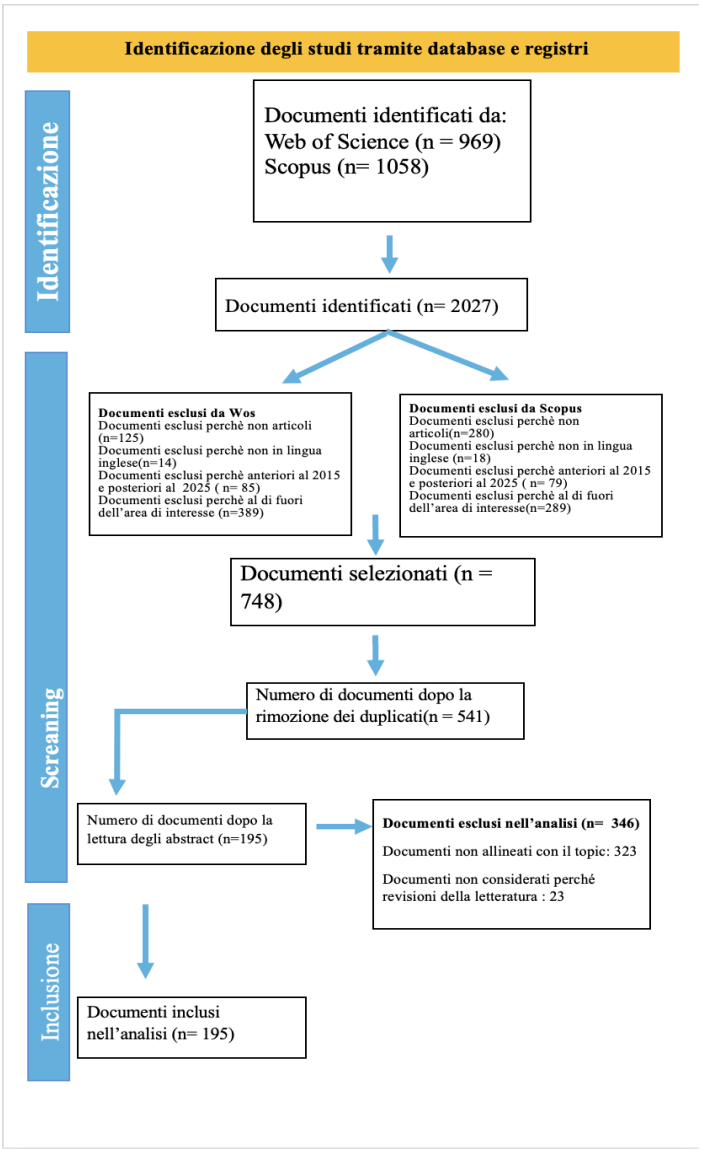
RQ1. *Come si è evoluta nel tempo la letteratura sul coinvolgimento degli stakeholder, la co-creazione di valore e la sostenibilità nelle piccole e medie imprese (PMI)?*

RQ2. *Quali sono i principali filoni tematici, cluster concettuali e prospettive teoriche che caratterizzano la ricerca sul coinvolgimento degli stakeholder nelle strategie di sostenibilità delle PMI?*

RQ3. *Quali gap di ricerca, aree ancora poco esplorate e future direzioni di studio emergono dalla letteratura sul rapporto tra stakeholder engagement e sostenibilità nelle PMI?*

Attraverso un'analisi sistematica e bibliometrica della letteratura, lo studio offre una mappatura strutturata di un campo di ricerca ancora disperso e interdisciplinare, relativo al coinvolgimento degli stakeholder, alla co-creazione di valore e alla sostenibilità nelle PMI. In particolare, l'analisi consente di delimitare il campo, identificare i principali filoni tematici, le prospettive teoriche dominanti, l'evoluzione del dibattito scientifico e le aree ancora poco esplorate. I risultati contribuiscono quindi ad approfondire la comprensione del posizionamento teorico del tema e a individuare future direzioni di ricerca, offrendo al contempo indicazioni utili per studiosi, manager e policy maker interessati a promuovere strategie di coinvolgimento più inclusive e orientate alla sostenibilità.

3. Metodologia. Lo scopo di questo studio è analizzare la letteratura sul coinvolgimento degli stakeholder nelle PMI per vedere in che modo questi processi contribuiscono alla co-creazione di valore, evidenziando i temi emergenti che potrebbero guidare la ricerca futura. Per la ricerca è stato utilizzato un approccio bibliometrico, riconosciuto nella letteratura per la sua capacità di mappare gli studi su un determinato argomento e di evidenziare le tendenze della ricerca (Paul & Criado, 2020), e particolarmente appropriato in questo studio per analizzare un ambito recente, in rapida crescita e ancora frammentato sotto il profilo tematico, geografico e teorico. L'obiettivo è quello di identificare la letteratura, generare nuove domande di ricerca ed esplorare le tendenze future (Van Raan, 2003; Aria et al., 2020). Il campione è stato selezionato attraverso una serie di passaggi successivi utilizzando il protocollo PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses).



3.1 Selezione della query. Per quanto riguarda la selezione delle parole chiave per la ricerca, si è deciso di concentrarsi sugli articoli indicizzati nei database Web of Science (WoS) di Clarivate Analytics (171 milioni di record) e Scopus di

Elsevier (78 milioni di record), noti per la loro autorevolezza nel garantire la qualità delle riviste scientifiche (Chavarro et al. 2018). Le parole chiave utilizzate nei database sono elencate di seguito:

stakeholder AND (engag* OR involv* OR collaborat* OR interact* OR participat* OR partnership* OR relationship*) AND("small and medium enterprise*" OR SME* OR "small firm*" OR "small enterprise*" OR "medium enterprise*") AND(sustainab* OR "sustainable development" OR "corporate sustainability" OR ESG OR "environmental social and governance" OR "social responsibility" OR CSR OR "environmental sustainability")*

3.2 Raccolta e definizione del campione. Il processo di analisi è descritto in dettaglio nella Figura 1 riportata di seguito.

Figura 1 - Prisma

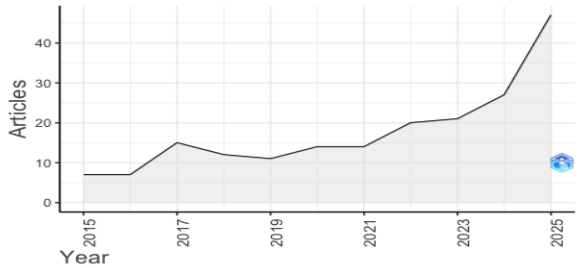
Fonte: elaborazione propria

Come già accennato, la ricerca è stata condotta su più banche dati per fornire una sintesi completa della letteratura (Cook, 2009). Nello specifico, per ciascuna banca dati, la ricerca è stata condotta per abstract, titolo, parole chiave e risultati per tutti i termini considerati. Gli articoli sono stati prima filtrati in base a vari criteri, poi combinati tra le due banche dati ed eliminati i duplicati. In particolare, sono stati utilizzati quattro criteri di selezione: tipo di contributo, lingua, data e area. In primo luogo, sono stati considerati solo gli articoli pubblicati su riviste e scritti esclusivamente in inglese, escludendo quindi gli atti di conferenze e i capitoli di libri. In secondo luogo, sono stati considerati solo i contributi pubblicati tra il 2015 e il 2025, escludendo quindi i contributi più vecchi e quelli del 2026, poiché questi erano in corso e avrebbero distorto le analisi temporali. Infine, sono stati presi in considerazione solo i contributi relativi alle categorie di gestione, economia, etica e contabilità. I due corpora sono stati quindi uniti e i duplicati sono stati eliminati, ottenendo un corpus di 541 articoli. Dopo un'attenta lettura degli abstract, i contributi identificati hanno portato a un corpus di 195 articoli, escludendo 323 articoli perché non pertinenti all'argomento di ricerca e 23 articoli perché erano revisioni della letteratura.

3. Risultati

3.1 Strumento utilizzato nell'analisi bibliometrica. L'analisi è stata condotta utilizzando il software R, in particolare il pacchetto Bibliometrix (versione 4.1.4) (Aria & Cuccurullo, 2017; Belfiore et al., 2022). Il documento è attualmente in fase di elaborazione e per ora sono state condotte analisi descrittive con informazioni sul set di dati bibliografici, tra cui la produzione scientifica annuale, i paesi, le riviste e gli autori più produttivi sull'argomento (Aria & Cuccurullo, 2017), ponendo le basi per successivi approfondimenti sulla struttura concettuale e sull'evoluzione tematica del campo. L'analisi è stata facilitata dal pacchetto Bibliometrix, che consente anche l'analisi della struttura della conoscenza di un campo tematico, ovvero la sua struttura concettuale e sociale.

3.2 Caratteristiche del campione. Il campione di articoli analizzati comprende 195 documenti pubblicati tra il 2015 e il 2025. Gli articoli includono 745 parole chiave fornite dagli autori e 544 attribuite dalle riviste. La produzione scientifica mostra un tasso di crescita annuo del 21% con una media di 31,25 citazioni per documento, corrispondenti a 4,94 citazioni all'anno per documento. Dei 195 documenti, 30 sono stati scritti da un unico autore con una media di 3,23 coautori per documento.



3.3. Analisi descrittiva. Nella ricerca bibliometrica, il processo di analisi descrittiva consente di identificare temi generali e argomenti promettenti in un determinato periodo, consentendo così lo sviluppo di approfondimenti che arricchiscono l'interpretazione complessiva del settore in questione (Aria & Cuccurullo, 2017). In questa prospettiva, lo studio valuterà innanzitutto l'andamento delle pubblicazioni nel corso degli anni; proseguirà poi con un'analisi dei paesi più produttivi, per concludersi con un'analisi degli autori più produttivi e, infine, con una valutazione della produttività delle riviste.

3.3.1 L'andamento delle pubblicazioni nel corso degli anni. Il set di dati analizza articoli pubblicati tra il 2015 e il 2025, con una media annuale di 17,72 contributi. Il periodo di tempo è stato selezionato al fine di bilanciare la completezza storica e la rilevanza contemporanea delle pubblicazioni, garantendo al contempo un volume di dati gestibile per i ricercatori.

Come mostrato nella figura sottostante, è possibile identificare tre fasi evolutive delle pubblicazioni. La prima (2015-2016) mostra una produzione stabile con sette articoli all'anno, probabilmente segno dell'avvio del campo di ricerca. La seconda fase (2017-2021), con una media di 11,4 articoli all'anno, mostra il primo picco nel 2017 con la pubblicazione di 15 articoli, a dimostrazione di una crescita più che doppia rispetto all'anno precedente. Dopo il 2017 si osserva una fase di instabilità, con un calo nel 2018 e nel 2019. Infine, la seconda fase si conclude con un periodo di stabilizzazione, con 14 pubblicazioni all'anno nel 2020 e nel 2021. Infine, la terza fase (2022-2025) mostra una crescita esponenziale, con una media di 28,8 pubblicazioni all'anno, più del doppio rispetto al periodo precedente. Il punto di svolta è il 2022, quando vengono pubblicati 20 articoli, seguito da una progressiva accelerazione nel 2023 con 21 articoli, nel 2024 con 27 pubblicazioni e nel 2025 con 47 articoli pubblicati. Pertanto, le pubblicazioni nel 2025 rappresentano circa il 24% dell'intera produzione decennale.

La crescita esponenziale potrebbe indicare un graduale aumento dell'interesse per l'argomento. Questo trend esponenziale (CAGR 20,98%) testimonia l'emergere di questo campo come area di crescente importanza nella comunità scientifica. Tuttavia, resta da chiarie, attraverso approfondimenti successivi, se tale crescita corrisponda anche a una maggiore maturità teorica del campo.

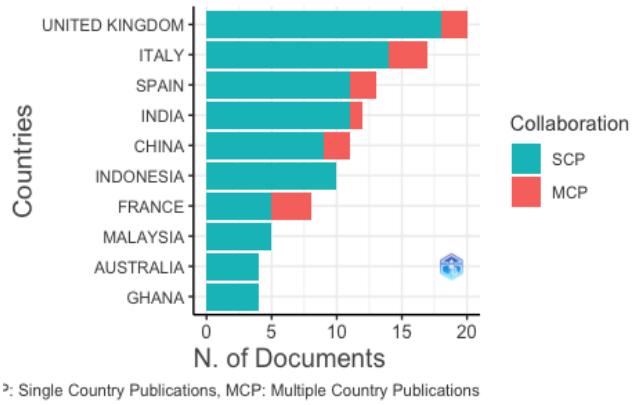
Figura 2. Produzione scientifica annuale

Fonte: elaborazione propria

3.3.2 Produttività per paese. La figura 3 mostra la distribuzione della produttività scientifica dei paesi, distinguendo tra pubblicazioni di un singolo paese (SCP) e pubblicazioni di più paesi (MCP). Questo approccio non solo ci permette di cogliere il volume dei contributi nazionali, ma anche di osservare il grado di collaborazione internazionale.

Nel complesso, la produzione è molto concentrata, con i primi 10 paesi che rappresentano 104 contributi, pari a circa il 63% dell'intero dataset.

In Europa, il Regno Unito è in testa alla classifica con 20 articoli pubblicati, seguito dall'Italia (17) e dalla Spagna (13), mentre la Francia si colloca al settimo posto con 8 pubblicazioni, preceduta da India (12), Cina (11) e Indonesia (10). La Malesia completa il quadro con 5 pubblicazioni, seguita da Australia e Ghana con 4 pubblicazioni ciascuna.



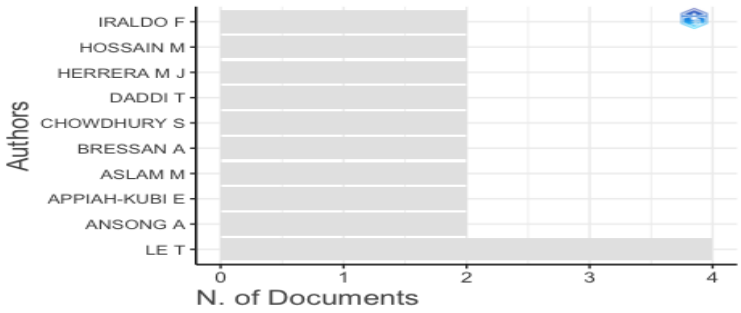
È interessante notare che i primi tre paesi rappresentano oltre il 30% del totale delle pubblicazioni. Tuttavia, nel complesso, la presenza asiatica suggerisce che la ricerca in questo campo ha attirato l'attenzione di un gruppo eterogeneo ma selezionato di nazioni.

Dal punto di vista delle collaborazioni internazionali, si registra una chiara prevalenza del lavoro nazionale. Infatti, ci sono 91 pubblicazioni attribuibili a un singolo paese, rispetto a 13 pubblicazioni nate da collaborazioni internazionali, il che suggerisce che la ricerca viene svolta in gran parte all'interno dei confini nazionali.

Tuttavia, un dato interessante riguarda la Francia, che ha il rapporto MCP più alto (0,375) con 3 pubblicazioni su 8 risultanti da collaborazioni internazionali. Seguono la Cina (0,181), l'Italia (0,176) e la Spagna (0,153), che mostrano livelli moderati di collaborazione internazionale, mentre il Regno Unito (0,100) e l'India (0,083) mostrano tassi più bassi di co-autorevolezza internazionale. Al contrario, Indonesia, Malesia, Australia e Ghana non mostrano alcuna co-autorialità internazionale, il che suggerisce una produzione interamente nazionale nel campione considerato.

Questa distribuzione rivela, da un lato, che i sistemi di ricerca consolidati (Regno Unito, Italia, Spagna) dimostrano un'elevata produttività con vari gradi di internazionalizzazione; dall'altro lato, i contributori emergenti (Indonesia, Malesia, Ghana) mostrano una produzione significativa ma un'integrazione globale limitata. La supremazia del Regno Unito in termini di volume, accompagnata da un modesto rapporto MCP (0,100), suggerisce una forte capacità di ricerca interna, mentre il tasso di collaborazione più elevato della Francia potrebbe indicare un posizionamento strategico all'interno delle reti internazionali. Nel complesso tali evidenze preliminari non segnalano soltanto differenti livelli di produttività scientifica, ma suggeriscono anche che il dibattito si stia articolando in modo non uniforme nei diversi contesti nazionali.

Figure 3. Paesi più produttivi



Fonte: elaborazione propria

4.2 Produttività degli autori. Per quanto riguarda la produttività degli autori, il quadro che emerge è quello di una bassa concentrazione. Infatti, la figura 4 mostra una distribuzione molto piatta, senza alcuna evidenza di un piccolo gruppo che domini il campo.

Tutti gli autori nella top 10 hanno due pubblicazioni ciascuno. L'autore più produttivo ha quattro pubblicazioni. Ciò significa che anche ai vertici i valori sono modesti. Pertanto, il campo sembra essere dominato da molti autori con poche pubblicazioni ciascuno.

In conclusione, si può affermare che la produttività è frammentata, poiché il settore non è guidato da autori super prolifici, ma da una vasta comunità, e le collaborazioni sono significative ma non uniformi. Infatti, mentre alcuni autori pubblicano spesso come parte di un team, altri tendono a pubblicare come autori singoli.

Figure 4. Autori più produttivi

Fonte: elaborazione propria

4.3 La produttività delle riviste. Per quanto riguarda la produttività della rivista, come mostra la tabella sottostante, emerge una struttura chiara in cui poche riviste concentrano una percentuale significativa di articoli sull'argomento, mentre il resto della produzione scientifica è distribuito su diverse riviste.

L'analisi mostra che il Journal of Cleaner Production è la fonte più rilevante con un totale di 20 articoli pubblicati che rappresentano il 37% della produzione scientifica totale.

Questa chiara predominanza è coerente con l'attenzione della rivista, tradizionalmente incentrata sulla sostenibilità e sulle aree correlate.

Corporate Social Responsibility and Environmental Management segue con 11 articoli, confermando l'importanza della CSR e della governance della sostenibilità, mentre Business Strategy and the Environment la segue con 6 contributi, sottolineando l'importanza di una lettura strategica dell'integrazione della sostenibilità nei processi decisionali e nella competitività aziendale. Successivamente vi è una sequenza di tre riviste (Journal of Business Ethics, Journal of Business Research e Sustainable Futures) con quattro pubblicazioni ciascuna, che le colloca nella fascia media. In generale, i temi centrali di queste riviste si riferiscono a prospettive normative etiche, argomenti di gestione generale e di business, e contributi orientati alle traiettorie future della sostenibilità. Infine, quattro riviste con tre pubblicazioni ciascuna si posizionano in fondo alla tabella. Queste riviste sono: Cogent Business & Management, International Journal of Accounting and Economics Studies, International Journal of Production Economics e Journal of Sustainable Tourism, indicando una diffusione dell'argomento in ambiti eterogenei. Gli argomenti di interesse in queste riviste spaziano dalle prospettive sul business e la gestione generale, le operazioni e le traiettorie di produzione, alle applicazioni settoriali come il turismo sostenibile. In conclusione, si può osservare che la maggior parte dei contributi sull'argomento sono pubblicati su riviste specializzate dedicate alla sostenibilità e alla CSR. Tuttavia, l'analisi mostra che l'argomento compare anche in riviste appartenenti ad altri settori disciplinari. Ciò suggerisce che si tratti di un tema di interesse trasversale, capace di attirare l'attenzione di diverse discipline che lo affrontano da prospettive differenti.

5. Limiti della Ricerca. La ricerca presenta diversi limiti, soprattutto considerando che si tratta di un documento in fase di elaborazione. In primo luogo, considerato lo stato di avanzamento del lavoro, le analisi risultano puramente descrittive; manca pertanto un'analisi della struttura intellettuale e concettuale del campo. In secondo luogo, l'analisi si basa su due banche dati (Wos e Scopus) e prende in considerazione articoli scritti esclusivamente in inglese; ricerche future potrebbero prendere in considerazione altre banche dati, come EBSCO e Google Scholar, nonché contributi scritti in lingue diverse. Infine, l'analisi della letteratura è di natura bibliometrica, quindi ricerche future potrebbero analizzare la letteratura in modo sistematico, identificando i principali vantaggi del coinvolgimento degli stakeholder nelle PMI.

6. Implicazioni Manageriali. I risultati dell'analisi bibliometrica offrono alcune implicazioni manageriali rilevanti per gli imprenditori e i manager delle PMI interessati a integrare strategie di sostenibilità attraverso il coinvolgimento degli stakeholder. In primo luogo, la significativa crescita delle pubblicazioni negli ultimi anni evidenzia come il coinvolgimento degli stakeholder stia diventando un tema sempre più centrale nelle strategie di sostenibilità aziendale. Per i manager delle PMI, ciò suggerisce la necessità di considerare il coinvolgimento degli stakeholder non solo come uno strumento di comunicazione, ma come una leva strategica a sostegno dell'attuazione delle pratiche ESG. In secondo luogo, la concentrazione di pubblicazioni nelle principali riviste accademiche dedicate alla sostenibilità e alla responsabilità sociale indica che il legame tra il coinvolgimento degli stakeholder e la sostenibilità è sempre più riconosciuto come un elemento chiave della competitività aziendale. I manager delle PMI possono quindi utilizzare pratiche di coinvolgimento strutturate per identificare le priorità di sostenibilità più rilevanti e migliorare la legittimità delle loro iniziative nei confronti dei clienti, delle comunità locali e degli altri stakeholder. Infine, i risultati evidenziano che il tema del coinvolgimento degli stakeholder nelle PMI è ancora relativamente emergente rispetto alla ricerca sulle grandi aziende. Ciò implica che i manager delle PMI possono svolgere un ruolo attivo nello sviluppo di approcci più partecipativi e collaborativi alla sostenibilità, sfruttando la maggiore flessibilità organizzativa tipica delle piccole e medie imprese.

Tabella 1. Riviste più rilevanti

JOURNAL OF SUSTAINABLE TOURISM	3

Fonte: elaborazione propria

7. Originalità. Questo studio offre una delle prime mappature bibliometriche sistematiche dell'intersezione tra stakeholder engagement, sostenibilità e value co-creation nel contesto delle PMI, con l'obiettivo di chiarire la struttura iniziale del campo e individuarne le principali lacune teoriche. A differenza degli studi precedenti, che hanno analizzato separatamente le grandi aziende e il loro impatto sul coinvolgimento degli stakeholder, sulla co-creazione di valore e sulla sostenibilità, questo lavoro esamina sistematicamente come questi processi interagiscono e generano valore reciproco nelle PMI, che sono spesso caratterizzate da risorse limitate. L'approccio bibliometrico ci permette di identificare modelli di frammentazione nel campo scientifico, dimostrando che, nonostante il crescente interesse, la letteratura rimane in gran parte descrittiva e priva di quadri teorici integrati. Lo studio contribuisce al progresso della ricerca sulle PMI chiarendo la struttura delle conoscenze relative al coinvolgimento degli stakeholder e alla co-creazione di valore nelle PMI, identificando le tendenze emergenti e le lacune teoriche della loro intersezione e proponendo un programma di ricerca integrato che collega i meccanismi di coinvolgimento ai risultati di sostenibilità e all'innovazione del modello di business. Inoltre, l'analisi evidenzia che la ricerca in questo settore è concentrata in poche riviste di riferimento e limitata a un gruppo selezionato di paesi, con un basso livello di collaborazione internazionale, suggerendo opportunità per studi più globali, diversificati e interdisciplinari. Combinando indicatori bibliometrici con un'analisi sostanziale dei modelli di pubblicazione, della produttività degli autori, il lavoro fornisce una base empirica utile sia per lo sviluppo teorico sia per futuri approfondimenti del campo.

The impact of Stakeholder Engagement on Circular Economy performance in Family Firms

FRANCESCO GANGI*, LUCIA MICHELA DANIELE•

Abstract. *This study investigates how Stakeholder Engagement (SE) practices influence Circular Economy (CE) performance within the organizational context of Family Firms (FFs). Although prior research increasingly acknowledges FFs' propensity toward sustainable development, limited attention has been devoted to the drivers that foster the adoption of CE practices in this organizational setting. Accordingly, grounded in Stakeholder Theory and the Socioemotional Wealth (SEW) perspective, this study examines whether proactive and structured stakeholder management enhances FFs' ability to integrate diverse stakeholder expectations into strategic decision-making, thereby promoting the adoption of CE practices.*

Drawing on an international panel of 185 FFs', observed over the 2013–2024 period, we test the direct effect of SE practices on CE performance, measured through Waste Recycling Initiatives (WRI) and Policies on Water Efficiency (PWE). Fixed-effects panel data estimations reveal a positive and statistically significant association between stakeholder engagement practices and both waste recycling initiatives and policy of water efficiency. Accordingly, the findings suggest that FFs adopting structured stakeholder dialogue are better positioned to strengthen CE practices. By highlighting the role of stakeholder-oriented governance mechanisms, reinforced by SEW preservation goals, this study contributes to the emerging literature on CE in family firms, showing how stakeholder engagement can support the transition toward more sustainable and efficient business models.

Keywords: *stakeholder engagement; circular economy; waste recycling; water efficiency; family firms.*

Framing of the research. *After decades of sustained global economic growth (global GDP increased from approximately $3 trillion in 1970 to $117.2 trillion in 2025) policymakers, businesses, and scholars have increasingly recognized that uncontrolled development can generate significant social and environmental pressures. Rising inequality, the depletion of natural resources, and escalating climate risks have intensified concerns regarding the long-term sustainability of prevailing economic systems (Stiglitz, 2017; Piketty, 2020). At the same time, the global population has reached 8 billion people, further increasing the demand for energy and materials (Schandl et al., 2024) and placing additional pressure on the Earth's life-support systems and natural resources (Green and Healy, 2022).*

In response to these challenges, the circular economy (CE) emerged as a key paradigm aimed at reconciling economic development with environmental sustainability (Geissdoerfer et al., 2017). According to the Ellen MacArthur Foundation, the CE refers to "a system in which materials never become waste and nature is regenerated, while products and materials are kept in circulation through processes such as maintenance, reuse, remanufacturing, recycling, and composting." Within this framework, production and consumption systems are conceptualized as closed-loop systems in which resource flows are continuously regenerated and environmental impacts are minimized (Murray et al., 2017; Geissdoerfer et al., 2017; Kirchherr et al., 2023). Central to this approach is the 3R hierarchy—reduce, reuse, and recycle — which provides firms with a structured pathway to enhance resource efficiency across productive and organizational processes (Kirchherr et al., 2017; 2023).

Despite the growing attention devoted to circular strategies, the global economy remains largely linear. Recent evidence shows that only 6.9% of economic activities currently operate according to circular principles, and this share has even declined in recent years (Circle Economy, 2025). Among the most critical areas for advancing the CE transition, the efficient use of natural resources—particularly water management—represents a pivotal dimension for mitigating resource pressures and supporting sustainable development (Symbola, 2025). This scenario highlights the need to better understand the organization drivers that can foster the adoption of CE practices, particularly within contexts characterized by distinct governance structures and strategic orientations. In this regard, family firms (FFs) represent one of the most prevalent corporate forms worldwide and play a key role in global economic development (Chen, 2014; Deloitte, 2025). Indeed, given both their economic relevance and their distinctive governance characteristics, FFs constitute a particularly relevant context for examining the organizational mechanisms that may facilitate firms' engagement in CE practices.

However, despite FFs are recognized as theoretically inclined toward environmental engagement, empirical evidence on this point is mixed, with some studies funding a positive relationship between family ownership and environmental performance (e.g., Agostino and Ruberto, 2021; Gómez-Mejía et al., 2025; Gangi et al., 2025), while other authors show a negative o no relationship (e.g., Herrero et al., 2024; Miroshnychenko and De Massis, 2022). This is consistent with

• Associate Professor of Management – University of Campania, Luigi Vanvitelli
e-mail: luciamichela.daniele@unicampania.it

Miroshnychenko et al. (2022), who confirm that the impact of FFs on environmental performance range from extremely negative to no impact, thus living open the debate. Furthermore, only few studies are specifically focused on CE practices in FFs setting (e.g., Núñez-Cacho et al., 2018; Doucet et al., 2025; Agarwal al., 2025).

Based on prior research (Gómez-Mejía et al., 2007; Berrone et al., 2012; Gómez-Mejía et al., 2018), decision-making processes in FFs are characterize by the influence of socioemotional wealth (SEW), which is considered "one of the most important features that differentiate the family firms of other organizations" (Barros et al., 2017, p. 14).

Indeed, SEW refers to the "family's stock of social, emotional, and affective endowments vested in the firm," including the preservation of family reputation, the maintenance of strong relationships with stakeholders, and the intention to pass the business to future generations (Gómez-Mejía et al., 2018, p. 1370). Accordingly, decision-making in FFs is often strongly influenced by family owners, who prioritize long-term relational and reputational goals alongside financial objectives (Gómez-Mejía et al., 2018). This orientation encourages the preservation of collective social capital, trust-based relationships with stakeholders, and the protection of family reputation and legacy.

Within this context, the increasing complexity of the social and competitive environment has strengthened the importance of trusting relationships with stakeholders to help business continuity and transgenerational succession among FFs (Gangi et al., 2025). These goals are consistent with the priority of pursuing SEW preservation (Neubam et al., 2012). Accordingly, the stakeholder engagement (SE) emerges as a relevant managerial approach for FFs.

Following prior studies (e.g., Greenwood, 2007), stakeholder engagement refers to the set of organizational practices aimed at actively involving stakeholders in corporate decision-making and activities. In its proactive form, stakeholder engagement goes beyond a reactive response to external pressures, reflecting instead the systematic integration of stakeholder expectations into business strategies and operations (Cennamo et al., 2012).

Hence, combining the two theoretical lenses, FFs may be particularly inclined to adopt proactive stakeholder engagement practices, while preserving SEW principles that permeate corporate decisions. In this sense, Cennamo et al. (2012) argue that maintaining strong and enduring relationships with stakeholders contributes to safeguard family reputation, legitimacy, and long-term continuity. Consequently, FFs may be inclined to address stakeholders' needs, including the development of environmentally oriented initiatives. Among the latter, CE practices represent the innovative form to conceive how production and consumption models may help the preservation of natural resources for next generation. This sense of continuity in environmentally friendly business models is consistent with the conception of FFs as organizations interested in firm perpetuation and succession legacy.

Moreover, CE strategies typically require collaboration among multiple stakeholders—including industry actors, consumers, policymakers, and academic institutions—whose resources and capabilities enable the implementation of circular solutions (Kirchherr et al., 2023). In this regard, SEW perspective suggests that FFs, motivated to preserve reputation, long-term legitimacy, and trust-based relationships with stakeholders, are more likely to adopt proactive SE practices (Cennamo et al., 2012). Indeed, by actively involving stakeholders in decision-making processes and aligning business strategies with their expectations, FFs may strengthen relational capital and access valuable knowledge and resources. In turn, such stakeholder-oriented governance can facilitate the development and implementation of CE practices, which inherently depend on both corporate decision making and stakeholders' coordination.

Building on the arguments above, in this study we analyse if and to what extent the stakeholder engagement of FFs affects two key CE performance, that is waste recycling initiatives (WRI), and policies aimed at improving water efficiency (PWE). To test these relationships, we employ fixed-effects panel estimations on a global sample of 185 family firms observed over the 2013–2024 period. The results indicate that SE positively affects both WRI and PWE, suggesting that FFs—due to their inclination to nurture and sustain stakeholder dialogue—may be well positioned to implement CE practices.

Hence, overall, this study advances the literature by deepening the understanding of both the organizational drivers of CE practices and the relevant role of FFs in developing these innovative initiatives. Indeed, we find stakeholder engagement as a key governance mechanism that helps environmental transition through improved CE performance of FFs.

Purpose of the paper. *Despite gaining increasing mainstream attention, the implementation of the CE remains a significant challenge (Doucet et al., 2025; Circle Economy, 2025). In the business context, adopting CE requires sustained commitment and substantial strategic and operational transformations aimed at decoupling business growth from resource depletion. Indeed, CE strategies entails building resilient and sustainable supply chains, fostering collaboration with stakeholders, improving resource efficiency, redesigning products to extend their lifespan, achieving cost and energy savings, and generating long-term market opportunities (Kirchherr et al., 2023). Accordingly, identifying the drivers that can accelerate the adoption of CE is essential to support the transition toward a more sustainable economy, while ensuring firms' long-term competitiveness.*

However, the adoption of CE practices is not uniform across firms and may vary depending on specific organizational characteristics and governance structures (Faller and zu Knyphausen-Aufseb, 2018; Doucet et al., 2025). In this regard, FFs represent a unique organizational setting in which SEW orientation may distinguish the approach to environmentally oriented initiatives (Cennamo et al., 2012; Agostino and Ruberto, 2021). This aspect is relevant to the broader debate on which managerial practices can reverse the trend toward a general lack of commitment to the circular economy (The Circularity Gap Report, 2025), giving the economic relevance of FFs on global scale (De Massis et al., 2018).

According to Cennamo et al. (2012), the distinctive SEW approach permeates the inclination of family owners to adopt SE strategies. In particular, neglecting stakeholder expectations may expose FFs to reputational risks and legitimacy losses that could threaten the family's image and long-term standing in the community. For this reason, FFs should be inclined to engage in active dialogue with stakeholders, avoiding the perception as irresponsible actors, and, thus, safeguarding the family's reputation.

In this sense, SE aligns closely with the core dimensions of SEW (Berrone et al., 2012; Cennamo et al., 2012). First, from an instrumental perspective, family owners may use SE to cultivate relationships with key stakeholders whose support is essential for ensuring the continuity and stability of both the family and the business. Second, engaging stakeholders contributes to the development of relational networks that can sustain transgenerational value creation and long-term organizational longevity. Third, stakeholder dialogue helps protect and enhance the reputation of the family and the firm, which are often closely intertwined in family-controlled businesses. Fourth, the strong emotional attachment of family owners to the firm often encourages greater transparency and responsiveness toward stakeholders to prevent reputational damage. Finally, consistent with both the SEW and stakeholder perspectives, engagement practices strengthen trust-based relationships and social bonds with stakeholders, thereby reinforcing the socioemotional assets that family owners seek to preserve over time (Gómez-Mejía et al., 2018; Cennamo et al., 2012).

Accordingly, the commitment to the SE can be closely related to the way family owners conceive their approach to business, to the extent that both emphasize a long-term orientation toward non-financial objectives (Cennamo et al., 2012). Indeed, while FFs tend to nurture key socioemotional values—such as family image, strong social ties, and affective endowments—SE represents a deliberate managerial choice characterizing FFs (Cennamo et al., 2012).

By engaging with stakeholders and fostering structured dialogue mechanisms, FFs preserve reputation, trust-based relationships, and legitimacy in the long run. Accordingly, the SEW perspective provides a useful framework to explain why FFs can be characterized by a strong orientation toward SE, which, in turn, may support the design and adoption of environmentally friendly initiatives, including innovative CE practices. The latter, indeed, frequently require collaboration, coordination, and alignment with stakeholders' expectations. Then, this convergence of interests, may help to depict a win-win scenario for all the parts involved. Finally, the collaboration with stakeholders in managerial practices may be the source of new knowledge and experience that contribute to support FFs' performance (Gangi et al., 2025). Accordingly, SE can be beneficial to the accruing of skills and capabilities necessary for improved CE performance.

Therefore, based on the above considerations the current study aims to test the following research question:

***RQ:** Does proactive stakeholder engagement positively affect CE performance in the FFs context?*

Methodology. *The study relies on data from several sources. Specifically, we refer to LSEG Data & Analytic for data on both CE and SE practices, Worldscope database for financial data, and World Bank database for gross domestic product (GDP) data. Relative to the sample selection, we started from the FFs included in the World's Top 750 Family Businesses, reporting the worldwide top FFs ranked by Family Capital, supported by PwC. According to Cambrea et al. (2022), which relies on to the cut-off of 25% or more of the voting shares to identify FFs, Family Capital defines "family business" those companies in which the family or group of families held at least the 30% of the voting rights. Thus, to build our sample, we match Family Capital's initial list with LSEG and Worldscope databases. We exclude 565 FFs for which employed databases do not disclose any data over the time horizon of the study (2013-2024). This procedure leads to a panel of 185 FFs, for a total of 2.200 observations. Relative to main variables of the study, we refer to LSEG database for data on FFs' stakeholder engagement practices and CE proxy, Worldscope database for financial data, and World Bank database for GDP.*

As main variables of the study, we consider a) the waste recycling initiatives (WRI) and the policies of water efficiency (PWE), as proxies of CE practices; b) the presence of stakeholder engagement (SE) mechanisms at corporate governance level. Relative to CE proxies, aligned with recent studies (e.g., Symbola, 2025; Circle Economy, 2025), we consider two aspects related to resource efficiency. First, we focus on waste recycling initiatives (WRI), proxied by a dummy variable equal to 1 if the company is engaged and report initiatives and partnership aiming to recycle, reduce, reuse, substitute, treat or phase out total waste, 0 otherwise. Second, we consider the Policies on Water Efficiency (PWE), a dummy variable equal to 1 if the company has established a formal policy aimed at improving water efficiency, 0 otherwise. This includes the presence of documented systems, procedures, or operational mechanisms designed to promote the efficient use of water and support continuous improvement in water management practices.

Moreover, we measure SE through a dummy variable equal to 1 if the company is equipped of formal procedures and practices through which stakeholders are engaged in the decision-making process, 0 otherwise. Accordingly, the SE variable captures the presence of structured, two-way communication mechanisms between the firm and its key stakeholder groups, reflecting the extent to which organizations promote dialogue, consultation, and feedback in managing stakeholder relationships.

To mitigate potential model misspecification, we include a set of control variables. Specifically, we control for firm size, measured as the natural logarithm of total assets (Size); financial leverage, proxied by the ratio of total debt to total capital (Leverage); and the percentage of shares available to ordinary investors (Free Float). We also account for the presence of a corporate social responsibility (CSR) strategy, through a dummy variable equal to 1 if the firm has a CSR strategy, 0 otherwise, as well as governance structure through a dummy variable equal to 1 if the CEO simultaneously

chairs the board and 0 otherwise (CEO separation). Finally, we include the gross domestic product (GDP) as country-level control.

Regarding the empirical approach, relying on the Hausman test (p. value lower than .05), we perform a fixed effect (FE) panel regression analysis. Moreover, in line with prior studies (Jo and Harjoto, 2012), independent variables are lagged 1 year to address reverse causality and simultaneity issues. The regression equation is formalized as follows:

$$CE_{i,t} = a + \beta\ Stakeholder\ Engagement_{i,t-1} + \gamma X_{i,t-1} + \varepsilon_i \quad (1)$$

where CE represents circular economy performance of family firms i at time t; Stakeholder Engagement represents the presence of stakeholder management practices of a family firm i, a time t-1; X is a vector of control variables, while ε is the random error term. We estimate Equation (1) two times, due to the adoption of two different measurements of CE, namely the WRI and PWE.

Results. *Table 1 reports the descriptive statistics of the variables included in the analysis. As reported in Table 2, all correlation coefficients are below the commonly accepted threshold of 0.70 (Ratner, 2009), suggesting that multicollinearity is not a concern. This evidence is further supported by the Variance Inflation Factor (VIF) values, which range from 1.04 to 2.25 (mean VIF 1.69).*

Table 3 presents the results of the empirical models estimating the influence of FFs' SE on CE performance, proxied by WRI and PWE. Specifically, Models 1–2 use WRI as the dependent variable, while Models 3–4 adopt PWE. For each CE proxy, two model specifications are estimated depending on the inclusion of year fixed effects. All models include SE as the main explanatory variable together with firm-level and country-level controls.

Models 1 and 2 show that SE has a positive and statistically significant effect on WRI. The SE coefficient is significant at the 1% level in both specifications (Model 1: t = 3.13; Model 2: t = 2.73), suggesting that proactive SE enhances CE performance in FFs in terms of recycling activities. Consistent evidence emerges from Models 3 and 4, which examine the impact of SE on PWE. The coefficient of SE remains positive and statistically significant, at the 5% level in Model 3 (t = 2.45) and at the 10% level in Model 4 (t = 1.94). This finding further suggests that the integration of stakeholders' perspectives into organizational decision-making can also facilitate the adoption of policies aimed at improving water-use efficiency. Overall, the empirical evidence of the current study allows to positively answer the research question on the impact of SE on CE performance under the FFs organizational setting.

Research limitations. *Notwithstanding findings obtained, the study is subject to some limitations. First, with reference to SE, this is measured through a dummy variable capturing the presence of formal stakeholder engagement practices. Future research could adopt more nuanced measures of SE, incorporating additional informative sources on different SE dimensions.*

Second, to proxy CE performance, the study focuses on waste recycling initiatives and policies aimed at improving water efficiency. Although these dimensions represent relevant aspects of CE practices, further studies could expand the analysis by considering additional CE proxies, such as supply chain circularity rate.

Third, the empirical analysis relies on a sample of international family firms. Then, future research could further explore whether and to what extent stakeholder engagement supports CE practices in small and medium-sized family firms, which may face different organizational constraints in implementing CE strategies.

Fourth, to make more robust our findings, future research agenda could include a comparison with non-family firms.

Finally, due to differences in environmental sensitivity and rule among social and economic contexts, next studies can investigate country related aspects may affect the link between SE and CE performance.

Managerial implications. *The present study contributes to the current knowledge relative to the drivers of CE performance in FFs. Specifically, the findings highlight the importance of SE practices as mechanisms through which FFs can acquire and integrate diverse perspectives and knowledge resources, thereby improving waste management practices and enhancing water efficiency within organizational and production processes. Accordingly, for managers, the results encourage FFs to adopt structured SE policies to better understand and respond to stakeholders' expectations regarding environmental practices. In this regard, our study also suggests that SE can represent a strategic tool for balancing the transition toward CE models, while nurturing long-term oriented and trust-based relationships with key stakeholders.*

Originality of the paper. *The present study offers several contributions to the literature. First, it contributes to the emerging debate on the organizational drivers of CE performance. Second, by specializing our analysis in the FFs organizational setting, we contribute to FFs literature on the attitude of these firms toward environmentally friendly practices. Indeed, while prior research increasingly acknowledges the role of family businesses in promoting environmental sustainability, limited attention has been devoted to the mechanisms that can facilitate the adoption of circular practices in this organizational setting. This is a big matter due to the worldwide circularity gap and the economic relevance of FFs at global level.*

Our findings identify SE as a key managerial mechanism through which FFs can integrate stakeholders' expectations into strategic decision-making and enhance CE performance. In doing so, the study highlights how stakeholder-oriented managerial practices can foster the adoption of circular initiatives in FFs, which are characterized by the pursuit of non-

financial objectives related to the preservation of the SEW. In this regard, our results complement prior studies on proactive stakeholder management in family firms (e.g., Cennamo et al., 2012).

Second, the study focuses on a category of firms playing a pivotal role in the CE transition. Given FFs' economic relevance and long-term orientation, understanding drivers of engagement in CE practices is relevant. In this context, and considering the growing concerns regarding natural resource management, the study examines two critical dimensions related to resources efficiency, namely waste recycling initiatives and policies aimed at improving water efficiency. In this perspective, the study provides novel insights into how SE can facilitate the adoption of CE initiatives and support the transition toward more sustainable and resource-efficient business models in family-controlled firms.

Third, our empirical analysis relies on an international panel of family firms, thereby enhancing the generalizability of the findings and addressing the limitations of prior studies on the link between FFs and environmental responsibility that are focused on single-country settings or based on single case-study (e.g., Berrone et al., 2010; Núñez-Cacho et al., 2018; Dini et al., 2019).

Hence, overall, the current paper advances earlier knowledge on environmental responsibility of FFs and drivers of CE performance, by showing how SE can act as a strategic driver of these practices in the distinctive context of family business.

Table 1. Descriptive statistics

Variables	Obs.	Mean	Median	SD

The regenerative firm: evolution and upgrade of the sustainable firm able to increase its resilience and agility

MAXIMILIAN BROGLIO[1]

Abstract. *The global context in which we find ourselves is, as is unfortunately well known, characterized by widespread degradation and the crossing of numerous planetary boundaries: issues such as global warming linked to anthropogenic emissions of climate-altering gases, the contamination (and in some cases the compromise) of air, water, and soil, the indiscriminate use of non-renewable resources and the reckless use of renewable ones (i.e., without waiting for natural regeneration rates), the impact on the health of natural ecosystems with the resulting loss of numerous species, and the effects on human health linked to human interference have led to the need to rethink how we view the world and how we manage it. In this sense, the concept of sustainability was born, which seeks to holistically support the planet without harming it in any of its facets. Naturally, this concept has also become a key element in the corporate world, quickly becoming a foundation for reputation and competitiveness. This concept embraces the idea of continuous improvement, and precisely in this context, its potential evolution should be considered: the idea of the regenerative company.*

The regenerative company goes beyond the dictates of the sustainable company, which seeks simply to reduce its ecological footprint, and simultaneously aims to expand its positive socio-ecological footprint, restoring the health of people, places, communities, and the planet, thus seeking to ensure a positive impact (not limited to avoiding harm). Ongoing work seeks to define the characteristics and unique features of the regenerative company, analysing possible strategies, including through the concrete cases of companies that have already implemented them, thus going beyond the potential limits of sustainability. Companies must be able to go beyond sustainability to increase their positive impact on the planet, their reputation, their resilience, and their agility.

Keywords: *Regenerative firms; regenerative strategies; sustainable development; corporate strategy; ESG.*

Framing of the research. *In terms of research framing, it is important to immediately recognize that the concept of "regenerative firm" and its associated strategies are intimately connected to the sustainability movement, which has seen a veritable boom in recent years; however, it is important to clarify that the concept of regeneration seeks to transcend the most conservative dictates of sustainability, aiming to have a positive impact on the entire ecosystem (both socially and environmentally). Research in this new field is still highly conceptual, unconnected to concrete reality, and it is precisely this gap that this work seeks to address; reducing the conceptual nature of this field is crucial to ensure that regenerative strategies are understood, applicable, effective, and compatible with corporate profitability.*

The research also fits well within the ESG framework, which is increasingly crucial at the corporate level in terms of reputation, competitiveness, access to credit, and business continuity: this is due to the well-known crossing of planetary boundaries, which inexorably forces companies to rethink their operations, shifting toward more environmentally and socially responsible practices, and given the growing concern of the average consumer.

Furthermore, socio-environmental regeneration is perfectly aligned with all the latest European requirements (regulations and directives) that require companies to pay greater attention to the impacts of their operations (impacts related to the production site, supply chain[2], product, communities involved, etc.); indeed, it can represent an upgrade, as it goes beyond simply avoiding harm and aims to go further, towards the proactive concept of positive impact, whereby the company cares for and improves the socio-environmental ecosystem within which it operates.

The ongoing work, in order to better explore the concept of regeneration, thus seeks to thoroughly analyse the meaning of regeneration through the evaluation of its possible definitions and to evaluate the possible regenerative strategies also connected to specific business cases.

Purpose of the paper. *The paper's primary purpose can be divided into two: the first is informative, that is, to provide, after an intense and in-depth analysis of recent and specific literature on the topic, precise definitions that fully describe the concept of a regenerative company, a careful detailed analysis of regenerative strategies through both their categorization and a detailed analysis, and concrete cases to realistically (not just conceptually) analyse their state of the art, real-world applicability, and effectiveness. The aim is therefore to shed light on a topic that is still too conceptual, rather avant-garde, and therefore viewed with suspicion by the corporate world.*

The second objective is a direct consequence of the first: acting as a driving force for companies; in fact explaining what the concept of a regenerative company represents and the possible regenerative strategies that can be implemented within different fields (categorizing them to better understand the specific areas of intervention within a corporate context, dispelling any doubts and removing the halo of conceptuality that surrounds it), seeking to demonstrate how in the current

[1] Universitas Mercatorum – Roma, e-mail: maximilian.broglio@studenti.unimercatorum.it

[2] Directive (EU) 2024/1760 of the European Parliament and of the Council of 13 June 2024 on corporate sustainability due diligence.

global context, doing no harm is no longer enough, but rather that it is necessary to be proactive and have a positive impact (not just zero, therefore); presenting concrete success stories in which pioneering companies have adopted regenerative strategies without affecting their profits while simultaneously increasing their positive impact on the environment and society, their reputation with stakeholders, their resilience, and their agility (thus representing the prototype of an ideal company in the challenging global context in which we live), it can represent a valuable source of information for companies, a potential boost especially for those hesitant, undecided (and probably even a little fearful) about whether or not to adopt these new and interesting business strategies; the reassuring and compelling effect of the dual process of clarification and presentation of successful case studies can undoubtedly be an important driving force for the confident adoption of these strategies, so crucial to the deteriorating health of the planet.

Methodology. *From a methodological standpoint, a purely qualitative approach was chosen: it was decided to undertake a review of existing technical-scientific literature to thoroughly examine the definitions and characteristics of a regenerative enterprise, the most recent and innovative regenerative strategies, and successful case studies in which pioneering companies have implemented interesting regenerative solutions. In terms of scoping, a recent time frame was chosen for the analysis to include only the most recent and innovative solutions (logically, they have been tested to a greater or lesser extent depending on their level of technical maturity). Geographical scoping also considered cases from around the world, avoiding geographical exclusions (it would be pointless to limit the analysis, for example, to just Europe, as this would risk severely undermining the range of options and case studies useful for the research).*

Bearing in mind that this is an ongoing project, a subsequent quantitative phase involving statistical surveys on a representative sample of companies is possible. This will provide a concrete idea of their actual awareness of these innovative strategies, their perception of them, and their potential future adoption.

Results. *The results should be divided into three groups: definition of the concept of a regenerative business (where the concept originates, what it refers to, what it may imply, and its relationship to the concept of sustainability); analysis of regenerative business strategies that can be implemented by companies to go beyond the level required by sustainability (and their categorization); and evaluation of case studies to identify concrete implementation examples.*

The general concept of a regenerative economy aims to restore and regenerate damaged ecosystems, thus going beyond the mere mitigation of negative impacts typical of a sustainable approach. Its goal is to create economic systems with a positive impact on the planet, actively contributing to the maintenance of biodiversity, soil regeneration, pollution reduction, and the restoration of damaged ecosystems, where human activities support the health and prosperity of the ecosystem.

This economic thinking draws inspiration from three concepts: a late twentieth-century agricultural concept, the regenerative agriculture movement, which focused on restoring and regenerating depleted agricultural soils through practices such as organic farming, the use of compost, and the restoration of biodiversity. The goal is to create agricultural systems capable of regenerating soil fertility while reducing the use of chemical fertilizers and pesticides. Another important contribution to the history of the regenerative economy was the concept of biomimicry, born in the 1990s. This concept is based on the idea that it is essential to seek to imitate nature (ecological structures and relationships) to develop efficient, resilient, and regenerative products, technologies, and systems. Finally, the concept of the circular economy (reducing waste, repairing and recycling materials, and adopting business models based on reuse and sharing resources) cannot be overlooked.

The concept of regenerative is linked to the work of Reed[3] (2007), in which, in his analysis of the trajectory of ecological design, he sees regenerative systems as a positive antipode to conventional systems, with sustainable systems representing neutrality (hence the need to go a step beyond the sustainable logic).

The regenerative firm, therefore, is a company aware of the difference between growth and development (socio-economic vs. socio-ecological progress) and is aware of the need to go a step further than a simple sustainable company: it is therefore not enough to do no harm, for example, by reducing one's ecological footprint, but there is a need[4] to expand, in an altruistic effort, one's positive socio-ecological footprint and thus restore the health of people, places, communities, and the planet; the regenerative enterprise is also linked to the need to transform anthropocentric business models into more ecocentric models characterised by an intrinsic orientation towards nature (therefore the perspective changes and we move towards a global transdisciplinary vision in which the creation of value must no longer be inevitably associated with the destruction of other external values but rather is linked to their protection and regeneration)[5].

In terms of strategies, as mentioned, regenerative strategies focus on restoring and improving ecosystems (going beyond sustainability) through a holistic approach that encompasses people empowerment, employee well-being, product

[3] Reed, B. (2007), *Shifting from 'sustainability' to regeneration*. Building Research & Information, 35:6, 674-680.

[4] This need also comes from consumers: in fact, according to a study conducted by the American consultancy firm *ReGenFirends*, regenerative brands are preferred by around 80% of consumers over sustainable ones (thanks to their less passive attitude towards socio-environmental issues).

[5] This business concept is most closely embodied in Italy by the benefit corporation, which, according to Law No. 208 of December 28, 2015, identifies those economic activities that «in addition to the purpose of profit sharing, pursue one or more common benefit goals and operate responsibly, sustainably, and transparently towards people, communities, territories, and the environment, cultural and social assets and activities, entities, associations, and other stakeholders».

and process innovation, stakeholder engagement, and land protection. An initial attempt to categorize strategies has identified three areas of application: the natural environment, people, and corporate structure and supply chain; the former includes interventions aimed at reforestation and biodiversity improvement (for example, through corporate tree planting projects, the creation of spaces that favour pollinators), the adoption of regenerative agricultural models (for example, through practices that restore soil fertility), the adoption of circular economy processes capable of regenerating waste, returning it to the beginning of the production cycle as new raw materials, and the use of tools that quantify impact and thus enable improvement and subsequent restoration processes; for the second one, regenerative interventions focus on enhancing human capital through strategies that promote employee well-being and ongoing training, the co-creative engagement of various stakeholders, and the development of regenerative leadership models; whilst for third one, regenerative interventions focus on defining a clear corporate purpose capable of addressing pressing socio-environmental issues, fostering greater transparency within the supply chain (to create a more horizontal rather than vertical relationship), and establishing a connection with the local community in which the company operates to truly understand the issues and needs of local communities. According to several authors, this is defined as triple regeneration, an integrated strategy to coherently and synergistically restore and improve the so-called 3Ps (people, places, planet).

Das and Bocken (2024)[6] instead outline a more detailed characterization (the analytical specification increases) based on six archetypal regenerative corporate strategies: regenerative leadership[7], nature regeneration[8], social regeneration[9], responsible sourcing[10], human health and well-being focus[11], and employee level focus[12].

Hahn and Tampe (2021)[13] identify three main directions for regenerative corporate strategies: restoration (such as reforestation), preservation (such as maintaining the health of an ecosystem), and improvement.

Finally, regarding case studies, some concrete examples are proposed in which pioneering companies have successfully adopted regenerative strategies to demonstrate their feasibility and to provide inspiration. Through its "One Planet. One Health" program, Danone is promoting regenerative agriculture in North America to support soil regeneration, biodiversity, animal welfare, local farming communities, and to try to curb the indiscriminate use of fertilizers and pesticides. Ecosia, a search engine, uses 100% of its profits for the planet (funding reforestation projects) and produces twice the renewable energy needed to power all its research, thus increasing its positive impact. Patagonia is investing in organic and regenerative farming practices, as are General Mills and Illy Caffè (the latter in particular is testing regenerative practices on two plantations in Ethiopia and Guatemala where crops are rotated, minimizing the use of mineral fertilizers, pesticides and herbicides, in an attempt to operate in a carbon-neutral or carbon-negative manner and also aims to remunerate farmers fairly and reduce emissions); Interface (a global manufacturer of modular floor coverings) has developed the "Factory as a Forest" project in Australia, a production plant that, in principle, is able to provide the surrounding environment with many positive ecosystem services (thanks to the collaboration with Biomimicry 3.8 the production plant is more similar to a high-performance ecosystem than a factory); Wildling (a shoe manufacturer) promotes the regenerative economy and proactively seeks sustainable alternatives for materials (for example hemp); Fairafric has decided to establish its production plants of chocolate in Ghana to generate greater wealth in the places where cocoa is directly grown; CarbonEthics restores mangroves in Indonesia, thereby restoring marine and coastal ecosystems (while sequestering carbon); Japanese insurance company Meiji Yasuda, with its ten-year plan "MY Mutual Way 2030", aims to become «the most accessible and industry-leading life insurance, contributing to people's well-being and community vitality» by adopting a new paradigm based on prevention.

These examples, if applied on a large scale, could truly represent a turning point in increasing people's well-being and health, revitalizing ecosystems and communities, and reversing the curve of climate change.

In conclusion, these examples refute the thesis that regenerative business strategies cannot succeed in a competitive market. Indeed, this new paradigm, the evolution of sustainability, can represent a powerful tool for regenerating planetary health and community development.

The ongoing work seeks to serve as a source of information, to dispel doubts, and to act as a catalyst to inspire more and more companies to adopt these innovative regenerative strategies. While it may seem complicated to achieve a fully

Sustainable Production and Consumption, Volume 49, September 2024, Pages 529-544. Comprehensive practice review of 84 regenerative business cases from 15 sectors, to build the novel Regenerative Business Case Database. According to this study the predominant sectors with regenerative innovations were food, consumer goods, and fashion and many companies were found to be employing multiple strategies simultaneously, while also collaborating with local organizations.

[7] For example, transparent verification of claims, creating new regeneration pathways in supply chain, reinvesting profits for planet and people, advocating for equity and justice.

[8] For example, biodiversity regeneration, soil health/land regeneration, ecosystem restoration, water body restoration, carbon sequestration, forest restoration, marine regeneration, forest conservation, biodiversity conservation, animal welfare.

[9] For example, community regeneration, creation of alternative livelihoods – climate adaptation, involving local communities in decision-making, just labour conditions, connecting stakeholders to nature and communities.

[10] For example, traceable supply chain, fairer compensation for farmers, supporting small businesses, long term contract commitments, true pricing.

[11] For example, human-health & well-being regeneration, 100% nature-based products, urban green spaces restoration.

[12] For example, fair wages for workers, just labour conditions, increasing employee involvement in decision-making, improving employee health & wellness.

[13] HAHN, T., TAMPE, M. (2021), *Strategies for regenerative business*. Strategic Organization, 19(3), 456-477.

regenerative business in a linear systemic context, it is essential that these changes be implemented, even gradually, to achieve broader changes.

Future research in this field could explore questions such as the correlation between company type and the rate of adoption of regenerative strategies, which regulatory frameworks enable them to thrive, and what potential obstacles or triggers exist for their implementation.

Research limitations. *One of main problems related to this topic is that, to date, most research in the literature is largely conceptual, lacking the necessary physical-empirical connection needed to truly delineate distinctive features and understand how to effectively implement these regenerative strategies.*

This work attempts to address concrete cases, going beyond purely conceptual aspects, but it is still fair to assert that the overall context in this area is still relatively immature and underexplored, and therefore requires further future research in this direction to better understand and contextualize the implementation of regenerative strategies at the corporate level (for example, it could be interesting to better evaluate any correlations between types of companies (sector, size, location) and level of implementation to understand if there could be any barriers or triggers.

Another potential major problem is the potential greenwashing practiced by companies regarding the adoption of regenerative practices: it is essential to be able (and this it is not so easy) to carefully evaluate the interventions implemented to be able to judge whether or not they can be considered truly regenerative.

Moreover, it should be said that there are no references to regulatory frameworks that, potentially, allow regenerative strategies to flourish and this could be certainly addressed further on in the course of research progress.

Managerial implications. *The description and analytical explanation of the concept of a regenerative company, the evaluation of potential regenerative strategies, and the assessment of concrete business cases applying these strategies create a robust information base accessible to a broad audience of interested companies.*

From a practical perspective, thoroughly explaining the essence of a regenerative company, accompanied by success stories of implemented strategies, can only serve as an important accelerator for all those companies that see the future in this new business paradigm, a future that goes beyond the now-familiar dictates of sustainability to embrace a system that not only causes no harm but also has a positive impact on the planet. It has to be remarked that case studies showcasing examples of companies regenerating the environment and society, while also remaining financially viable may, at the same time, alleviate fears of embracing regenerative strategies. Regenerative strategies can prove to be fundamental in terms of resilience, risk management, and mitigation, especially in this era of volatile supply chains (related to climate disasters and conflicts).

Originality of the paper. *This work represents an important opportunity to thoroughly analyse the concept of the regenerative company and contextualize it in the current socioeconomic context, characterized by multiple crises ranging from environmental and climate issues to geopolitical ones. Its originality lies precisely in the detailed analysis of all the specificities of this new concept of business, which goes beyond the now overused concept of the sustainable company. The ultimate goal is to clearly outline regenerative strategies that can serve as inspiration and future cornerstones of corporate strategy in order to increase resilience and agility.*

The Road Not Taken: the social acceptability of competing mobility interventions in peri-urban corridors

GIOVANNI GESIOT, FRANCESCO GHEZZI, FRANCESCO RIZZI, ELEONORA ANNUNZIATA

Abstract. *This paper investigates the social acceptability of three competing mobility intervention scenarios spanning the supply-demand spectrum – Business as Usual (status quo), Road Enhancement (supply-side capacity expansion), and a TDM-based multimodal package (demand-side management) – along the SGC FI-PI-LI corridor in Tuscany, deployed as an empirical context typifying the governance dilemmas faced by peri-urban corridors. Fourteen semi-structured stakeholder interviews informed the construction of the scenarios. A web-based survey then obtained 1,995 valid citizen responses across the provinces of Florence, Pisa, and Livorno, collecting both acceptability scores and attitudinal profiles of respondents. Quantitative analysis combines clustering to identify homogeneous respondent profiles and Propensity Score Matching (PSM) to estimate the causal effect of individual attitudinal variables on collective-level scenario acceptability. Clustering analysis reveals a stable ordinal ranking across all profiles: the TDM-based multimodal package consistently commands the highest collective acceptability, followed by Road Enhancement, with BAU obtaining the lowest scores in every cluster. PSM analysis identifies institutional trust as the single most powerful cross-scenario enabler, car dependence as the primary driver of Road Enhancement support, pro-public-transport and pro-cycling orientations as selective amplifiers of TDM-based package acceptability, and road safety salience as the key mechanism behind BAU rejection. The paper contributes to the sustainable mobility literature providing an empirically grounded, causally identified map of the attitudinal determinants of mobility scenario acceptability, and, methodologically, demonstrating the value of PSM as a complement to hybrid choice modelling for corridor-level policy evaluation in peri-urban contexts.*
Keywords: *mobility acceptability; transport attitudes; propensity score matching; attitudinal segmentation; transport policy; SGC FI-PI-LI*

Framing of the research.

"Two roads diverged in a wood, and I— I took the one less travelled by, and that has made all the difference."
(Frost, 1916)

Private motorised transport is the structural backbone of European mobility. Approximately 90% of terrestrial transport demand across EU member states is concentrated on the road network, of which around 79.5% is satisfied by private light vehicles (EUCRA, 2022; EEA, 2023). Overall transport demand is projected to grow further in the coming decades with private vehicle use expected to increase in absolute terms and its dominant modal share to remain substantially unchanged through 2050 (EUCRA, 2022). This trajectory carries severe environmental consequences. Transport is one of the highest-impact sectors in the European economy due to its profound dependence on fossil fuels: in 2019 it accounted for 29.5% of total EU greenhouse gas emissions (EUCRA, 2022). Although projections indicate a decline in transport emissions after 2030, with a projected 22% reduction by 2050, this trajectory falls far short of the 90% sectoral emission reduction required under the European Green Deal (European Commission, 2019). Commuters, freight operators, local businesses, and residents produce heterogeneous and often conflicting mobility demands, and policymakers must choose between supply-side infrastructure expansion and demand-side management (Batur et al., 2019; Gärling & Schuitema, 2007).

Travel demand management (TDM) encompasses the demand-side policy instruments – modal-shift incentives, road pricing, access restrictions, and multimodal service integration – used to reduce private car dependence and steer mobility toward more sustainable patterns (Batur & Koç, 2017). Research on TDM effectiveness has established that soft, pull-oriented measures generate consistent but modest reductions in private car, while push measures prove more effective at inducing behavioural change but attract systematically lower public support (Wang et al., 2020). This push-pull acceptability asymmetry is the central empirical regularity of the TDM literature: combined packages pairing both components have emerged as the pragmatic response, achieving greater modal shift than pull-only designs while remaining politically viable when the pull component is sufficiently attractive (Moeinaddini et al., 2026; Moeinaddini & Habibian, 2023). Beyond the policy-level push-pull asymmetry, a second strand of the literature asks why individuals respond differently to the same TDM measures. Kim et al. (2023) identifies perceived fairness, infringement of freedom, and perceived effectiveness as the primary predictors. Attitudinal segmentation research has demonstrated that identifiable traveller typologies respond differently to TDM stimuli independently of socio-demographic characteristics (Soza-Parra & Cats, 2024), a finding corroborated by recent hybrid choice modelling showing that pro-car and pro-environment latent constructs are structural determinants of both mode choice utility and TDM policy package acceptability (Adamidis et al., 2025; Moeinaddini & Habibian, 2025). What the literature has not yet adequately addressed is how these attitudinal typologies shape collective-level evaluations of bundled scenario alternatives and whether their effects hold under causal inference designs that control for the selection processes shaping attitudinal profiles.

A further gap concerns the methodological treatment of attitudinal variables in policy acceptability research. The dominant approach – embedding attitudes as latent variables in hybrid choice models (Walker & Ben-Akiva, 2002; Adamidis et al., 2025) – is well suited to predicting individual mode choice utility but is not designed to estimate the causal contribution of attitudinal profiles to collective policy acceptability ratings (Chorus et al., 2014). Standard regression-based treatments share the same limitation: they quantify correlational associations between attitude scores and acceptance outcomes without addressing the selection effects that make certain attitudinal profiles more prevalent among specific demographic groups, nor the endogeneity that arises when attitudes and preferences are jointly shaped by unobserved characteristics (Guerrero et al., 2021; Graham, 2025). Propensity score matching (PSM) offers a more robust alternative, enabling quasi-experimental comparisons between groups defined by distinct attitudinal dispositions while controlling for observable confounding factors (Rosenbaum & Rubin, 1983; Cao et al., 2010). Despite its established track record in transport behaviour research, causal inference methods including PSM remain substantially under-deployed in the acceptability literature relative to their inferential potential (Graham, 2025). Its application to peri-urban corridor acceptability research represents a methodological contribution with direct relevance to the broader class of TDM governance challenges in which policy choice is collective, attitudinal profiles are heterogeneous, and causal identification is required.

The SGC FI-PI-LI is used in this paper as the empirical context for investigating a governance challenge structurally shared by peri-urban corridors across European metropolitan regions. As one of Tuscany's most heavily trafficked arterial corridors, it concentrates competing pressures from urban mobility, industrial logistics, and inter-regional connectivity, making it a rich and policy-relevant arena in which to examine how different citizen profiles evaluate competing mobility intervention scenarios that span the supply-side/demand-side spectrum (Regione Toscana, 2025). The social dimension of potential interventions along this corridor remains empirically underexplored and the analytical question it raises is broadly shared across peri-urban contexts where policymakers face analogous scenario-selection challenges.

Purpose of the paper. *The paper addresses two research questions (RQ). RQ1: Which are the citizen's social acceptability profiles across mobility scenarios spanning the supply-demand spectrum? RQ2: Which attitudinal constructs causally drive differential collective acceptability across mobility scenarios independently of socio-demographic selection?*

In addressing these objectives, the paper contributes to both the sustainable mobility policy acceptability literature and the methodological debate on causal inference in transport policy research (Moeinaddini et al., 2026; Graham, 2025). By supplying rigorous, empirically grounded evidence on the distribution of citizen preferences and their attitudinal determinants, the paper serves two audiences: regional administrators, transport planners, and local authorities directly engaged in transportation management activities, and the wider community of researchers confronting analogous mobility scenario-selection challenges in other peri-urban contexts.

Methodology. *The study adopts a quantitative design, with an integration of qualitative interviews. In the first phase, fourteen semi-structured face-to-face interviews were conducted with key informants from regional and municipal administrations, public-sector companies, private firms, and trade associations along the FI-PI-LI corridor. Once informational saturation was reached, the insights were synthesized into three reality-grounded scenarios: Business as Usual (BAU), Road Enhancement, and a TDM-based multimodal package In the BAU scenario, the transport infrastructure remains largely unchanged aside from already planned interventions, while the financial resources that would otherwise be invested are allocated to other areas of public spending. The Road Enhancement scenario involves substantial investment in supply-side infrastructure expansion, including the construction of an additional driving lane. Finally, the TDM-based multimodal package scenario proposes a holistic set of demand-side management measures, including the development of multimodal hubs, reinforcement of public transport, cycling-rail integration, and the implementation of a regional Mobility-as-a-Service platform.*

In the subsequent quantitative phase, a web-based survey was administered to citizens across the provinces of Florence, Pisa and Livorno, collecting 1,995 valid responses collected between June and August 2025. Attitudinal constructs –car dependence, pro-drive, pro-public-transport, pro-cycling propensity, transportation safety perception, environmental consciousness, openness to change and institutional trust – were measured on seven-point Likert scales using items adapted from validated instruments (Cao, 2010; Kim et al., 2013). The construct structure of the attitudinal battery was validated through Exploratory Factor Analysis (EFA) prior to modelling, following established practice in hybrid choice modelling research (Adamidis et al., 2025). Each scenario was presented via a short video stimulus that included a description of the main features of the scenario, as well as their positive and negative impacts. Respondents then rated its collective acceptability as a public investment priority (Kim et al., 2013). The citizen dataset was then subjected to a two-stage inferential analysis. In the first stage, k-means cluster analysis was applied to identify homogeneous respondent profiles on the basis of their mobility preferences and attitudinal scores. The number of clusters was determined by a combination of statistical criteria and interpretive criteria aimed at maximizing both within-group coherence and between-group distinctiveness (Jaeger & Banks, 2023). In the second stage, Propensity Score Matching was employed to strengthen the inferential basis of the analysis and move toward causal estimation (Graham, 2025). PSM enabled the estimation of the Average Treatment Effect on the Treated (ATET) by comparing scenario acceptability and perceived utility between respondents who differ with respect to a specific treatment variable while remaining

comparable across all other covariates (Rosenbaum & Rubin, 1983). Matching was performed using a nearest-neighbour algorithm (nn=1), with covariate balance verified post-matching in each specification. This procedure allows the mean treatment effect on scenario acceptability to be quantified by isolating the variation attributable to the treatment variable from that explained by other covariates.

Results. *Clustering analysis (k-means, k = 4) identifies four respondent profiles with broadly balanced sample sizes (381–568 respondents), differentiated primarily by age, gender, and educational attainment. All acceptability scores are measured on a seven-point Likert scale. Across clusters, the ranking of scenarios by collective acceptability is consistent: the TDM-based multimodal package is the most acceptable, followed by Road Enhancement, while BAU is the least acceptable. Differences between clusters therefore concern the magnitude of these preferences rather than their ordering.*

The two younger and more educated clusters assign the highest acceptability to the TDM-based multimodal package. In the first (n = 517), composed mainly of women, mean acceptability scores are 5.04 for the TDM-based package – the highest across clusters – 4.61 for Road Enhancement, and 4.12 for BAU. In the second younger-educated cluster (n = 529), the TDM-based package scores 4.86, Road Enhancement 4.49, and BAU 4.08.

The elderly cluster (n = 568) exhibits the lowest acceptability across all scenarios: 4.66 for the TDM-based package, 4.21 for Road Enhancement, and 3.61 for BAU. Although the preference ordering remains unchanged, the smaller margin over Road Enhancement compared with younger clusters suggests a more conservative disposition toward mobility change, indicating that age moderates rather than reverses the preference structure.

Finally, the middle-aged, lower-educated cluster composed mainly of men (n = 381) is the only group in which Road Enhancement approaches parity with the TDM-based package (4.52 vs. 4.69), a gap of only 0.17 scale points compared with 0.37–0.43 in the other clusters. BAU scores 4.09 in this group. This narrower differential is consistent with a profile characterized by stronger structural car dependence, male predominance, and a more direct personal stake in road capacity (Sierra Muñoz et al., 2024).

PSM analysis estimates the ATET for five attitudinal treatment variables. Each variable is dichotomised using a theoretically motivated binary threshold designed to identify respondents with a meaningfully elevated level of the attitude while preserving adequate treated-group size for reliable matching (Ortiz-de-Mandojana & Bansal, 2016). Within each treatment, treated and control respondents are matched on all observable socio-demographic covariates using nearest-neighbour matching, isolating the acceptability difference attributable to the attitudinal variable itself.

Car-dependence attitude produces significant positive effects on BAU and Road Enhancement acceptability (ATET = +0.31 and +0.56 respectively, $p<0.01$ for both), while its effect on the TDM-based package is positive but statistically negligible (ATET ≈ +0.13, $p>0.1$). The contrast is theoretically informative: car-oriented respondents differentially support scenarios that preserve or expand road infrastructure, but their attitudinal disposition carries no significant independent weight when evaluating a multimodal collective mobility scenario.

Pro-public-transport attitude produces a mirror-image pattern. Its effect on the TDM-based package is strongly positive and significant (ATET = +0.41, $p<0.001$), while its effect on Road Enhancement is negative and significant (ATET = −0.25, $p<0.05$), indicating that pro-PT respondents actively discount infrastructure-expansion scenarios on the collective acceptability dimension. The effect on BAU is modestly positive (ATET = +0.26, $p<0.05$), suggesting that pro-PT respondents are not generically opposed to the status quo but specifically favour scenarios oriented toward collective mobility.

Pro-cycling attitude reinforces this pattern. Treated respondents assign significantly higher collective acceptability to both the TDM-based package (ATET = +0.42, $p<0.001$) and BAU (ATET = +0.51, $p<0.001$), while the effect on Road Enhancement is negligible and non-significant (ATET = +0.09, $p = 0.34$). The asymmetry confirms that cycling-oriented respondents are selectively supportive of scenarios compatible with active and integrated mobility, and indifferent to supply-side road interventions.

Institutional trust emerges as the single most powerful and cross-cutting attitudinal determinant. It produces large, significant positive effects on collective acceptability across all three scenarios: ATET = +1.00 for BAU ($p<0.001$), +0.49 for Road Enhancement ($p<0.001$), and +0.49 for the TDM-based package ($p<0.001$). The magnitude of the BAU effect is particularly striking and indicates that trust in institutions substantially raises acceptability of the status quo independently of its substantive content. More broadly, institutional trust operates as a general enabler of policy acceptability rather than as a scenario-specific attitudinal driver, consistent with its identification in the literature as a meta-level disposition that conditions how attitudinal and policy-specific signals translate into acceptability judgements (Morton et al., 2021; Palomo-Vélez et al., 2023).

Road safety perception is the only treatment variable that produces a negative significant effect on the BAU scenario specifically, and the only one whose negative effect targets the status quo rather than an active intervention. Respondents with high safety salience, in fact, actively reject BAU (ATET = −0.23, $p<0.05$), consistent with the interpretation that the status quo is perceived as failing on the safety dimension. At the same time, they assign significantly higher collective acceptability to both Road Enhancement (ATET = +0.34, $p<0.01$) and the TDM-based package (ATET = +0.40, $p<0.01$), suggesting that safety-oriented respondents are not mode-biased but change-oriented: they favour any scenario that signals a departure from current conditions, regardless of whether the intervention is supply-side or demand-side in character.

Taken together, the PSM results confirm the attitudinal structure identified in the clustering analysis and sharpen its causal interpretation. Car dependence reinforces acceptance of supply-side scenarios; pro-PT and pro-cycling orientations selectively amplify acceptance of the TDM-based package while discounting Road Enhancement; institutional trust elevates acceptability all scenarios; and safety salience drives rejection of the status quo without discriminating between the two active intervention types. These attitudinal effects are independent of socio-demographic composition, confirming that mobility policy preferences are structurally grounded in attitudinal profiles rather than reducible to age, education, or habitual modal behaviour alone (Batur & Koç, 2017).

Research limitations. *Several limitations qualify the interpretation of the findings. The quantitative sample, while numerically substantial (N = 1,995), is not fully representative of the Tuscan population, most of all in relation with the education profile of respondents, and the use of a web-based self-administered survey introduces the possibility of self-selection bias: citizens more engaged with mobility issues may be systematically overrepresented.*

The study relies on cross-sectional, observational data. Although PSM substantially reduces confounding from observable characteristics, it cannot eliminate bias arising from unobserved heterogeneity, and the causal estimates should be interpreted as plausible rather than conclusive. The three scenarios were presented via short video stimuli, a pragmatic choice that ensures comparability but inevitably simplifies complex trade-offs, potentially shaping responses in ways that may not fully replicate reactions to real-world implementations. Future research would benefit from longitudinal designs, stratified territorial sampling, and deliberative formats that allow respondents more time to engage with the implications of each scenario.

Managerial implications. *The findings carry concrete implications for regional transport planning and infrastructure governance. Most immediately, the broad rejection of the BAU scenario – driven above all by road safety concerns– signals an urgent need for substantive intervention. The status quo, with just some incremental maintenance, is perceived as inadequate across all demographic groups, and policymakers who delay acting risk further erosion of the institutional trust that the results identify as the single most powerful cross-scenario enabler of acceptability (Morton et al., 2021). The evidence on Road Enhancement warrants particular attention, as its collective acceptability consistently lags behind that of the TDM-based package across three of four citizen profiles. This divergence between private benefit and social legitimacy is a well-documented pattern in transport infrastructure evaluation, where large-scale supply-side investments tend to generate concentrated private gains while dispersing costs and externalities broadly across the population (Gärling & Schuitema, 2007; Rosenfield et al., 2020). Communication strategies that acknowledge the legitimate concerns of car-dependent users while building support for sustainable alternatives among younger cohorts will be essential to securing the social legitimacy required for effective implementation (Tertoolen et al., 1998).*

At a strategic level, the results support the TDM-based multimodal package as the more durable and socially legitimate policy direction. While the Road Enhancement scenario does not command generalised consensus even among car-dependent respondents, the TDM-based package, by contrast, is recognised across all citizen profiles as the option more likely to generate collective benefits. This finding is consistent with the literature showing that combined push-pull packages, when the pull component is sufficiently attractive, can bridge the acceptability gap between supply-side and demand-side interventions (Eriksson et al., 2008; Moeinaddini & Habibian, 2023). Its modular architecture allows phased and reversible investment over an extended planning horizon, reducing the lock-in risks associated with large-scale road infrastructure and permitting progressive adjustment in response to citizen feedback (Driscoll et al., 2014). This adaptive, experimental logic aligns with the emerging governance literature on iterative policy design, which argues that incremental, monitorable interventions are better suited to building public trust and facilitating gradual behavioural change than irreversible infrastructure commitments (Driscoll et al., 2014). The extended implementation timeline also allows citizens to adapt mobility habits progressively, supporting the cultural shift toward intermodal and sustainable travel that the results show is already more advanced among younger, more educated cohorts (Nikitas et al., 2024). The preference structure has implications that extend beyond transport policy proper. The alignment between the TDM-based package and the preferences of younger, highly educated citizens suggests that sustainable mobility investment functions as a locational amenity in regional competition for skilled human capital – a mechanism well established in the literature on knowledge economy development and talent attraction (Florida, 2002; Wagner & Growe, 2023). Sectors most likely to reinforce demand for the TDM-based option are also those whose workforce is most mobile, most educated, and most sensitive to urban quality-of-life conditions, including transport accessibility and environmental sustainability.

Originality of the paper. *This paper makes several original contributions to the literature on sustainable mobility's social acceptability. Substantively, it deploys the SGC FI-PI-LI corridor as an analytically generative empirical context – a high-salience, real-world case that combines the complexity of competing mobility intervention scenarios spanning the supply-demand spectrum, a large and diverse citizen sample, and locally validated attitudinal constructs. The substantive contribution lies not in the corridor's singularity but in the analytical framework's capacity to reveal how attitudinal heterogeneity structures mobility scenario acceptability in ways that are transferable to other peri-urban corridor governance contexts facing analogous scenario-selection dilemmas.*

Methodologically, the application of Propensity Score Matching to attitudinal treatment variables represents a significant innovation for the field. While PSM is well established in programme evaluation and health economics, and has precedent in transport behaviour research as a tool for addressing self-selection in built-environment studies (Cao

et al., 2010), its use in transport policy acceptability research remains limited (Graham, 2025). Critically, the inferential logic differs from the hybrid choice modelling approach that currently dominates attitudinal transport research (Adamidis et al., 2025; Moeinaddini & Habibian, 2025). Where HCM embeds attitudes as latent continuous variables to improve the fit of individual utility functions for discrete mode choices, PSM treats attitudinal profiles as binary quasi-experimental treatments to estimate the causal effect of certain attitudes on collective policy acceptability scores.

The unintended consequences of collaborative consumption: A quantitative investigation on household rebound effects in the sharing economy

CECILIA GRIECO[1], VERONICA CAPONE[2], VALENTINA CASCIO[3]

Abstract. *It is commonly believed that the sharing economy (SE) promotes sustainable consumption. However, a debate is open on its possible negative effects. The cost savings and convenience of sharing practices generates the so-called "rebound effect", a response to a measure that offsets the effect of the measure itself. The purpose of this research is to shed light on the rebound effects that are associable with the SE, focusing on the household level. This emerges as a gap in the wider stream of research about SE and consumer behavior, that is currently receiving great attention, and for which extended knowledge has been called for. Yet, despite some sparse efforts, an investigation on the possible micro-rebound effect is currently missing. The study adopts a quantitative approach based on an online questionnaire administered to users of sharing economy platforms (n=265). The data were analyzed using Partial Least Squares Structural Equation Modeling (PLS-SEM). The results show that economic rebound effects are primarily associated with perceptions of the sharing economy's affordability and value-driven adoption factors. Meanwhile, a platform's experiential and emotional value proposition generates both economic and social effects. Environmental rebound effects, on the other hand, are more closely linked to the complementary − rather than substitutive − use of sharing economy platforms. Overall, the study demonstrates that the economic, environmental, and social dimensions of rebound are interconnected, offering new evidence on the potential externalities of the sharing economy.*
Keywords: *sharing economy; rebound effect; consumer behavior; regression model*.

Framing of the research. *The sharing economy (SE) has emerged as an economic paradigm based on resource redistribution and on the optimized use of assets' idle capacity (Pouri and Hilty, 2021). This virtuous value proposition led this form of consumption to be praised for its inner sustainability, yet it also raises several questions about the appropriateness of this association (Grieco and Palagonia, 2024). Within the debate around the relation between SE and sustainability, a branch of studies about the negative effects (i.e., dark side) of the SE has emerged, with the aim to shed light on the damages it has created at economic, social, and environmental levels (Buhalis et al., 2020). In this context, the discourse about rebound effects is becoming a prominent area of investigation. Despite it has been widely addressed in other related domains such as that of circular economy, studies about the rebound effects in SE are so far scant and fragmented (Henry et al., 2021). The concept of rebound effect has been originally developed concerning energy conservation and it refers to the establishment of behaviors or other responses that offset the potentially positive benefits an initiative might have. For example, when improved energy efficiency leads to potential energy savings, consumers might be inclined to increase their usage of electric devices and ultimately limiting or even canceling out the expected benefit (Dütschke et al., 2018). The interest about the rebound effect in the SE context has recently increased as its exponential growth leads to a higher consumption, severely questioning the actual economic, environmental and social benefits that the SE could bring about (Meshulam et al., 2022).*

Purpose of the paper. *In the SE domain, rebound effects have been scantly investigated. Moreover, extant literature is quite fragmented, with contributions focused on specific effects (e.g., Ackermann and Tunn, 2024) and/or specific product/service categories (e.g., Warmington-Lundström and Laurenti, 2020; Meshulam et al., 2023). For this reason, the purpose of the research is to investigate rebound effects in the SE, quantitatively assessing the impact of different variables on their manifestation. The research is a part of a wider project aimed at mapping these effects in the SE domain and it follows a previous qualitative investigation with SE users. Thus, merging the outputs of a literature search and of the qualitative empirical analysis, the aim is to test a set of hypotheses about the determinants and the typologies of rebound effects.*

The SE is often considered an economically convenient option compared to its non-sharing counterparts (e.g., sharing a car instead of owning one, or doing secondhand shopping instead of buying new garments). Studies about rebound effect in circular economy shed light on the way this perception impacts on the typologies of rebound effect. For example, Zink and Geyer (2017) identify circular products affordability as a source of overconsumption. The same applies to the degree of substitution, which, in the circular economy domain is considered as a potential source of rebound effect. This happens because the secondary good cannot fully substitute the traditional one, leading individuals to an ultimate increase in consumption (Zink and Geyer, 2017; Bączyk et al., 2024). Despite in the circular economy domain this effect has been tested from an economic perspective, it might also lead to different types of effects (i.e., social and

[3] Sapienza University of Roma. E-mail: valentina.cascio@uniroma1.it

environmental). A key role is surely played by the drivers which lead individuals to adopt SE services. Scholars agree that the magnitude of rebound effect is increased by consumers economic motivations and decreased by environmental motivation (Merino-Saum et al., 2023; Ribera Jemio et al., 2024). In parallel, the platform itself could play a role through its value proposition which might orient consumers towards incorrect behaviors and in turn support the manifestation of rebound effects. In the circular economy domain, Bączyk et al. (2024) unveil that rebound effect increases when the value proposition entails convenience or enables new forms of consumption, while it decreases when sufficiency is promoted.

SE spreads across different industries, and the differences among products/services offered through the platforms do have an impact on the manifestation of rebound effects. As stated by Merino-Saum et al. (2023), different industries are associated with different levels of rebound effects, which for example is higher in the clothing industry (Wood et al., 2018) and lower for the reselling of smartphones or in boat-sharing (Makov and Font Vivanco, 2018; Warmington-Lundström and Laurenti, 2020). Yet extant contributions usually adopt an environmental perspective, while industrial differences might also impact on different types of rebound effects (i.e., at economic and social level). Finally, the specificities of geographical contexts might have an influence on the manifestation of rebound effects in terms of laws and regulations that can be very different from one country to another. Differences might also emerge from the areas in which individuals live, i.e., large cities versus smaller countries, with specific needs for example in the mobility industry.

Basing on the aforementioned considerations, the following set of hypotheses has been formulated:

H1. The perception of convenience has an impact on the nature and intensity of rebound effects.

H2. The degree of substitution of SE product/service over the non-sharing alternative has an impact on the nature and intensity of rebound effects.

H3. The drivers of adoption which lead to the sharing economy have an impact on the nature and intensity of rebound effects.

H4. Platform's value proposition has an impact on the nature and intensity of rebound effects.

H5. The industry has an impact on the nature and intensity of rebound effects.

H6. The geographical context has an impact on the nature and intensity of rebound

Methodology. *This research adopts a quantitative design aimed at empirically testing the proposed theoretical model in relation to the use of sharing economy platforms and the resulting rebound effects. The data was collected using a structured questionnaire administered online via Google Forms and distributed through digital channels.*

The questionnaire is structured to analyze how users utilize the platforms and to measure, in a first phase, certain internal dimensions, such as adoption drivers, and external dimensions, such as the platform's value proposition. Subsequently, the tool detects the rebound effects − economic, environmental, and social − resulting from the use of sharing economy platforms. The constructs were measured using scales validated and adapted for the research: perceived economic convenience (PEC) (Hawlitschek, 2016), drivers of adoption (DA) (Kurisu, 2021), degree of substitution (DS) (Lamberton and Rose, 2012), platform value proposition (VP) (Zhang et al., 2019), economic rebound effects (ECOR) (Parguel, 2018), environmental rebound effects (ENVR) (Visschers et al., 2016), and social rebound effects (SR) (Mittendorf, 2018). All items were evaluated using a five-point Likert scale.

A non-probability sampling strategy was adopted for convenience, widely used in studies aimed at verifying theoretical models rather than inferring population characteristics (Etikan et al., 2016). The questionnaire was administered to individuals who are familiar with or use sharing economy platforms to ensure the relevance of the responses. The final sample consisted of 265 valid responses, deemed adequate for analysis.

Data analysis was conducted using Partial Least Squares Structural Equation Modeling (PLS-SEM) with R software. In a preliminary phase, a Principal Component Analysis (PCA) was performed on the constructs to verify the factorial structure of the scales used. The principal component analysis (PCA) led to a partial reorganization of some constructs in the model. The PEC (Perceived Economic Convenience) construct remained unchanged.

The DA (Drivers of Adoption) construct was divided into two dimensions: DA1, relating to value-oriented adoption drivers (e.g., economic convenience), and DA2, relating to experience-oriented drivers (e.g., meeting new people). Similarly, the DS (Degree of Substitution) construct was divided into DS1, which expresses full substitution for traditional alternatives, and DS2, which reflects complementary use of the platform. The platform's value proposition (VP) is also divided into two dimensions: VP1, linked to the functional aspects of the service, and VP2, connected to the experiential and emotional dimension. Finally, rebound effects were divided into specific sub-dimensions: EBR (Economic Behavioral Rebound) and EPB (Economic Psychological Rebound) for the economic dimension; SD (Social Distrust), SDE (Social Disengagement), and NSI (Negative Social Impact) for the social dimension; EDP (Environmental Damage Perception) and EW (Environmental Waste) for the environmental dimension.

The PLS-SEM method is widely used in marketing, management, and social science studies due to its high predictive power and flexibility in analyzing complex models, nonlinear relationships, and heterogeneous data (Hair et al., 2014). Following the two-stage approach proposed by Anderson and Gerbing (1988), the analysis was divided into two phases: in the first phase, the measurement model was evaluated, while in the second phase, the structural model was estimated and analyzed in order to examine the causal relationships between the latent constructs.

Results. *The structure of the measurement model was evaluated through construct reliability and validity analysis. This procedure allows for verification of the consistency between empirical data and the hypothesized theoretical structure, evaluating the contribution of the indicators to their respective latent constructs (Brown, 2015).*

The factor loadings of the items are generally adequate, with values ranging from 0.60 to 0.94 (Hair et al., 2010). Composite reliability (rhoC) ranges from 0.74 to 0.93, above the recommended threshold of 0.70 (Hair et al., 2010). Convergent validity is also satisfied, with AVE values ranging from 0.56 to 0.86, above the minimum limit of 0.50 (Fornell and Larcker, 1981).

Cronbach's alpha exceeds the threshold of 0.70 for most constructs (Hair et al., 1998); for some slightly lower values, it was nevertheless decided to keep them in the model, considering the exploratory nature of the analysis and compliance with the composite reliability and AVE criteria (Hair et al., 2010).

Table 1 shows the values of factor loadings, Cronbach's alpha (α), composite reliability (ρc), and AVE for each construct considered in the model.

Table 1. Reliability and validity test

Construct	*Alpha*	*rhoC*	*AVE*
PEC	*0.885*	*0.921*	*0.745*
DA1	*0.627*	*0.795*	*0.566*
DA2	*0.641*	*0.780*	*0.474*
DS1	*0.586*	*0.827*	*0.705*
DS2	*0.553*	*0.815*	*0.688*
VP1	*0.480*	*0.765*	*0.630*
VP2	*0.767*	*0.894*	*0.808*
EBR	*0.639*	*0.845*	*0.732*
EPB	*0.697*	*0.864*	*0.762*
EDP	*0.853*	*0.931*	*0.872*
EW	*0.315*	*0.745*	*0.593*
SD	*0.843*	*0.927*	*0.864*
SDE	*0.418*	*0.745*	*0.608*
NSI	*0.846*	*0.928*	*0.866*

The relationships hypothesized in the model were tested using Partial Least Squares Structural Equation Modeling (PLS-SEM) with SmartPLS software. Subsequently, to assess the significance of the estimated coefficients, a bootstrap procedure with 5,000 resamples and two-tailed tests was applied, in line with the methodological guidelines in the literature (Hair et al., 2010).

The model's results reveal several significant relationships among the variables analyzed, providing empirical support for some of the hypotheses formulated.

First, the perceived economic convenience (PEC) emerges as one of the main predictors of economic rebound effects. In particular, PEC positively influences both the behavioral and psychological dimensions of economic rebound. This result provides partial support for hypothesis H1, as perceived convenience significantly affects the economic dimension of rebound, while no significant effects emerge on the social and environmental dimensions.

The complementary use of both sharing economy platforms and traditional goods (DS2), on the other hand, influences environmental waste (EW). Therefore, the study provides partial support for hypothesis H2, suggesting that when platforms are used as a complement rather than a substitute for traditional forms of consumption, environmental rebound effects may emerge. Value-oriented adoption drivers (DA1), such as the pursuit of cost savings, also have a positive effect on behavioral economic rebound. This suggests that motivations related to cost savings and perceived value may encourage greater use of sharing economy platforms and, consequently, foster trends toward increased consumption. Therefore, hypothesis H3 is partially confirmed, as adoption drivers primarily influence the economic dimension of the rebound.

The platform's value proposition exhibits varying effects depending on its components. In particular, the functional dimension (VP1) is most strongly associated with economic and social rebound effects, while the experiential and emotional dimension (VP2) plays a particularly significant role in the model, positively influencing both economic and environmental rebound effects. These results suggest that the platform's value proposition may facilitate the generation of rebound effects.

Finally, with regard to the effects of social rebound, significant relationships emerge between the economic and environmental dimensions of rebound and certain manifestations of the social dimension. In particular, social disengagement (SDE) is influenced by psychological economic rebound and the perception of environmental waste. At the same time, social distrust (SD) is positively associated with both the perception of environmental harm and the perception of waste.

The structural model explains a significant portion of the variance, particularly for behavioral economic rebound ($R^2 = 0.458$). Slightly lower values emerge for the psychological economic rebound ($R^2 = 0.237$) and for the social effects, with R^2 equal to 0.205 for SR1, 0.246 for SR2, and 0.232 for SR3. However, these values are close to the 30% threshold, which is generally considered satisfactory in social and behavioral science studies, confirming the robustness of the estimated model (Hair et al., 2010). The environmental rebound dimension is less well explained, with R^2 equal to 0.040

for ENVR1 and 0.116 for ENVR2; however, interesting significant relationships emerge, suggesting the possible presence of additional relevant predictors for these dimensions.

Table 2. Hypothesis testing

Path	β	p
PEC → EBR	0.397	.000
PEC → EPB	0.358	.000
DS2 → EW	0.147	.039
DA1 → EBR	0.172	.018
VP1 → EBR	0.127	.053
VP1 → SDE	0.160	.032
VP2 → EPB	0.196	.003
VP2 → EBR	0.130	.013
VP2 → EDP	0.173	.035
VP2 → EW	0.224	.002
EPB → SDE	0.189	.006
EBR → EW	0.192	.052
EW → SDE	0.180	.003
EW → SD	0.188	.009
EW → NSI	0.189	.008
EDP → SD	0.263	.000
EDP → NSI	0.310	.000
EDP → SDE	0.125	.052

To verify whether the platform's industry sector is a predictor of rebound effects, a one-way ANOVA analysis was conducted, a statistical technique used to compare differences between the means of several independent groups.

The results highlight differences between sectors for certain rebound dimensions. In particular, economic rebound effects (EBR and EPB) are higher in the food sector. With regard to social rebound, significant differences emerge for the dimension of social disengagement (SDE), which is more pronounced in the second-hand and food sectors. Finally, with regard to environmental rebound, the dimension of environmental waste (EW) shows higher levels in the food sector.

Therefore, H5 is partially confirmed, and only with regard to the economic rebound effect. With regard to H6, the results of the ANOVA analysis do not reveal any statistically significant differences among the various geographic contexts considered (small, medium, and large towns); therefore, H6 is not supported.

Table 3. One-way ANOVA

	Second-hand		Accommodation		Mobility		Food		ANOVA one-way	
Rebound effect	μ	ds	μ	ds	μ	ds	μ	ds	F	p
EBR	3.394	0.980	3.098	0.955	2.312	0.948	3.625	0.762	10.140	<0.001
EPB	3.028	1.093	2.866	1.110	2.375	0.967	3.312	0.957	3.678	0.006
SD	2.156	0.811	1.991	0.887	1.859	0.864	2.016	0.828	1.282	0.277

Overall, the results show that rebound effects in sharing economy platforms emerge from a complex dynamic between users' economic motivations, platform value strategies, and how services are used. In particular, the perceived economic convenience of the platform remains one of the main factors fueling economic rebound, suggesting that the savings generated by using the platform tend to translate into increased consumption or greater spending power. At the same time, value-oriented adoption drivers, such as the search for convenience or the perceived choice of sustainability, also contribute to amplifying these dynamics.

The experiential and emotional value proposition of platforms also plays a particularly important role, not only reinforcing the effects of economic rebound but also contributing to an increase in the size of the environmental rebound, both in terms of perceived environmental damage and waste generated. This suggests that platforms that emphasize experiential and relational dimensions can indirectly stimulate higher levels of consumption or service use.

The results also show that the different dimensions of rebound do not operate in isolation but are interconnected. In particular, economic and environmental effects tend to propagate into the social dimension: perceived environmental waste and psychological economic rebound are associated with higher levels of social disengagement, while the perception of environmental damage and waste is also linked to higher levels of social distrust and a perception of negative social impacts.

Research limitations. *This research is a part of a wider project aimed at investigating rebound effects in the SE domain. The questionnaire has thus been built basing on the merge of extant literature and the findings of a previous qualitative investigation with SE users. In this sense, the items do not always refer to established construct, which might have undermined the validity of the model. A second limitation comes from the research being based on self-reported behaviors which might be biased from individual perspectives and from social desirability.*

Managerial implications. *From a managerial point of view understanding consumer behavior in relation to the SE and the negative effects these behaviors might generate is of strategic relevance. In fact, platform managers can support consumer education towards a wiser use of SE platforms in order to mitigate the possible rebound effect that has the potential to nullify the benefits of the SE. This is particularly true when considering the link between the SE and sustainability, that has so far been highly debated. In fact, while some scholars pinpoint to their closeness, others claim that in the consumers' view the desire to adopt a more sustainable lifestyle is nothing more than a positive side effect of SE adoption.*

Originality of the paper. *The purpose of the research is to understand the rebound effect of the SE, adding on the field of research about its negative externalities at economic, environmental and social level that are referred to as its "dark side". The value of this research is manifold. From the academic perspective, the research allows to fill a gap about the investigation of the rebound effect in the SE domain. The interest towards the topic is witnessed by recent contributions where the need to go in depth in this analysis is raised. Moreover, some attempts have been made, resulting in the identification of specific effect and/or referring to specific product/service categories. Yet, a complete overview is currently lacking, while its development could benefit both scholars and practitioners. The research considers different industries of the SE, answering the call for future studies that integrate the ambivalent impact that is generated relating to different product/service categories.*

Unveiling Systemic Trade-offs in the Dairy Industry: Beyond Local Optimization of Sustainability Performance

GIADA SALVATORE[1]

Abstract. *The dairy sector represents a vital socio-economic engine but faces significant environmental pressures. While Sustainability Performance Measurement Systems are essential for managing Triple Bottom Line performance, current literature highlights a profound methodological fragmentation. This study employs a Systematic Literature Review of 76 peer-reviewed articles to map how sustainability is operationalized across the supply chain. Findings reveal a dominant eco-efficiency logic, where environmental metrics are systematically paired with economic indicators, while the social dimension remains a marginalized pillar, rarely treated as a performance-driven metric.*

Crucially, the research investigates the interaction dynamics between sustainability dimensions in each study, specifically analyzing whether economic, environmental, and social goals result in synergies or trade-offs. Using Fisher's Exact Test, the study statistically validates a structural break: while localized, single-stage assessments frequently report synergies, 100% of end-to-end systemic studies identify trade-offs ($p < 0.05$). This evidence suggests that win-win scenarios are often artifacts of narrow analytical boundaries. For managers, these results necessitate a transition from fragmented optimization toward the strategic governance of systemic frictions.

Keywords: *Dairy Supply Chain; Sustainability; Triple Bottom Line; Performance Measurement; Sustainability Measurement; Performance Indicators*

Framing of the research. The dairy sector represents a critical nexus within global food systems, playing a dual role as both a vital socio-economic engine and a significant environmental pressure point (McGarr-O'Brien et al., 2023). From a socio-economic perspective, dairy is key for global food security and nutrition, and a fundamental pillar for rural livelihoods and economic resilience, contributing directly to multiple Sustainable Development Goals (Gliszczyńska-Świgło et al., 2023; Wattiaux, 2023). However, this economic importance is mirrored by substantial environmental challenges: the sector is responsible for a huge portion of total GHG emissions, exerting also significant pressure on natural resources through high freshwater consumption, extensive land use, and energy-intensive processing stages. Consequently, the dairy sector is considered a critical arena for global sustainability planning (Ineichen et al., 2022).

In light of these pressures, implementing rigorous sustainability assessment frameworks is now a strategic necessity: such systems provide the objective evidence required to move beyond descriptive analysis toward actionable management interventions. Hence, Sustainability Performance Measurement Systems (SPMS) are essential for monitoring and managing Triple Bottom Line (TBL) performance (Carvalho et al., 2022). Their strategic value lies in their ability to enable tailored evaluations across the supply chain, converting sustainability scores into actionable knowledge for strategic decision making (Damtof et al., 2025; Nappi et al., 2024). By providing a structured architecture of Key Performance Indicators (KPIs), SPMS allow managers to align targeted interventions with corporate strategy and context, ensuring that sustainability goals are integrated into the firm's value proposition (Damtof et al., 2025).

However, despite the acknowledged importance of such systems, current scientific literature highlights a profound methodological fragmentation that limits their effectiveness. Many indicators used in the dairy sector are described as fragile and in their initial stages, often proving insufficient for a holistic assessment of the industry (Feil et al., 2020; Carvelho et al., 2022).

In a management context, such fragmentation acts as a barrier to coordination, obscuring the real impact of sustainability efforts and making it difficult to achieve a consistent and comparable assessment across different supply chain stages. Ultimately, the industry lacks a coherent sustainability language, which hinders the strategic ability to track and manage performance from farm to fork as a unified value chain.

Purpose of the paper. This study is part of a broader research project aimed at defining a comprehensive framework for sustainability management within the dairy industry. Given the significant methodological fragmentation identified in literature, the purpose of this research is to provide a synthesis of how sustainability is operationalized and managed across the sector. Particularly, this paper seeks to map research efforts to clarify the locus of sustainability assessment across supply chain stages. In a management perspective, this mapping identifies where sustainability efforts are concentrated, revealing whether the industry is driven by a logic of fragmented optimization or a more advanced systemic coordination. Moving beyond a static categorization, the research investigates the relational dynamics between sustainability dimensions, exploring whether the reported interaction results in synergies or trade-offs depending on the analytical scope. In doing so, the research reveals how system boundaries can bias perception of performance, helping managers to distinguish between localized successes and systemic trade-offs.

[1] University of Modena and Reggio Emilia, Email: giada.salvatore@unimore.it

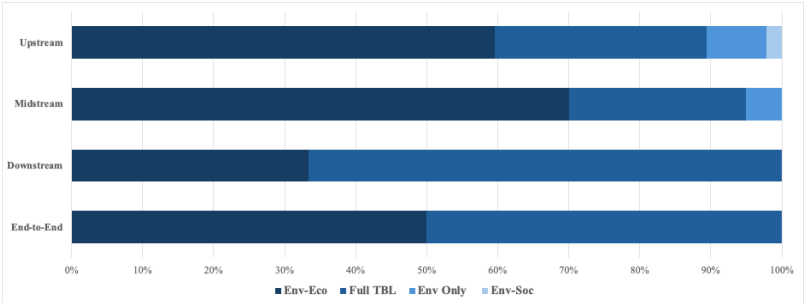
Methodology. This study employs a Systematic Literature Review methodology, strictly following PRISMA guidelines (Page et al., 2021) to ensure transparency and scientific validity.

Conducted in April 2025, the search utilized Scopus and Web of Science, targeting the intersection of the dairy supply chain with sustainability metrics, KPIs, and reporting frameworks.

The selection process followed a two-stage protocol to ensure thematic alignment with research goals. Initially, titles and abstracts were screened, requiring an explicit focus on the sustainability, contextual relevance to the dairy or agri-food sector, and the use of structured methods. Studies focusing strictly on technical efficiency or purely descriptive historical trends were excluded. The second phase of full-text assessment ensured that the empirical content substantiated the claims made in the abstracts, filtering out papers that were overly conceptual, lacked operational metrics, or were too technically granular for strategic application, resulting in a final sample of 76 documents. For each article, the following variables were extracted: Sustainability Coverage; Supply Chain Stage; Interaction Dynamics (Synergies vs. Trade-offs).

The analysis was structured to evaluate both the scope and the nature of sustainability measurement. Initially, a descriptive analysis was performed to evaluate how the literature adheres to the TBL paradigm. Studies were disaggregated by sustainability dimensions, identifying whether they focus on single pillars or integrated frameworks, and by supply chain stages, providing a visual and quantitative assessment of the distribution of sustainability goals across the value chain. Moving beyond this static map, the study investigates the relational dynamics between sustainability dimensions. Given that most research utilizes multi-dimensional frameworks, it is essential to clarify the nature of the reported interactions, specifically whether the pursuit of sustainability goals results in Synergies or Trade-offs. To determine if these outcomes are structurally dependent on the analytical scope, an inferential statistical framework was applied. The Upstream, Midstream, and Downstream stages were aggregated into a Single-Stage cluster and compared against the End-to-End cluster. A Fisher's Exact Test was performed on the resulting 2x2 contingency table. This specific test was selected over the Pearson's Chi-square test for two critical reasons:

- sample size constraints: the limited size of the End-to-End cluster (n=6) makes the large-sample approximations of the chi-square test unreliable;
- zero-frequency cells: the presence of a zero-frequency cell (0 Synergies in the End-to-End group) violates the fundamental assumptions of chi-square.



This approach ensures a mathematically rigorous validation of how system boundaries influence the nature of sustainability interactions reported in the literature.

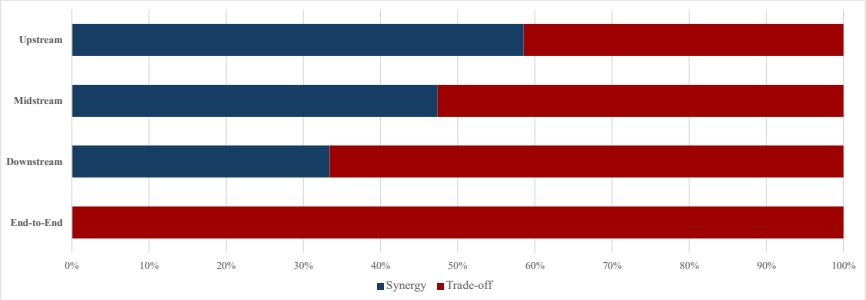
Results. The analysis of sustainability dimensions reveals a significant structural imbalance within the selected literature. The dominant logic identified is centered on Eco-Efficiency (60%, n=46), where environmental metrics are systematically paired with economic indicators. Integrated sustainability approaches, defined as Full TBL, account for 32% of the sample (n=24). Notably, the social dimension emerges as the missing pillar of the discipline: actually, the analysis shows a complete absence of independent social investigations, with no studies focused exclusively on social metrics and the Environment-Social (Env-Soc) configuration being virtually non-existent (n=1). The remaining studies of the sample (n=5) focuses exclusively on environmental metrics, adopting a one-dimensional approach without integrating economic or social factors.

These data indicate that literature prioritizes operational efficiency, defined as doing more with less cost, while treating social equity as a secondary or optional layer: this marginalization is not merely a quantitative gap but reflects a hierarchy in research priorities, suggesting that the social is often treated as a qualitative narrative rather than a performance-driven metric.

Disaggregating TBL configurations by supply chain stage (Fig. 1) reveals structural homogeneity. The Eco-Efficiency paradigm prevails across most operational stages, particularly dominating the Upstream and Midstream sectors. In these phases, which focus on production and processing, sustainability is operationalized primarily as technical efficiency.

Figure 1: Distribution of TBL dimensions across dairy supply chain tiers

Source: Authors' own elaboration.



The only notable exception occurs at the Downstream stage, where the Full TBL configuration appears to prevail over the Eco-Efficiency logic. However, this deviation must be interpreted with caution due to the marginal representativeness of this cluster (n=3). Crucially, even within the End-to-End cluster, which encompasses the entire system and its

stakeholders, the adoption of a comprehensive Full TBL framework is not the default standard. This confirms that the marginalization of social equity is a systemic feature of the current literature, framing sustainability through resource efficiency rather than holistic well-being.

The analysis further explores the dynamic interactions between dimensions, classifying outcomes as Synergies (simultaneous improvements) or Trade-offs (conflicts or negative side effects), based on the explicit qualitative assessments of the original authors. To maintain methodological consistency, single-dimension studies and the non-representative Env-Soc (n=1) configuration were excluded. As a result, the analysis focused exclusively on the Env-Eco and Full TBL frameworks.

The relationship between Interaction Dynamics and Supply Chain Stage reveals a radical polarization between local and systemic perspectives (Fig. 2). When the analysis is confined to a single stage, the literature reports a significant presence of both Synergies and Trade-offs. The Upstream appears to be the most optimistic, with Synergies prevailing over Trade-offs, a trend likely driven by the intrinsic alignment between farm-level resource efficiency and cost reduction, where optimization naturally translates into economic benefit. However, a drastic shift occurs as analytical boundaries expand to an End-to-End perspective: the reported possibility of Synergy vanishes, with 100% of systemic studies identifying Trade-offs. This evidence suggests that win-win scenarios are primarily phenomena of local scope, which lose viability when the supply chain is evaluated as a holistic, interconnected system. Complexity, in this context, acts as a filter that reveals the underlying structural frictions between profitability and planetary boundaries that remain obscured in localized assessments.

Figure 2: Distribution of synergies and trade-offs across dairy supply chain tiers

Source: Authors' own elaboration

To validate this dichotomy, a Fisher's Exact Test was performed by aggregating the Upstream, Midstream, and Downstream stages into a Single-Stage cluster (n=63) and comparing it against the End-to-End cluster (n=6). The test yielded a statistically significant result ($p = 0.0248$, $p < 0.05$), confirming that the observed pattern is not random: the expansion of system boundaries to the End-to-End level is a statistically significant predictor of trade-offs.

Hence, the evidence confirms a structural break determined by the scope of analysis. While local optimizations allow for the alignment of competing goals in almost half of single-stage research, this flexibility vanishes in holistic assessments, confirming the idea that complexity acts as a filter, inevitably revealing the underlying structural conflicts between profitability, planetary boundaries, and social equity that remain partially hidden in localized analyses.

Research limitations. Based on the systematic selection process and the resulting analytical framework, several limitations should be acknowledged. First, a primary constraint involves the statistical sample size of the End-to-End cluster. While the Fisher's Exact Test was specifically selected to ensure mathematical validity when dealing with small groups and zero-frequency cells, the limited number of systemic studies (n=6) may constrain the generalizability of the findings regarding the absolute prevalence of trade-offs at the supply chain level. Second, the use of the 2024 ABS Academic Journal Guide as a quality filter, while essential to ensure a strategic and managerial focus, may have excluded high-quality technical, agronomic, or engineering-focused studies that might offer different perspectives not yet codified within business and management literature. Finally, the classification of interactions into Synergies and Trade-offs relies on the explicit qualitative assessments provided by the original authors, assuming a level of terminological consistency across diverse research groups that may not be absolute.

Managerial implications. This research statistically demonstrates that sustainability outcomes are inherently scale-dependent: interactions that can appear as win-win at a single stage tend to dissipate when the system is analyzed in its entirety, suggesting that sustainability is not a sum of local efficiencies, but a systemic balance. Beyond technical measurement, these findings call for a paradigm shift carrying profound implications for supply chain strategy: managers must transition from a logic of isolated optimization to one of strategic orchestration, addressing the synergy illusion of localized gains. In terms of supply chain management, focusing exclusively on localized operational efficiency can lead to myopia and managers risk inadvertently shifting environmental or social burdens to other stages of the dairy chain, creating negative externalities that remain invisible within fragmented performance assessments. These systemic frictions, if left unmanaged, represent a significant strategic risk to the long-term stability of the sector. Consequently, in this holistic

view, the ability to govern interdependencies across the value chain replaces simple operational excellence as the true source of competitive advantage. Competitiveness, therefore, no longer resides in the efficiency of a single node, but in the strategic orchestration of the entire system's frictions.

This shift underscores the urgent need to move toward co-opetition and shared governance models, where implementing inter-stage performance measurement systems is essential not just for monitoring, but for negotiating shared solutions that distribute the weight of identified trade-offs equitably. Furthermore, ignoring these systemic tensions exposes the firm to unpredictable supply and market risks that, for instance, can arise when an economic improvement at one stage triggers environmental or social fragility at another, compromising the entire chain's resilience. Consequently, trade-off analysis must be deeply integrated into strategic planning processes, prompting managers to evaluate sustainability initiatives not only for their immediate gains but for their fundamental contribution to the long-term stability and health of the entire production system.

Finally, the study highlights that the social dimension remains a marginalized pillar, creating a blind spot in governance and suggesting that social equity is treated as a secondary layer rather than a core strategic driver for sector stability. From a management perspective, elevating the social dimension to a strategic priority is not merely an ethical choice, but a necessity for the regeneration of the human and social capital upon which the entire dairy ecosystem depends, addressing systemic risks related to labor, rural resilience, and social equity.

Originality of the paper. The originality of this research lies in its ability to expose the scale-dependency of sustainability narratives within the dairy sector. While other systematic reviews have focused on categorizing indicators or mapping general trends, this study provides a unique contribution by identifying a complexity threshold. It demonstrates that the viability of the win-win paradigm is often an artifact of localized analysis, which tends to dissolve when the dairy supply chain is evaluated as a holistic, interconnected system. Furthermore, by statistically validating the synergy illusion, the paper challenges current managerial orthodoxy, shifting the focus from fragmented optimization to the mandatory management of structural tensions. This work thus moves the conversation from a descriptive mapping of KPIs to a deeper understanding of the structural tensions that define the path toward truly integrated sustainability, providing a new conceptual lens through which to recognize that sustainability is not merely the sum of local efficiencies, but rather the strategic resolution of systemic frictions.

Artificial Intelligence and Digitalisation in the Tourism Sector: Strategies for a Sustainable Future in the Travel Industry

LUIGI ZINGONE[1]

Abstract. *Tourism is one of the fastest growing sectors globally, but increasing demand and environmental pressures make the transition to sustainable models increasingly necessary. This paper, intended as a preliminary phase of a project that will involve future empirical validation, examines how digitalisation and artificial intelligence (AI) technologies can provide a structured response to these challenges, analysing concrete applications, scientific literature and three international case studies. The research highlights how AI can be understood not only as a tool for operational efficiency, but also as a catalyst for the environmental, economic and social sustainability of tourism.*
Keywords: *artificial intelligence; sustainable tourism; digitalisation; machine learning; smart tourism destination*

Framing of the research. *The global tourism sector is facing dual pressure: on the one hand, exponential growth in demand; on the other, the need to reduce the negative socio-economic and environmental impacts generated by mass tourism. External factors such as geopolitical instability, climate change, health crises and economic crises make the sector particularly vulnerable (Garcia Madurga and Grillo Méndez, 2023) . In this context, the fourth industrial revolution — known as Industry 4.0 — and the spread of technologies such as artificial intelligence, machine learning and big data offer concrete tools to address these critical issues (Zeqiri et al., 2020). Being able to predict tourism demand and adapt quickly to market changes is becoming more important than ever to ensure the competitiveness and resilience of the sector (Ali Louati et al., 2024).*

Tourism has already been transformed by three previous technological trends — Global Distribution System, Central Reservation System and the Internet — which have connected destinations and operators globally, radically changing the way travellers make their decisions (Zeqiri et al., 2020). Now, with the advent of AI, we are facing a fourth transformation, potentially more profound than the previous ones, capable of affecting not only management processes but also the tourist experience, cultural heritage conservation and destination governance (Garcia Madurga and Grillo Méndez, 2023). Technologies such as Cyber Physical Systems, augmented reality, virtual reality and robotics are components of Industry 4.0 that will profoundly change the tourism sector, contributing to the decline of mass tourism and promoting individual and sustainable experiences (Zeqiri et al., 2020).

The spread of the internet and social media has radically changed the decision-making process of travellers, who now search for and plan their experiences online. User-generated content and social media marketing significantly influence tourists' choices, making behavioural analysis a strategic factor for businesses in the sector (Ali Louati et al., 2024). AI has the ability to analyse these behaviours, anticipate trends and offer personalised responses in real time. This work fits into this framework, with the aim of systematically analysing the potential and critical issues of AI applied to sustainable tourism, offering a contribution that links the theoretical dimension to the applicative and managerial dimensions. It should be noted that this is a work in progress: the theoretical framework and comparative analysis of the case studies have been established, but the collection and empirical validation of the primary data are still ongoing; therefore, the results presented here are preliminary and may be further explored in subsequent stages of the research.

Purpose of the paper. *The main objective of the research is to understand how digitisation and the application of artificial intelligence-based technologies can contribute positively to transforming the tourism industry into a sustainable and long-lasting model. In particular, the study aims to: (1) analyse existing scientific literature on AI applied to tourism; (2) examine the main technological applications already in use in the sector, from service personalisation to revenue management, from chatbots to cultural heritage management; (3) assess the concrete impact through three international case studies from different geographical contexts — China, Spain and Saudi Arabia — in order to obtain comparative and multidimensional feedback and provide a solid theoretical basis for future empirical research.*

The work aims to answer the following research question: to what extent can technologies based on artificial intelligence and machine learning support the development of sustainable tourism, and what are the organisational, institutional and technological conditions necessary for this transition to be effective, inclusive and lasting?

The theoretical and practical relevance of the topic is considered to be significant: scholars, tourism businesses, destinations and policy makers need to explore the analytical and practical tools available to guide their strategies in a context of rapid technological change. The study aims to help meet this need by offering an integrated framework that links academic research and operational applicability, with a particular focus on small businesses that are often excluded from the debate on technological innovation in tourism. The ultimate goal is to demonstrate that AI is not only a lever for efficiency, but can also become the driving force behind a structural transformation of tourism towards environmental, economic and social sustainability.

[1] E-Campus University email:luigi.zingone@uniecampus.it

Methodology. *The research adopts a methodological design structured on two complementary levels: a Systematic Literature Review (SLR) conducted according to the criteria of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocol and a multi-case comparative analytical framework. This combination makes it possible to overcome the limitations of purely descriptive approaches, ensuring methodological rigour in the selection and analysis of sources and interpretative soundness in the evaluation of empirical results.*

The SLR was conducted through a three-stage structured procedure. In the identification phase, the bibliographic search covered the main international academic databases — Scopus, Web of Science, Google Scholar and EBSCO — using Boolean search strings built around the key descriptors: "artificial intelligence", "tourism", "sustainability", "machine learning", "smart tourism destination", "digitalisation" and "big data". In the screening phase, the identified contributions were evaluated by title and abstract, excluding works not relevant to the thematic scope of the research. In the eligibility phase, only peer-reviewed contributions published in indexed journals were included, with a time frame mainly between 2018 and 2025, with the exception of seminal works in the field (Anderson and Xie, 2010; McCarthy et al., 2006). The final corpus consists of over 45 scientific contributions covering the thematic areas of personalisation of the tourist experience, AI-based revenue management, chatbots and virtual assistants, predictive analytics and big data, virtual tourism and digital cultural heritage.

The second methodological level consists of a multi-case comparative analytical framework, inspired by Yin's (2014) approach to case study research. Three international case studies with marked contextual heterogeneity were selected: China (Song and Chen, 2025), representative of a continental-scale domestic tourism market; Alpujarra in Spain (Flores Crespo et al., 2022), emblematic of the challenges faced by small rural European destinations subject to overtourism; and Saudi Arabia (Ali Louati et al., 2024), an example of a rapidly expanding post-pandemic destination with a national sustainable tourism strategy. The geographical, dimensional and institutional diversity of the three contexts was deliberately sought in order to maximise the variance of the cases and strengthen the analytical generalisability of the results, in line with the replication logic inherent in the multi-case design.

Each case was analysed using a grid of comparable variables: AI technologies implemented or proposed, stated sustainability objectives, data collection and analysis methodology, results obtained, limitations recognised by the authors, and implications for tourism management and governance. The analytical grid allowed us to conduct both a within-case analysis, exploring the specificities of each context, and a cross-case analysis, aimed at identifying cross-cutting patterns, convergences and divergences between the three cases. The triangulation between the results of the SLR, the evidence from the case studies and the technological applications described in the literature ensures greater interpretative robustness of the overall research results.

Results. *Analysis of the literature and case studies shows that AI applied to tourism has positive effects in several areas: operational, environmental, economic and relational. At the operational level, hybrid recommendation systems, chatbots and AI-based revenue management tools improve process efficiency and service quality (Nugroho et al., 2024; Hanji and Hanji, 2023; Millauer and Vellekoop, 2019). Chatbots, in particular, enable automated management of bookings, 24-hour assistance and check-ins, reducing time and operating costs (Benaddi et al., 2024). The use of AI reduces the time spent making travel reservations by almost 90% (Chen and Prentice, 2024), and platforms such as Booking.com already use AI-based chatbots to analyse user search histories and preferences, offering personalised destinations and accommodation in real time (Chen et al., 2022).*

Revenue management systems are another area where AI is producing significant results. First developed in the airline industry some sixty years ago and subsequently adopted in the hotel sector, these tools have evolved from simple occupancy management to dynamic price optimisation (Millauer and Vellekoop, 2019). AI-based automated revenue management systems effectively and accurately analyse a much larger number of variables than human operators, objectively choosing the options most in line with the company's strategy. For large hotel chains, automation allows the revenue of all properties to be managed with a small number of central supervisors; for smaller businesses, it allows them to gain independence without resorting to expensive external services (Millauer and Vellekoop, 2019). Furthermore, integration with big data allows for the development of customised packages and pricing strategies tailored to each customer segment, while maximising guest satisfaction and company revenue.

On the environmental front, the Chinese case study conducted by Nanchang University (Song and Chen, 2025) demonstrates a positive and statistically robust correlation between AI adoption and improved carbon efficiency in tourism (Tourism Carbon Efficiency, TCE). The study, based on panel data from Chinese provinces, identifies three main channels through which AI promotes TCE: improving tourism labour productivity, rationalising the industry structure, and advances in tourism technology. The researchers verified the robustness of the results through endogeneity tests and excluded data relating to the pandemic period (2020-2022), still obtaining positive TCE regressions. A significant geographical propagation effect was also found: the development of AI in one region contributes to the improvement of TCE in adjacent areas as well, highlighting the importance of interregional cooperation in the sustainable development of tourism. Tourism is responsible for 8% of global greenhouse gas emissions (Song and Chen, 2025) — significantly higher than many other sectors — and these results indicate that AI can become a key tool in the fight against carbon inefficiency. However, the study warns that disproportionate and uncontrolled growth of AI could in turn increase energy consumption and pollution, thus requiring a balanced and monitored approach.

The case study on Saudi Arabia, conducted by Prince Sattam bin Abdulaziz University (Ali Louati et al., 2024), demonstrates how machine learning algorithms applied to real tourism data — 72 monthly data points collected between 2016 and 2021 in collaboration with the Saudi Tourism Authority — can be used to predict tourism trends up to 2030 with a high degree of accuracy. The researchers analysed four categories of flow: inbound tourism, domestic tourism, national tourism and outbound tourism, examining their evolution in three distinct periods — pre-pandemic, pandemic and post-pandemic. The results show that machine learning predictive models are particularly useful for managing economic fluctuations, anticipating periods of high demand and optimising resource allocation. Predictive analysis also makes it possible to forecast areas of growth in the sector and plan for labour needs before they arise (Ali Louati et al., 2024), with important implications for the economic and social sustainability of destinations. The Saudi case is also emblematic of the institutional collaboration between universities and public tourism authorities, which has provided access to a large and reliable dataset: a model of public-private partnership that could be replicated in other national contexts.

The Spanish case study on Alpujarra (Flores Crespo et al., 2022), conducted by the University of Granada, addresses an issue often overlooked by academic research: the impact of mass tourism on small rural communities. The Alpujarra region, at the foot of the Sierra Nevada, consists of the villages of Pampaneira (313 inhabitants), Bubión (361 inhabitants) and Capileira (559 inhabitants), which together form a single tourist hub with only 43 accommodation facilities. Seasonal overcrowding causes a shortage of parking spaces, difficulties for residents, job instability for local operators and the risk of degradation of the natural and cultural heritage. The solution proposed by the researchers is the creation of a scalable Smart City framework, based on the installation of cameras and sensors capable of detecting vehicle number plates, monitoring tourist movements and measuring footfall in local businesses. The system, integrated with machine learning algorithms — and with Generative Adversarial Networks (GAN) to generate synthetic data where real data is insufficient — would make it possible to predict tourist flows, estimate parking occupancy, distribute visitors along alternative routes and adopt sustainable flow management policies. The researchers point out that, if successfully applied, this solution could be transferred to other small rural areas with similar characteristics, representing a turning point for tourism governance in small villages.

Across the three cases and the literature analysed, some common trends of great significance emerge. First, big data is confirmed as an essential enabler of AI: predictive analysis, service personalisation and sustainable resource management depend on the availability, quality and accessibility of data (Hartatik et al., 2024). Secondly, the growing importance of Smart Tourism Destinations (STDs) is emerging, i.e. destinations that combine personalised experiences with sustainable growth policies: cities such as Singapore, Amsterdam, Málaga, Seoul and Busan are already using AI to improve economic, environmental and administrative sustainability (Florido Benítez and De Alcaraz Martínez, 2024). Thirdly, virtual tourism and the digitisation of cultural heritage are opening up new prospects for reducing physical mass tourism by offering immersive experiences with low environmental impact: the virtual tourism market, valued at around £10 billion in 2024, is set to reach £19 billion by 2035 (Siddiqui et al., 2022). Finally, there is a strong need to balance automation and human interaction: the personal touch remains an essential element of the tourist customer experience, especially in the luxury segment, where establishments such as Four Seasons Hotels and Resorts adopt AI for tailored recommendations but emphasise the importance of human contact as a distinctive element of service (Al-Hyari et al., 2023; Nugroho et al., 2024). Table 1 shows a comparative summary of the case studies, highlighting the main elements analysed for each of them and the related results.

Table 1 – Comparative summary of case study results

Dimension	Cina (Song e Chen, 2025)	Spagna – Alpujarra (Flores Crespo et al., 2022)	Arabia Saudita (Ali Louati et al., 2024)	Common trends
AI technologies used	Econometric models and panel data; predictive algorithms on Chinese provinces	ML, GAN for synthetic data, IoT sensors and smart cameras	Machine learning (regression, classification), predictive analysis on tourism big data	Big data, ML, IoT, chatbot, revenue management IA
Sustainability goal	Carbon emissions reduction in tourism (TCE)	Sustainable management of flows in small rural communities	Resilience and post-pandemic recovery; economic and environmental sustainability	Operational efficiency, reduced environmental impact, customisation
Main results	Positive correlation between AI and TCE; interregional geographical propagation effect	Scalable framework for forecasting flows, parking spaces and tourist distribution	Tourism forecast for 2030; resource optimisation and work planning	AI as a driver of efficiency and sustainability; STD as an emerging model

Dimension	Cina (Song e Chen, 2025)	Spagna – Alpujarra (Flores Crespo et al., 2022)	Arabia Saudita (Ali Louati et al., 2024)	Common trends
Limits	Data limited to China; AI energy impact not measured	Sensor network not yet installed;	Insufficient real data Privacy and data extrapolation difficulties;	Lack of direct empirical data; limited geographical contexts
Managerial implication	Smart tourism policies; interregional cooperation; AI training	Open data and shared infrastructure for small villages; local governance	Replicable public-private partnership model; dynamic AI pricing	Balance between automation and human relations; transparency and privacy protection

Source: Author's elaboration

Research limitation and future directions. *This study has some limitations that should be explained. Firstly, despite the adoption of a structured SLR protocol, the research is based exclusively on secondary sources — scientific literature and published case studies — without direct collection of empirical data through surveys, interviews or field experiments. This limits the possibility of controlling contextual variables that are not observable in the analysed texts and of verifying the applicability of the results in specific contexts not examined by the available literature.*

Secondly, the selected case studies are relatively recent and are still in the preliminary stages of technological implementation. The Spanish case of Alpujarra (Flores Crespo et al., 2022) had not yet completed the installation of the physical sensor network at the time of publication of the study, making the available results predominantly conceptual in nature and not yet empirically validated on a real scale. The novelty of the technologies analysed does not yet allow for sufficient longitudinal data to assess the sustainability and effectiveness of the interventions in the long term: a longer time horizon will be necessary to distinguish structural effects from cyclical ones.

Thirdly, each of the three case studies is geographically and culturally limited — China, Spain, Saudi Arabia — and is affected by the specific regulatory, institutional and economic characteristics of their respective national contexts. As recognised by the authors of the cases analysed, the transferability of the results to other tourism markets requires caution and further empirical verification (Song and Chen, 2025; Ali Louati et al., 2024). The Chinese case, in particular, is based on panel data relating to a political-economic system with characteristics that are difficult to replicate in Western contexts or in developing countries, limiting the generalisability of its policy implications.

A fourth limitation concerns the energy dimension of AI, which the case studies analysed do not adequately measure. The increase in the adoption of AI technologies — in particular deep learning models and the data centres needed to train them — entails growing energy consumption which, in the absence of infrastructure powered by renewable sources, could partially contradict the environmental sustainability objectives pursued (Song and Chen, 2025) . This trade-off between tourism carbon efficiency and the energy footprint of AI is a critical variable that future research will need to address using Life Cycle Assessment (LCA) methodologies specifically adapted to the context of digital tourism.

The limitations identified open up a number of promising avenues for future research. First, subsequent studies should integrate mixed methods research designs, combining SLR with quantitative surveys of samples of tourism businesses or destinations and qualitative research based on interviews with managers, destination managers and policy makers. This would allow for empirical testing of the causal relationships hypothesised in the literature between AI adoption and sustainability performance, overcoming the limitations of documentary analysis.

Secondly, it is necessary to broaden the geographical scope of the analysis to include contexts that have been underrepresented in the literature to date, such as South-East Asia, sub-Saharan Africa, Latin America and small tourist islands, which present unique sustainability challenges and levels of technological maturity that are very different from those of the case studies analysed. The construction of shared international datasets — through collaborations between universities, tourism authorities and international organisations such as the UNWTO — is a strategic priority for research in the sector (Ali Louati et al., 2024; Song and Chen, 2025).

Thirdly, future research should explore the dynamics of technology acceptance by tourists and industry operators, analysing how variables such as age, level of education, culture of origin and market segment influence the propensity to adopt AI tools. Customer attitudes towards new technologies range from enthusiasm to anxiety (Chen and Prentice, 2024), and understanding these mechanisms is key to designing implementations that maximise acceptance and minimise resistance.

Fourthly, the issue of the social sustainability of digital tourism — i.e. the impact of automation on employment, worker training and the redistribution of value generated by AI along the tourism supply chain — represents an urgent and still largely unexplored research agenda. The rapid growth of technology raises important questions about the future of human workers in the sector (Florido Benítez and De Alcaraz Martínez, 2024), and future studies will need to rigorously address the ethical and distributional dimensions of the digital transition in tourism. Finally, the development of regulatory frameworks and international standards for AI governance in tourism — balancing innovation, privacy,

transparency and inclusiveness — represents a frontier of interdisciplinary research involving management, law, computer science and social sciences.

In line with the work-in-progress nature of this contribution, the directions outlined above are not only suggestions for the scientific community but also represent the stages of the research path that the authors intend to follow in the next phases. In particular, the next planned developments concern the design of an empirical survey tool — questionnaire or interview grid — to be administered to managers and destination managers in European contexts, with the aim of validating in the field the theoretical hypotheses that emerged from the SLR and the comparative analysis of the case studies. This paper is therefore submitted to the scientific community of the conference with the explicit aim of gathering critical feedback to guide and enrich the next stages of the research.

Managerial implications. *The research results offer concrete and detailed guidance for managers in the tourism sector, smart tourism destinations and policy makers. Firstly, the adoption of AI systems for revenue management, experience personalisation and predictive demand analysis is a strategic competitive lever that can simultaneously improve operational efficiency and customer satisfaction (Millauer and Vellekoop, 2019; Nugroho et al., 2024). Tourism businesses that invest in these technologies reap tangible benefits: reduced operating costs, increased sales, optimised customer journeys and improved productivity (Florido Benítez and De Alcaraz Martínez, 2024).*

For hotel managers, implementing AI in revenue management requires a review of internal organisational processes: staff must be properly trained to interact with the new systems, handle customer requests generated by automation, and deal with any technical issues (Kaul, 2021). The transition to automated systems does not eliminate the need for human skills, but transforms their nature from operational to supervisory and strategic. Large hotel chains can centralise revenue management across all properties with a small number of specialists, while independent establishments gain the ability to compete on a more level playing field with the big players without incurring the costs of external consultants (Millauer and Vellekoop, 2019).

On the sustainability front, tourism authorities should integrate AI into their governance policies, promoting smart tourism and incentivising private operators to adopt data-driven technologies. The Chinese study (Song and Chen, 2025) suggests that policymakers should aim to create interregional tourism development alliances, maximising the geographical propagation effects of AI on TCE. In areas with insufficient tourism resources, priority should be given to investments in AI-based technologies; in areas where the impact is less discernible, greater attention should be paid to sustainable tourism projects that build fundamental capacities for the future. It would also be essential to invest in AI-oriented education and training programmes for tourism development, accelerating technological upgrading and improving energy efficiency.

For destinations experiencing overtourism — as in the case of Alpujarra — AI allows for more balanced monitoring and distribution of tourist flows, reducing the impact on local communities and ecosystems (Flores Crespo et al., 2022). This type of application is particularly relevant for small villages and rural areas, which are often excluded from technological innovation despite being among the most vulnerable to the negative effects of mass tourism. Local institutions should promote the availability of open data and the construction of shared digital infrastructure at the territorial level, lowering the barriers to access to technology for smaller operators. The use of Generative Adversarial Networks (GANs) to generate synthetic data where real data is insufficient is an innovative solution to overcome one of the main obstacles to the adoption of AI in small destinations (Flores Crespo et al., 2022).

On the cybersecurity front, managers need to be aware that increased digitalisation exposes accommodation facilities to growing risks: hotels handle large volumes of personal and financial data, making them potential targets for cyberattacks (Kaul, 2021). AI-based security systems are capable of analysing parameters such as access behaviour, IP address location and device used in real time, assigning risk scores and automatically activating protective measures in the event of suspicious activity. However, it is essential that these systems are implemented in a way that is transparent to users in order to maintain customer trust and comply with privacy regulations: higher levels of transparency and privacy protection lead to greater perceived value, trust and satisfaction among guests (Chen and Prentice, 2024).

Finally, for managers operating in the premium and luxury segments, the main challenge is to find the optimal balance between automation and human interaction. AI should enhance — not replace — the interaction between staff and guests, ensuring personalised experiences and simplifying operations, while preserving that human touch that remains the cornerstone of hospitality.

Originality of the paper. *The original contribution of this work lies in the integrated and comparative approach adopted in the analysis of AI applied to sustainable tourism. Unlike studies focused on individual technological applications or specific geographical contexts, this work offers an overview that links the literature review, the analysis of applications in use, and the comparative evaluation of three international case studies from contexts that are radically different in terms of size, culture, and stage of technological development.*

Particular attention is paid to small rural areas — often neglected by academic research, which tends to favour large urban centres — demonstrating how even contexts with limited resources can benefit from the implementation of smart technologies for sustainable tourism management (Flores Crespo et al., 2022). The work also contributes to the debate on the relationship between AI and environmental sustainability in tourism, providing empirical evidence on the correlation between AI adoption and improved carbon efficiency (Song and Chen, 2025).

Artificial Intelligence and Small and Medium-Sized Enterprises in the Accommodation Sector. A Systematic Literature Review from an Economic and Managerial Perspective

CLAUDIA FRABONI[1], TONINO PENCARELLI[2]

Abstract. ***Frame of the research****. The accommodation sector is a central component of tourism systems and, in many European contexts, is largely composed of SMEs facing digital transformation, sustainability pressures, changing customer expectations, and increasing uncertainty.*

Purpose of the paper*. This paper examines how the management and economics literature explains the role of artificial intelligence (AI) in shaping performance, customer experience, organizational structures, and strategic decision-making in the accommodation sector, with particular attention to SMEs.*

Methodology. *The study adopts a systematic literature review informed by PRISMA and SPAR-4-SLR principles. Peer-reviewed journal articles published between 2010 and early 2026 and indexed in Scopus and Web of Science were selected through a multi-stage process, resulting in a final sample of 95 articles.*

Results. *The findings identify four main dimensions of AI adoption: operational performance, customer experience, organizational transformation, and strategic decision-making. AI supports forecasting, revenue management, automation, personalization, review analytics, and market sensing, but its effects depend on data quality, managerial interpretation, organizational readiness, employee capabilities, customer trust, and ecosystem conditions.*

Research limitations. *The review is limited to English-language peer-reviewed articles indexed in two databases and excludes grey literature and purely technical studies.*

Managerial implications. *Accommodation SMEs should approach AI adoption as a staged, selective, and problem-driven process while preserving human hospitality and responsible governance.*

Originality of the paper. *The paper offers a sector-specific and SME-sensitive framework for understanding AI-enabled managerial transformation in accommodation firms.*

Keywords: *artificial intelligence; accommodation sector; tourism; SMEs; hospitality management; systematic literature review*

1. Framing of the research. The accommodation sector represents one of the most strategically relevant components of contemporary tourism systems, contributing to employment generation, local development, territorial competitiveness, and the valorization of cultural and environmental resources. In many European contexts, and especially in Southern Europe, the sector is largely composed of small and medium-sized enterprises (SMEs), including family-owned hotels, boutique properties, agritourism businesses, independent lodging providers, and locally embedded hospitality firms. These organizations play a crucial socio-economic role within destination ecosystems, but they often operate with limited financial resources, restricted access to specialized knowledge, weak digital infrastructures, and reduced economies of scale (Pencarelli, 2022).

Over the last decade, accommodation firms have been exposed to a set of interconnected pressures that are reshaping both tourism demand and managerial practice. These include the acceleration of digitalization, increasing sustainability requirements, changing customer expectations, labor shortages, demographic shifts, and geopolitical uncertainty affecting tourism flows and supply chains (Gössling et al., 2021; Sánchez-Sánchez et al., 2026). Within this evolving environment, artificial intelligence (AI) is emerging as a relevant driver of transformation, not only because it enables automation, but also because it changes how firms collect information, interpret markets, interact with customers, and organize decision-making processes.

AI refers to a broad family of technologies, including machine learning, predictive analytics, natural language processing, service robots, chatbots, recommendation systems, computer vision, and generative AI. These technologies allow firms to process large volumes of structured and unstructured data, automate repetitive tasks, support managerial decisions, and personalize services at scale (Davenport et al., 2020; Huang & Rust, 2021). In the accommodation sector, AI applications are increasingly visible in revenue management, demand forecasting, guest communication, online reputation monitoring, predictive maintenance, customer segmentation, dynamic personalization, energy management, and service automation (Ivanov et al., 2020; Verma et al., 2022).

However, AI adoption remains highly uneven. Large hotel chains and digital-native platforms are generally better positioned to exploit AI because they can rely on stronger technological infrastructures, larger datasets, dedicated analytics teams, and greater investment capacity. SMEs, by contrast, often face higher barriers connected to costs, limited

digital skills, fragmented data, uncertainty about return on investment, and dependence on external technology providers (Tavanxhiu et al., 2026). This creates a dual-speed transformation dynamic that may widen competitive gaps within the sector.

For this reason, AI should not be interpreted merely as an operational tool or as a set of isolated technological applications. Its adoption raises broader questions about organizational learning, human-AI collaboration, managerial cognition, customer trust, ethical accountability, data governance, and the changing nature of hospitality work (Kabadayi et al., 2019; Sharma & Mattila, 2026). The accommodation sector therefore provides a particularly relevant context for examining AI as a managerial and socio-technical transformation, especially when the focus is placed on SMEs and their specific adoption pathways.

2. Positioning within existing literature and research gap. Research on AI in tourism and hospitality has expanded rapidly across several disciplinary domains, including tourism studies, hospitality management, information systems, service management, marketing, and strategic management (Mariani et al., 2023; Tuo et al., 2025). This growing body of literature has already been synthesized by recent reviews, which provide important but different contributions to the field. Doborjeh et al. (2022) review AI methods and applications across hospitality and tourism; Law et al. (2024) offer a state-of-the-art overview of AI research in hospitality; and Della Corte et al. (2025) identify future research directions through an umbrella review. While these contributions provide a valuable basis for understanding the evolution of the field, they mostly adopt broad tourism or hospitality perspectives. As a result, they tend to aggregate heterogeneous domains such as accommodation, restaurants, transport, platforms, destinations, and tourism marketing. This broad scope is useful for mapping the field, but it may obscure the distinctive managerial features of accommodation firms, which are characterized by service intensity, labor dependence, simultaneous production and consumption, strong experiential content, and a close relationship between physical spaces, digital touchpoints, and customer perceptions (Tussyadiah, 2020; Verma et al., 2022). These features influence how AI is adopted, evaluated, and integrated into managerial routines.

To clarify the contribution of this paper, Table 1 compares the present review with selected recent reviews on AI in tourism and hospitality. The comparison shows that this study addresses a more specific gap by focusing on accommodation SMEs and by interpreting AI adoption through a managerial and strategic lens.

Table 1. Positioning of our study in relation to selected prior reviews on AI tourism and hospitality

Review	Scope	Main Focus	Limitation addressed by this study
Doborjeh et al. (2022)	Hospitality & Tourism	AI methods/applications	Limited SME focus
Law et al. (2024)	Hospitality	State-of-the-art review	Limited theoretical integration
Della Corte et al. (2025)	Umbrella Review	Future AI research directions	Broad sectoral lens
This Study	Accommodation SMEs	Managerial/strategic AI transformation	Integrative SME-specific framework

Source: our elaboration

The SME perspective also remains comparatively underdeveloped. Although SMEs dominate many accommodation markets, their specific constraints and capabilities are rarely placed at the center of analysis. Smaller accommodation firms differ from large hotel chains in terms of resources, governance, absorptive capacity, entrepreneurial orientation, local embeddedness, and dependence on external ecosystems. These differences shape both the barriers to AI adoption and the ways in which AI may generate value (Pencarelli, 2022; Tavanxhiu et al., 2026). A generic account of AI in hospitality therefore risks overlooking the differentiated adoption trajectories of smaller firms.

A further gap concerns the theoretical interpretation of AI. Much of the literature focuses on technologies, customer acceptance, or specific application domains, while the strategic and organizational meaning of AI remains less fully theorized. AI is often treated as a technological artifact rather than as a mechanism that can reconfigure routines, decision architectures, value creation processes, and managerial capabilities over time. This limitation is particularly relevant for accommodation SMEs, where AI adoption is rarely a purely technical decision and is instead shaped by resource constraints, managerial cognition, customer proximity, and dependence on external digital ecosystems. Moreover, the existing literature only partially explains how smaller firms can transform external technological solutions into context-specific managerial capabilities. This issue is crucial because many accommodation SMEs do not develop AI internally, but access it through platforms, software providers, destination-level infrastructures, and service ecosystems. A more integrated perspective is therefore needed to connect technological applications with organizational conditions, ecosystem relationships, and managerial outcomes. This paper addresses this gap by reviewing AI adoption in the accommodation sector through an economic-managerial lens, focusing on performance, customer experience, organizational transformation, and strategic decision-making.

3. Purpose of the paper. Against this background, the paper addresses the following research question: How does the scientific literature in management and economics explain the role of artificial intelligence in shaping performance,

customer experience, organizational structures, and strategic decision-making in the accommodation sector, particularly for SMEs?

The aim of the paper is to provide a systematic and theoretically grounded synthesis of the literature, clarifying how AI adoption affects accommodation firms and why SMEs require specific analytical attention. The study responds to the need for a more integrated understanding of AI in hospitality management, moving beyond fragmented analyses of individual technologies or isolated use cases. Rather than cataloguing AI applications, the paper examines the mechanisms through which AI influences managerial practices, organizational capabilities, service relationships, and strategic adaptation in accommodation markets.

More specifically, the paper seeks to connect the technological dimension of AI adoption with its economic and managerial implications. This means investigating not only what AI tools are used in accommodation firms, but also how these tools contribute to efficiency, customer value creation, organizational learning, and strategic adaptation. In this perspective, AI is treated as a multi-level managerial phenomenon whose effects unfold across operational, relational, organizational, and strategic domains.

A further purpose of the paper is to place SMEs at the center of the analysis. This focus is important because smaller accommodation firms are often treated as a residual category within broader hospitality studies, despite their central role in tourism systems. SMEs face specific constraints in terms of financial resources, digital skills, data availability, and access to technological expertise. At the same time, they may rely on flexibility, entrepreneurial orientation, local embeddedness, and close customer relationships as distinctive strengths. The paper therefore aims to clarify how AI adoption may generate opportunities and risks for SMEs, and under which conditions it can support rather than undermine their competitive and relational advantages.

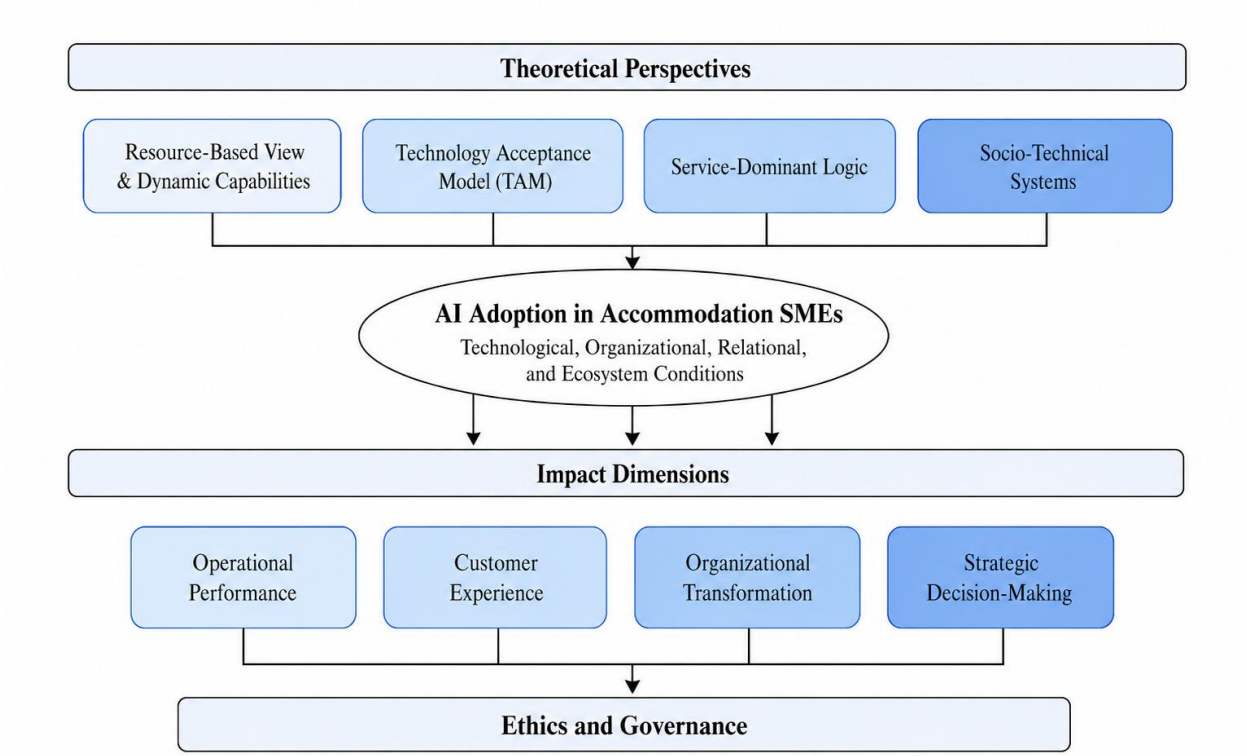
By addressing these issues, the paper intends to contribute to debates on digital transformation, AI in management, and tourism competitiveness. It also aims to provide a conceptual bridge between research on AI applications in hospitality and broader management debates on dynamic capabilities, socio-technical change, service innovation, and responsible governance.

4. Theoretical background and conceptual framework. The evolution of AI in tourism and hospitality can be interpreted as part of a broader trajectory moving from digitalization toward intelligent, autonomous, and adaptive socio-technical systems (Buhalis, 2003; Gretzel, 2011). Earlier studies tended to frame intelligent technologies as components of digital infrastructures and smart tourism ecosystems. More recent research emphasizes their transformative role in reshaping value creation, personalization, organizational learning, and managerial decision-making across the tourism value chain (Gretzel et al., 2015; Mariani et al., 2023; Verma et al., 2022). This evolution reflects a shift from viewing technology as a support function to understanding it as a constitutive force in organizational and strategic change.

Several theoretical lenses contribute to understanding AI adoption in accommodation firms. The resource-based view and dynamic capabilities perspective conceptualize AI as a strategic resource that can enhance firms' ability to sense environmental change, seize opportunities, and reconfigure routines in turbulent contexts (Barney, 1991; Teece, 2007). From this perspective, AI does not create value simply because it is acquired or implemented. Its value depends on complementary capabilities, including data quality, managerial interpretation, organizational learning, process redesign, and the capacity to translate algorithmic outputs into action (Mikalef et al., 2019; Huang & Rust, 2021).

Technology adoption approaches, including the Technology Acceptance Model, emphasize perceived usefulness, ease of use, trust, and risk perceptions in shaping the acceptance of AI systems by managers, employees, and customers (Pillai & Sivathanu, 2020; Nookhao & Homsud, 2026). These factors are particularly relevant in hospitality, where service experiences depend not only on efficiency but also on empathy, authenticity, reliability, and relational quality. In this context, the success of AI-enabled services depends on both functional performance and social legitimacy.

Service-dominant logic provides an additional perspective by interpreting AI as an enabler of value co-creation. Recommendation engines, conversational agents, sentiment analysis tools, and predictive interaction systems can help firms personalize experiences and engage customers across multiple touchpoints. At the same time, this perspective highlights the tension between automation and human hospitality, since excessive technological mediation may weaken emotional connection, perceived authenticity, and relational value (Tussyadiah et al., 2020; Verma et al., 2022).



Socio-technical perspectives further suggest that AI is not a neutral instrument added to existing organizations, but a component that reshapes roles, routines, decision architectures, and forms of agency between humans and technologies (Kabadayi et al., 2019). This perspective is especially useful in accommodation firms, where AI adoption affects both back-office processes and customer-facing interactions. It also helps explain why similar technologies may produce different outcomes depending on organizational readiness, employee involvement, governance structures, and customer expectations.

An additional element emerging from this theoretical debate concerns the role of external ecosystems in shaping AI adoption. Accommodation SMEs rarely develop AI capabilities internally and often access them through property management systems, online travel agencies, booking platforms, software providers, destination management organizations, and consultancy networks. This condition suggests that AI adoption is not only a firm-level process but also an ecosystem-mediated phenomenon. For smaller accommodation firms, the availability of external technological infrastructures may reduce adoption barriers, but it may also generate dependence on external actors and limit control over data, customer relationships, and strategic choices. Integrating this ecosystem perspective into the theoretical

background is therefore important to understand why AI adoption depends not only on resources and acceptance, but also on the quality of interorganizational relationships and the governance of digital infrastructures (Gretzel et al., 2015; Pencarelli, 2022; Tavanxhiu et al., 2026).

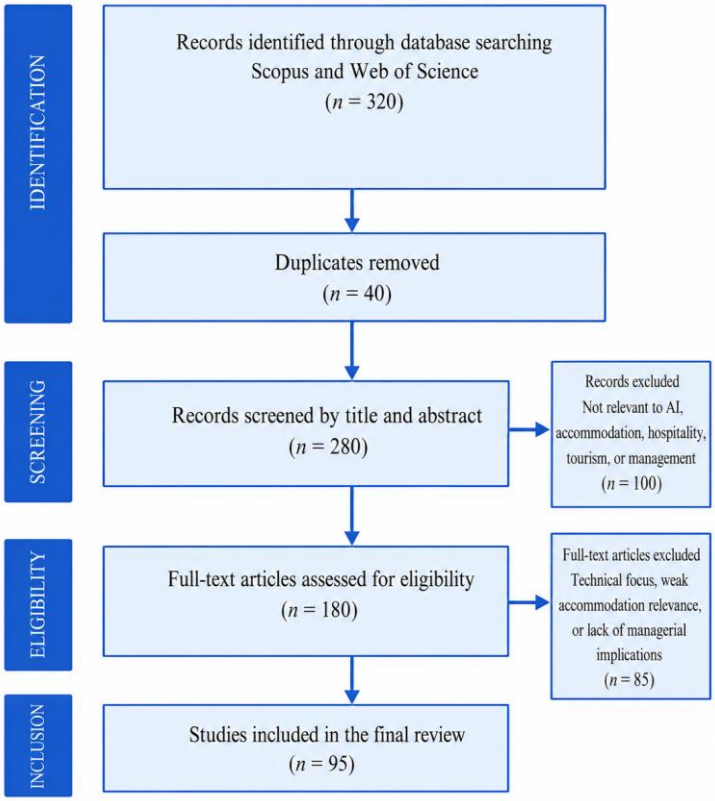
Building on these perspectives, this paper conceptualizes AI adoption as a multi-level phenomenon involving technological, organizational, relational, and ecosystem dimensions. The proposed framework interprets AI as an intermediate transformational mechanism linking enabling conditions to four interconnected outcomes: operational performance, customer experience, organizational transformation, and strategic decision-making. The framework does not claim to introduce entirely new theoretical constructs. Its originality lies in integrating existing theories into a sector-specific and SME-sensitive model that clarifies how AI reshapes accommodation firms rather than merely listing technologies or application areas. This perspective is especially relevant for accommodation SMEs, where AI adoption depends on the interaction between internal capabilities, customer relationships, and external digital infrastructures. The framework therefore interprets AI not as an isolated technological input, but as a process through which firms transform technological solutions into managerial value. The conceptual framework developed from this theoretical integration is presented in Figure 1, which links the main theoretical perspectives to AI adoption conditions, impact dimensions, and transversal governance issues in accommodation SMEs.

Figure 1. Conceptual framework of AI adoption in accommodation SMEs

Source: our elaboration based on Barney (1991), Teece (2007), Pillai and Sivathanu (2020), Tussyadiah et al. (2020), Huang and Rust (2021), Kabadayi et al. (2019), and recent AI in hospitality literature.

5. Methodology. This study adopts a systematic literature review (SLR) methodology to synthesize the role of AI in the accommodation sector from a managerial and economic perspective. The SLR approach is appropriate because research on AI in tourism and hospitality is expanding rapidly but remains fragmented across disciplines and research traditions (Erdös et al., 2025; Tuo et al., 2025). The review design follows PRISMA and SPAR-4-SLR principles to improve transparency, rigor, and replicability (Page et al., 2021; Paul et al., 2021). The aim is not only to summarize prior studies, but also to develop an interpretive synthesis capable of explaining how AI affects managerial and organizational dynamics in accommodation firms.

In line with the SPAR-4-SLR protocol, the review process was structured around three main phases: assembling, arranging, and assessing. The assembling phase concerned the definition of the research domain, databases, search strings, and inclusion criteria; the arranging phase involved duplicate removal, screening, eligibility assessment, and corpus refinement; and the assessing phase included coding, descriptive bibliographic analysis, thematic synthesis, and robustness checks.



The review was conducted in Scopus and Web of Science, selected because of their broad coverage of management, tourism, hospitality, and information systems journals, and was updated during manuscript preparation to include publications available up to early 2026. The search strategy combined AI-related terms with tourism, hospitality, accommodation, and management/SME terms. The final search logic was: ((“artificial intelligence” OR “AI” OR

"machine learning" OR "generative AI" OR "intelligent systems" OR "service robots" OR "chatbots" OR "predictive analytics") AND ("hospitality" OR "tourism" OR "accommodation" OR "hotel" OR "lodging sector") AND ("SME" OR "small and medium enterprise" OR "firm" OR "organization" OR "management" OR "strategy")). Boolean operators and alternative terminology were used to capture the conceptual variety of the field while maintaining coherence with the research question.

The review included peer-reviewed journal articles published in English between 2010 and early 2026. This time frame was selected to capture the contemporary phase of AI diffusion in tourism and hospitality. Articles were retained when they addressed managerial, organizational, strategic, economic, adoption-related, or customer-related dimensions of AI in tourism, hospitality, or accommodation. Technical studies without explicit managerial implications, conference papers, book chapters, editorials, dissertations, and non-peer-reviewed documents were excluded.

The initial search identified 320 records. After removing 40 duplicates, 280 records were screened by title and abstract. At this stage, 100 records were excluded because they were not sufficiently relevant to AI, accommodation, hospitality, tourism, or management. The remaining 180 articles were assessed in full text, leading to the exclusion of 85 articles mainly due to technical focus, weak accommodation relevance, or lack of explicit managerial implications. The final sample consisted of 95 articles. Exclusions at the full-text stage mainly concerned technical focus, weak relevance to accommodation, or lack of managerial implications. The main steps of the article selection procedure are summarized in Figure 2.

Figure 2. PRISMA-based study selection process

Source: our elaboration based on PRISMA logic

Additional details on the search strategy, inclusion and exclusion criteria, and coding scheme are reported in the methodological appendices.

A structured coding scheme was developed to extract descriptive variables, theoretical perspectives, methodological features, AI applications, firm or sector focus, outcome dimensions, managerial implications, and research gaps. The coding process combined deductive and inductive logic. Deductive coding reflected the research question and conceptual framework, while inductive coding allowed additional themes to emerge from the selected studies. The analysis combined a descriptive bibliographic overview and thematic synthesis. The descriptive overview was used to identify publication trends, leading journals, dominant methods, and recurring AI technologies, while thematic analysis supported the interpretation of recurring mechanisms, contradictions, and conceptual patterns. The coding procedure directly informed the structure of the results section: AI applications were synthesized in Table 3, outcome dimensions guided the thematic subsections, evidence strength informed Table 4, and SME relevance was discussed across the results, discussion, and managerial implications. To further enhance transparency, Appendix G reports the thematic distribution of the 95 studies included in the review. Each article was assigned to one dominant topic according to the coding scheme, while

acknowledging that several studies informed more than one analytical dimension. This appendix provides an aggregate bridge between the coding procedure and the thematic synthesis presented in the results section.

6. Results. The review shows that AI is reshaping the accommodation sector through interrelated operational, experiential, organizational, and strategic mechanisms. The literature does not present AI adoption as a homogeneous or linear process. Instead, it reveals differentiated patterns depending on firm size, technological readiness, managerial capabilities, customer expectations, and ecosystem conditions.

Research has accelerated markedly since the mid-2010s, reflecting the diffusion of machine learning, smart tourism ecosystems, online review analytics, conversational agents, and service automation (Gretzel et al., 2015; Xiang et al., 2017; Ivanov et al., 2020; Tyagi et al., 2026). Customer-facing technologies receive substantial attention, while the organizational and strategic implications of AI adoption in accommodation SMEs remain less developed.

Before presenting the thematic synthesis, a descriptive bibliographic overview was conducted to clarify the structure of the corpus. Table 2 summarizes the main bibliometric indicators emerging from the 95 selected articles. The overview shows a strong acceleration of publications after 2017 and confirms the interdisciplinary nature of the field, with contributions concentrated in hospitality management, tourism studies, service management, and information systems journals.

Table 2. Descriptive bibliographic overview of the reviewed corpus

BIBLIOMETRIC INDICATOR	MAIN EVIDENCE
PUBLICATION PERIOD	Strong acceleration after 2017
MAIN JOURNALS	IJCHM, IJHM, Tourism Management, Annals of Tourism Research, JHTT
DOMINANT METHODS	Reviews, surveys, conceptual papers, bibliometric studies
DOMINANT TECHNOLOGIES	Chatbots, service robots, predictive analytics, online review analytics
UNDERDEVELOPED AREAS	SME-specific adoption, longitudinal studies, governance tools

Source: our elaboration

These indicators confirm that AI adoption in accommodation is not a purely technological issue, but an emerging managerial research field shaped by multiple disciplinary traditions. At the same time, the reviewed studies remain unevenly distributed across themes: customer-facing applications and service automation are more frequently examined than organizational redesign, strategic decision-making, and SME-specific implementation processes. This imbalance calls for a thematic synthesis linking AI applications to managerial implications. Table 3 therefore summarizes the main dimensions emerging from the coding process, distinguishing representative corpus studies from theoretical anchoring references.

Table 3. Thematic synthesis of AI adoption in the accommodation sector

THEMATIC DIMENSION	DOMINANT AI APPLICATIONS	MAIN MANAGERIAL FOCUS	REPRESENTATIVE CORPUS STUDIES	THEORETICAL ANCHORING	INTERPRETIVE INSIGHT
OPERATIONAL PERFORMANCE	Revenue management, demand forecasting, predictive analytics, energy management, process automation	Efficiency, cost reduction, productivity, resource allocation	Millauer and Vellekoop (2019); García et al. (2020); Ivanov et al. (2020); Sánchez-Medina and C-Sánchez (2020)	Dynamic capabilities; analytics capabilities	AI enhances operational performance when forecasting, pricing, and automation tools are integrated with managerial routines and data capabilities rather than adopted as stand-alone technologies.
CUSTOMER EXPERIENCE	Chatbots, virtual assistants, recommendation systems, sentiment analysis, personalization engines	Satisfaction, trust, service responsiveness, personalization, perceived empathy	Pillai and Sivathanu (2020); Tussyadiah et al. (2020); Aransyah et al. (2026); Akhtar et al. (2026)	Service-dominant logic; technology acceptance perspectives	AI improves responsiveness and personalization but may generate discomfort when transparency, customer control, and human warmth are insufficient.
ORGANIZATIONAL TRANSFORMATION	Digital capabilities, data-driven routines, human-AI	Capability development, workforce	Kabadayi et al. (2019); Mikalef et al. (2019); Verma et al.	Socio-technical systems theory;	AI adoption requires complementary organizational change,

THEMATIC DIMENSION	DOMINANT AI APPLICATIONS	MAIN MANAGERIAL FOCUS	REPRESENTATIVE CORPUS STUDIES	THEORETICAL ANCHORING	INTERPRETIVE INSIGHT
	collaboration, service robot integration	redesign, cross-functional integration, organizational learning	(2022); Sharma et al. (2026); Tavanxhiu et al. (2026)	dynamic capabilities	particularly in SMEs where resource constraints, digital skills, and dependence on external providers shape implementation pathways.
STRATEGIC DECISION-MAKING	Business intelligence, strategic analytics, dynamic pricing, market sensing, ecosystem participation	Competitive positioning, innovation, strategic agility, business model renewal	Mariani et al. (2023); Verma et al. (2022); Nookhao and Homsud (2026); Tavanxhiu et al. (2026); Tuo et al. (2025)	Resource-based view; dynamic capabilities; strategic AI perspectives	AI supports market sensing and strategic adaptation when algorithmic insights are combined with managerial interpretation, contextual knowledge, and the ability to reconfigure resources.
ETHICS AND GOVERNANCE	Algorithmic transparency, data privacy, bias control, robot accountability, responsible AI	Trust, legitimacy, accountability, regulatory compliance, human oversight	Akhtar et al. (2026); Wang et al. (2026); Sharma and Mattila (2026); Kabadayi et al. (2019)	Responsible AI governance; socio-technical theory	The managerial value of AI depends on governance mechanisms that balance automation, accountability, privacy, transparency, and service legitimacy.

Source: our elaboration

Operational performance is the most consolidated area of AI application. AI-enabled revenue management, demand forecasting, process automation, predictive maintenance, and energy management can improve efficiency, reduce uncertainty, and support resource allocation (Millauer & Vellekoop, 2019; García et al., 2020; Ivanov et al., 2020). Revenue management is particularly relevant because accommodation services are perishable and demand fluctuates according to seasonality, booking windows, customer segments, and competitive dynamics. However, performance benefits depend on data quality, managerial interpretation, and the integration of AI outputs into organizational routines (Davenport et al., 2020; Mikalef et al., 2019). For SMEs, modular tools such as review analytics, AI-supported pricing, and automated communication may be more realistic than complex integrated systems.

Customer experience is another dominant theme. Chatbots, recommendation engines, sentiment analysis, and virtual assistants can improve response speed, personalization, and service availability (Pillai & Sivathanu, 2020; Aransyah et al., 2026). These tools are useful for managing repetitive and time-sensitive requests concerning availability, check-in procedures, amenities, cancellation rules, or local information. Yet the literature also shows tensions between efficiency and relational quality. In hospitality, customers value empathy, authenticity, control, and trust. AI-mediated interactions may therefore generate discomfort or "creepiness" when they appear intrusive, opaque, or excessively automated (Tussyadiah et al., 2020; Akhtar et al., 2026). For SMEs, AI should augment rather than replace human hospitality.

Organizational transformation emerges as a necessary condition for AI adoption. Firms need data literacy, analytical capabilities, employee adaptation, cross-functional coordination, and governance awareness. AI changes not only tasks but also roles, decision processes, and accountability structures (Kabadayi et al., 2019; Sharma et al., 2026). This is particularly relevant for SMEs, where decision-making is often centralized and digital skills are limited. At the same time, flexibility, proximity to customers, and entrepreneurial orientation may support selective experimentation (Pencarelli, 2022). The evidence suggests that AI adoption among SMEs depends not only on internal resources, but also on access to external providers, digital ecosystems, and managerial learning opportunities.

Strategic decision-making represents a growing research cluster. AI supports market sensing, competitor monitoring, customer segmentation, demand prediction, and business model innovation (Davenport et al., 2020; Huang & Rust, 2021; Mariani et al., 2023). It can make patterns visible and support more anticipatory management. Nevertheless, AI-generated insights require critical managerial interpretation, especially in accommodation SMEs, where strategy is often connected to local identity, family ownership, destination embeddedness, and experiential value. The strategic role of AI therefore depends on the ability to combine data-driven insights with contextual knowledge.

Ethics and governance cut across all dimensions. Privacy, transparency, algorithmic bias, accountability, and human oversight are increasingly relevant because AI systems process sensitive data and mediate customer relationships (Wang et al., 2026; Sharma & Mattila, 2026). SMEs may be particularly exposed because they often depend on external platforms

and software providers while lacking formal data governance structures. Responsible AI adoption therefore becomes both a technical and managerial issue.

Overall, the results confirm that AI adoption in the accommodation sector cannot be reduced to technological implementation. Operational gains depend on organizational capabilities; customer experience depends on trust and relational legitimacy; strategic value depends on managerial interpretation; and all dimensions are conditioned by governance and ethical considerations. This integrative interpretation supports the conceptual framework proposed in this paper. The findings also clarify why SMEs deserve specific attention within the broader AI in hospitality debate.

Table 4. Established findings, emerging trends, and research gaps

DIMENSION	ESTABLISHED FINDINGS	EMERGING TRENDS	RESEARCH GAPS
Operational performance	AI supports forecasting, pricing, and automation.	AI linked to sustainability and energy management	Limited evidence on long-term effects in SMEs.
Customer experience	AI improves responsiveness and personalization.	Growing attention to transparency, empathy and discomfort.	Limited research on authenticity in small firms.
Organizational transformation	AI requires skills, learning, and data capabilities.	Human-AI collaboration and socio-technical redesign.	Few longitudinal studies on workforce change.
Strategic decision-making	AI supports market sensing and adaptive decisions.	Ecosystems and AI-enabled business model renewal.	Need for stronger SME-specific theorization.
Ethics and governance	Privacy and accountability are central concerns.	Responsible AI and robot responsibility.	Lack of practical governance tools for SMEs.

Source: our elaboration

7. Discussion. The findings suggest that AI adoption in the accommodation sector should be interpreted as a systemic managerial transformation rather than as the implementation of isolated digital tools. The value of AI emerges from the interaction between technologies, organizational capabilities, customer relationships, managerial interpretation, and ecosystem conditions. This interpretation helps explain why AI adoption remains uneven across firms and why SMEs require specific attention within the broader hospitality debate.

The relationship between technology and capability development is central to this interpretation. The results show that AI can improve forecasting, pricing, automation, and resource allocation, but these effects depend on whether algorithmic outputs are translated into managerial routines and organizational action. This supports resource-based and dynamic capabilities perspectives, which suggest that technological resources generate advantage only when combined with complementary capabilities such as data quality, managerial learning, process redesign, and strategic flexibility (Barney, 1991; Teece, 2007; Mikalef et al., 2019). For accommodation SMEs, the relevant issue is not how to replicate the AI architectures of large hotel chains, but how to select scalable tools that match specific needs and available capabilities.

At the same time, AI adoption must be understood in relation to the distinctive nature of hospitality services. Customer-facing AI can increase responsiveness and personalization, but it may weaken perceived service quality when interactions become opaque, intrusive, or insufficiently human (Tussyadiah et al., 2020; Akhtar et al., 2026). This tension is particularly important for SMEs, whose competitive advantage often depends on authenticity, proximity, and personalized relationships. AI should therefore be interpreted through a logic of service augmentation: it can support employees, reduce repetitive tasks, and improve information flows, but it should not erase the relational dimension that remains central to hospitality.

The organizational implications of AI adoption are equally relevant. AI requires data literacy, digital coordination, employee involvement, and ethical awareness. Socio-technical perspectives are useful because they show that AI reshapes tasks, roles, decision authority, and accountability rather than simply improving existing processes (Kabadayi et al., 2019). SMEs may be constrained by limited resources and skills, but their flexibility and shorter decision chains may also facilitate experimentation when external support is available. This dual condition makes SMEs both vulnerable to digital gaps and potentially capable of agile adoption.

The findings also highlight the ecosystemic nature of AI adoption. Smaller accommodation firms often access AI through booking platforms, property management systems, review platforms, and technology providers. These relationships can reduce technological barriers but may also create dependency, data asymmetry, and reduced strategic autonomy. AI-related capabilities may therefore be distributed across networks rather than contained entirely within individual firms. This point is important because it connects firm-level adoption with destination-level and platform-level governance.

Ethics and governance represent a transversal condition of AI-enabled value creation. Privacy, bias, transparency, accountability, and human oversight directly affect customer trust and organizational legitimacy (Wang et al., 2026; Sharma & Mattila, 2026). This is especially relevant for SMEs, which may adopt AI tools through external providers

without having strong internal governance capabilities. Responsible AI adoption therefore requires practical rules, supplier accountability, and managerial awareness.

Taken together, these considerations support the conceptualization of AI in accommodation as a dynamic socio-technical capability. AI is dynamic because it supports sensing, seizing, and reconfiguring in uncertain environments; it is socio-technical because its effects depend on the interaction between technologies, managers, employees, customers, and ecosystems. This interpretation helps explain why similar AI applications may produce different outcomes depending on firm size, organizational readiness, service identity, and governance conditions.

8. Managerial implications. The findings suggest that accommodation firms should approach AI adoption as a staged and problem-driven process rather than as a one-off technological investment. Managers should identify specific needs, such as demand forecasting, price optimization, guest communication, review monitoring, energy efficiency, or customer segmentation, and select AI applications consistent with their resource base, data maturity, and service positioning. This approach is particularly important for SMEs, where indiscriminate adoption may generate costs and complexity without proportional benefits. For SMEs, low-complexity and high-impact tools may represent appropriate entry points. Automated guest messaging, AI-supported pricing, online reputation analytics, and basic demand forecasting can reduce administrative burdens and improve responsiveness without requiring radical restructuring. More advanced applications, such as predictive maintenance, personalization engines, or strategic analytics, can be introduced gradually as firms develop data literacy and digital confidence.

AI should also be used to augment hospitality rather than replace it. Chatbots and virtual assistants can handle standardized requests, multilingual communication, and after-hours assistance, but complaint management, emotional interactions, and high-value relational moments often require human involvement (Pillai & Sivathanu, 2020; Tussyadiah et al., 2020). This is especially important for SMEs, whose competitive advantage frequently relies on authenticity, customer proximity, and personalized service. Managers should therefore design an explicit division of labor between AI systems and employees, ensuring that automation strengthens service responsiveness without weakening trust and relational value.

Organizationally, AI adoption requires investment in employee skills, digital coordination, and ethical awareness. Employees should understand the purpose and limits of AI tools so that technology supports rather than threatens their work. Even small firms should define basic governance principles concerning customer data, automated interactions, human oversight, and responsibility for AI-mediated decisions (Wang et al., 2026; Sharma & Mattila, 2026). Policy actors can support this process by providing training, shared infrastructures, advisory services, ethical guidelines, and funding for experimentation. Destination management organizations, universities, chambers of commerce, and industry associations can help smaller firms adopt AI while preserving the relational, cultural, and territorial value of hospitality.

9. Research limitations and future research. This study has limitations. The review focused on English-language peer-reviewed journal articles indexed in Scopus and Web of Science. This supports rigor and replicability but may exclude relevant contributions in other languages, regional journals, industry reports, policy documents, and grey literature. This limitation is relevant because accommodation and tourism are strongly shaped by local contexts, national policy environments, and practitioner experimentation.

The review adopted a managerial and economic perspective. Technical and engineering studies were excluded when they lacked explicit managerial implications. This choice is consistent with the objective of the paper, but it may limit coverage of emerging AI architectures whose managerial implications are still developing. Future research could integrate management, tourism, information systems, and computer science perspectives to better capture the complexity of AI-enabled transformation.

The corpus is heterogeneous, including conceptual papers, empirical studies, bibliometric analyses, customer acceptance research, and strategic management contributions. The selected studies differ in methods, contexts, AI applications, and outcome measures. The synthesis should therefore be interpreted as an analytical review of patterns and gaps, not as evidence of causal effects. Moreover, AI technologies evolve rapidly, so future reviews should periodically update the evidence base.

Further empirical research is needed on accommodation SMEs. Existing studies often discuss barriers such as resource scarcity, skills gaps, and dependence on external providers, but fewer examine how SMEs adopt, adapt, govern, and evaluate AI over time. Longitudinal studies, qualitative case studies, surveys, and cross-country comparisons would be particularly useful for understanding how AI becomes embedded in routines and how its effects change across implementation phases.

Future research should also investigate the balance between automation and human hospitality. AI can improve efficiency and personalization, but it may also create concerns about authenticity, empathy, privacy, and discomfort. More research is needed to understand when customers prefer AI-mediated service, when they prefer human interaction, and how hybrid human-AI service models can be designed.

Ethics, governance, and platform dependence also deserve further attention. SMEs often access AI through external providers and booking platforms, which may reduce adoption barriers but also create data asymmetries and reduced strategic autonomy. Future studies should examine how value, data, power, and responsibility are distributed within AI-enabled tourism ecosystems.

10. Original contribution of the paper. Unlike prior reviews that mainly map AI applications across the broader tourism and hospitality domain, this paper advances a sector-specific and SME-sensitive interpretation of AI adoption in accommodation firms, emphasizing the managerial mechanisms through which AI reshapes performance, service relationships, organizational routines, strategic decision-making, and governance.

The contribution of the paper can therefore be specified at three levels. At the sectoral level, it isolates accommodation firms as a specific context within the broader hospitality and tourism literature, emphasizing their service intensity, experiential nature, operational complexity, and dependence on customer relationships. At the organizational level, it foregrounds SMEs as firms characterized by distinctive constraints and capabilities, rather than treating them as a residual category within general hospitality research. At the theoretical level, it connects fragmented perspectives into an interpretive framework that explains AI adoption as the outcome of interactions among technological conditions, organizational readiness, customer relationships, ecosystem participation, and governance mechanisms.

The main conceptual contribution is the interpretation of AI as a dynamic socio-technical capability. This perspective integrates strategic management, technology adoption, service-dominant logic, and socio-technical theory, showing that AI-enabled value creation depends on the interaction between technologies, managerial cognition, organizational learning, customer relationships, governance mechanisms, and ecosystem conditions.

The proposed framework clarifies how AI reshapes accommodation firms through four interconnected dimensions: the main operational, experiential, organizational, and strategic dimensions of AI adoption. In doing so, the paper moves beyond descriptive lists of AI applications and provides an integrated lens for understanding AI-enabled managerial transformation in tourism and hospitality SMEs.

11. Conclusions. This study examined how the management and economics literature explains the role of AI in the accommodation sector, with particular attention to SMEs. Through a systematic literature review, the paper synthesized a fragmented research field and proposed an integrated interpretation of AI adoption as a managerial transformation affecting operations, service relationships, organizational routines, strategic decision-making, and governance.

The findings show that AI can support forecasting, revenue management, automation, personalization, review analytics, market sensing, and adaptive responses to uncertainty. At the same time, its benefits depend on data quality, managerial interpretation, organizational learning, employee adaptation, customer trust, and responsible governance. These conditions are especially relevant for accommodation SMEs, which face resource constraints but may also benefit from flexibility, customer proximity, and local embeddedness.

A central conclusion is that AI should not be understood merely as a technological tool. Its value depends on the ability of firms to embed AI within organizational capabilities, managerial judgment, service relationships, and governance mechanisms. For accommodation SMEs, AI adoption is likely to be most effective when it is selective, incremental, and aligned with specific managerial problems rather than imitative of large hotel chains' digital strategies.

Overall, the paper contributes to the literature by showing that AI-enabled value creation in accommodation firms depends on the combination of digital innovation, organizational learning, human hospitality, ethical governance, and territorial value creation.

Appendix E. Thematic Analysis Procedure. The thematic analysis was conducted in three steps. The selected articles were initially read to identify their main research focus, theoretical orientation, AI application, and managerial relevance. Each article was then coded according to the categories reported in Appendix D. During this phase, studies were assigned to one or more thematic dimensions depending on their substantive contribution. Finally, the coded material was compared across studies to identify convergences, divergences, emerging trends, and research gaps.
The four main dimensions of the analysis, operational performance, customer experience, organizational transformation, and strategic decision-making, were derived from the research question and conceptual framework. Ethics and governance emerged as a transversal theme cutting across all four dimensions. This procedure allowed the review to move beyond a descriptive listing of AI applications and toward an interpretive synthesis of how AI reshapes accommodation firms, particularly SMEs.

Appendix F. Robustness and Bias Checks. Several procedures were adopted to improve the robustness of the review. A subset of articles was re-coded after the first round of analysis to verify consistency in category assignment. Ambiguous studies were revisited and compared with similar contributions to refine coding decisions. Particular attention was devoted to studies with broad tourism or hospitality scope, which were retained only when their findings were clearly applicable to accommodation management.
Potential sources of bias were also considered. The focus on English-language peer-reviewed articles may have excluded local or practitioner-oriented contributions. The use of Scopus and Web of Science may have limited the visibility of

research published in regional journals. The exclusion of technical studies without managerial implications may have reduced coverage of emerging AI architectures. Finally, the rapid evolution of AI technologies implies that some findings may require periodic updating as new applications and governance challenges emerge.

Appendix G. Thematic organization of the 95 reviewed articles. The following table summarizes the thematic distribution of the 95 articles included in the systematic literature review. Each article was assigned to one dominant topic according to the coding scheme. Since several studies address more than one theme, the classification should be interpreted as an analytical synthesis rather than as an exclusive categorization of the literature.

Table G1. Thematic distribution of the reviewed corpus

Topic cluster	Main inclusion logic	Main AI-related focus	Managerial / theoretical focus	Number of articles
Systematic reviews, bibliometric studies and state-of-the-art contributions	Articles retrieved through combinations of "artificial intelligence", "tourism", "hospitality", "review", "bibliometric", "future research agenda"	Mapping of AI applications, methods, trends and research trajectories in tourism and hospitality	Positioning of the field; identification of research gaps; methodological and theoretical consolidation	10
Smart tourism, digital platforms and tourism ecosystems	Articles addressing AI within smart tourism, digital infrastructures, online platforms, data flows and destination ecosystems	Smart tourism systems, online platforms, digital traces, user-generated content, platform-mediated interactions	Ecosystem conditions, platform dependence, data access, destination-level digital transformation	10
Operational performance, revenue management and forecasting	Articles focused on AI tools supporting efficiency, demand prediction, pricing, resource allocation and operational optimization	Revenue management, demand forecasting, predictive analytics, process automation, booking cancellation prediction	Efficiency, productivity, cost reduction, data-driven operational decisions	12
Customer experience, chatbots and personalization	Articles addressing customer-facing AI and AI-mediated service interactions	Chatbots, conversational agents, virtual assistants, recommendation systems, sentiment analysis, personalization engines	Customer satisfaction, trust, perceived empathy, service responsiveness, acceptance and discomfort	18
Service robots, automation and human–AI interaction	Articles focused on robotics, automation and hybrid human–technology service encounters	Service robots, robotic automation, intelligent service encounters, human–robot interaction	Automation, labor transformation, service quality, customer trust, human–AI collaboration	13
Organizational transformation, digital capabilities and SME adoption	Articles focused on organizational readiness, capabilities, barriers and adoption processes, especially in smaller firms	AI adoption, digital skills, data literacy, organizational learning, absorptive capacity, technology readiness	SME constraints, capability development, employee adaptation, managerial learning, implementation barriers	12
Strategic decision-making, dynamic capabilities and business model renewal	Articles examining AI as a support for strategy, market sensing and managerial decision-making	Business intelligence, market sensing, customer segmentation, strategic analytics, dynamic pricing, business model innovation	Strategic agility, decision support, competitive positioning, dynamic capabilities	8
Ethics, governance, privacy and accountability	Articles focused on responsible AI, algorithmic transparency, privacy, bias, accountability and robot responsibility	Data privacy, algorithmic bias, transparency, responsible AI, robot accountability, human oversight	Trust, legitimacy, governance, regulatory compliance, responsible innovation	7
Sustainability, rural tourism and territorial value creation	Articles connecting AI, sustainability, tourism development, territorial competitiveness and rural/accommodation contexts	AI for sustainability, energy efficiency, sustainable rural tourism, destination resilience, territorial innovation	Sustainable management, local development, territorial embeddedness, SME resilience	5

Concert Societies and the Future of Classical Music. Organisational Models and Sustainability in Contemporary Italy

MARTHA FRIEL[1], ANGELO MIGLIETTA[2], ANDREA SANGERMANO[3]

Abstract. *Concert societies represent one of the longest-standing and most significant organisational forms in the dissemination of classical music in Italy. Historically deeply rooted in the cultural fabric of cities and often born from civil society initiatives, these institutions have played a central role in the musical programming of large Italian cities, as well as small towns, for over a century, promoting the circulation of artists and audience development.*

In the contemporary context, however, these interesting and hybrid entities are facing necessary organisational and managerial transformations due to shifts in cultural consumption patterns, evolving funding channels, and the need to develop new audiences. Despite their widespread presence and role, these cultural organisations have received little attention in the academic literature. This study, therefore, aims to contribute to a greater understanding of these entities by analysing their organisational and economic characteristics.

The research is based on an empirical investigation conducted through questionnaires and financial statements collected from a sample of 20 Italian concert societies active in 2025. The collected data were analysed using descriptive techniques to explore the relationships between organisational characteristics, economic size, production capacity, and audience composition.

Preliminary data analysis—which does not yet include an examination of financial statements—highlights significant heterogeneity among the organisations analysed in terms of economic size, production capacity, and programming models, as well as a sustainability model heavily dependent on public funding, ticket sales and season ticket revenues. At the same time, the analysis highlights a number of patterns in audience composition and governance structures, characterised by strong stability and limited turnover in artistic direction. Overall, these findings suggest potential evolutions in the governance models and management practices of concert organisations, particularly with regard to diversifying funding sources, developing audiences, and strengthening organisational capabilities to ensure sustainability and continuity over time.

Keywords: *Concert societies; cultural management; governance; audience development; economic sustainability*

Framing of the research. *Concert societies represent one of the longest-standing and most significant organisational forms in the dissemination of classical music in Italy. Established between the second half of the 19th century and the early decades of the 20th century within a broader tradition of musical associations—which included academies, philharmonic societies, and cultural circles—they have played a fundamental role in promoting instrumental music and educating audiences about chamber music.*

From an organisational perspective, since their inception, concert societies have been organisations promoted by civil society and supported by local cultural elites, characterised by a membership-based or subscriber-based structure and ongoing artistic programming. This organisational model has, over time, favoured the dissemination of classical music even in cities lacking large, established musical institutions, contributing significantly to the development of Italian musical life and the circulation of artists from the 19th century to the present (Macchione, 2002; Carlini, 2006).

Historical studies of individual concert institutions show how these organisations have been a central element of the cultural life of numerous Italian cities for over a century, ensuring continuity of programming and strong local roots (Galla & Meneghini, 2010; Brighenti, 2012; Bossini, 2014).

From an organisational and economic perspective, concert societies can be considered organisations that manage portfolios of musical programs, whose sustainability depends - as also highlighted for other actors in the music sector - on the combination of artistic production, programming, and management of available resources (Mariani & Zan, 2011). In this framework, it can be said that they play a coordinating role between artistic production, cultural programming, and audience education, contributing to the structuring of local music markets and the circulation of artists. Their organisational model, based on a mix of public resources, private contributions, and member participation, represents a rather unique formula that combines civic initiative and professional management of artistic activities (Friel & Cavazzoni, 2014).

Despite their historical role in disseminating classical music and shaping local musical life, concert societies have so far been relatively understudied in the cultural management literature, which has devoted greater attention to other types of musical organisations, such as symphony orchestras, opera houses, and music festivals.

Like many other players in the "Classical Music industry" (Dromey & Haferkorn, 2018), however, concert societies are now called upon to innovate their organizsational models and audience development strategies to maintain their

[3] IULM University, Milan, e-mail: andrea.sangermano@iulm.it

cultural and social relevance in a contemporary context of significant change in both demand (Kolb, 2001; Tong et al., 2016) and production and distribution (Dromey & Haferkorn, 2018). All of this, therefore, requires cultural organisations to develop new ways of engaging audiences and building cultural experiences (Kolb, 2013; Dollman, 2023) while also preserving their economic and organisational sustainability over time.

Purpose of the paper. *In this context, this study aims to contribute to the literature by analysing the organisational and economic characteristics of a sample of Italian concert societies active in 2025. Specifically, the study explores the organisational models and economic sustainability mechanisms that characterise these institutions, as well as their role in cultural production and distribution, and in audience building. Through this analysis, the article also aims to identify management recommendations to strengthen the sustainability and development of concert societies' activities in the contemporary context.*

Specifically, the research focuses on the following questions:

***RQ1**. What organisational models characterise contemporary Italian concert societies?*

***RQ2**. What are the main economic characteristics of these organisations, and what sources of funding support their activities?*

***RQ3**. How do concert societies contribute to musical programming and audience building in the contemporary Italian music context?*

Methodology. *Our study adopts an exploratory research design based on the collection and analysis of primary data relating to the organisational, cultural programming, and economic characteristics of Italian concert societies. The research builds on a 2014 study of concert societies operating in Italy, which aimed to describe the role of these institutions in the musical life of the regions and to identify their main organisational and management characteristics (Friel and Cavazzoni, 2014). The survey, conducted in 2025, was designed by repeating and expanding the structure of the 2014 survey, also to allow for observation of the evolution of the Italian concert scene.*

Data collection was conducted by administering a structured questionnaire to a sample of Italian concert societies via Google Forms. The questionnaire, comprising 74 closed- and open-ended questions, was divided into several sections covering the main organisational and management aspects of the institutions analysed. Specifically, the questionnaire collected information regarding: (1) general characteristics of the organisation, including legal form and year of foundation; (2) organisational structure and human resources; (3) concert activity and artistic programming; (4) audience characteristics and audience engagement initiatives; (5) communication and promotion methods. To complement the organisational analysis with an assessment of the financial characteristics, the participating organisations were also asked to provide their main accounting documents for the previous year.

The selection of organisations involved in the survey followed the sample defined in the 2014 study, which included 25 Italian organisations. The 2025 survey included 20 concert companies, 14 of which were already in the original sample. This partial overlap between the two samples provides a potentially useful information base for future comparative analyses on the evolution of the organisational and financial characteristics of Italian concert companies. The data collected through the questionnaire and accounting documents were analysed using descriptive techniques, and the preliminary results are presented in the following section.

Results.

***A descriptive analysis of organisational, economic, and management characteristics.** The organisations considered in many cases represent historic institutions of Italian musical life. 75% of the responding societies were founded between 1900 and 1989, 15% before 1900, and 10% after 1990. Among the oldest organisations is the Trento Philharmonic Society, founded in 1795, while the most recent organisation in the sample is Musikàmera of Venice, founded in 2016. Almost all societies have operated continuously over time, with interruptions limited mainly to the two world wars, and only 25% of the organisations reported periods of suspension of their activities. This data highlights the strong historical roots of concert societies in the Italian music system.*

From a legal perspective, the vast majority of organisations are established as associations, three are foundations; 60% have legal status, and approximately one-third have achieved Third Sector Entity (ETS) status.

Regarding infrastructure and material resources, most organisations do not have their own spaces: over 70% rent spaces for their concerts, while 20% provide free space. Only a small percentage own their own venues, and 90% of organisations use third-party musical instruments, indicating limited financial resources.

In terms of offerings, the organisations analysed offer a diverse musical program: in addition to traditional chamber music, 14 organisations offer symphonic repertoire, 13 choral performances, 12 jazz events, and 5 ballet performances. Only one institution in the sample maintains a program exclusively dedicated to chamber music, and it is interesting to note the near absence of early music in the programs. Overall, activities other than chamber music represent an average of 35.26% of the program, with a standard deviation of 23.33%, indicating considerable variability among organisations. Among the institutions with the greatest programming diversity are the Unione Musicale di Torino and the Società Aquilana dei Concerti.

During the 2023/2024 season, the analysed concert societies organised a total of 1,472 performances, averaging approximately 74 per organization; however, there is significant heterogeneity in production capacity among the institutions, and if some organisations have particularly busy schedules, such as the Mantua Chamber Orchestra with

250 events and Asolo Musica – Associazione Amici della Musica di Asolo with 168 events, others operate with more limited programs. Looking at the types of performances, 340 solo concerts and 861 chamber music concerts were organised, while the remaining events were in other musical genres (symphonic, jazz, dance, and others).

The analysis of production costs also highlights variability across the organisations analysed, with the average cost per performance in the 2023/2024 season at €5,434.

Regarding the composition of revenue, the central role of public funding in supporting concert organisations' activities emerges. Almost all of the organisations analysed benefit from contributions from various institutional levels, including the National Fund for Live Performances (FNSV), and regional and local governments funds. Alongside public contributions, the other main component of revenue is generated by the public through ticket and season ticket sales, which in many cases constitute a significant portion of the organisation's overall budget.

Conversely, revenue from sponsorships and other private funding sources is generally more limited and less widespread among the organisations studied this suggesting that the economic model of Italian concert societies remains predominantly based on a combination of public support and audience participation through ticketing and subscriptions, and that the use of structured forms of private fundraising appears less developed than for other cultural organisations.

Finally, the analysis of artistic governance highlights strong stability and low turnover rates in artistic leadership: only three organisations have an artistic director under the age of 50, and seven organisations have had no or only one artistic director change in the last twenty years. It is also interesting to note that 17 out of 19 organisations have a male artistic director.

Audiences and Communication Activities. *On the audience front, concert societies continue to rely on a system of members and season ticket holders. The average number of members is 72, with a standard deviation of 117.5, indicating a very uneven distribution across organisations. The highest number is recorded by the Fondazione Società del Quartetto di Milano ETS, with 423 members, while some organisations do not have a formal membership base. Looking at age, the audience is predominantly mature as the majority of members are in the 51-70 and over 70 age ranges, while the presence of young people under 25 appears marginal. Despite this fact, almost all organisations offer special offers for young people, including reduced or free season tickets.*

However, numerous efforts are being made in audience development and engagement. In addition to their concert programming, many organisations develop educational and outreach activities: 47% of organisations conduct training activities, while approximately 79% organize activities for or in schools, including educational concerts, workshops, and concert-lessons. Almost all organisations also promote initiatives to disseminate musical culture at their own offices or at partner institutions.

Regarding communication, all organisations have a website and use at least one social media platform to communicate with the public. Facebook remains the most popular platform, while Instagram is growing as a communication channel. A comparative analysis of followers on Facebook and Instagram (data from October 25, 2025) confirms the existence of different communication models. Facebook remains the predominant channel for most organisations: on average, Instagram followers account for approximately 45% of the Facebook base, with only two organisations recording a higher number of Instagram followers. Six organisations exhibit a nearly balanced profile between the two platforms (IG/FB ratio between 50% and 80%), a sign of a more mature and diversified digital presence, while seven remain heavily skewed toward Facebook (less than 30% followers on Instagram). Finally, four organisations do not have an Instagram profile.

These data give a picture of the digital transition in concert societies, and while Facebook remains the primary communication tool for a loyal, generally older audience, Instagram is emerging as a channel among younger organisations or those more oriented toward audiences under 35. Companies that invest in visual content, regular updates, and digital engagement strategies demonstrate a greater balance between the two platforms, signalling an evolution in their relationship with the public and a strengthening of the participatory dimension. Digitalisation thus emerges as an indicator of organisational capacity and openness to new audiences. The presence of multilingual materials, cultural content disseminated online, and integrated communication strategies demonstrates a growing focus on accessibility and the internationalisation of concert offerings.

A preliminary correlation analysis. *To further explore the relationships among the organisational, economic, and social dimensions, a correlation analysis was conducted using the quantitative variables collected via the questionnaire. The objective was to identify statistically significant relationships between economic-financial, production, audience composition, and internal structure aspects of the organisations. The analyses were conducted using the Pearson correlation coefficient, which measures the strength and direction of the linear relationship between two quantitative variables, with values ranging from -1 (perfect negative correlation) to +1 (perfect positive correlation). The adopted method considers only the available cases for each pair of variables (pairwise complete observations) to reduce the impact of missing data. Two areas of study were identified:*

1. *The financing and production area, which investigates the relationships between financial resources and artistic production capacity;*
2. *The social and organisational area, which analyses the connections between audience composition, youth presence, and staff structure. This division allowed for greater clarity of interpretation and a precise understanding of the internal dynamics within each area.*

In the financing and production area, the correlation analysis highlights a significant positive relationship between the main sources of public funding (FNSV, Municipality, Region) and parameters related to artistic production (number of performances, average concert cost, and the cost of the most expensive performance).

In particular, the companies that receive greater resources from the FNSV and local authorities are also those that schedule a greater number of performances and have higher average costs, a sign of a broader and more structured artistic programming. The positive correlation between the different funding channels (FNSV, Municipality, Region, and non-FNSV calls) suggests the presence of an integrated system of public support, in which entities that benefit from one source of funding tend to receive more than one. This confirms a tendency toward the concentration of resources in the most established entities.

An inverse relationship, albeit weak, is also observed between overall funding and the percentage of artistic costs to the total. This would seem to indicate that, as financial resources increase, concert societies tend to expand the organisational and management component (staff, promotion, facilities), reducing the proportion allocated exclusively to artistic costs. This trend suggests that the effectiveness of public support is not limited to the quantity of events produced, but also contributes to the quality and stability of cultural offerings in the area.

Regarding the social and organisational area, however, the correlation matrix highlights the relationships between the age composition of members, youth participation, and audience size, in relation to staff structure. The age groups of members (<25, 25–35, 36–50) show positive correlations, suggesting that organisations capable of engaging younger members tend to maintain a balanced demographic profile even in later age groups: a sign of turnover and continuity in the membership base.

The percentage of youth season tickets is positively associated with both the total number of season ticket holders and ticket sales, indicating that initiatives aimed at the under-30s not only foster loyalty among that segment but are also associated with a larger overall audience.

Regarding staff structure, the observed relationships between the number of temporary and permanent staff offer insights into organisational professionalisation: where a more structured workforce is present, there is generally a greater capacity to plan and support audience-oriented activities (season tickets and tickets). While not inferring causality, the covariation between youth attendance and audience indicators with staff structure suggests more mature organisational models in organisations with greater job stability.

Research limitations. *While these preliminary results reveal interesting and recurring characteristics of Italian concert societies, our study has several limitations that should be acknowledged. First, it should be noted that this short paper focuses primarily on the questionnaire analysis and does not delve into the findings of the ongoing analysis of accounting documents. Completing this analysis will certainly allow for a better understanding of the dynamics of economic and financial sustainability of concert societies.*

The analysis is also based on a relatively small sample of Italian concert societies: although it includes several historically significant institutions from different geographical areas, the results cannot be considered representative of the entire population of concert societies active in Italy, which, among other things, predominantly refers to organisations in Northern Italy.
